## Julia Burdge

Periodic Table of the Elements

List of the Elements with Their Symbols and Atomic Masses*

| Element | Symbol | Atomic Number | Atomic Mass ${ }^{\dagger}$ | Element | Symbol | Atomic Number | Atomic Mass ${ }^{\dagger}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Actinium | Ac | 89 | (227) | Mendelevium | Md | 101 | (258) |
| Aluminum | Al | 13 | 26.9815386 | Mercury | Hg | 80 | 200.59 |
| Americium | Am | 95 | (243) | Molybdenum | Mo | 42 | 95.94 |
| Antimony | Sb | 51 | 121.760 | Neodymium | Nd | 60 | 144.242 |
| Argon | Ar | 18 | 39.948 | Neon | Ne | 10 | 20.1797 |
| Arsenic | As | 33 | 74.92160 | Neptunium | Np | 93 | (237) |
| Astatine | At | 85 | (210) | Nickel | Ni | 28 | 58.6934 |
| Barium | Ba | 56 | 137.327 | Niobium | Nb | 41 | 92.90638 |
| Berkelium | Bk | 97 | (247) | Nitrogen | N | 7 | 14.0067 |
| Beryllium | Be | 4 | 9.012182 | Nobelium | No | 102 | (259) |
| Bismuth | Bi | 83 | 208.98040 | Osmium | Os | 76 | 190.23 |
| Bohrium | Bh | 107 | (272) | Oxygen | O | 8 | 15.9994 |
| Boron | B | 5 | 10.811 | Palladium | Pd | 46 | 106.42 |
| Bromine | Br | 35 | 79.904 | Phosphorus | P | 15 | 30.973762 |
| Cadmium | Cd | 48 | 112.411 | Platinum | Pt | 78 | 195.084 |
| Calcium | Ca | 20 | 40.078 | Plutonium | Pu | 94 | (244) |
| Californium | Cf | 98 | (251) | Polonium | Po | 84 | (209) |
| Carbon | C | 6 | 12.0107 | Potassium | K | 19 | 39.0983 |
| Cerium | Ce | 58 | 140.116 | Praseodymium | Pr | 59 | 140.90765 |
| Cesium | Cs | 55 | 132.9054519 | Promethium | Pm | 61 | (145) |
| Chlorine | Cl | 17 | 35.453 | Protactinium | Pa | 91 | 231.03588 |
| Chromium | Cr | 24 | 51.9961 | Radium | Ra | 88 | (226) |
| Cobalt | Co | 27 | 58.933195 | Radon | Rn | 86 | (222) |
| Copper | Cu | 29 | 63.546 | Rhenium | Re | 75 | 186.207 |
| Curium | Cm | 96 | (247) | Rhodium | Rh | 45 | 102.90550 |
| Darmstadtium | Ds | 110 | (281) | Roentgenium | Rg | 111 | (280) |
| Dubnium | Db | 105 | (268) | Rubidium | Rb | 37 | 85.4678 |
| Dysprosium | Dy | 66 | 162.500 | Ruthenium | Ru | 44 | 101.07 |
| Einsteinium | Es | 99 | (252) | Rutherfordium | Rf | 104 | (267) |
| Erbium | Er | 68 | 167.259 | Samarium | Sm | 62 | 150.36 |
| Europium | Eu | 63 | 151.964 | Scandium | Sc | 21 | 44.955912 |
| Fermium | Fm | 100 | (257) | Seaborgium | Sg | 106 | (271) |
| Fluorine | F | 9 | 18.9984032 | Selenium | Se | 34 | 78.96 |
| Francium | Fr | 87 | (223) | Silicon | Si | 14 | 28.0855 |
| Gadolinium | Gd | 64 | 157.25 | Silver | Ag | 47 | 107.8682 |
| Gallium | Ga | 31 | 69.723 | Sodium | Na | 11 | 22.98976928 |
| Germanium | Ge | 32 | 72.64 | Strontium | Sr | 38 | 87.62 |
| Gold | Au | 79 | 196.966569 | Sulfur | S | 16 | 32.065 |
| Hafnium | Hf | 72 | 178.49 | Tantalum | Ta | 73 | 180.94788 |
| Hassium | Hs | 108 | (270) | Technetium | Tc | 43 | (98) |
| Helium | He | 2 | 4.002602 | Tellurium | Te | 52 | 127.60 |
| Holmium | Но | 67 | 164.93032 | Terbium | Tb | 65 | 158.92535 |
| Hydrogen | H | 1 | 1.00794 | Thallium | Tl | 81 | 204.3833 |
| Indium | In | 49 | 114.818 | Thorium | Th | 90 | 232.03806 |
| Iodine | I | 53 | 126.90447 | Thulium | Tm | 69 | 168.93421 |
| Iridium | Ir | 77 | 192.217 | Tin | Sn | 50 | 118.710 |
| Iron | Fe | 26 | 55.845 | Titanium | Ti | 22 | 47.867 |
| Krypton | Kr | 36 | 83.798 | Tungsten | W | 74 | 183.84 |
| Lanthanum | La | 57 | 138.90547 | Uranium | U | 92 | 238.02891 |
| Lawrencium | Lr | 103 | (262) | Vanadium | V | 23 | 50.9415 |
| Lead | Pb | 82 | 207.2 | Xenon | Xe | 54 | 131.293 |
| Lithium | Li | 3 | 6.941 | Ytterbium | Yb | 70 | 173.04 |
| Lutetium | Lu | 71 | 174.967 | Yttrium | Y | 39 | 88.90585 |
| Magnesium | Mg | 12 | 24.3050 | Zinc | Zn | 30 | 65.409 |
| Manganese | Mn | 25 | 54.938045 | Zirconium | Zr | 40 | 91.224 |
| Meitnerium | Mt | 109 | (276) |  |  |  |  |

*These atomic masses show as many significant figures as are known for each element. The atomic masses in the periodic table are shown to four significant figures, which is sufficient for solving the problems in this book.
$\dagger$ Approximate values of atomic masses for radioactive elements are given in parentheses.

## ABOUT THE Author

Julia Burdge received her Ph.D. (1994) from the University of Idaho in Moscow, Idaho. Her research and dissertation focused on instrument development for analysis of trace sulfur compounds in air and the statistical evaluation of data near the detection limit.

In 1994 she accepted a position at The University of Akron in Akron, Ohio, as an assistant professor and director of the Introductory Chemistry program. In the year 2000, she was tenured and promoted to associate professor at The University of Akron on the merits of her teaching, service, and research in chemistry education. In addition to directing the general chemistry program and supervising the teaching activities of graduate students, she helped establish a future-faculty development
 program and served as a mentor for graduate students and postdoctoral associates. Julia has recently relocated back to the Northwest to be near family. She and her children live in Pullman, Washington, home of Washington State University; and she holds an affiliate faculty position in the Chemistry Department at the University of Idaho. She also continues to work with students in Ohio and Florida via an online tutoring program.

Julia and her children are animal lovers and moved three horses, three cats, and a dog with them to the Northwest. They are enjoying the changes of seasons, long horseback rides on the Palouse, and frequent visits with family.

To the people who will always matter the most: Katie, Beau, and Sam.

## ${ }^{\text {brifi }}$ Contents

1 Chemistry: The Central Science ..... 2
2 Atoms, Molecules, and Ions ..... 34
3 Stoichiometry: Ratios of Combination ..... 76
4 Reactions in Aqueous Solutions ..... 116
5 Thermochemistry ..... 170
6 Quantum Theory and the Electronic Structure of Atoms ..... 210
7 Electronic Configuration and the Periodic Table ..... 256
8 Chemical Bonding I: Basic Concepts ..... 296
9 Chemical Bonding II: Molecular Geometry and Bonding Theories ..... 338
10 Organic Chemistry ..... 386
11 Gases ..... 440
12 Intermolecular Forces and the Physical Properties of Liquids and Solids ..... 492
13 Physical Properties of Solutions ..... 538
14 Chemical Kinetics ..... 578
15 Chemical Equilibrium ..... 628
16 Acids and Bases ..... 672
17 Acid-Base Equilibria and Solubility Equilibria ..... 726
18 Entropy, Free Energy, and Equilibrium ..... 776
19 Electrochemistry ..... 816
20 Nuclear Chemistry ..... 858
21 Environmental Chemistry ..... 892
22 Coordination Chemistry ..... 920
23 Metallurgy and the Chemistry of Metals ..... 944
24 Nonmetallic Elements and Their Compounds ..... 968
25 Modern Materials ..... 998
Appendix 1 Mathematical Operations ..... A-1
Appendix 2 Thermodynamic Data at 1 atm and $25^{\circ} \mathrm{C}$ ..... A-6
Appendix 3 Solubility Product Constants at $25^{\circ} \mathrm{C}$ ..... A-12

## Contents

A Visual Approach Integrating Art and Media ..... xx
List of Applications ..... xxii
Preface ..... xxiii
$360^{\circ}$ Development Process ..... xxviii
Acknowledgments ..... xxxi
Enhanced Support for Faculty \& Students ..... xxxii
1 Chemistry: The Central Science ..... 2
1.1 The Study of Chemistry ..... 4

- Chemistry You May Already Know 4 • The Scientific Method ..... 5
What Do Molecules Look Like? ..... 5
1.2 Classification of Matter ..... 6
- States of Matter 6-Elements 6•Compounds 7 • Mixtures ..... 7
1.3 Scientific Measurement ..... 8
- SI Base Units 9 • Mass 10 - Temperature ..... 10
Fahrenheit Temperature Scale ..... 11
- Derived Units: Volume and Density ..... 12
1.4 The Properties of Matter ..... 14
- Physical Properties ..... 14
■ Why Are Units So Important? ..... 14
- Chemical Properties 15 • Extensive and Intensive Properties ..... 15
1.5 Uncertainty in Measurement ..... 17
- Significant Figures 17 - Calculations with Measured Numbers 18 - Accuracy and Precision ..... 20
1.6 Using Units and Solving Problems ..... 22
- Conversion Factors 22 • Dimensional Analysis—Tracking Units ..... 22
How Can I Enhance My Chances of Success in Chemistry Class? ..... 23

2 Atoms, Molecules, and Ions ..... 34
2.1 The Atomic Theory ..... 36
2.2 The Structure of the Atom ..... 39
- Discovery of the Electron 39 • Radioactivity 40 - The Proton and the Nucleus 41 - Nuclear Model of the Atom 42
- The Neutron ..... 43
2.3 Atomic Number, Mass Number, and Isotopes ..... 44
2.4 The Periodic Table ..... 45
- Distribution of Elements on Earth ..... 47
- How Are Atomic Masses Measured? ..... 48
2.5 The Atomic Mass Scale and Average Atomic Mass ..... 48
2.6 Molecules and Molecular Compounds ..... 50
- Molecules 50 • Molecular Formulas 51 - Naming Molecular Compounds 52•Empirical Formulas 54
2.7 Ions and Ionic Compounds ..... 58
- Atomic Ions 58 • Polyatomic Ions ..... 59 - Formulas of Ionic
Compounds 60 • Naming Ionic Compounds ..... 61
- How Are Oxoanions and Oxoacids Named? ..... 62
- Hydrates 64 • Familiar Inorganic Compounds ..... 65
3 STOICHIOMETRY: RATIOS OF COMBINATION ..... 76
3.1 Molecular and Formula Masses ..... 78
3.2 Percent Composition of Compounds ..... 79
3.3 Chemical Equations ..... 80
- Interpreting and Writing Chemical Equations 80 - Balancing Chemical Equations 81
■ The Stoichiometry of Metabolism ..... 84
3.4 The Mole and Molar Masses ..... 86
- The Mole 86 • Determining Molar Mass 88 • Interconverting Mass, Moles, and Numbers of Particles 89 • Empirical Formula from Percent Composition 90
3.5 Combustion Analysis ..... 91
- Determination of Empirical Formula 91 - Determination of Molecular Formula 92
3.6 Calculations with Balanced Chemical Equations ..... 94
- Moles of Reactants and Products 94 - Mass of Reactants andProducts 95
3.7 Limiting Reactants ..... 97
- Determining the Limiting Reactant ..... 97
Limiting Reactant Problems ..... 98
- Reaction Yield ..... 101
■ How Am I Supposed to Remember All These Reactions? ..... 104

## 4 <br> Reactions in Aqueous Solutions

4.1 General Properties of Aqueous Solutions ..... 118

- Electrolytes and Nonelectrolytes 118 • Strong Electrolytes and Weak Electrolytes 118
- The Invention of Gatorade ..... 120
■ How Can I Tell if a Compound Is an Electrolyte? ..... 122
4.2 Precipitation Reactions ..... 122
- Solubility Guidelines for Ionic Compounds inWater 122 - Molecular Equations 125 • IonicEquations 126 - Net Ionic Equations 126
4.3 Acid-Base Reactions ..... 128
- Strong Acids and Bases 128 • Brønsted Acids and Bases 129 - Acid-Base Neutralization ..... 131
4.4 Oxidation-Reduction Reactions ..... 133
- Oxidation Numbers 134 - Oxidation of Metals in Aqueous Solutions 135 • Balancing Simple Redox Equations 135
- How Do I Assign Oxidation Numbers? ..... 137
- Other Types of Redox Reactions ..... 140
4.5 Concentration of Solutions ..... 142
- Molarity 142 • Dilution 144 • Serial Dilution ..... 145
Preparing a Solution from a Solid ..... 146
- Solution Stoichiometry ..... 149
- How Can We Measure Solution Concentrations? ..... 150
4.6 Aqueous Reactions and Chemical Analysis ..... 154
- Gravimetric Analysis 154 • Acid-Base Titrations ..... 155
5 Thermochemistry ..... 170

5.1 Energy and Energy Changes ..... 172- Forms of Energy 172 • Energy Changes in ChemicalReactions 172 • Units of Energy 173
5.2 Introduction to Thermodynamics ..... 176- States and State Functions 176 - The First Law of
Thermodynamics 177 • Work and Heat ..... 178
5.3 Enthalpy ..... 179
- Reactions Carried Out at Constant Volume or at ConstantPressure 179 • Enthalpy and Enthalpy Changes 181
- Thermochemical Equations ..... 182
5.4 Calorimetry ..... 184
- Specific Heat and Heat Capacity 184 - Constant-PressureCalorimetry185
Determination of $\Delta H_{\mathrm{rxn}}^{\circ}$ by Constant-Pressure Calorimetry ..... 186
- Heat Capacity and Hypothermia ..... 189
Determination of Specific Heat by Constant-Pressure Calorimetry ..... 190
What if the Heat Capacity of the Calorimeter Isn't Negligible? ..... 192
- Constant-Volume Calorimetry ..... 193
5.5 Hess's Law ..... 195
5.6 Standard Enthalpies of Formation ..... 197
6 Quantum Theory and the Electronic Structure of Atoms ..... 210
6.1 The Nature of Light ..... 212
- Properties of Waves 212 • The Electromagnetic Spectrum 213 •The Double-Slit Experiment 213
6.2 Quantum Theory ..... 215
- Quantization of Energy ..... 215
- Laser Pointers ..... 216
- Photons and the Photoelectric Effect ..... 217
■ Where Have I Encountered the Photoelectric Effect? ..... 218
6.3 Bohr's Theory of the Hydrogen Atom ..... 220
- Atomic Line Spectra 220 • The Line Spectrum of Hydrogen ..... 221
Emission Spectrum of Hydrogen ..... 224
- Lasers ..... 227
6.4 Wave Properties of Matter ..... 228
- The de Broglie Hypothesis 228 - Diffraction of Electrons ..... 230
6.5 Quantum Mechanics ..... 230
- The Uncertainty Principle 231 • The SchrödingerEquation 232 - The Quantum Mechanical Description of theHydrogen Atom 232
6.6 Quantum Numbers ..... 233- Principal Quantum Number (n) 233 • Angular Momentum QuantumNumber $(\ell) 233$ • Magnetic Quantum Number $\left(m_{\ell}\right) 233$ • ElectronSpin Quantum Number $\left(m_{s}\right) \quad 234$
6.7 Atomic Orbitals ..... 236
- $s$ Orbitals $236 \cdot p$ Orbitals $237 \cdot d$ Orbitals and Other Higher-Energy Orbitals 237 • Energies of Orbitals 238
6.8 Electron Configuration ..... 239
- Energies of Atomic Orbitals in Many-Electron Systems 239 - ThePauli Exclusion Principle 240 • The Aufbau Principle 241 • Hund'sRule 241 - General Rules for Writing Electron Configurations 242
6.9 Electron Configurations and the Periodic Table ..... 243

7 Electron Configuration and the Periodic Table 256

7.1 Development of the Periodic Table ..... 258
■ The Chemical Elements of Life ..... 259
7.2 The Modern Periodic Table ..... 261
- Classification of Elements ..... 261
- Why Are There Two Different Sets of Numbers at the Top of the Periodic Table? ..... 262
- Representing Free Elements in Chemical Equations ..... 264
7.3 Effective Nuclear Charge ..... 264
7.4 Periodic Trends in Properties of Elements ..... 265
Affinity 269 • Metallic Character 271
What Causes the Periodic Trends in Properties? ..... 272
7.5 Electron Configuration of Ions ..... 273
- Ions of Main Group Elements 273 • Ions of $d$-Block Elements ..... 274
7.6 Ionic Radius ..... 275
- Comparing Ionic Radius with Atomic Radius 275 • Isoelectronic Series 276
7.7 Periodic Trends in Chemical Properties of the Main Group Elements ..... 278
- General Trends in Chemical Properties 278 • Properties of the
Active Metals 279 • Properties of Other Main Group Elements ..... 281
- Comparison of Group 1A and Group 1B Elements ..... 285
■ Radioactive Bone ..... 286
- Variation in Properties of Oxides Within a Period ..... 286
8 Chemical Bonding I: Basic Concepts ..... 296
8.1 Lewis Dot Symbols ..... 298
8.2 Ionic Bonding ..... 299
- Lattice Energy 300 - The Born-Haber Cycle ..... 302
Born-Haber Cycle ..... 304
8.3 Covalent Bonding ..... 306- Lewis Structures 306 • Multiple Bonds 307 • Comparison ofIonic and Covalent Compounds 307
8.4 Electronegativity and Polarity ..... 308
- Electronegativity 309 • Dipole Moment, Partial Charges, andPercent Ionic Character 311
8.5 Drawing Lewis Structures ..... 313
8.6 Lewis Structures and Formal Charge ..... 315
8.7 Resonance ..... 318
8.8 Exceptions to the Octet Rule ..... 320
- Incomplete Octets 320 • Odd Numbers of Electrons ..... 320
- The Power of Radicals ..... 321
- Expanded Octets ..... 321
- Which Is More Important: Formal Charge or the Octet Rule? ..... 324
8.9 Bond Enthalpy ..... 325
9 Chemical Bonding II: Molecular Geometry and Bonding Theories ..... 338
9.1 Molecular Geometry ..... 340- The VSEPR Model 340 • Electron-Domain Geometry andMolecular Geometry 342 • Deviation from Ideal Bond Angles 345
- Geometry of Molecules with More Than One Central Atom ..... 345
9.2 Molecular Geometry and Polarity ..... 347
■ Can More Complex Molecules Contain Polar Bonds and Still Be Nonpolar? ..... 348
■ How Are Electrons in Orbitals Represented? ..... 350
9.3 Valence Bond Theory ..... 350
9.4 Hybridization of Atomic Orbitals ..... 353
- Hybridization of $s$ and $p$ Orbitals 354 - Hybridization of $s, p$, and $d$Orbitals357
9.5 Hybridization in Molecules Containing Multiple Bonds ..... 361
Formation of Pi Bonds in Ethylene and Acetylene ..... 366
9.6 Molecular Orbital Theory ..... 368- Bonding and Antibonding Molecular Orbitals 368 - $\sigma$ MolecularOrbitals 369 • Bond Order 370 • $\pi$ MolecularOrbitals 370 • Molecular Orbital Diagrams 372
9.7 Bonding Theories and Descriptions of Molecules with Delocalized Bonding ..... 375
10 Organic Chemistry ..... 386
10.1 Why Carbon Is Different ..... 388
10.2 Classes of Organic Compounds ..... 390
- How Are Organic Compounds Named? ..... 392
■ How Do We Name Molecules with More Than One Substituent? ..... 397
- How Do We Name Compounds with Specific Functional Groups? ..... 398
10.3 Representing Organic Molecules ..... 400
- Condensed Structural Formulas 400 • Kekulé Structures ..... 401
- Skeletal Structures 401 - Resonance ..... 403
10.4 Isomerism ..... 406
- Constitutional Isomerism 406 • Stereoisomerism ..... 406
■ Plane-Polarized Light and 3-D Movies ..... 409

- Biological Activity of Enantiomers ..... 410
10.5 Organic Reactions ..... 410
- Addition Reactions 411 - Substitution Reactions ..... 413
- $\mathrm{S}_{\mathrm{N}} 1$ Reactions ..... 414
- Other Types of Organic Reactions ..... 418
- The Chemistry of Vision ..... 419
10.6 Organic Polymers ..... 420
- Addition Polymers 420 - Condensation Polymers ..... 421
- Biological Polymers ..... 422
11 Gases ..... 440
11.1 Properties of Gases ..... 442
- Characteristics of Gases 443 - Gas Pressure: Definition and Units 443 • Calculation of Pressure 444 - Measurement of Pressure 444
11.2 The Gas Laws ..... 447- Boyle's Law: The Pressure-Volume Relationship 447 - Charles'sand Gay-Lussac's Law: The Temperature-Volume Relationship 449- Avogadro's Law: The Amount-Volume Relationship 452 - TheCombined Gas Law: The Pressure-Temperature-Amount-VolumeRelationship 453
11.3 The Ideal Gas Equation ..... 455
- Deriving the Ideal Gas Equation from the Empirical Gas Laws ..... 455
- Applications of the Ideal Gas Equation ..... 456
11.4 Reactions with Gaseous Reactants and Products ..... 458
- Calculating the Required Volume of a Gaseous Reactant ..... 459
- Determining the Amount of Reactant Consumed Using Change in
Pressure 460 - Predicting the Volume of a Gaseous Product ..... 461
11.5 Gas Mixtures ..... 462
- Dalton's Law of Partial Pressures 462 • Mole Fractions ..... 463
- Using Partial Pressures to Solve Problems ..... 464
■ Hyperbaric Oxygen Therapy ..... 466
Molar Volume of a Gas ..... 468
11.6 The Kinetic Molecular Theory of Gases ..... 470
- Application to the Gas Laws 470 • Molecular Speed ..... 471
- Diffusion and Effusion ..... 474
11.7 Deviation from Ideal Behavior ..... 476
- Factors That Cause Deviation from Ideal Behavior 476 - The van der Waals Equation 476- What's Really the Difference Between Real Gasesand Ideal Gases? 479

## 12 Intermolecular Forces and the Physical Properties of Liquids and Solids 492

12.1 Intermolecular Forces 494

- Dipole-Dipole Interactions 494 • Hydrogen Bonding 495
- Sickle Cell Disease 496
- Dispersion Forces 498 • Ion-Dipole Interactions 500

### 12.2 Properties of Liquids 500

- Surface Tension 500 - Viscosity 501 - Vapor Pressure 502
12.3 Crystal Structure 505
- Unit Cells 505 • Packing Spheres 506 - Closest Packing 508
- How Do We Know the Structures of Crystals? 510
12.4 Types of Crystals 512
- Ionic Crystals 513 - Covalent Crystals 515 - Molecular

Crystals 515 - Metallic Crystals 516
12.5 Amorphous Solids 517
12.6 Phase Changes 517

- Liquid-Vapor Phase Transition 518 • Solid-Liquid Phase Transition 520 • Solid-Vapor Phase Transition 521
■ The Dangers of Phase Changes 522
12.7 Phase Diagrams 524

13 Physical Properties of Solutions 538

### 13.1 Types of Solutions <br> 540

13.2 The Solution Process ..... 541

- Why Do Some Things Dissolve and Not Others? ..... 542
Vitamin Solubility ..... 544
13.3 Concentration Units ..... 547- Molality 547 • Percent by Mass 547 - Comparison ofConcentration Units 548
13.4 Factors That Affect Solubility ..... 550
- Temperature 550 • Pressure ..... 550
13.5 Colligative Properties ..... 553
- Vapor-Pressure Lowering 553 • Boiling-Point Elevation ..... 555
- Freezing-Point Depression 556 - Osmotic Pressure ..... 557
- Electrolyte Solutions ..... 558
- Intravenous Fluids ..... 560
- Hemodialysis ..... 562
13.6 Calculations Using Colligative Properties ..... 563
13.7 Colloids ..... 565

## 14 chemical Kinetics 578

### 14.1 Reaction Rate <br> 580

- Average Reaction Rate 580 • Instantaneous Rate 582
- Stoichiometry and Reaction Rate 584

### 14.2 Dependence of Reaction Rate on Reactant Concentration 587 <br> - The Rate Law 587 • Experimental Determination of the Rate Law 587

14.3 Dependence of Reactant Concentration on Time 591

## A Visual Approach Integrating Art and Media

## Sample Problem 2.7

Write the empirical formulas for the following molecules: (a) glucose $\left(\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}\right)$, a substance known as blood sugar; (b) adenine ( $\left(C_{5} H_{5} \mathrm{~N}_{5}\right)$, also known as vitamin $\mathrm{B}_{4}$; and (c) nitrous oxide $\left(\mathrm{N}_{2} \mathrm{O}\right)$, a gas
that is used as an anesthetic ("laughing gas") and as an aerosol propellant for whipped cream.
Strategy To write the empirical formula, the subscripts in the molecular formula must be reduced to
the smallest possible whole numbers (without altering the relative numbers of atoms)
Setup The molecular formulas in parts (a) and (b) each contain subscripts that are divisible by
common numbers. Therefore, we will be able to express the formulas with smaller whel common numbers. Therefore, we will be able to express the formulas with smaller whole numbe than those in the molecular formulas. In part (c), the molecule has only one O atom, so it
impossible to simplify this formula furthe impossible to simplify this formula further

Think About It Make sure
Solution (a) Dividing each of the subscripts in the molecular formula for glucose by 6 , we obtain the empirical formula, $\mathrm{CH}_{2} \mathrm{O}$. If we had divided the subscripts by 2 or 3 , we would have obtained
the formulas $\mathrm{C}_{3} \mathrm{H}_{\mathrm{H}} \mathrm{O}$ and $\mathrm{C}_{2} \mathrm{H}_{\mathrm{H}} \mathrm{O}$, respectively Although the ratio of carbon to hydrogen to oxygen atoms in each of these formulas is correct (1:2:1), neither is the simplest formula because the subscripts are not in the smallest possible whole-number ratio.
(b) Dividing each subscript in the molecular formula of adenine by 5 , we get the empirical formula, CHN (c) Because the subscripts in the formula for nitrous oxide are already the smallest possible whole numbers, its empirical formula is the same as its molecular formula, $\mathrm{N}_{2} \mathrm{O}$.
that the ratio in each empirical
formula is the same as that in the corresponding molecular formula and that the subscripts are the smallest possible whole numb In part (a), for example, the atio of C:H:O in the molecular
ormula is $6: 12: 6$, which is equal to $1: 2: 1$, the ratio expressed in the empirical formula.

Practice Problem A Write empirical formulas for the following molecules: (a) caffeine $\left(\mathrm{C}_{8} \mathrm{H}_{10} \mathrm{~N}_{4} \mathrm{O}_{2}\right)$ Practice Problem A Write empirical formulas for the following molecules: (a) caffeine $\left(\mathrm{C}_{8} \mathrm{H}\right.$
a stimulant found in tea and coffee, (b) butane $\left(\mathrm{C}_{4} \mathrm{H}_{10}\right)$, which is used in cigarette lighters, and a stimulant found in tea and coffee, bly
(c) glycine $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{NO}_{2}\right)$, an amino acid.
 Practice Problem B For which of the following molecular formulas is the formula shown in parenthese
the correct empirical formula? (a) $\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}\left(\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}\right)$, (b) $\mathrm{C}_{8} \mathrm{H}_{12} \mathrm{O}_{4}\left(\mathrm{C}_{4} \mathrm{H}_{6} \mathrm{O}_{2}\right),\left(\right.$ c) $\mathrm{H}_{2} \mathrm{O}_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)$ ?
11.74 Consider the three containers shown, all of which have the same volume and are at the same temperature. (a) Which container has the smallest mole fraction of gas A (red)? (b) Which container has the highest partial pressure of gas B (green)? (c) Which container has the highest total pressure?

## Sample Problems:

Strong problem-solving skills are essential for student success. I provide a consistent, step-wise approach in every worked example.

Strategy: Read the problem carefully and identify an approach that can be used to answer the question.

Setup: Gather the necessary information, including data, constants, and equations.

Solution: Following the appropriate strategy, use the information to solve the problem.

Think About It: Evaluate the result to make sure that it makes sense. Does it have the right sign, units, and/or magnitude?

Practice Problem A: This is a problem similar to the sample problem that students can solve using the same strategy.

Practice Problem B: This problem is about the same topic, but is sufficiently different from the Sample Problem that it cannot be solved using the same strategy. These problems encourage students to develop problem-solving strategies on their own-helping them to build the confidence necessary to tackle unfamiliar problems.

## Art:

I have worked closely with artists to develop engaging two-page "Visualizing Chemistry" figures. These pieces are step-wise illustrations of processes and common laboratory procedures, and are designed to make sure students get the right take-away message. Visualizing Chemistry figures have also been made into animations, which I narrate myself. They can be shown in the classroom or viewed by students in the electronic homework. Each figure is accompanied by a series of conceptual end-of-chapter problems, which are also integrated into the online homework.

## What's the point?

My book has been developed and written with the student in mind. Information is presented clearly in a digestible format with engaging artwork, designed to bring concepts to life; concept art is used consistently to foster better comprehension; and pedagogical features foster the kinds of student activities that lead to competence and confidence in problem-solving .

## Preface

Welcome to the exciting and dynamic world of Chemistry! My desire to create a new general chemistry textbook grew out of my concern for the interests of students and faculty alike. Having taught general chemistry for many years and having helped new teachers and future faculty develop the skills necessary to teach general chemistry, I believe I have developed a distinct perspective on the common problems and misunderstandings that students encounter while learning the fundamental concepts of chemistry-and that professors encounter while teaching them. I believe that it is possible for a textbook to address many of these issues while conveying the wonder and possibilities that chemistry offers. With this in mind, I have tried to write a text that balances the necessary fundamental concepts with engaging real-life examples and applications, while utilizing a consistent step-by-step problem-solving approach and an innovative art and media program.

## What's New in This Edition?

## New Visualizing Chemistry Figures

I have designed eight new two-page Visualizing Chemistry figures to enhance student understanding of chemical processes and laboratory techniques. The new pieces are:

Determination of $\Delta H_{\mathrm{rxn}}^{\circ}$ by Constant-Pressure Calorimetry
Determination of Specific Heat by Constant-Pressure Calorimetry
Born-Haber Cycle
Molar Volume of a Gas
Using Equilibrium Tables to Solve Problems
Factors That Influence the Entropy of a System
Construction of a Galvanic Cell
Nuclear Fission and Fusion

Figure 5.9
Figure 5.10
Figure 8.3
Figure 11.15
Figure 16.2
Figure 18.4
Figure 19.1
Figure 20.7

For each Visualizing Chemistry figure, I have also added a series of conceptual end-ofchapter problems. These problems allow students to assess their understanding of the principles in each figure and have been incorporated into the online homework.

## New and Updated Chapter Content

- Chapter 4: New section on serial dilution with Sample and Practice Problems.
- Chapter 7: Incorporation of the concept of diagonal relationships into the main text.
- Chapter 8: New section on percent ionic character with Sample and Practice Problems.
- Chapter 11: New section on the combined gas law with Sample and Practice Problems; and new coverage of deviation from ideal behavior and compressibility factor, Z , including a new figure, inquiry box, and Sample and Practice Problems.
- Chapter 13: Expanded coverage of intermolecular forces, including a new table that includes molecular structures.
- Chapter 16: New section on percent ionization with a new figure (Figure 16.3) showing percent ionization of weak acid as a function of concentration, and new Sample and Practice Problems.
- Chapter 18: New introduction of the concept of entropy, including a new two-page Visualizing Chemistry figure that provides a qualitative illustration of several factors that affect a system's entropy.
- Chapter 25: Introduction of graphene, its properties, and uses.

Having received overwhelmingly positive feedback from students and instructors about the Section Checkpoint questions, I have added more-many of them conceptual.

Many new Sample Problems and Practice Problems have been included in this edition to provide more structure and practice to help students develop strong problem-solving skills. A significant number of these new problems appear in FAQ boxes, designed to help students master important material that is commonly misunderstood. New FAQ boxes answer such commonly asked questions as "How can I tell if a proposed reaction mechanism is plausible?" and "Why do some substances dissolve and not others?" Most FAQ boxes contain Sample and Practice Problems, giving students the opportunity to assess and improve their comprehension.

All Sample Problems are now followed by two Practice Problems, A and B. Practice Problem B, while probing comprehension of the same material as Practice Problem A, is almost always sufficiently different as to require a different strategy to solve it. This provides students with more varied practice and is intended to foster the development of a robust set of problemsolving skills.

## Modern Content—Solid Science

The world we live in is constantly changing and the science of chemistry continues to expand and evolve to meet the challenges of our modern world. So I have continued developing this textbook to provide a solid grounding in the basic principles of chemistry while setting them within a context of up-to-date information that serves to capture and hold students' attention and prepare them for studies in a variety of fields. I have tried to connect the study of chemistry to the study of other sciences-including physical, biological, environmental, medical, and engineering. My goal is to help students build a solid conceptual understanding and to encourage mastery of chemical conventions-including models, laws and equations, and such universally important principles as nomenclature, stoichiometry, measurement, and scale. While doing so I have integrated coverage of organic chemistry, biochemistry, green chemistry, and other examples to enhance the relevance of fundamental principles.

Toward this end, I have placed my chapter on organic chemistry (10) earlier than you would find it in most texts. It is not an exhaustive chapter, but presents a handful of organic reactions, germane to applications presented in the book, in the context of bonding and molecular structure. One example is the reaction of the hydroxide ion with carbon dioxide to form the hydrogen carbonate ion. Examples such as this are intended to serve both as a functional introduction to organic chemistry and as reinforcement of bonding theories and the importance of hybridization, molecular polarity, and electron density. I believe that this approach will be particularly beneficial to those who go on to take organic chemistry.

Each individual chapter outline serves as an advance organizer for key concepts and is followed by a brief statement of chapter learning objectives-these are two of the many pedagogical devices designed to foster crucial organization and good study habits. Additionally, I have used my own teaching experiences to identify and address common student misconceptions. One way that I have done this is through the use of "student annotations," margin notes written specifically for the student. These notes include "bite-sized" additional information such as common pitfall alerts, analogies to clarify concepts, pertinent reminders, and alternative perspectives.

## Building Problem-Solving Skills

The entirety of the text emphasizes the importance of problem solving as a crucial element in the study of chemistry. Beginning with Chapter 1, a basic guide fosters a consistent approach to solving problems throughout the text. Each Sample Problem is divided into four consistently applied steps:

1. Strategy This step lays the basic framework for the problem. We begin by reading the problem thoroughly to determine exactly what is being asked. Next, we determine what skills will be needed, and lay out a plan for solving the problem. Where appropriate, we make an estimate of the sign and/or the ballpark magnitude of the correct result.
2. Setup In this step we gather the necessary information for solving the problem, including information given within the problem itself, equations, constants, and tabulated data.
3. Solution Using the information gathered in the second step, we now calculate the answer to the problem. Attention to units is emphasized in this step, and each answer is reported to the proper number of significant figures
4. Think About It At this stage we consider whether or not the result makes sense. In some cases, the Think About It section shows an alternate route to the same answer. In other cases, it may include information that illustrates the relevance of the problem.

After working through this problem-solving approach in the Sample Problems, students are given two Practice Problems to solve. Practice Problem A is always very similar to the Sample Problem and can be solved using the same strategy and approach. Although Practice Problem B probes comprehension of the same concept as Practice Problem A, it generally is sufficiently different that it cannot be solved using the exact approach used in the Sample Problem. Practice Problem B takes problem solving to another level by requiring students to develop a strategy independently. The regular use of the sample problems and practice problems in this text will help students develop a robust and versatile set of problem-solving skills.

| Sample Problem 3.10 |  |
| :---: | :---: |
| Urea $\left[\left(\mathrm{NH}_{2}\right)_{2} \mathrm{CO}\right]$ is a by-product of protein metabolism. This waste product is formed in the liver and then filtered from the blood and excreted in the urine by the kidneys. Urea can be synthesized in the laboratory by the combination of ammonia and carbon dioxide according to the equation |  |
| (a) Calculate the amount of urea that will be produced by the complete reaction of 5.25 moles of ammonia. (b) Determine the stoichiometric amount of carbon dioxide required to react with 5.25 moles of ammonia. |  |
| Strategy Use the balanced chemical equation to determine the correct stoichiometric conversion factors, and then multiply by the number of moles of ammonia given. |  |
| Setup According to the balanced chemical equation, the conversion factor for ammonia and urea is either $\frac{2 \mathrm{~mol} \mathrm{NH}_{3}}{1 \mathrm{~mol}\left(\mathrm{NH}_{2}\right)_{2} \mathrm{CO}} \text { or } \frac{1{\mathrm{~mol}\left(\mathrm{NH}_{2}\right)_{2} \mathrm{CO}}_{2 \mathrm{~mol} \mathrm{NH}}^{3}}{}$ |  |
| To multiply by moles of $\mathrm{NH}_{3}$ and have the units cancel properly, we use the conversion factor with moles of $\mathrm{NH}_{3}$ in the denominator. <br> Similarly, the conversion factor for ammonia and carbon dioxide can be written as |  |
| $\frac{2 \mathrm{~mol} \mathrm{NH}_{3}}{1 \mathrm{~mol} \mathrm{CO}_{2}} \text { or } \frac{1 \mathrm{~mol} \mathrm{CO}_{2}}{2 \mathrm{~mol} \mathrm{NH}_{3}}$ | Think About It As always, check to be sure that units cancel properly in the calculation. Also, the balanced equation indicates that there will be fewer moles of urea produced than ammonia consumed. Therefore, your calculated number of moles of urea (2.63) should be smaller than the number of moles given in the problem (5.25). Similarly, the stoichiometric coefficients in the balanced equation are the same for carbon dioxide and urea, so your answers to this problem should also be the same for both species. |
| Again, we select the conversion factor with ammonia in the denominator so that moles of $\mathrm{NH}_{3}$ will cancel in the calculation. |  |
| Solution |  |
|  <br> (b) moles $\mathrm{CO}_{2}$ required $=5.25 \mathrm{~mol}_{\mathrm{AH}_{3}} \times \frac{1 \mathrm{~mol} \mathrm{CO}_{2}}{2 \mathrm{~mol} \mathrm{NH}_{3}}=2.63 \mathrm{~mol} \mathrm{CO}_{2}$ |  |
| Practice Problem A Nitrogen and hydrogen react to form ammonia according to the following balanced equation: $\mathrm{N}_{2}(\mathrm{~g})+3 \mathrm{H}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{NH}_{3}(\mathrm{~g})$. Calculate the number of moles of hydrogen required to react with 0.0880 mole of nitrogen, and the number of moles of ammonia that will form. |  |

balanced equation: $\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \longrightarrow 2 \mathrm{NH}_{3}(g)$. Calculate the number of moles of hydrogen
required to react with 0.0880 mole of nitrogen, and the number of moles of ammonia that will forn
EPractice Problem B Tetraphosphorus decoxide $\left(\mathrm{P}_{4} \mathrm{O}_{10}\right)$ reacts with water to produce phosphoric acid. Write and balance the equation for this reaction, and determine the number of moles of each reactant required to produce 5.80 moles of phosphoric acid.

Every section of the book that has Sample and Practice Problems ends with a set of Checkpoint questions. These are multiple-choice questions designed to help students assess their readiness to move on to the next section. Checkpoints include computational problems and, new to this edition, conceptual questions.

## Greater Relevance Through Modern Examples and Applications

I believe that the study of chemistry can be less daunting for students if they know how it applies to interesting, real-life examples. For this reason, I introduce each chapter with a brief and, I hope, interesting story that relates the concepts in the chapter to something familiar. Examples include Chemical Reactions and Chemotherapy (3), Lasers in Medicine (6) and Contaminated

Infant Formula (12). The Applying What You've Learned feature at the end of each chapter recalls the subject of the opening story and includes a multi-part exercise requiring students to use several of the skills they have just learned. Each part of the applying-what-you've-learned

## FAQ You May Be Wondering...

## How Can We Measure Solution Concentrations?

As you may know, white light is actually composed of all the colors of the rainbow. In fact, a rainbow results from the separation of white light by water droplets into the colors or wavelengths that make up the visible spectrum [ $\boldsymbol{H}$ Section 6.1]. Selective absorption of visible light is what makes some solutions appear colored; and, for a solution that is colored, the intensity of color is related to the solution's concentration (see Figure 4.9). This effect gives rise to a type of analysis known as visible spectrophotometry. A visible spectrophotometer compares the intensity of light that enters a sample (called the incident light) $I_{0}$, with the intensity of the light that is transmitted through the sample, $I$. Transmittance $(T)$ is the ratio of $I$ to $I_{0}$.

exercise links back to a specific Sample Problem within the chapter. Bringing Chemistry to Life segments also work toward this goal, utilizing engaging narrative to further explore applications in the real world, such as The Stoichiometry of Metabolism (3) or Heat Capacity and Hypothermia (5). FAQ boxes always address a question of interest. These may tackle a topical subject such as How Important Are Units? (1) but many also address important fundamental skills such as How Do I Assign Oxidation Numbers? (4) or How Am I Supposed to Remember All These Reactions? (3). The end-of-chapter Problem Sets also include a wide range of real-world problems and specific science, medical, and engineering applications. By using so many authentic, modern, and real-world examples, I hope that I have placed the science of chemistry within a human context that will provide for a more engaging learning environment and lead to a fuller understanding of the subject matter and a greater capacity to apply and retain the material.

## Greater Understanding Through Chemical Visualization

This text seeks to enhance student understanding through a variety of both unique and conventional visual techniques. A truly unique element in this text is the inclusion of a distinctive feature entitled Visualizing Chemistry. These two-page spreads appear as needed to emphasize fundamental, vitally important principles of chemistry. Setting them apart visually makes them easier to find and revisit as needed throughout the course term. Students asked for more Visualizing Chemistry art and we responded by adding eight new two-page figures. As an example, Chapter 8 includes a Visualizing Chemistry figure on the Born-Haber Cycle (pp. 304-305) and Chapter 18 on Factors That Influence the Entropy of a System (pp. 786-787). Each Visualizing Chemistry figure concludes with a "What's the point?" box that emphasizes the correct take-away message.

There is a series of conceptual end-of-chapter problems for each Visualizing Chemistry figure. These problems allow students to assess their understanding of the principles presented and have been incorporated into the online homework

The use of both Macro-Micro Art and ThreeDimensional Art builds on the principle of breaking down the complex into simpler, more user-friendly
 concepts. Breaking down chemical processes into molecular-level figures makes it easier for students to grasp what is happening on an atomic level. The same theory of breaking down the complex is evident in the treatment of Hybrid Orbitals. Through experience, I have learned that this is often a difficult-yet fundamentally crucial-element to grasp. So, for example, I have broken down the process of hybridization through a simple step-by-step visual treatment. Flow Charts and a variety of intertextual materials such as Rewind and Fast Forward Buttons and Checkpoint sections are meant to enhance student understanding and comprehension by reinforcing current concepts and connecting new concepts to those covered in other parts of the text.

## Access to Media

In addition to the text itself, students will have access to innovative applications of new educational technologies. Each new Visualizing Chemistry figure has been made into another captivating and pedagogically effective animation for additional reinforcement of subject matter first encountered in the textbook. MPEG Files of the Visualizing Chemistry figures will be available for download as Podcasts, allowing for convenient viewing to foster increased comprehension.

You will find the electronic homework integrated into the text in numerous places. Each animation is noted by , with the Visualizing Chemistry animations noted with . All Practice Problems B are available in our electronic homework program for practice or assignments. A multitude of end-of-chapter problems are in the electronic homework manager and noted by $\boldsymbol{f}$.

G11.74 Consider the three containers shown, all of which have the same volume and are at the same temperature. (a) Which container has the smallest mole fraction of gas A (red)? (b) Which container has the highest partial pressure of gas B (green)? (c) Which container has the highest total pressure?

For me, this text will always remain a work in progress. I encourage you to contact me with any comments or questions.

## $3^{360^{\circ}}$ Development Process

A key principle in the development of any general chemistry text is its ability to adapt to teaching specifications in a universal way. The only way to do so is by contacting those universal voicesand learning from their suggestions. Raymond Chang, a veteran author of general chemistry texts, has continued his involvement in the development of this text. Raymond's guidance and expertise proved to be instrumental in the creation of the first edition of this text, and his influential role continued during the development and production of this second edition.

We are confident that our book has the most current content the industry has to offer, thus pushing our desire for accuracy and up-to-date information to the highest standard possible. Extensive and open-minded advice is critical in the production of a superior text.

Here is a brief overview of the initiatives included in the $360^{\circ}$ Development Process of Chemistry, Second Edition, by Julia Burdge.

Board of Advisors A hand-picked group of trusted teachers, active in the general chemistry course, served as chief advisors and consultants to the author and editorial team during manuscript development. The Board of Advisors reviewed parts of the manuscript, and served as a sounding board for pedagogical, media, and design concerns, and as consultants on organizational changes.

Symposia Every year McGraw-Hill conducts a general chemistry symposium, which is attended by instructors from across the country. These events are an opportunity for editors from McGrawHill to gather information about the needs and challenges of instructors teaching these courses. This information helped to improve the book plan for Chemistry. These events also offer a forum for the attendees to exchange ideas and experiences with colleagues they might have not otherwise met.

Focus Group In addition to the symposia, we held a focus group specifically for improving the second edition. These selected chemistry professors provided ideas on improvements and suggestions for fine-tuning the content, pedagogy, and art.

Text Review Panels Over 100 teachers and academics from across the country and internationally reviewed the first edition to give feedback on content, design, pedagogy, and organization. This feedback was summarized by the book team and used to guide the direction of the text.

Accuracy Panel A select group of chemistry experts served as the chief advisors for the accuracy and clarity of the text and solutions manual. These individuals reviewed page proofs in the first rounds, and oversaw the writing and accuracy check of the instructor's solutions manuals, test bank, and other ancillary materials.

Student Focus Groups on Content and Design Two student class tests and three student focus groups provided the editorial team with an understanding of how content and the design of a textbook impact a student's homework and study habits in the general chemistry course.

Art Development Julia Burdge, along with our designer and editors, worked closely with Precision Graphics, an art development company, to create the visual program within this text. Several personal visits to Precision Graphics in Champaign, IL, enabled the author and art team to work together in developing the individual art pieces, art-photo combinations, process boxes, and new animations of chemical processes. Julia's entirely unique Visualizing Chemistry figures have been expanded in her second edition based on student and instructor feedback. The end result is a distinctive and innovative visual program that ensures accuracy in relation to textual information, and a style that is uniquely Burdge.

## Acknowledgments

I wish to thank the many people who have contributed to the continued development of this text.
Raymond Chang's contributions have again been invaluable. His unfaltering diligence and attention to detail and his ongoing commitment to the quality of this book have had an immeasurable impact on the project.

My Board of Advisors-Tim Brewer, Dana Chatellier, Chris Cheatum, Barbara Cole, Gregg Dieckmann, John Hopkins, Philip Klebba, Rosemary Loza, Steve Watkins and Chris Yerkeshave generously contributed their time, their energy, and their talent to impact the revision of this text. Many have used the book in its first edition and have provided essential feedback for its continued development.

Mike McIntire checked the revised manuscript, solving all of the in-chapter problems and ensuring their accuracy-often going above and beyond the call to contribute to the overall quality of the finished product.

A talented group of people at Precision Graphics worked with me closely on my art program and paging.

My family, as always, continues to be there for me-no matter what.
Finally, I wish to thank my McGraw-Hill family for their continued confidence and support: Publisher Ryan Blankenship, Senior Sponsoring Editor Tami Hodge, Senior Developmental Editor Shirley Oberbroeckling, Senior Project Manager Gloria Schiesl, Senior Designer David Hash, and Senior Marketing Manager Todd Turner.

## ENHANCED SUPPORT FOR Faculty \& Students

McGraw-Hill offers various tools and technology products in support of Chemistry to both faculty and students alike. Instructors can obtain teaching aides by calling the McGraw-Hill Customer Service Department at 1-800-338-3987, visiting our online catalog at www.mhe.com, or by contacting their local McGraw-Hill sales representative.

## For the Instructor

## ARIS

The Assessment, Review, and Instruction System, also known as ARIS, is an electronic homework and course management system designed for greater flexibility, power, and ease of use than any other system. Whether you are looking for a preplanned course or one you can customize to fit your course needs, ARIS is your solution.

In addition to having access to all student digital learning objects, ARIS enables instructors to:

- Build assignments
- Track student progress
- Be flexible

## McGraw-Hill TEGRITY Campus ${ }^{\text {™ }}$

Tegrity Campus is a service that makes class time available all the time by automatically capturing every lecture in a searchable format for students to review when they study and complete assignments. With a simple one-click start-and-stop process, you capture all computer screens and corresponding audio. Students replay any part of any class with easy-to-use browser-based viewing on a PC or Mac.

## Presentation Center

The Presentation Center is a complete set of electronic book images and assets for instructors. You can build instructional materials wherever, whenever, and however you want! Accessed from your textbook's ARIS website, the Presentation Center is an online digital library containing photos, artwork, animations, and other media types that can be used to create customized lectures, visually enhanced tests and quizzes, compelling course websites, or attractive printed support materials. All assets are copyrighted by McGraw-Hill Higher Education, but can be used by instructors for classroom purposes. The visual resources in this collection include:

- Art. Full-color digital files of all illustrations in the book.
- Photos. The photos collection contains digital files of photographs from the text.
- Tables. Every table that appears in the text is available electronically.
- Animations. Numerous full-color animations illustrating important processes are also provided.
- PowerPoint ${ }^{(8)}$ Lecture Outlines. Ready-made presentations for each chapter of the text.
- PowerPoint Slides. All illustrations, photos, and tables are preinserted by chapter into blank PowerPoint slides.

Presentation Center's dynamic search engine allows you to explore by discipline, course, textbook chapter, asset type, or keyword.

## Computerized Test Bank Online

A comprehensive bank of test questions by Debbie Beard (University of Mississippi) is provided within a computerized test bank, enabling you to create paper and online tests or quizzes in this easy-to-use program. Imagine being able to create and access your test or quiz anywhere, at any time.

The test bank contains over 3,000 multiple-choice, true/false, and short answer questions. The questions, which are graded in difficulty, are comparable to the problems in the text.

## Instructors Manual

Written by Nick Flynn from San Angelo State University, the instructor's manual provides literature citations, tips, integration of media, and end-of-chapter problem difficulty levels and categories.

## Student Response System

Wireless technology brings interactivity into the classroom or lecture hall. Instructors and students receive immediate feedback through wireless response pads that are easy to use and engage students. This system can be used by instructors to:

- Take attendance
- Administer quizzes and tests
- Create a lecture with intermittent questions
- Manage lectures and student comprehension through the use of the gradebook
- Integrate interactivity into their PowerPoint presentations

## Content Delivery Flexibility

Chemistry by Julia Burdge is available in many formats in addition to the traditional textbook to give instructors and students more choices when deciding on the format of their chemistry text. Choices include:

- Color Custom by Chapter For even more flexibility, we offer the Burdge: Chemistry text in a full-color, custom version that allows instructors to pick the chapters they want included. Students pay for only what the instructor chooses.
- eBook If you or your students are ready for an alternative version of the traditional textbook, McGraw-Hill brings you innovative and inexpensive electronic textbooks. eBooks from McGrawHill are smart, interactive, searchable and portable. Included is a powerful suite of built-in tools that allow detailed searching, highlighting, note taking, and student-to-student or instructor-to-student note sharing. In addition, the media-rich eBook for Chemistry integrates relevant animations and videos into the textbook content for a true multimedia learning experience.

## Cooperative Chemistry Laboratory Manual

By Melanie Cooper (Clemson University), this innovative guide features open-ended problems designed to simulate experience in a research lab. Working in groups, students investigate one problem over a period of several weeks, so that they might complete three or four projects during the semester, rather than one preprogrammed experiment per class. The emphasis here is on experimental design, analysis, problem solving, and communication.

## For the Students

Students can order supplemental study materials by contacting their campus bookstore, calling 1-800-262-4729, or online at www.shopmcgraw-hill.com.

To help students maximize their learning experience in chemistry, McGraw-Hill offers the following options to students:

## McGraw-Hill ARIS

ARIS (Assessment, Review, and Instruction System) is an electronic study system that offers students a digital portal of knowledge.

Students can readily access a variety of digital learning objects, which include:

- Chapter level quizzing
- Animations
- Interactives
- MP3 and MP4 downloads of selected content

## Student Solutions Manual

In this manual by Jon Booze (AccuMedia Publishing Services) and Julia Burdge, the student will find detailed solutions and explanations for the odd-numbered problems in this text.

## Student Study Guide

This study guide, by Lydia Martinez-Rivera (University of Texas at San Antonio), helps students focus their time and energy on important concepts. The study guide offers students a variety of tools:

- Practice questions
- Outline/summary of fundamental concepts-efficient listing of key concepts
- Key terms
- Strategies for difficult concepts

## How the Scientific Method Helped Defeat Smallpox

To advance understanding of science, researchers use a set of guidelines known as the scientific method. The guidelines involve careful observations, educated reasoning, and the development of hypotheses and theories, which must undergo extensive testing. One of the most compelling examples of the success of the scientific method is the story of smallpox.

Smallpox is one of the diseases classified by the Centers for Disease Control and Prevention (CDC) as a Category A bioterrorism agent. This disease has had an immeasurable impact on human history. During the sixteenth century, European explorers brought smallpox with them to the Americas, devastating native populations and leaving them vulnerable to attack-in effect, shaping the conquest of the New World. In the twentieth century alone the disease killed an estimated half a billion people worldwide-leaving many more permanently disfigured, blind, or both.
Late in the eighteenth century, an English doctor named Edward Jenner observed that even during outbreaks of smallpox in Europe, milkmaids seldom contracted the disease. He reasoned that when people who had frequent contact with cows contracted cowpox, a similar but far less harmful disease, they developed a natural immunity to smallpox. He predicted that intentional exposure to the cowpox virus would produce the same immunity. In 1796 Jenner exposed an 8 -year-old boy named James Phipps to the cowpox virus using pus from the cowpox lesions of a milkmaid named Sarah Nelmes. Six weeks later, when Jenner then exposed Phipps to the smallpox virus, the boy did not contract the disease. Subsequent experiments using the same technique (later dubbed vaccination from the Latin vacca meaning "cow") confirmed that immunity to smallpox could be induced.

The last naturally occurring case of smallpox occurred in 1977 in Somalia. In 1980 the World Health Organization declared smallpox officially eradicated. This historic triumph over a dreadful disease, one of the greatest medical advances of the twentieth century, began with Jenner's astute observations, inductive reasoning, and careful experimenta-tion-the essential elements of the scientific method.

Student Annotation: Category A agents are those believed to pose the greatest potential threat to the public and that have a moderate to high potential for large-scale dissemination.

Until recently, almost everyone had a smallpox vaccine scar-usually on the upper arm.

Student Annotation: Although naturally occurring smallpox was wiped out worldwide, samples have been kept in research laboratories in the United States and the former Soviet Union, and several countries are now thought to have unauthorized stockpiles of the virus.

At the end of this chapter, you will be able to answer several questions related to the smallpox vaccine [ $n$ Page 25].

## In This Chapter, You Will Learn:

Some of what chemistry is and how it is studied using the scientific method. You will learn about the system of units used by scientists and about expressing and dealing with the numbers that result from scientific measurements.

## Before you begin, you should review

- Basic algebra
- Scientific notation [ $\boldsymbol{M}$ Appendix 1]

### 1.1 The Study of Chemistry

Chemistry often is called the central science because knowledge of the principles of chemistry can facilitate understanding of other sciences, including physics, biology, geology, astronomy, oceanography, engineering, and medicine. Chemistry is the study of matter and the changes that matter undergoes. Matter is what makes up our bodies, our belongings, our physical environment, and in fact our universe. Matter is anything that has mass and occupies space.

## Chemistry You May Already Know

You may already be familiar with some of the terms used in chemistry. Even if this is your first chemistry course, you may have heard of molecules and know them to be tiny pieces of a substance-much too tiny to see. Further, you may know that molecules are made up of atoms, even smaller pieces of matter. And even if you don't know what a chemical formula is, you probably know that $\mathrm{H}_{2} \mathrm{O}$ is water. You may have used, or at least heard, the term chemical reaction; and you are undoubtedly familiar with a variety of chemical reactions, such as those shown in Figure 1.1.

Figure 1.1 Many familiar processes are chemical reactions: (a) The flame of a gas stove is the combustion of natural gas, which is primarily methane. (b) The bubbles produced when Alka-Seltzer dissolves in water are carbon dioxide, produced by a chemical reaction between two ingredients in the tablets. (c) The formation of rust is a chemical reaction that occurs when iron, water, and oxygen are all present. (d) Many baked goods "rise" as the result of a chemical reaction that produces carbon dioxide.

## FA@ You May Be Wondering...

## What Do Molecules Look Like?

Molecules are far too small for us to observe them directly. An effective means of visualizing them is by the use of molecular models. Throughout this book, we will represent matter at the molecular level using molecular art, the two-dimensional equivalent of molecular models. In these pictures, atoms are represented as spheres and atoms of particular elements are represented using specific colors. Table 1.1 lists some of the elements that you will encounter most often and the colors used to represent them in this book.

Molecular art can be of ball-and-stick models, in which the bonds connecting atoms appear as sticks [Figure 1.2(b)], or of space-filling models, in which the atoms appear to overlap one another [Figure 1.2(c)]. Ball-and-stick and space-filling models

## TABLE 1.1

Colors of Elements Commonly Used in Molecular Art

illustrate the specific, three-dimensional arrangement of the atoms. The ball-and-stick model does a good job of illustrating the arrangement of atoms, but exaggerates the distances between atoms, relative to their sizes. The space-filling model gives a more accurate picture of these interatomic distances but can obscure the details of the three-dimensional arrangement.

Figure 1.2 Water represented with a (a) molecular formula, (b) ball-and-stick model, and (c) space-filling model.

The reactions in Figure 1.1 are all things that you can observe at the macroscopic level. In other words, these processes and their results are visible to the human eye. In studying chemistry, you will learn to visualize and understand these same processes at the molecular level.

Although it can take many different forms, all matter consists of various combinations of atoms of only a relatively small number of simple substances called elements. The properties of matter depend on which of these elements it contains and on how the atoms of those elements are arranged.

## The Scientific Method

Experiments are the key to advancing our understanding of chemistry-or any science. Although not all scientists will necessarily take the same approach to experimentation, they all follow a set of guidelines known as the scientific method to add their results to the larger body of knowledge within a given field. The flowchart in Figure 1.3 illustrates this basic process. The method begins with the gathering of data via observations and experiments. Scientists study these data and try to identify patterns or trends. When they find a pattern or trend, they may summarize their findings with a law, a concise verbal or mathematical statement of a reliable relationship between phenomena. Scientists may then formulate a hypothesis, a tentative explanation for their observations. Further experiments are designed to test the hypothesis. If experiments indicate that the hypothesis is incorrect, the scientists go back to the drawing board, try to come up with

Figure 1.3 Flowchart of the scientific method.

Student Annotation: Some books refer to substances as pure substances. These two terms generally mean the same thing although the adjective pure is unnecessary in this context because a substance is, by definition, pure.

Student Annotation: Solids and liquids sometimes are referred to collectively as the condensed phases. Liquids and gases sometimes are referred to collectively as fluids.
a different interpretation of their data, and formulate a new hypothesis. The new hypothesis will then be tested by experiment. When a hypothesis stands the test of extensive experimentation, it may evolve into a theory. A theory is a unifying principle that explains a body of experimental observations and the laws that are based on them. Theories can also be used to predict related phenomena, so theories are constantly being tested. If a theory is disproved by experiment, then it must be discarded or modified so that it becomes consistent with experimental observations.

### 1.2 Classification of Matter

Chemists classify matter as either a substance or a mixture of substances. A substance may be further categorized as either an element or a compound. A substance is a form of matter that has a definite (constant) composition and distinct properties. Examples are salt (sodium chloride), iron, water, mercury, carbon dioxide, and oxygen. Substances can be either elements (such as iron, mercury, and oxygen) or compounds (such as salt, water, and carbon dioxide). They differ from one another in composition and can be identified by appearance, smell, taste, and other properties.

## States of Matter

All substances can, in principle, exist as a solid, a liquid, and a gas, the three physical states depicted in Figure 1.4. In a solid, particles are held close together in an orderly fashion with little freedom of motion. As a result, a solid does not conform to the shape of its container. Particles in a liquid are close together but are not held rigidly in position; they are free to move past one another. Thus, a liquid conforms to the shape of the part of the container it fills. In a gas, the particles are separated by distances that are very large compared to the size of the particles. A sample of gas assumes both the shape and the volume of its container.

The three states of matter can be interconverted without changing the chemical composition of the substance. Upon heating, a solid (e.g., ice) will melt to form a liquid (water). Further heating will vaporize the liquid, converting it to a gas (water vapor). Conversely, cooling a gas will cause it to condense into a liquid. When the liquid is cooled further, it will freeze into the solid form. Figure 1.5 shows the three physical states of water.

## Elements

An element is a substance that cannot be separated into simpler substances by chemical means. Iron, mercury, oxygen, and hydrogen are just 4 of the 117 elements that have been identified. Most of the known elements occur naturally on Earth. The others have been produced by scientists via nuclear processes, which are discussed in Chapter 20. As shown in Figure 1.6(a) and (b), an element may consist of atoms or molecules.

For convenience, chemists use symbols of one or two letters to represent the elements. Only the first letter of an element's chemical symbol is capitalized. A list of the elements and their

Figure 1.4 Molecular-level illustrations of a solid, liquid, and gas.
symbols appears on the inside front cover of this book. The symbols of some elements are derived from their Latin names-for example, Ag from argentum (silver), Pb from plumbum (lead), and Na from natrium (sodium)—while most of them come from their English names-for example, H for hydrogen, Co for cobalt, and Br for bromine.

## Compounds

Most elements can combine with other elements to form compounds. Hydrogen gas, for example, burns in the presence of oxygen gas to form water, which has properties that are distinctly different from those of either hydrogen or oxygen. Thus, water is a compound, a substance composed of atoms of two or more elements chemically united in fixed proportions [Figure 1.6(c)]. The elements that make up a compound are called the compound's constituent elements. For example, the constituent elements of water are hydrogen and oxygen.

A compound cannot be separated into simpler substances by any physical process. (A physical process [ Section 1.4] is one that does not change the identity of the matter. Examples of physical processes include boiling, freezing, and filtering.) Instead, the separation of a compound into its constituent elements requires a chemical reaction.

## Mixtures

A mixture is a combination of two or more substances [Figure 1.6(d)] in which the substances retain their distinct identities. Like pure substances, mixtures can be solids, liquids, or gases. Some familiar examples are mixed nuts, 14-carat gold, apple juice, milk, and air. Mixtures do not have a universal constant composition. Therefore, samples of air collected in different locations will differ in composition because of differences in altitude, pollution, and other factors. Various brands of apple juice may differ in composition because of the use of different varieties of apples, or there may be differences in processing and packaging, and so on.

Mixtures are either homogeneous or heterogeneous. When we dissolve a teaspoon of sugar in a glass of water, we get a homogeneous mixture because the composition of the mixture is

Figure 1.5 Water as a solid (ice), liquid, and gas. (We can't actually see water vapor, any more than we can see the nitrogen and oxygen that make up most of the air we breathe. When we see steam or clouds, what we are actually seeing is water vapor that has condensed upon encountering cold air.)

[^0]

Figure 1.6 (a) Isolated atoms of an element. (b) Molecules of an element. (c) Molecules of a compound, consisting of more than one element. (d) A mixture of atoms of an element and molecules of an element and a compound.

Figure 1.7 (a) A heterogeneous mixture contains iron filings and sand. (b) A magnet is used to separate the iron filings from the mixture.

Figure 1.8 Flowchart for the classification of matter.
uniform throughout. If we mix sand with iron filings, however, the sand and the iron filings remain distinct and discernible from each other (Figure 1.7). This type of mixture is called a heterogeneous mixture because the composition is not uniform.

Mixtures, whether homogeneous or heterogeneous, can be separated by physical means into pure components without changing the identities of the components. Thus, sugar can be recovered from a water solution by evaporating the solution to dryness. Condensing the vapor will give us back the water component. To separate the sand-iron mixture, we can use a magnet to remove the iron filings from the sand, because sand is not attracted to the magnet [see Figure 1.7(b)]. After separation, the components of the mixture will have the same composition and properties as they did prior to being mixed. The relationships among substances, elements, compounds, and mixtures are summarized in Figure 1.8.

### 1.3 Scientific Measurement

Scientists use a variety of devices to measure the properties of matter. A meterstick is used to measure length; a buret, pipet, graduated cylinder, and volumetric flask are used to measure volume (Figure 1.9); a balance is used to measure mass; and a thermometer is used to measure temperature. Properties that can be measured are called quantitative properties because they are expressed using numbers. When we express a measured quantity with a number, though, we must always include the appropriate unit; otherwise, the measurement is meaningless. For example, to say that the depth of a swimming pool is 3 is insufficient to distinguish between one that is 3 feet ( 0.9 meters) and one that is 3 meters ( 9.8 feet) deep. Units are essential to reporting measurements correctly.

The two systems of units with which you are probably most familiar are the English system (foot, gallon, pound, etc.) and the metric system (meter, liter, kilogram, etc.). Although there has been an increase in the use of metric units in the United States in recent years, English units still are used commonly. For many years scientists recorded measurements in metric units, but in 1960, the General Conference on Weights and Measures, the international authority on units, proposed a revised metric system for universal use by scientists. We will use both metric and revised metric (SI) units in this book.

## SI Base Units

The revised metric system is called the International System of Units (abbreviated SI, from the French Système Internationale d'Unités). Table 1.2 lists the seven SI base units. All other units of measurement can be derived from these base units. The SI unit for volume, for instance, is derived by cubing the SI base unit for length. The prefixes listed in Table 1.3 are used to denote decimal fractions and multiples of SI units. This enables scientists to tailor the magnitude of a unit to a particular application. For example, the meter (m) is appropriate for describing the dimensions of a classroom, but the kilometer $(\mathrm{km}), 1000 \mathrm{~m}$, is more appropriate for describing the distance between two cities. Units that you will encounter frequently in the study of chemistry include those for mass, temperature, volume, and density.

| TABLE 1.2 | Base SI Units |
| :--- | :--- |
| Base Quantity | Name of Unit |
| Length | meter |
| Mass | kilogram |
| Time | second |
| Electric current | ampere |
| Temperature | kelvin |
| Amount of substance | mole |
| Luminous intensity | candela |

Figure 1.9 (a) A volumetric flask is used to prepare a precise volume of a solution for use in the laboratory. (b) A graduated cylinder is used to measure a volume of liquid. It is less precise than the volumetric flask. (c) A volumetric pipette is used to deliver a precise amount of liquid. (d) A burette is used to measure the volume of a liquid that has been added to a container. A reading is taken before and after the liquid is delivered, and the volume delivered is determined by subtracting the first reading from the second.

Volumetric flask
(a)

(b)

Student Annotation: According to the U.S. Metric Association (USMA), the United States is "the only significant holdout" with regard to adoption of the metric system. The other countries that continue to use traditional units are Myanmar (formerly Burma) and Liberia.
(c)

Student Annotation: Depending on the precision required, the conversion from degrees Celsius to kelvin often is done simply by adding 273, rather than 273.15.

Think About It Check your math and remember that converting a temperature from degrees Celsius to kelvin is different from converting a difference in temperature from degrees Celsius to kelvin.

## TABLE 1.3 Prefixes Used with SI Units

| Prefix | Symbol | Meaning | Example |
| :--- | :---: | :--- | :--- |
| Tera- | T | $1 \times 10^{12}(1,000,000,000,000)$ | 1 teragram $(\mathrm{Tg})=1 \times 10^{12} \mathrm{~g}$ |
| Giga- | G | $1 \times 10^{9}(1,000,000,000)$ | 1 gigawatt $(\mathrm{GW})=1 \times 10^{9} \mathrm{~W}$ |
| Mega- | M | $1 \times 10^{6}(1,000,000)$ | 1 megahertz $(\mathrm{MHz})=1 \times 10^{6} \mathrm{~Hz}$ |
| Kilo- | k | $1 \times 10^{3}(1,000)$ | 1 kilometer $(\mathrm{km})=1 \times 10^{3} \mathrm{~m}$ |
| Deci- | d | $1 \times 10^{-1}(0.1)$ | 1 deciliter $(\mathrm{dL})=1 \times 10^{-1} \mathrm{~L}$ |
| Centi- | c | $1 \times 10^{-2}(0.01)$ | 1 centimeter $(\mathrm{cm})=1 \times 10^{-2} \mathrm{~m}$ |
| Milli- | m | $1 \times 10^{-3}(0.001)$ | 1 millimeter $(\mathrm{mm})=1 \times 10^{-3} \mathrm{~m}$ |
| Micro- | $\mu$ | $1 \times 10^{-6}(0.000001)$ | 1 microliter $(\mu \mathrm{L})=1 \times 10^{-6} \mathrm{~L}$ |
| Nano- | n | $1 \times 10^{-9}(0.000000001)$ | 1 nanosecond $(\mathrm{ns})=1 \times 10^{-9} \mathrm{~s}$ |
| Pico- | p | $1 \times 10^{-12}(0.000000000001)$ | 1 picogram $(\mathrm{pg})=1 \times 10^{-12} \mathrm{~g}$ |

## Mass

Although the terms mass and weight often are used interchangeably, they do not mean the same thing. Strictly speaking, weight is the force exerted by an object or sample due to gravity. Mass is a measure of the amount of matter in an object or sample. Because gravity varies from location to location (gravity on the moon is only about one-sixth that on Earth), the weight of an object varies depending on where it is measured. The mass of an object remains the same regardless of where it is measured. The SI base unit of mass is the kilogram (kg), but in chemistry the smaller gram (g) often is more convenient and is more commonly used:

$$
1 \mathrm{~kg}=1000 \mathrm{~g}=1 \times 10^{3} \mathrm{~g}
$$

## Temperature

There are two temperature scales used in chemistry. Their units are degrees Celsius $\left({ }^{\circ} \mathrm{C}\right)$ and kelvin $(\mathrm{K})$. The Celsius scale was originally defined using the freezing point $\left(0^{\circ} \mathrm{C}\right)$ and the boiling point $\left(100^{\circ} \mathrm{C}\right)$ of pure water at sea level. As Table 1.2 shows, the SI base unit of temperature is the kelvin. Kelvin is known as the absolute temperature scale, meaning that the lowest temperature possible is 0 K , a temperature referred to as "absolute zero." No degree sign $\left({ }^{\circ}\right)$ is used to represent a temperature on the Kelvin scale. The theoretical basis of the Kelvin scale has to do with the behavior of gases and is discussed in Chapter 11.

Units of the Celsius and Kelvin scales are equal in magnitude, so a degree Celsius is equivalent to a kelvin. Thus, if the temperature of an object increases by $5^{\circ} \mathrm{C}$, it also increases by 5 K . Absolute zero on the Kelvin scale is equivalent to $-273.15^{\circ} \mathrm{C}$ on the Celsius scale. We use the following equation to convert a temperature from units of degrees Celsius to kelvin:

Equation 1.1

$$
\mathrm{K}={ }^{\circ} \mathrm{C}+273.15
$$

Sample Problem 1.1 illustrates conversions between these two temperature scales.

## Sample Problem 1.1

Normal human body temperature can range over the course of the day from about $36^{\circ} \mathrm{C}$ in the early morning to about $37^{\circ} \mathrm{C}$ in the afternoon. Express these two temperatures and the range that they span using the Kelvin scale.

Strategy Use Equation 1.1 to convert temperatures from the Celsius scale to the Kelvin scale. Then convert the range of temperatures from degrees Celsius to kelvin, keeping in mind that $1^{\circ} \mathrm{C}$ is equivalent to 1 K .

Setup Equation 1.1 is already set up to convert the two temperatures from degrees Celsius to kelvin. No further manipulation of the equation is needed. The range in kelvin will be the same as the range in degrees Celsius.

Solution $36^{\circ} \mathrm{C}+273=309 \mathrm{~K}, 37^{\circ} \mathrm{C}+273=310 \mathrm{~K}$, and the range of $1^{\circ} \mathrm{C}$ is equal to a range of 1 K .

Practice Problem A Express the freezing point of water $\left(0^{\circ} \mathrm{C}\right)$, the boiling point of water $\left(100^{\circ} \mathrm{C}\right)$, and the range spanned by the two temperatures using the Kelvin scale.

EPractice Problem B According to the website of the National Aeronautics and Space Administration (NASA), the average temperature of the universe is 2.7 K . Convert this temperature to degrees Celsius.

## Bringing Chemistry to Life

## Fahrenheit Temperature Scale

Outside of scientific circles, the Fahrenheit temperature scale is the one most used in the United States. Before the work of Daniel Gabriel Fahrenheit (German physicist, 1686-1736), there were numerous different, arbitrarily defined temperature scales, none of which gave consistent measurements. Accounts of exactly how Fahrenheit devised his temperature scale vary from source to source. In one account, in 1724 , Fahrenheit labeled as $0^{\circ}$ the lowest artificially attainable temperature at the time (the temperature of a mixture of ice, water, and ammonium chloride). Using a traditional scale consisting of 12 degrees, he labeled the temperature of a healthy human body as the twelfth degree. On this scale, the freezing point of water occurred at the fourth degree. For better resolution, each degree was further divided into eight smaller degrees. This convention makes the freezing point of water $32^{\circ}$ and normal body temperature $96^{\circ}$. Today we consider normal body temperature to be somewhat higher than $96^{\circ} \mathrm{F}$.

The boiling point of water on the Fahrenheit scale is $212^{\circ}$, meaning that there are 180 degrees $\left(212^{\circ}-32^{\circ}\right)$ between the freezing and boiling points. This separation is considerably more than the 100 degrees between the freezing point and boiling point of water on the Celsius scale [named after Swedish physicist Ander Celsius (1701-1744)]. Thus, the size of a degree on the Fahrenheit scale is only $100 / 180$ or five-ninths of a degree on the Celsius scale. Equations 1.2 and 1.3 give the relationship between Fahrenheit and Celsius temperatures.
temperature in Celsius $=\left(\right.$ temperature in Fahrenheit $\left.-32^{\circ} \mathrm{F}\right) \times \frac{5^{\circ} \mathrm{C}}{9^{\circ} \mathrm{F}}$

## Equation 1.2

and
temperature in Fahrenheit $=\frac{9^{\circ} \mathrm{F}}{5^{\circ} \mathrm{C}} \times($ temperature in degrees Celsius $)+32^{\circ} \mathrm{F} \quad$ Equation 1.3

## Sample Problem 1.2

A body temperature above $39^{\circ} \mathrm{C}$ constitutes a high fever. Convert this temperature to the Fahrenheit scale.

Strategy We are given a temperature in Celsius and are asked to convert it to Fahrenheit.
Setup We use Equation 1.3:

$$
\text { temperature in Fahrenheit }=\frac{9^{\circ} \mathrm{F}}{5^{\circ} \mathrm{C}} \times(\text { temperature in Celsius })+32^{\circ} \mathrm{F}
$$

## Solution

$$
\text { temperature in Fahrenheit }=\frac{9^{\circ} \mathrm{F}}{5^{\circ} \mathrm{C}} \times 39^{\circ} \mathrm{C}+32^{\circ} \mathrm{F}=102.2^{\circ} \mathrm{F}
$$

Think About It Knowing that "normal" body temperature on the Fahrenheit scale is approximately $99^{\circ} \mathrm{F}\left(98.6^{\circ} \mathrm{F}\right.$ is the number most often cited), $102.2^{\circ} \mathrm{F}$ seems like a reasonable answer.

Practice Problem A Convert the temperatures $45.0^{\circ} \mathrm{C}$ and $90.0^{\circ} \mathrm{C}$, and the difference between them, to degrees Fahrenheit.

GPractice Problem B In Ray Bradbury's 1953 novel Fahrenheit $451,451^{\circ} \mathrm{F}$ is said to be the temperature at which books, which have been banned in the story, ignite. Convert $451^{\circ} \mathrm{F}$ to the Celsius scale.

## Derived Units: Volume and Density

There are many quantities, such as volume and density, that require units not included in the base SI units. In these cases, we must combine base units to derive appropriate units for the quantity.

The derived SI unit for volume, the meter cubed $\left(\mathrm{m}^{3}\right)$, is a larger volume than is practical in most laboratory settings. The more commonly used metric unit, the liter $(\mathrm{L})$, is derived by cubing the decimeter (one-tenth of a meter) and is therefore also referred to as the cubic decimeter $\left(\mathrm{dm}^{3}\right)$. Another commonly used metric unit of volume is the milliliter ( mL ), which is derived by cubing the centimeter ( $1 / 100$ of a meter). The milliliter is also referred to as the cubic centimeter $\left(\mathrm{cm}^{3}\right)$. Figure 1.10 illustrates the relationship between the liter $\left(\right.$ or $\left.\mathrm{dm}^{3}\right)$ and the milliliter ( $\mathrm{or} \mathrm{cm}^{3}$ ).

Density is the ratio of mass to volume. Oil floats on water, for example, because, in addition to not mixing with water, oil has a lower density than water. That is, given equal volumes of the two liquids, the oil will have a smaller mass than the water. Density is calculated using the following equation:

$$
\text { Equation } 1.4 \quad d=\frac{m}{V}
$$

Oil floating on water is a familiar

where $d, m$, and $V$ denote density, mass, and volume, respectively. The SI-derived unit for density is the kilogram per cubic meter $\left(\mathrm{kg} / \mathrm{m}^{3}\right)$. This unit is too large for most common uses, however, so grams per cubic centimeter $\left(\mathrm{g} / \mathrm{cm}^{3}\right)$ and its equivalent, grams per milliliter $(\mathrm{g} / \mathrm{mL})$, are used to express the densities of most solids and liquids. Water, for example, has a density of $1.00 \mathrm{~g} / \mathrm{cm}^{3}$ at $4^{\circ} \mathrm{C}$. Because gas densities generally are very low, we typically express them in units of grams per liter ( $\mathrm{g} / \mathrm{L}$ ):

$$
\begin{gathered}
1 \mathrm{~g} / \mathrm{cm}^{3}=1 \mathrm{~g} / \mathrm{mL}=1000 \mathrm{~kg} / \mathrm{m}^{3} \\
1 \mathrm{~g} / \mathrm{L}=0.001 \mathrm{~g} / \mathrm{mL}
\end{gathered}
$$

Sample Problem 1.3 illustrates density calculations.

## Sample Problem 1.3

Ice cubes float in a glass of water because solid water is less dense than liquid water. (a) Calculate the density of ice given that, at $0^{\circ} \mathrm{C}$, a cube that is 2.0 cm on each side has a mass of 7.36 g , and (b) determine the volume occupied by 23 g of ice at $0^{\circ} \mathrm{C}$.

Strategy (a) Determine density by dividing mass by volume (Equation 1.4), and (b) use the calculated density to determine the volume occupied by the given mass.

Setup (a) We are given the mass of the ice cube, but we must calculate its volume from the dimensions given. The volume of the ice cube is $(2.0 \mathrm{~cm})^{3}$, or $8.0 \mathrm{~cm}^{3}$. (b) Rearranging Equation 1.4 to solve for volume gives $V=m / d$.

## Solution

(a) $d=\frac{7.36 \mathrm{~g}}{8.0 \mathrm{~cm}^{3}}=0.92 \mathrm{~g} / \mathrm{cm}^{3} \quad$ or $\quad 0.92 \mathrm{~g} / \mathrm{mL}$
(b) $V=\frac{23 \mathrm{~g}}{0.92 \mathrm{~g} / \mathrm{cm}^{3}}=25 \mathrm{~cm}^{3}$ or 25 mL

Practice Problem A Given that 25.0 mL of mercury has a mass of 340.0 g , calculate (a) the density of mercury and (b) the mass of 120.0 mL of mercury.

HPractice Problem B Calculate (a) the density of a solid substance if a cube measuring 2.33 cm on one side has a mass of 117 g and (b) the mass of a cube of the same substance measuring 7.41 cm on one side.

The box on page 14 illustrates the importance of using units carefully in scientific work.

## Checkpoint 1.3 Scientific Measurement

1.3.1 The coldest temperature ever recorded on Earth was $-128.6^{\circ} \mathrm{F}$ (recorded at Vostok Station, Antarctica, on July 21, 1983). Express this temperature in degrees Celsius and in kelvins.
a) $-89.2^{\circ} \mathrm{C},-89.2 \mathrm{~K}$
b) $-289.1^{\circ} \mathrm{C},-15.9 \mathrm{~K}$
c) $-89.2^{\circ} \mathrm{C}, 183.9 \mathrm{~K}$
d) $-173.9^{\circ} \mathrm{C}, 99.3 \mathrm{~K}$
e) $-7.0^{\circ} \mathrm{C}, 266.2 \mathrm{~K}$
1.3.2 What is the density of an object that has a volume of $34.2 \mathrm{~cm}^{3}$ and a mass of 19.6 g ?
a) $0.573 \mathrm{~g} / \mathrm{cm}^{3}$
b) $1.74 \mathrm{~g} / \mathrm{cm}^{3}$
c) $670 \mathrm{~g} / \mathrm{cm}^{3}$
d) $53.8 \mathrm{~g} / \mathrm{cm}^{3}$
e) $14.6 \mathrm{~g} / \mathrm{cm}^{3}$
1.3.3 A sample of water is heated from room temperature to just below the boiling point. The overall change in temperature is $72^{\circ} \mathrm{C}$. Express this temperature change in kelvins.
a) 345 K
b) 72 K
c) 0 K
d) 201 K
e) 273 K
1.3.4 Given that the density of gold is $19.3 \mathrm{~g} / \mathrm{cm}^{3}$, calculate the volume (in $\mathrm{cm}^{3}$ ) of a gold nugget with a mass of 5.98 g .
a) $3.23 \mathrm{~cm}^{3}$
b) $5.98 \mathrm{~cm}^{3}$
c) $115 \mathrm{~cm}^{3}$
d) $0.310 \mathrm{~cm}^{3}$
e) $13.3 \mathrm{~cm}^{3}$

Think About It For a sample with a density less than $1 \mathrm{~g} / \mathrm{cm}^{3}$, the number of cubic centimeters should be greater than the number of grams. In this case, $25\left(\mathrm{~cm}^{3}\right)>23(\mathrm{~g})$.

## FAQ You May Be Wondering... <br> Why Are Units So Important?

On December 11, 1998, NASA launched the 125-million-dollar Mars Climate Orbiter, which was intended to be the Red Planet's first weather satellite. After a 416-million-mile (mi) journey, the spacecraft was supposed to go into Mars's orbit on September 23, 1999. Instead, it entered Mars's atmosphere about 100 km ( 62 mi ) lower than planned and was destroyed by heat. Mission controllers later determined that the spacecraft was lost because English measurement units were not converted to metric units in the navigation software.

Engineers at Lockheed Martin Corporation, who built the spacecraft, specified its thrust in pounds, which is an English unit of force. Scientists at NASA's Jet Propulsion Laboratory, on the other hand, who were responsible for deployment, had assumed that the thrust data they were given were expressed in newtons, a metric unit. To carry out the conversion between pound and new-
ton, we would start with $1 \mathrm{lb}=0.4536 \mathrm{~kg}$ and, from Newton's second law of motion,

$$
\begin{aligned}
\text { force } & =(\text { mass })(\text { acceleration })=(0.4536 \mathrm{~kg})\left(9.81 \mathrm{~m} / \mathrm{s}^{2}\right) \\
& =4.45 \mathrm{~kg} \cdot \mathrm{~m} / \mathrm{s}^{2}=4.45 \mathrm{~N}
\end{aligned}
$$

because 1 newton $(\mathrm{N})=1 \mathrm{~kg} \cdot \mathrm{~m} / \mathrm{s}^{2}$. Therefore, instead of converting 1 lb of force to 4.45 N , the scientists treated it as a force of 1 N . The considerably smaller engine thrust employed because of the engineers' failure to convert from English to metric units resulted in a lower orbit and the ultimate destruction of the spacecraft.

Commenting on the failure of the Mars mission, one scientist said, "This is going to be the cautionary tale that will be embedded into introduction to the metric system in elementary school, high school, and college science courses till the end of time."

Mars Climate Orbiter during preflight tests.

### 1.4 The Properties of Matter

Substances are identified by their properties as well as by their composition. Properties of a substance may be quantitative (measured and expressed with a number) or qualitative (not requiring explicit measurement).

## Physical Properties

Color, melting point, boiling point, and physical state are all physical properties. A physical property is one that can be observed and measured without changing the identity of a substance. For
example, we can determine the melting point of ice by heating a block of ice and measuring the temperature at which the ice is converted to water. Liquid water differs from ice in appearance but not in composition; both liquid water and ice are $\mathrm{H}_{2} \mathrm{O}$. Melting is a physical change; one in which the state of matter changes, but the identity of the matter does not change. We can recover the original ice by cooling the water until it freezes. Therefore, the melting point of a substance is a physical property. Similarly, when we say that nitrogen dioxide gas is brown, we are referring to the physical property of color.

## Chemical Properties

The statement "Hydrogen gas burns in oxygen gas to form water" describes a chemical property of hydrogen, because to observe this property we must carry out a chemical change -burning in oxygen (combustion), in this case. After a chemical change, the original substance (hydrogen gas in this case) will no longer exist. What remains is a different substance (water, in this case). We cannot recover the hydrogen gas from the water by means of a physical process, such as boiling or freezing.

Every time we bake cookies, we bring about a chemical change. When heated, the sodium bicarbonate (baking soda) in cookie dough undergoes a chemical change that produces carbon dioxide gas. The gas forms numerous little bubbles in the dough during the baking process, causing the cookies to "rise." Once the cookies are baked, we cannot recover the sodium bicarbonate by cooling the cookies, or by any physical process. When we eat the cookies, we cause further chemical changes that occur during digestion and metabolism.

## Extensive and Intensive Properties

All properties of matter are either extensive or intensive. The measured value of an extensive property depends on the amount of matter. Mass is an extensive property. More matter means more mass. Values of the same extensive property can be added together. For example, two gold nuggets will have a combined mass that is the sum of the masses of each nugget, and the length of two city buses is the sum of their individual lengths. The value of an extensive property depends on the amount of matter.

The value of an intensive property does not depend on the amount of matter. Density and temperature are intensive properties. Suppose that we have two beakers of water at the same temperature and we combine them to make a single quantity of water in a larger beaker. The density and the temperature of the water in the larger combined quantity will be the same as they were in the two separate beakers. Unlike mass and length, which are additive, temperature, density, and other intensive properties are not additive. Sample Problem 1.4 shows you how to differentiate chemical and physical processes.

## Sample Problem 1.4

The diagram in (a) shows a compound made up of atoms of two elements (represented by the green and red spheres) in the liquid state. Which of the diagrams in (b) to (d) represent a physical change, and which diagrams represent a chemical change?

Strategy We review the discussion of physical and chemical changes. A physical change does not change the identity of a substance, whereas a chemical change does change the identity of a substance.

Setup The diagram in (a) shows a substance that consists of molecules of a compound, each of which contains two different atoms, represented by green and red spheres. Diagram (b) contains the same number of red and green spheres, but they are not arranged the same way as in diagram (a).

Think About It A chemical change changes the identity of matter. A physical change does not.

In (b), each molecule is made up of two identical atoms. These are molecules of elements, rather than molecules of a compound. Diagram (c) also contains the same numbers of red and green spheres as diagram (a). In (c), however, all the atoms are shown as isolated spheres. These are atoms of elements, rather than molecules of a compound. In diagram (d), the spheres are arranged in molecules, each containing one red and one green sphere. Although the molecules are farther apart in diagram (d), they are the same molecules as shown in diagram (a).

Solution Diagrams (b) and (c) represent chemical changes. Diagram (d) represents a physical change.

Practice Problem A Which of the following processes is a physical change? (a) evaporation of water; (b) combination of hydrogen and oxygen gas to produce water; (c) dissolution of sugar in water; (d) separation of sodium chloride (table salt) into its constituent elements, sodium and chlorine; (e) combustion of sugar to produce carbon dioxide and water.

EPractice Problem B The diagram in the margin represents the result of a process. Which of the diagrams [(i) to (iii)] could represent the starting material if the process were physical, and which could represent the starting material if the change were chemical?

### 1.5 Uncertainty in Measurement

Chemistry makes use of two types of numbers: exact and inexact. Exact numbers include numbers with defined values, such as 2.54 in the definition 1 inch (in) $=2.54 \mathrm{~cm}, 1000$ in the definition $1 \mathrm{~kg}=1000 \mathrm{~g}$, and 12 in the definition 1 dozen $=12$ objects. (The number 1 in each of these definitions is also an exact number.) Exact numbers also include those that are obtained by counting. Numbers measured by any method other than counting are inexact.

Measured numbers are inexact because of the measuring devices that are used, the individuals who use them, or both. For example, a ruler that is poorly calibrated will result in measurements that are in error-no matter how carefully it is used. Another ruler may be calibrated properly but have insufficient resolution for the necessary measurement. Finally, whether or not an instrument is properly calibrated or has sufficient resolution, there are unavoidable differences in how different people see and interpret measurements.

## Significant Figures

An inexact number must be reported in such a way as to indicate the uncertainty in its value. This is done using significant figures. Significant figures are the meaningful digits in a reported number. Consider the measurement of the memory card in Figure 1.11 using the ruler above it. The card's width is between 2 and 3 cm . We may record the width as 2.5 cm , but because there are no gradations between 2 and 3 cm on this ruler, we are estimating the second digit. Although we are certain about the 2 in 2.5 , we are not certain about the 5 . The last digit in a measured number is referred to as the uncertain digit; and the uncertainty associated with a measured number is generally considered to be $\pm 1$ in the place of the last digit. Thus, when we report the width of the memory card to be 2.5 cm , we are implying that its width is $2.5 \pm 0.1 \mathrm{~cm}$. Each of the digits in a measured number, including the uncertain digit, is a significant figure. The reported width of the memory card, 2.5 cm , contains two significant figures.

A ruler with millimeter gradations would enable us to be certain about the second digit in this measurement and to estimate a third digit. Now consider the measurement of the memory card using the ruler below it. We may record the width as 2.45 cm . Again, we estimate one digit beyond those we can read. The reported width of 2.45 cm contains three significant figures. Reporting the width as 2.45 cm implies that the width is $2.45 \pm 0.01 \mathrm{~cm}$.

The number of significant figures in any number can be determined using the following guidelines:

1. Any digit that is not zero is significant (112.1 has four significant figures).
2. Zeros located between nonzero digits are significant (305 has three significant figures, and 50.08 has four significant figures).
3. Zeros to the left of the first nonzero digit are not significant ( 0.0023 has two significant figures, and 0.000001 has one significant figure).
4. Zeros to the right of the last nonzero digit are significant if the number contains a decimal point (1.200 has four significant figures).
5. Zeros to the right of the last nonzero digit in a number that does not contain a decimal point may or may not be significant ( 100 may have one, two, or three significant figures-it is impossible to tell without additional information). To avoid ambiguity in such cases, it is best to express such numbers using scientific notation. If the intended number of significant figures is one, the number is written as $1 \times 10^{2}$; if the intended number of significant figures is two, the number is written as $1.0 \times 10^{2}$; and if the intended number of significant figures is three, the number is written as $1.00 \times 10^{2}$.

Sample Problem 1.5 lets you practice determining the number of significant figures in a number.

Figure 1.11 The width we report for the memory card depends on which ruler we use to measure it.

Student Annotation: It is important not to imply greater certainty in a measured number than is realistic. For example, it would be inappropriate to report the width of the memory card in Figure 1.11 as 2.4500 cm, because this would imply an uncertainty of $\pm 0.0001$.

Student Annotation: Appendix 1 reviews scientific notation.

Think About It Be sure that you have identified zeros correctly as either significant or not significant. They are significant in (b), (d), and (f); they are not significant in (c); and it is not possible to tell in (e).

## Sample Problem 1.5

Determine the number of significant figures in the following measurements: (a) 443 cm , (b) 15.03 g , (c) 0.0356 kg , (d) $3.000 \times 10^{-7} \mathrm{~L}$, (e) 50 mL , (f) 0.9550 m .

Strategy All nonzero digits are significant, so the goal will be to determine which of the zeros is significant.

Setup Zeros are significant if they appear between nonzero digits or if they appear after a nonzero digit in a number that contains a decimal point. Zeros may or may not be significant if they appear to the right of the last nonzero digit in a number that does not contain a decimal point.

Solution (a) 3 ; (b) 4 ; (c) 3 ; (d) 4 ; (e) 1 or 2 , an ambiguous case; (f) 4

Practice Problem A Determine the number of significant figures in the following measurements:
(a) 1129 m , (b) 0.0003 kg , (c) 1.094 cm , (d) $3.5 \times 10^{12}$ atoms, (e) 150 mL , (f) 9.550 km .

FPractice Problem B Determine the number of significant figures in each of the following numbers: (a) $3.050 \times 10^{-4}$, (b) 432.00 , (c) 8.001 , (d) 0.000310 , (e) 150 , (f) 5.0071 .

## Calculations with Measured Numbers

Because we often use one or more measured numbers to calculate a desired result, a second set of guidelines specifies how to handle significant figures in calculations.

1. In addition and subtraction, the answer cannot have more digits to the right of the decimal point than the original number with the smallest number of digits to the right of the decimal point. For example:

| 102.50 | $\leftarrow$ two digits after the decimal point |
| ---: | :--- |
| $\frac{+0.231}{102.731}$ | $\leftarrow$ three digits after the decimal point |
| 143.29 | $\leftarrow$ round to 102.73 |
| $\frac{-20.1}{123.19}$ | $\leftarrow$ two digits after the decimal point |
|  | $\leftarrow$ one digit after the decimal point to 123.2 |

The rounding procedure works as follows. Suppose we want to round 102.13 and 54.86 each to one digit to the right of the decimal point. To begin, we look at the digit(s) that will be dropped. If the leftmost digit to be dropped is less than 5 , as in 102.13 , we round down (to 102.1), meaning that we simply drop the digit(s). If the leftmost digit to be dropped is equal to or greater than 5, as in 54.86, we round up (to 54.9), meaning that we add 1 to the preceding digit.
2. In multiplication and division, the number of significant figures in the final product or quotient is determined by the original number that has the smallest number of significant figures. The following examples illustrate this rule:

$$
\begin{array}{ll}
1.4 \times 8.011=11.2154 & \leftarrow \text { round to } 11 \text { (limited by } 1.4 \text { to two significant } \\
\frac{11.57}{305.88}=0.037825290964 & \text { figures) } \\
& \begin{array}{l}
\text { significant figures) }
\end{array}
\end{array}
$$

3. Exact numbers can be considered to have an infinite number of significant figures and do not limit the number of significant figures in a calculated result. For example, a penny minted after 1982 has a mass of 2.5 g . If we have three such pennies, the total mass is

$$
3 \times 2.5 \mathrm{~g}=7.5 \mathrm{~g}
$$

The answer should not be rounded to one significant figure because 3 is an exact number.
4. In calculations with multiple steps, rounding the result of each step can result in "rounding error." Consider the following two-step calculation:

First step: $\quad A \times B=C$
Second step: $\quad C \times D=E$
Suppose that $A=3.66, B=8.45$, and $D=2.11$. The value of $E$ depends on whether we round off $C$ prior to using it in the second step of the calculation.

$$
\begin{array}{cc}
\text { Method 1 } & \text { Method 2 } \\
\hline C=3.66 \times 8.45=30.9 & C=3.66 \times 8.45=30.93 \\
E=30.9 \times 2.11=65.2 & E=30.93 \times 2.11=65.3
\end{array}
$$

In general, it is best to retain at least one extra digit until the end of a multistep calculation, as shown by method 2 , to minimize rounding error.

Sample Problems 1.6 and 1.7 show how significant figures are handled in arithmetic operations.

## Sample Problem 1.6

Perform the following arithmetic operations and report the result to the proper number of significant figures: (a) $317.5 \mathrm{~mL}+0.675 \mathrm{~mL}$, (b) $47.80 \mathrm{~L}-2.075 \mathrm{~L}$, (c) $13.5 \mathrm{~g} \div 45.18 \mathrm{~L}$, (d) $6.25 \mathrm{~cm} \times$ 1.175 cm , (e) $5.46 \times 10^{2} \mathrm{~g}+4.991 \times 10^{3} \mathrm{~g}$.

Strategy Apply the rules for significant figures in calculations, and round each answer to the appropriate number of digits.

Setup (a) The answer will contain one digit to the right of the decimal point to match 317.5 , which has the fewest digits to the right of the decimal point. (b) The answer will contain two digits to the right of the decimal point to match 47.80 . (c) The answer will contain three significant figures to match 13.5 , which has the fewest number of significant figures in the calculation. (d) The answer will contain three significant figures to match 6.25. (e) To add numbers expressed in scientific notation, first write both numbers to the same power of 10 . That is, $4.991 \times 10^{3}=49.91 \times 10^{2}$, so the answer will contain two digits to the right of the decimal point (when multiplied by $10^{2}$ ) to match both 5.46 and 49.91 .

## Solution

(a) 317.5 mL
$+0.675 \mathrm{~mL}$
$318.175 \mathrm{~mL} \quad \leftarrow$ round to 318.2 mL
(b) 47.80 L
$\frac{-2.075 \mathrm{~L}}{45.725 \mathrm{~L}}$
$\leftarrow$ round to 45.73 L
(c) $\frac{13.5 \mathrm{~g}}{45.18 \mathrm{~L}}=0.298804781 \mathrm{~g} / \mathrm{L} \quad \leftarrow$ round to $0.299 \mathrm{~g} / \mathrm{L}$
(d) $6.25 \mathrm{~cm} \times 1.175 \mathrm{~cm}=7.34375 \mathrm{~cm}^{2} \quad \leftarrow$ round to $7.34 \mathrm{~cm}^{2}$
(e) $\quad 5.46 \times 10^{2} \mathrm{~g}$

| $5.46 \times 10^{2} \mathrm{~g}$ |
| :--- |
| $+49.91 \times 10^{2}$ |
| $55.37 \times 10^{2} \mathrm{~g}$ |$=5.537 \times 10^{3} \mathrm{~g}$

Practice Problem A Perform the following arithmetic operations, and report the result to the proper number of significant figures: (a) $105.5 \mathrm{~L}+10.65 \mathrm{~L}$, (b) $81.058 \mathrm{~m}-0.35 \mathrm{~m}$, (c) $3.801 \times 10^{21}$ atoms $+1.228 \times 10^{19}$ atoms, (d) $1.255 \mathrm{dm} \times 25 \mathrm{dm}$, (e) $139 \mathrm{~g} \div 275.55 \mathrm{~mL}$.

GPractice Problem B Perform the following arithmetic operations, and report the result to the proper number of significant figures: (a) $1.0267 \mathrm{~cm} \times 2.508 \mathrm{~cm} \times 12.599 \mathrm{~cm}$, (b) $15.0 \mathrm{~kg} \div 0.036 \mathrm{~m}^{3}$, (c) $1.113 \times 10^{10} \mathrm{~kg}-1.050 \times 10^{9} \mathrm{~kg}$, (d) $25.75 \mathrm{~mL}+15.00 \mathrm{~mL}$, (e) $46 \mathrm{~cm}^{3}+180.5 \mathrm{~cm}^{3}$.

Think About It It may look as though the rule of addition has been violated in part (e) because the final answer $\left(5.537 \times 10^{3} \mathrm{~g}\right)$ has three places past the decimal point, not two. However, the rule was applied to get the answer $55.37 \times 10^{2} \mathrm{~g}$, which has four significant figures. Changing the answer to correct scientific notation doesn't change the number of significant figures, but in this case it changes the number of places past the decimal point.

Think About It In this case, although each of the three numbers we started with has four significant figures, the solution has only two significant figures.

(a)

(b)

(c)

Figure 1.12 The distribution of papers shows the difference between accuracy and precision.
(a) Good accuracy and good precision.
(b) Poor accuracy but good precision.
(c) Poor accuracy and poor precision.

## Sample Problem 1.7

An empty container with a volume of $9.850 \times 10^{2} \mathrm{~cm}^{3}$ is weighed and found to have a mass of 124.6 g . The container is filled with a gas and reweighed. The mass of the container and the gas is 126.5 g . Determine the density of the gas to the appropriate number of significant figures.

Strategy This problem requires two steps: subtraction to determine the mass of the gas, and division to determine its density. Apply the corresponding rule regarding significant figures to each step.

Setup In the subtraction of the container mass from the combined mass of the container and the gas, the result can have only one place past the decimal point: $126.5 \mathrm{~g}-124.6 \mathrm{~g}=1.9 \mathrm{~g}$. Thus, in the division of the mass of the gas by the volume of the container, the result can have only two significant figures.

## Solution

$$
\begin{aligned}
\text { mass of gas } & =\begin{array}{c}
126.5 \mathrm{~g} \\
1.9 \mathrm{~g} \\
-124.6 \mathrm{~g}
\end{array} \leftarrow \text { one place past the decimal point (two significant figures) } \\
\text { density } & =\frac{1.9 \mathrm{~g}}{9.850 \times 10^{2} \mathrm{~cm}^{3}}=0.00193 \mathrm{~g} / \mathrm{cm}^{3} \leftarrow \text { round to } 0.0019 \mathrm{~g} / \mathrm{cm}^{3}
\end{aligned}
$$

The density of the gas is $1.9 \times 10^{-3} \mathrm{~g} / \mathrm{cm}^{3}$.

Practice Problem A An empty container with a volume of $150.0 \mathrm{~cm}^{3}$ is weighed and found to have a mass of 72.5 g . The container is filled with a liquid and reweighed. The mass of the container and the liquid is 194.3 g . Determine the density of the liquid to the appropriate number of significant figures.

FPractice Problem B Another empty container with an unknown volume is weighed and found to have a mass of 81.2 g . The container is then filled with a liquid with a density of $1.015 \mathrm{~g} / \mathrm{cm}^{3}$ and reweighed. The mass of the container and the liquid is 177.9 g . Determine the volume of the container to the appropriate number of significant figures.

## Accuracy and Precision

Accuracy and precision are two ways to gauge the quality of a set of measured numbers. Although the difference between the two terms may be subtle, it is important. Accuracy tells us how close a measurement is to the true value. Precision tells us how closely multiple measurements of the same thing are to one another (Figure 1.12).

Suppose that three students are asked to determine the mass of an aspirin tablet. Each student weighs the aspirin tablet three times. The results (in grams) are

|  | Student A | Student B | Student C |
| :--- | :---: | :---: | :---: |
| 0.335 | 0.357 | 0.369 |  |
|  | 0.331 | 0.375 | 0.373 |
|  | 0.333 | 0.338 | 0.371 |
| Average value | 0.333 | 0.357 | 0.371 |

The true mass of the tablet is 0.370 g . Student A's results are more precise than those of student B, but neither set of results is very accurate. Student C's results are both precise (very small deviation of individual masses from the average mass) and accurate (average value very close to the true value). Figure 1.13 shows all three students' results in relation to the true mass of the tablet. Highly accurate measurements are usually precise, as well, although highly precise measurements do not necessarily guarantee accurate results. For example, an improperly calibrated meterstick or a faulty balance may give precise readings that are significantly different from the correct value.

Figure 1.13 Graphing the students' data illustrates the difference between precision and accuracy. Student A's results are precise (values are close to one another) but not accurate because the average value is far from the true value. Student B's results are neither precise nor accurate. Student C's results are both precise and accurate.

## Checkpoint 1.5 Uncertainty in Measurement

1.5.1 What volume of water does the graduated cylinder contain (to the proper number of significant figures)?
a) 32.2 mL
b) 30.25 mL
c) 32.5 mL
d) 32.50 mL
e) 32.500 mL

1.5.2 Which of the following is the sum of the following numbers to the correct number of significant figures?

$$
3.115+0.2281+712.5+45=
$$

a) 760.8431
b) 760.843
c) 760.84
d) 760.8
e) 761
1.5.3 The true dependence of $y$ on $x$ is represented by the line. Three students measured $y$ as a function of $x$ and plotted their data on the graph. Which set of data has the best accuracy and which has the best precision, respectively?

a) red, green
b) green, green
c) green, purple
d) purple, purple
e) purple, green
1.5.4 What is the result of the following calculation to the correct number of significant figures?

$$
(6.266-6.261) \div 522.0=
$$

a) $9.5785 \times 10^{-6}$
b) $9.579 \times 10^{-6}$
c) $9.58 \times 10^{-6}$
d) $9.6 \times 10^{-6}$
e) $1 \times 10^{-5}$

Student Annotation: Because 1 in is defined as exactly 2.54 cm , neither the number 1 nor the number 2.54 limits the number of significant figures in a calculation where this conversion factor is used.

Student Annotation: If we had accidentally used the reciprocal of the conversion from centimeters to meters, the result would have been $3048 \mathrm{~cm}^{2} / \mathrm{m}$, which would make no sense-both because the units are nonsensical and because the numerical result is not reasonable. You know that 12 inches is a foot and that a foot is not equal to thousands of meters!

### 1.6 Using Units and Solving Problems

Solving problems correctly in chemistry requires careful manipulation of both numbers and units. Paying attention to the units will benefit you greatly as you proceed through this, or any other, science course.

## Conversion Factors

A conversion factor is a fraction in which the same quantity is expressed one way in the numerator and another way in the denominator. By definition, for example, 1 in $=2.54 \mathrm{~cm}$. We can derive a conversion factor from this equality by writing it as the following fraction:

$$
\frac{1 \mathrm{in}}{2.54 \mathrm{~cm}}
$$

Because the numerator and denominator express the same length, this fraction is equal to 1 ; as a result, we can equally well write the conversion factor as

$$
\frac{2.54 \mathrm{~cm}}{1 \mathrm{in}}
$$

Because both forms of this conversion factor are equal to 1 , we can multiply a quantity by either form without changing the value of that quantity. This is useful for changing the units in which a given quantity is expressed-something you will do often throughout this text. For instance, if we need to convert a length from inches to centimeters, we multiply the length in inches by the appropriate conversion factor.

$$
12.00 \mathrm{inf} \times \frac{2.54 \mathrm{~cm}}{1 \text { in }}=30.48 \mathrm{~cm}
$$

We chose the form of the conversion factor that cancels the unit inches and produces the desired unit, centimeters. The result contains four significant figures because exact numbers, such as those obtained from definitions, do not limit the number of significant figures in the result of a calculation. Thus, the number of significant figures in the answer to this calculation is based on the number 12.00 , not the number 2.54 .

## Dimensional Analysis-Tracking Units

The use of conversion factors in problem solving is called dimensional analysis or the factorlabel method. Many problems require the use of more than one conversion factor. The conversion of 12.00 into meters, for example, takes two steps: one to convert inches to centimeters, which we have already demonstrated, and one to convert centimeters to meters. The additional conversion factor required is derived from the equality

$$
1 \mathrm{~m}=100 \mathrm{~cm}
$$

and is expressed as either

$$
\frac{100 \mathrm{~cm}}{1 \mathrm{~m}} \text { or } \frac{1 \mathrm{~m}}{100 \mathrm{~cm}}
$$

We must choose the conversion factor that will introduce the unit meter and cancel the unit centimeter (i.e., the one on the right). We can set up a problem of this type as the following series of unit conversions so that it is unnecessary to calculate an intermediate answer at each step:

$$
12.00 \mathrm{inf} \times \frac{2.54 \mathrm{cmi}}{1 \text { in }} \times \frac{1 \mathrm{~m}}{100 \mathrm{~cm}}=0.3048 \mathrm{~m}
$$

Careful tracking of units and their cancellation can be a valuable tool in checking your work. If we had accidentally used the reciprocal of one of the conversion factors, the resulting units would have been something other than meters. Unexpected or nonsensical units can reveal an error in your problem-solving strategy.

Sample Problem 1.8 shows how to derive conversion factors and use them to do unit conversions.

# How Can I Enhance My Chances of Success in Chemistry Class? 

Success in a chemistry class depends largely on problem-solving ability. The sample problems throughout the text are designed to help you develop problem-solving skills. Each is divided into four steps: Strategy, Setup, Solution, and Think About It.

Strategy: Read the problem carefully and determine what is being asked and what information is provided. The Strategy step is where you should think about what skills are required and lay out a plan for solving the problem. Give some thought to what you expect the result to be. If you are asked to determine the number of atoms in a sample of matter, for example, you should expect the answer to be a whole number. Determine what, if any, units should be associated with the result. When possible, make a ballpark estimate of the magnitude of the correct result, and make a note of your estimate.

Setup: Next, gather the information necessary to solve the problem. Some of the information will have been given in the problem itself. Other information, such as equations, constants, and tabulated data (including atomic masses) should also be brought together in this step. Write down and label clearly all of the information you will use to solve the problem. Be sure to write appropriate units with each piece of information.

Solution: Using the necessary equations, constants, and other information, calculate the answer to the problem. Pay particular attention to the units associated with each number, tracking and canceling units carefully throughout the calculation. In the event that multiple calculations are required, label any intermediate results, but don't round to
the necessary number of significant figures until the final calculation. Always carry at least one extra significant figure in intermediate calculations. Make sure that the final answer has the correct number of significant figures.

Think About It: Consider your calculated result and ask yourself whether or not it makes sense. Compare the units and the magnitude of your result with your ballpark estimate from the Strategy step. If your result does not have the appropriate units, or if its magnitude or sign is not reasonable, check your solution for possible errors. A very important part of problem solving is being able to judge whether the answer is reasonable. It is relatively easy to spot a wrong sign or incorrect units, but you should also develop a sense of magnitude and be able to tell when an answer is either way too big or way too small. For example, if a problem asks how many molecules are in a sample and you calculate a number that is less than 1 , you should know that it cannot be correct.

Finally, each sample problem is followed by at least one practice problem. This typically is a very similar problem that can be solved using the same strategy. Most sample problems also have a second practice problem that tests the same skills, but requires an approach slightly different from the one used to solve the preceding sample and practice problems.

Regular use of the sample problems and practice problems in this text can help you develop an effective set of problemsolving skills. They can also help you assess whether you are ready to move on to the next new concepts. If you struggle with the practice problems, then you probably need to review the corresponding sample problem and the concepts that led up to it.

## Sample Problem 1.8

The Food and Drug Administration (FDA) recommends that dietary sodium intake be no more than 2400 mg per day. What is this mass in pounds (lb), if $1 \mathrm{lb}=453.6 \mathrm{~g}$ ?

Strategy This problem requires a two-step dimensional analysis, because we must convert milligrams to grams and then grams to pounds.

Assume the number 2400 has four significant figures.
Setup The necessary conversion factors are derived from the equalities $1 \mathrm{~g}=1000 \mathrm{mg}$ and $1 \mathrm{lb}=$ 453.6 g .

$$
\frac{1 \mathrm{~g}}{1000 \mathrm{mg}} \text { or } \frac{1000 \mathrm{mg}}{1 \mathrm{~g}} \quad \text { and } \quad \frac{1 \mathrm{lb}}{453.6 \mathrm{~g}} \text { or } \frac{453.6 \mathrm{~g}}{1 \mathrm{lb}}
$$

From each pair of conversion factors, we select the one that will result in the proper unit cancellation.
Solution

$$
2400 \mathrm{mg} \times \frac{1 \mathrm{~g}}{1000 \mathrm{mg}} \times \frac{1 \mathrm{lb}}{453.6 g^{g}}=0.005291 \mathrm{lb}
$$

Student Annotation: Because pounds are much larger than milligrams, a given mass will be a much smaller number of pounds than of milligrams.

Think About It Make sure that the magnitude of the result is reasonable and that the units have canceled properly. If we had mistakenly multiplied by 1000 and 453.6 instead of dividing by them, the result $(2400 \mathrm{mg} \times$ $1000 \mathrm{mg} / \mathrm{g} \times 453.6 \mathrm{~g} / \mathrm{lb}=$ $1.089 \times 10^{9} \mathrm{mg}^{2} / \mathrm{lb}$ ) would be unreasonably large-and the units would not have canceled properly.

Think About It Based on the preceding conversion factors, $1 \mathrm{~L}=1 \times 10^{-3} \mathrm{~m}^{3}$. Therefore, 5 L of blood would be equal to $5 \times 10^{-3} \mathrm{~m}^{3}$, which is close to the calculated answer.

Practice Problem A The American Heart Association recommends that healthy adults limit dietary cholesterol to no more than 300 mg per day. Convert this mass of cholesterol to ounces $(1 \mathrm{oz}=$ 28.3459 g). Assume 300 mg has just one significant figure.

EPractice Problem B An object has a mass of 24.98 g . What is its mass in ounces?

Sample Problem 1.9 shows how to handle problems in which conversion factors are squared or cubed in dimensional analysis.

## Sample Problem 1.9

An average adult has 5.2 L of blood. What is the volume of blood in cubic meters?
Strategy There are several ways to solve a problem such as this. One way is to convert liters to cubic centimeters and then cubic centimeters to cubic meters.

Setup $1 \mathrm{~L}=1000 \mathrm{~cm}^{3}$ and $1 \mathrm{~cm}=1 \times 10^{-2} \mathrm{~m}$. When a unit is raised to a power, the corresponding conversion factor must also be raised to that power in order for the units to cancel appropriately.

## Solution

$$
5.2 \mathrm{~L} \times \frac{1000 \mathrm{~cm}^{3}}{1 \mathrm{~L}} \times\left(\frac{1 \times 10^{-2} \mathrm{~m}}{1 \mathrm{~cm}}\right)^{3}=5.2 \times 10^{-3} \mathrm{~m}^{3}
$$

Practice Problem A The density of silver is $10.5 \mathrm{~g} / \mathrm{cm}^{3}$. What is its density in $\mathrm{kg} / \mathrm{m}^{3}$ ?
EPractice Problem B The density of mercury is $13.6 \mathrm{~g} / \mathrm{cm}^{3}$. What is its density in $\mathrm{mg} / \mathrm{mm}^{3}$ ?

## Checkpoint 1.6 Using Units and Solving Problems

1.6.1 The density of lithium metal is $535 \mathrm{~kg} / \mathrm{m}^{3}$. What is this density in $\mathrm{g} / \mathrm{cm}^{3}$ ?
a) $0.000535 \mathrm{~g} / \mathrm{cm}^{3}$
b) $0.535 \mathrm{~g} / \mathrm{cm}^{3}$
c) $0.0535 \mathrm{~g} / \mathrm{cm}^{3}$
d) $0.54 \mathrm{~g} / \mathrm{cm}^{3}$
e) $53.5 \mathrm{~g} / \mathrm{cm}^{3}$
1.6.2 Convert $43.1 \mathrm{~cm}^{3}$ to liters.
a) 43.1 L
b) $43,100 \mathrm{~L}$
c) 0.0431 L
d) 4310 L
e) 0.043 L
1.6.3 What is the volume of a $5.75-\mathrm{g}$ object that has a density of $3.97 \mathrm{~g} / \mathrm{cm}^{3}$ ?
a) $1.45 \mathrm{~cm}^{3}$
b) $0.690 \mathrm{~cm}^{3}$
c) $22.8 \mathrm{~cm}^{3}$
d) $0.0438 \mathrm{~cm}^{3}$
e) $5.75 \mathrm{~cm}^{3}$
1.6.4 How many cubic centimeters are there in a cubic meter?
a) 10
b) 100
c) 1000
d) $1 \times 10^{4}$
e) $1 \times 10^{6}$

## Applying What You've Learned

Although naturally occurring smallpox was eradicated by a superbly coordinated effort including the World Health Organization and health-care providers worldwide, the classification of smallpox as a Category A bioterrorism agent has renewed interest in its treatment and prevention. Moreover, although vaccination against the disease is considered relatively safe for most individuals, it is not entirely without risk.

The CDC estimates that 14 to 52 out of every million people who are vaccinated for smallpox will suffer serious, potentially life-threatening reactions to the vaccine. In these cases, immediate medical attention is required. The first course of treatment is with vaccinia immune globulin (VIG). If a patient does not respond to treatment with VIG, a second option is cidofovir, a drug that currently is approved by the Food and Drug Administration (FDA) to treat specific viral infections of the eye in individuals with compromised immune systems.

Cidofovir, marketed under the name Vistide, is distributed in vials containing 375 mg of the drug dissolved in 5 mL of water. The manufacturer specifies that the drug should be kept at room temperature $\left(68^{\circ} \mathrm{F}-77^{\circ} \mathrm{F}\right)$. The vial contents are first diluted with saline and then administered intravenously with a recommended dosage of 5 mg cidofovir per kilogram of body weight.

## Problems:

a) Convert cidofovir's recommended storage-temperature range to the Celsius scale. [ 14 Sample Problem 1.2]
b) If the fluid in a single vial of cidofovir has a volume of 5.00 mL and a mass of 5.89 g, what is the density of the fluid? [ 14 Sample Problem 1.3] (Report the density to the appropriate number of significant figures. [\$4 Sample Problem 1.6])
c) What mass of cidofovir should be administered to a $177-\mathrm{lb}$ man ( $1 \mathrm{lb}=0.4536 \mathrm{~kg}$ )? [ HA Sample Problem 1.8]
d) Convert the density in part (b) to $\mathrm{g} / \mathrm{L}$ and to $\mathrm{kg} / \mathrm{m}^{3}$. [ 14 Sample Problem 1.9]

Student Annotation: Smallpox vaccine is made from the vaccinia virus.

Student Annotation: Both drugs are available for use in the treatment of a serious reaction to smallpox vaccine only through the FDA's Investigational New Drug (IND) protocol.

Cidofovir

## Chapter Summary

## Section 1.1

- Chemistry is the study of matter and the changes matter undergoes.
- Chemists go about research using a set of guidelines and practices known as the scientific method, in which observations give rise to laws, data give rise to hypotheses, hypotheses are tested with experiments, and successful hypotheses give rise to theories, which are further tested by experiment.

## Section 1.2

- All matter exists either as a substance or as a mixture of substances. Substances may be elements (containing only one kind of atom) or compounds (containing two or more kinds of atoms). A mixture may be homogeneous (a solution) or heterogeneous. Mixtures may be separated using physical processes. Compounds can be separated into their constituent elements using chemical processes. Elements cannot be separated into simpler substances.

## Section 1.3

- Scientists use a system of units referred to as the International System of Units or SI units.
- There are seven base SI units including the kilogram (for mass) and the kelvin (for temperature). SI units for such quantities as volume and density are derived from the base units.

## Section 1.4

- Substances are identified by their quantitative (involving numbers) and qualitative (not involving numbers) properties.
- Physical properties are those that can be determined without the matter in question undergoing a chemical change. A physical change is one in which the identity of the matter involved does not change.
- Chemical properties are determined only as the result of a chemical change, in which the original substance is converted to a different substance. Physical and chemical properties may be extensive (dependent on the amount of matter) or intensive (independent of the amount of matter).

## Section 1.5

- Measured numbers are inexact. Numbers obtained by counting or that are part of a definition are exact numbers.
- Significant figures are used to specify the uncertainty in a measured number or in a number calculated using measured numbers. Significant figures must be carried through calculations such that the implied uncertainty in the final answer is reasonable.
- Accuracy refers to how close measured numbers are to a true value. Precision refers to how close measured numbers are to one another.

## Section 1.6

- A conversion factor is a fraction in which the numerator and denominator are the same quantity expressed in different units. Multiplying by a conversion factor is unit conversion.
- Dimensional analysis is a series of unit conversions used in the solution of a multistep problem.

## Key Equations

$1.1 \quad \mathrm{~K}={ }^{\circ} \mathrm{C}+273.15$
1.2 temperature in degrees Celsius $=\left(\right.$ temperature in degrees Fahrenheit $\left.-32^{\circ} \mathrm{F}\right) \times \frac{5^{\circ} \mathrm{C}}{9^{\circ} \mathrm{F}}$
1.3 temperature in degrees Fahrenheit $=\frac{9^{\circ} \mathrm{F}}{5^{\circ} \mathrm{C}} \times($ temperature in degrees Celsius $)+32^{\circ} \mathrm{F}$
$1.4 \quad d=\frac{m}{V}$

## Questions and Problems

## Section 1.1: The Study of Chemistry

## Review Questions

1.1 Define the terms chemistry and matter.
1.2 Explain what is meant by the scientific method.
1.3 What is the difference between a hypothesis and a theory?

## Problems

G1.4 Classify each of the following statements as a hypothesis, law, or theory. (a) Beethoven's contribution to music would have been much greater if he had married. (b) An autumn leaf gravitates toward the ground because there is an attractive force between the leaf and Earth. (c) All matter is composed of very small particles called atoms
1.5 Classify each of the following statements as a hypothesis, law, or theory. (a) The force acting on an object is equal to its mass times its acceleration. (b) The universe as we know it started with a big bang. (c) There are many civilizations more advanced than ours on other planets.
1.6 Identify the elements present in the following molecules (see Table 1.1).

(a)

(b)

(c)

(d)
1.7 Identify the elements present in the following molecules (see Table 1.1).

(a)

(b)

(c)

(d)

## Section 1.2: Classification of Matter

## Review Questions

1.8 Give an example for each of the following terms: (a) matter, (b) substance, (c) mixture.
1.9 Give an example of a homogeneous mixture and an example of a heterogeneous mixture.
1.10 Give an example of an element and a compound. How do elements and compounds differ?
1.11 What is the number of known elements?

## Problems

E 1.12 Give the names of the elements represented by the chemical symbols Li, F, P, Cu, As, Zn, Cl, Pt, Mg, U, Al, Si, Ne (see the table inside the front cover).
1.13 Give the chemical symbols for the following elements: (a) potassium, (b) tin, (c) chromium, (d) boron, (e) barium, (f) plutonium, (g) sulfur, (h) argon, (i) mercury (see the table inside the front cover).
1.14 Classify each of the following substances as an element or a compound: (a) hydrogen, (b) water, (c) gold, (d) sugar.

H1.15 Classify each of the following as an element, a compound, a homogeneous mixture, or a heterogeneous mixture: (a) seawater, (b) helium gas, (c) sodium chloride (salt), (d) a bottle of soft drink, (e) a milkshake, (f) air in a bottle, (g) concrete.
 mixture of two substances.

1.17 Identify each of the diagrams shown here as an element or a compound.

(a)

(b)

(c)

(d)

## Section 1.3: Scientific Measurement

## Review Questions

1.18 Name the SI base units that are important in chemistry, and give the SI units for expressing the following: (a) length, (b) volume, (c) mass, (d) time, (e) temperature.
1.19 Write the numbers represented by the following prefixes:
(a) mega-,
(b) kilo-, (c) deci-,
, (d) centi-, (e) milli-, (f) micro-,
(g) nano-, (h) pico-.
1.20 What units do chemists normally use for the density of liquids and solids? For the density of gas? Explain the differences.
1.21 What is the difference between mass and weight? If a person weighs 168 lb on Earth, about how much would the person weigh on the moon?
1.22 Describe the three temperature scales used in the laboratory and in everyday life: the Fahrenheit, Celsius, and Kelvin scales.

## Problems

1.23 Bromine is a reddish-brown liquid. Calculate its density (in $\mathrm{g} / \mathrm{mL}$ ) if 586 g of the substance occupies 188 mL .

E 1.24 The density of ethanol, a colorless liquid that is commonly known as grain alcohol, is $0.798 \mathrm{~g} / \mathrm{mL}$. Calculate the mass of 17.4 mL of the liquid.

G1.25 Convert the following temperatures to degrees Celsius or Fahrenheit: (a) $95^{\circ} \mathrm{F}$, the temperature on a hot summer day; (b) $12^{\circ} \mathrm{F}$, the temperature on a cold winter day; (c) a $102^{\circ} \mathrm{F}$ fever; (d) a furnace operating at $1852^{\circ} \mathrm{F}$; (e) $-273.15^{\circ} \mathrm{C}$ (theoretically the lowest attainable temperature).
1.26 (a) Normally the human body can endure a temperature of $105^{\circ} \mathrm{F}$ for only short periods of time without permanent damage to the brain and other vital organs. What is this temperature in degrees Celsius? (b) Ethylene glycol is a liquid organic compound that is used as an antifreeze in car radiators. It freezes at $-11.5^{\circ} \mathrm{C}$. Calculate its freezing temperature in degrees Fahrenheit. (c) The temperature on the surface of the sun is about $6300^{\circ} \mathrm{C}$. What is this temperature in degrees Fahrenheit?

E1.27 The density of water at $40^{\circ} \mathrm{C}$ is $0.992 \mathrm{~g} / \mathrm{mL}$. What is the volume of 2.50 g of water at this temperature?

E1.28 The density of platinum (Pt) is $21.5 \mathrm{~g} / \mathrm{cm}^{3}$ at $25^{\circ} \mathrm{C}$. What is the volume of 87.6 g of Pt at this temperature?

E1.29 Convert the following temperatures to kelvin: (a) $115.21^{\circ} \mathrm{C}$, the melting point of sulfur; (b) $37^{\circ} \mathrm{C}$, the normal body temperature; (c) $357^{\circ} \mathrm{C}$, the boiling point of mercury.
1.30 Convert the following temperatures to degrees Celsius: (a) 77 K , the boiling point of liquid nitrogen, (b) 4.22 K , the boiling point of liquid helium, (c) 600.61 K , the melting point of lead.

## Section 1.4: The Properties of Matter

## Review Questions

1.31 What is the difference between qualitative data and quantitative data?
1.32 Using examples, explain the difference between a physical property and a chemical property.
1.33 How does an intensive property differ from an extensive property?
1.34 Determine which of the following properties are intensive and which are extensive: (a) length, (b) volume, (c) temperature, (d) mass.

## Problems

1.35 Classify the following as qualitative or quantitative statements, giving your reasons. (a) The sun is approximately 93 million mi from Earth. (b) Leonardo da Vinci was a better painter than Michelangelo. (c) Ice is less dense than water. (d) Butter tastes better than margarine. (e) A stitch in time saves nine.

E 1.36 Determine whether the following statements describe chemical or physical properties: (a) Oxygen gas supports combustion. (b) Fertilizers help to increase agricultural production. (c) Water boils below $100^{\circ} \mathrm{C}$ on top of a mountain. (d) Lead is denser than aluminum. (e) Uranium is a radioactive element.

E1.37 Determine whether each of the following describes a physical change or a chemical change: (a) The helium gas inside a balloon tends to leak out after a few hours. (b) A flashlight beam slowly gets dimmer and finally goes out. (c) Frozen orange juice is reconstituted by adding water to it. (d) The growth of plants depends on the sun's energy in a process called photosynthesis. (e) A spoonful of salt dissolves in a bowl of soup.

E 1.38 A student pours 44.3 g of water at $10^{\circ} \mathrm{C}$ into a beaker containing 115.2 g of water at $10^{\circ} \mathrm{C}$. What are the final mass, temperature, and density of the combined water? The density of water at $10^{\circ} \mathrm{C}$ is $1.00 \mathrm{~g} / \mathrm{mL}$.

H1.39 A 37.2-g sample of lead $(\mathrm{Pb})$ pellets at $20^{\circ} \mathrm{C}$ is mixed with a $62.7-\mathrm{g}$ sample of lead pellets at the same temperature. What are the final mass, temperature, and density of the combined sample? The density of Pb at $20^{\circ} \mathrm{C}$ is $11.35 \mathrm{~g} / \mathrm{cm}^{3}$.

## Section 1.5: Uncertainty in Measurement

## Review Questions

1.40 Comment on whether each of the following statements represents an exact number: (a) 50,247 tickets were sold at a sporting event, (b) 509.2 mL of water was used to make a birthday cake, (c) 3 dozen eggs were used to make a breakfast, (d) 0.41 g of oxygen was inhaled in each breath, (e) Earth orbits the sun every 365.2564 days.
1.41 What is the advantage of using scientific notation over decimal notation?
1.42 Define significant figure. Discuss the importance of using the proper number of significant figures in measurements and calculations.
1.43 Distinguish between the terms accuracy and precision. In general, explain why a precise measurement does not always guarantee an accurate result.

## Problems

E1.44 Express the following numbers in scientific notation: (a) 0.000000027 , (b) 356 , (c) 47,764 , (d) 0.096 .
1.45 Express the following numbers as decimals: (a) $1.52 \times 10^{-2}$, (b) $7.78 \times 10^{-8}$, (c) $1 \times 10^{-6}$, (d) $1.6001 \times 10^{3}$.

E1 1.46 Express the answers to the following calculations in scientific notation:
(a) $145.75+\left(2.3 \times 10^{-1}\right)$
(b) $79,500 \div\left(2.5 \times 10^{2}\right)$
(c) $\left(7.0 \times 10^{-3}\right)-\left(8.0 \times 10^{-4}\right)$
(d) $\left(1.0 \times 10^{4}\right) \times\left(9.9 \times 10^{6}\right)$
1.47 Express the answers to the following calculations in scientific notation:
(a) $0.0095+\left(8.5 \times 10^{-3}\right)$
(b) $653 \div\left(5.75 \times 10^{-8}\right)$
(c) $850,000-\left(9.0 \times 10^{5}\right)$
(d) $\left(3.6 \times 10^{-4}\right) \times\left(3.6 \times 10^{6}\right)$

E 1.48 Determine the number of significant figures in each of the following measurements: (a) 4867 mi , (b) 56 mL , (c) 60,104 tons, (d) 2900 g , (e) $40.2 \mathrm{~g} / \mathrm{cm}^{3}$, (f) 0.0000003 cm , (g) 0.7 min , (h) $4.6 \times 10^{19}$ atoms.
1.49 Determine the number of significant figures in each of the following measurements: (a) 0.006 L , (b) 0.0605 dm , (c) 60.5 mg , (d) $605.5 \mathrm{~cm}^{2}$, (e) $9.60 \times 10^{3} \mathrm{~g}$, (f) 6 kg , (g) 60 m .

H 1.50 Carry out the following operations as if they were calculations of experimental results, and express each answer in the correct units with the correct number of significant figures:
(a) $5.6792 \mathrm{~m}+0.6 \mathrm{~m}+4.33 \mathrm{~m}$
(b) $3.70 \mathrm{~g}-2.9133 \mathrm{~g}$
(c) $4.51 \mathrm{~cm} \times 3.6666 \mathrm{~cm}$

H1.51 Carry out the following operations as if they were calculations of experimental results, and express each answer in the correct units with the correct number of significant figures:
(a) $7.310 \mathrm{~km} \div 5.70 \mathrm{~km}$
(b) $\left(3.26 \times 10^{-3} \mathrm{mg}\right)-\left(7.88 \times 10^{-5} \mathrm{mg}\right)$
(c) $\left(4.02 \times 10^{6} \mathrm{dm}\right)+\left(7.74 \times 10^{7} \mathrm{dm}\right)$
1.52 Three students (A, B, and C) are asked to determine the volume of a sample of ethanol. Each student measures the volume three times with a graduated cylinder. The results in milliliters are: A (87.1, 88.2, 87.6); B (86.9, 87.1, 87.2); C (87.6, 87.8, 87.9). The true volume is 87.0 mL . Comment on the precision and the accuracy of each student's results.

H1.53 Three apprentice tailors (X, Y, and Z) are assigned the task of measuring the seam of a pair of trousers. Each one makes three measurements. The results in inches are $\mathrm{X}(31.5,31.6,31.4)$; Y (32.8, 32.3, 32.7); $\mathrm{Z}(31.9,32.2,32.1)$. The true length is 32.0 in . Comment on the precision and the accuracy of each tailor's measurements.

## Section 1.6: Using Units and Solving Problems

## Problems

1.54 Carry out the following conversions: (a) 22.6 m to decimeters, (b) 25.4 mg to kilograms, (c) 556 mL to liters, (d) $10.6 \mathrm{~kg} / \mathrm{m}^{3}$ to $\mathrm{g} / \mathrm{cm}^{3}$.
11.55 Carry out the following conversions: (a) 242 lb to milligrams, (b) $68.3 \mathrm{~cm}^{3}$ to cubic meters, (c) $7.2 \mathrm{~m}^{3}$ to liters, (d) $28.3 \mu \mathrm{~g}$ to pounds.
1.56 The average speed of helium at $25^{\circ} \mathrm{C}$ is $1255 \mathrm{~m} / \mathrm{s}$. Convert this speed to miles per hour ( mph ).
1.57 How many seconds are there in a solar year (365.24 days)?
1.58 How many minutes does it take light from the sun to reach Earth? (The distance from the sun to Earth is 93 million mi; the speed of light is $3.00 \times 10^{8} \mathrm{~m} / \mathrm{s}$.)

E1.59 A slow jogger runs a mile in 13 min . Calculate the speed in (a) $\mathrm{in} / \mathrm{s}$, (b) $\mathrm{m} / \mathrm{min}$, (c) $\mathrm{km} / \mathrm{h}(1 \mathrm{mi}=1609 \mathrm{~m} ; 1 \mathrm{in}=2.54 \mathrm{~cm})$.

H1.60 A 6.0-ft person weighs 168 lb . Express this person's height in meters and weight in kilograms ( $1 \mathrm{lb}=453.6 \mathrm{~g} ; 1 \mathrm{~m}=3.28 \mathrm{ft}$ ).

E1.61 The current speed limit in some states in the United States is 55 mph . What is the speed limit in kilometers per hour ( $1 \mathrm{mi}=$ $1609 \mathrm{~m})$ ?
1.62 For a fighter jet to take off from the deck of an aircraft carrier, it must reach a speed of $62 \mathrm{~m} / \mathrm{s}$. Calculate the speed in miles per hour.

E 1.63 The "normal" lead content in human blood is about 0.40 part per million (that is, 0.40 g of lead per million grams of blood). A value of 0.80 part per million ( ppm ) is considered to be dangerous. How many grams of lead are contained in $6.0 \times 10^{3} \mathrm{~g}$ of blood (the amount in an average adult) if the lead content is 0.62 ppm ?

E1.64 Carry out the following conversions: (a) 1.42 light-years to miles (a light-year is an astronomical measure of distance-the distance traveled by light in a year, or 365 days; the speed of light is 3.00 $\times 10^{8} \mathrm{~m} / \mathrm{s}$ ), (b) 32.4 yd to centimeters, (c) $3.0 \times 10^{10} \mathrm{~cm} / \mathrm{s}$ to $\mathrm{ft} / \mathrm{s}$.
1.65 Carry out the following conversions: (a) 185 nm to meters, (b) 4.5 billion years (roughly the age of Earth) to seconds (assume 365 days in a year), (c) $71.2 \mathrm{~cm}^{3}$ to cubic meters, (d) $88.6 \mathrm{~m}^{3}$ to liters.
1.66 Aluminum is a lightweight metal (density $=2.70 \mathrm{~g} / \mathrm{cm}^{3}$ ) used in aircraft construction, high-voltage transmission lines, beverage cans, and foils. What is its density in $\mathrm{kg} / \mathrm{m}^{3}$ ?
1.67 The density of ammonia gas under certain conditions is $0.625 \mathrm{~g} / \mathrm{L}$. Calculate its density in $\mathrm{g} / \mathrm{cm}^{3}$.

E1 1.68 (a) Carbon monoxide (CO) is a poisonous gas because it binds very strongly to the oxygen carrier hemoglobin in blood. A concentration of $8.00 \times 10^{2} \mathrm{ppm}$ by volume of carbon monoxide is considered lethal to humans. Calculate the volume in liters occupied by carbon monoxide in a room that measures 17.6 m long, 8.80 m wide, and 2.64 m high at this concentration. (b) Prolonged exposure to mercury $(\mathrm{Hg})$ vapor can cause neurological disorder and respiratory problems. For safe air quality control, the concentration of mercury vapor must be under $0.050 \mathrm{mg} / \mathrm{m}^{3}$. Convert this number to $\mathrm{g} / \mathrm{L}$. (c) The general test for type II diabetes is that the blood sugar (glucose) level should be below 120 mg per deciliter ( $\mathrm{mg} / \mathrm{dL}$ ). Convert this number to micrograms per milliliter ( $\mu \mathrm{g} / \mathrm{mL}$ ).

E 1.69 The average time it takes for a molecule to diffuse a distance of $x \mathrm{~cm}$ is given by

$$
t=\frac{x^{2}}{2 D}
$$

where $t$ is the time in seconds and $D$ is the diffusion coefficient. Given that the diffusion coefficient of glucose is $5.7 \times 10^{-7} \mathrm{~cm}^{2} / \mathrm{s}$, calculate the time it would take for a glucose molecule to diffuse $10 \mu \mathrm{~m}$, which is roughly the size of a cell.
1.70 A human brain weighs about 1 kg and contains about $10^{11}$ cells. Assuming that each cell is completely filled with water (density $=$ $1 \mathrm{~g} / \mathrm{mL}$ ), calculate the length of one side of such a cell if it were a cube. If the cells are spread out into a thin layer that is a single cell thick, what is the surface area in square meters?

## Additional Problems

1.71 Using the appropriate number of significant figures, report the length of the blue rectangle (a) using the ruler shown above the rectangle and (b) using the ruler shown below the rectangle.

EI 1.72 A piece of metal with a mass of 13.2 g was dropped into a graduated cylinder containing 17.00 mL of water. The graduated cylinder after the addition of the metal is shown. Determine the density of the metal to the appropriate number of significant figures.

1.73 Which of the following statements describe physical properties and which describe chemical properties? (a) Iron has a tendency to rust. (b) Rainwater in industrialized regions tends to be acidic. (c) Hemoglobin molecules have a red color. (d) When a glass of water is left out in the sun, the water gradually disappears.
(e) Carbon dioxide in air is converted to more complex molecules by plants during photosynthesis.
© 1.74 In determining the density of a rectangular metal bar, a student made the following measurements: length, 8.53 cm ; width, 2.4 cm ; height, 1.0 cm ; mass, 52.7064 g . Calculate the density of the metal to the correct number of significant figures.

I 1.75 Calculate the mass of each of the following: (a) a sphere of gold with a radius of 10.0 cm (volume of a sphere with a radius $r$ is $V=\frac{4}{3} \pi r^{3}$; density of gold $\left.=19.3 \mathrm{~g} / \mathrm{cm}^{3}\right),(\mathrm{b})$ a cube of platinum of edge length 0.040 mm (density $=21.4 \mathrm{~g} / \mathrm{cm}^{3}$ ), (c) 50.0 mL of ethanol (density $=0.798 \mathrm{~g} / \mathrm{mL})$.

E1.76 A cylindrical glass tube 12.7 cm in length is filled with mercury $($ density $=13.6 \mathrm{~g} / \mathrm{mL})$. The mass of mercury needed to fill the tube is 105.5 g . Calculate the inner diameter of the tube (volume of a cylinder of radius $r$ and length $h$ is $V=\pi r^{2} h$ ).

E1.77 The following procedure was used to determine the volume of a flask. The flask was weighed dry and then filled with water. If the masses of the empty flask and filled flask were 56.12 g and 87.39 g , respectively, and the density of water is $0.9976 \mathrm{~g} / \mathrm{cm}^{3}$, calculate the volume of the flask in cubic centimeters.
1.78 The speed of sound in air at room temperature is about $343 \mathrm{~m} / \mathrm{s}$. Calculate this speed in miles per hour $(1 \mathrm{mi}=1609 \mathrm{~m})$.

H1.79 A piece of silver $(\mathrm{Ag})$ metal weighing 194.3 g is placed in a graduated cylinder containing 242.0 mL of water. The volume of water now reads 260.5 mL . From these data calculate the density of silver.
1.80 The experiment described in Problem 1.79 is a crude but convenient way to determine the density of some solids. Describe a similar experiment that would enable you to measure the density of ice. Specifically, what would be the requirements for the liquid used in your experiment?

E1.81 A lead sphere has a mass of $1.20 \times 10^{4} \mathrm{~g}$, and its volume is $1.05 \times 10^{3} \mathrm{~cm}^{3}$. Calculate the density of lead.

I 1.82 Lithium is the least dense metal known (density $=0.53 \mathrm{~g} / \mathrm{cm}^{3}$ ). What is the volume occupied by $1.20 \times 10^{3} \mathrm{~g}$ of lithium?

E 1.83 The medicinal thermometer commonly used in homes can be read to $\pm 0.1^{\circ} \mathrm{F}$, whereas those in the doctor's office may be accurate to $\pm 0.1^{\circ} \mathrm{C}$. Percent error is often expressed as the absolute value of the difference between the true value and the experimental value, divided by the true value:

$$
\text { percent error }=\frac{\mid \text { true value }- \text { experimental value } \mid}{\text { true value }} \times 100 \%
$$

The vertical lines indicate absolute value. In degrees Celsius, express the percent error expected from each of these thermometers in measuring a person's body temperature of $38.9^{\circ} \mathrm{C}$.
EI 1.84 Vanillin (used to flavor vanilla ice cream and other foods) is the substance whose aroma the human nose detects in the smallest amount. The threshold limit is $2.0 \times 10^{-11} \mathrm{~g}$ per liter of air. If the current price of 50 g of vanillin is $\$ 112$, determine the cost to supply enough vanillin so that the aroma could be detected in a large aircraft hangar with a volume of $5.0 \times 10^{7} \mathrm{ft}^{3}$.
$\boldsymbol{\Psi 1 . 8 5}$ At what temperature does the numerical reading on a Celsius thermometer equal that on a Fahrenheit thermometer?

E1.86 Suppose that a new temperature scale has been devised on which the melting point of ethanol $\left(-117.3^{\circ} \mathrm{C}\right)$ and the boiling point of ethanol $\left(78.3^{\circ} \mathrm{C}\right)$ are taken as $0^{\circ} \mathrm{S}$ and $100^{\circ} \mathrm{S}$, respectively, where
$S$ is the symbol for the new temperature scale. Derive an equation relating a reading on this scale to a reading on the Celsius scale. What would this thermometer read at $25^{\circ} \mathrm{C}$ ?
1.87 A resting adult requires about 240 mL of pure oxygen per minute and breathes about 12 times every minute. If inhaled air contains 20 percent oxygen by volume and exhaled air 16 percent, what is the volume of air per breath? (Assume that the volume of inhaled air is equal to that of exhaled air.)

G 1.88 (a) Referring to Problem 1.87, calculate the total volume (in liters) of air an adult breathes in a day. (b) In a city with heavy traffic, the air contains $2.1 \times 10^{-6} \mathrm{~L}$ of carbon monoxide (a poisonous gas) per liter. Calculate the average daily intake of carbon monoxide in liters by a person.

El 1.89 The total volume of seawater is $1.5 \times 10^{21} \mathrm{~L}$. Assume that seawater contains 3.1 percent sodium chloride by mass and that its density is $1.03 \mathrm{~g} / \mathrm{mL}$. Calculate the total mass of sodium chloride in kilograms and in tons $(1$ ton $=2000 \mathrm{lb} ; 1 \mathrm{lb}=453.6 \mathrm{~g})$.
1.90 Magnesium ( Mg ) is a valuable metal used in alloys, in batteries, and in the manufacture of chemicals. It is obtained mostly from seawater, which contains about 1.3 g of Mg for every kilogram of seawater. Referring to Problem 1.89, calculate the volume of seawater (in liters) needed to extract $8.0 \times 10^{4}$ tons of Mg , which is roughly the annual production in the United States.
1.91 A student is given a crucible and asked to prove whether it is made of pure platinum. She first weighs the crucible in air and then weighs it suspended in water (density $=0.9986 \mathrm{~g} / \mathrm{mL}$ ). The readings are 860.2 g and 820.2 g , respectively. Based on these measurements and given that the density of platinum is $21.45 \mathrm{~g} / \mathrm{cm}^{3}$, what should her conclusion be? (Hint: An object suspended in a fluid is buoyed up by the mass of the fluid displaced by the object. Neglect the buoyancy of air.)
1.92 The surface area and average depth of the Pacific Ocean are $1.8 \times 10^{8} \mathrm{~km}^{2}$ and $3.9 \times 10^{3} \mathrm{~m}$, respectively. Calculate the volume of water in the ocean in liters.

E 1.93 The unit "troy ounce" is often used for precious metals such as $\operatorname{gold}(\mathrm{Au})$ and platinum $(\mathrm{Pt})(1$ troy ounce $=31.103 \mathrm{~g})$. (a) A gold coin weighs 2.41 troy ounces. Calculate its mass in grams. (b) Is a troy ounce heavier or lighter than an ounce $(1 \mathrm{lb}=16 \mathrm{oz} ; 1 \mathrm{lb}=$ 453.6 g )?

E 1.94 Osmium (Os) is the densest element known (density $=$ $22.57 \mathrm{~g} / \mathrm{cm}^{3}$ ). Calculate the mass in pounds and in kilograms of an Os sphere 15 cm in diameter (about the size of a grapefruit) (volume of a sphere of radius $r$ is $\frac{4}{3} \pi r^{3}$ ).
1.95 Calculate the percent error for the following measurements: (a) The density of alcohol (ethanol) is found to be $0.802 \mathrm{~g} / \mathrm{mL}$ (true value $=0.798 \mathrm{~g} / \mathrm{mL}$ ). (b) The mass of gold in an earring is analyzed to be 0.837 g (true value $=0.864 \mathrm{~g}$ ).
H1.96 The natural abundances of elements in the human body, expressed as percent by mass, are oxygen $(\mathrm{O}), 65$ percent; carbon $(\mathrm{C})$, 18 percent; hydrogen $(\mathrm{H}), 10$ percent; nitrogen $(\mathrm{N}), 3$ percent; calcium $(\mathrm{Ca}), 1.6$ percent; phosphorus $(\mathrm{P}), 1.2$ percent; all other elements, 1.2 percent. Calculate the mass in grams of each element in the body of a $62-\mathrm{kg}$ person.

H1.97 The men's world record for running a mile outdoors (as of 1999) is 3 min 43.13 s . At this rate, how long would it take to run a $1500-\mathrm{m}$ race ( $1 \mathrm{mi}=1609 \mathrm{~m}$ )?

G1.98 Venus, the second closest planet to the sun, has a surface temperature of $7.3 \times 10^{2} \mathrm{~K}$. Convert this temperature to degrees Celsius and degrees Fahrenheit.

EI 1.99 Chalcopyrite, the principal ore of copper ( Cu ), contains 34.63 percent Cu by mass. How many grams of Cu can be obtained from $5.11 \times 10^{3} \mathrm{~kg}$ of the ore?
1.100 It has been estimated that $8.0 \times 10^{4}$ tons of gold $(\mathrm{Au})$ have been mined. Assume gold costs $\$ 900$ per Troy ounce. What is the total worth of this quantity of gold? $(1$ Troy ounce $=31.103 \mathrm{~g})$

H1.101 A $1.0-\mathrm{mL}$ volume of seawater contains about $4.0 \times 10^{-12} \mathrm{~g}$ of gold. The total volume of ocean water is $1.5 \times 10^{21} \mathrm{~L}$. Calculate the total amount of gold (in grams) that is present in seawater and the worth of the gold in dollars (see Problem 1.100). With so much gold out there, why hasn't someone become rich by mining gold from the ocean?
1.102 Measurements show that 1.0 g of iron $(\mathrm{Fe})$ contains $1.1 \times 10^{22} \mathrm{Fe}$ atoms. How many Fe atoms are in 4.9 g of Fe , which is the total amount of iron in the body of an average adult?

E1.103 The thin outer layer of Earth, called the crust, contains only 0.50 percent of Earth's total mass and yet is the source of almost all the elements (the atmosphere provides elements such as oxygen, nitrogen, and a few other gases). Silicon ( Si ) is the second most abundant element in Earth's crust ( 27.2 percent by mass). Calculate the mass of silicon in kilograms in Earth's crust (mass of Earth $=5.9 \times 10^{21}$ tons; 1 ton $\left.=2000 \mathrm{lb} ; 1 \mathrm{lb}=453.6 \mathrm{~g}\right)$.
1.104 The radius of a copper $(\mathrm{Cu})$ atom is roughly $1.3 \times 10^{-10} \mathrm{~m}$. How many times can you divide evenly a 10 -cm-long piece of copper wire until it is reduced to two separate copper atoms? (Assume there are appropriate tools for this procedure and that copper atoms are lined up in a straight line, in contact with each other. Round off your answer to an integer.)
1.105 One gallon of gasoline in an automobile's engine produces on the average 9.5 kg of carbon dioxide, which is a greenhouse gas; that is, it promotes the warming of Earth's atmosphere. Calculate the annual production of carbon dioxide in kilograms if there are 40 million cars in the United States and each car covers a distance of 5000 mi at a consumption rate of 20 miles per gallon.

E1.106 A sheet of aluminum (Al) foil has a total area of $1.000 \mathrm{ft}^{2}$ and a mass of 3.636 g . What is the thickness of the foil in millimeters (density of $\mathrm{Al}=2.699 \mathrm{~g} / \mathrm{cm}^{3}$ )?
1.107 Comment on whether each of the following is a homogeneous mixture or a heterogeneous mixture: (a) air in a closed bottle, (b) air over New York City.
1.108 Chlorine is used to disinfect swimming pools. The accepted concentration for this purpose is 1 ppm chlorine, or 1 g of chlorine per million grams of water. Calculate the volume of a chlorine solution (in milliliters) a homeowner should add to her swimming pool if the solution contains 6.0 percent chlorine by mass and there are $2.0 \times 10^{4}$ gallons (gal) of water in the pool $(1 \mathrm{gal}=3.79 \mathrm{~L}$; density of liquids $=1.0 \mathrm{~g} / \mathrm{mL})$.

H1.109 The world's total petroleum reserve is estimated at $2.0 \times$ $10^{22}$ joules [a joule $(\mathrm{J})$ is the unit of energy where $1 \mathrm{~J}=$ $\left.1 \mathrm{~kg} \cdot \mathrm{~m}^{2} / \mathrm{s}^{2}\right]$. At the present rate of consumption, $1.8 \times 10^{20}$ joules per year ( $\mathrm{J} / \mathrm{yr}$ ), how long would it take to exhaust the supply?
1.110 In water conservation, chemists spread a thin film of a certain inert material over the surface of water to cut down on the rate of evaporation of water in reservoirs. This technique was pioneered
by Benjamin Franklin three centuries ago. Franklin found that 0.10 mL of oil could spread over the surface of water about $40 \mathrm{~m}^{2}$ in area. Assuming that the oil forms a monolayer, that is, a layer that is only one molecule thick, estimate the length of each oil molecule in nanometers $\left(1 \mathrm{~nm}=1 \times 10^{-9} \mathrm{~m}\right)$.

E1.111 Fluoridation is the process of adding fluorine compounds to drinking water to help fight tooth decay. A concentration of 1 ppm of fluorine is sufficient for the purpose ( 1 ppm means one part per million, or 1 g of fluorine per 1 million g of water). The compound normally chosen for fluoridation is sodium fluoride, which is also added to some toothpastes. Calculate the quantity of sodium fluoride in kilograms needed per year for a city of 50,000 people if the daily consumption of water per person is 150 gal . What percent of the sodium fluoride is "wasted" if each person uses only 6.0 L of water a day for drinking and cooking (sodium fluoride is 45.0 percent fluorine by mass; $1 \mathrm{gal}=3.79 \mathrm{~L} ; 1$ year $=365$ days; 1 ton $=2000 \mathrm{lb} ; 1 \mathrm{lb}=453.6 \mathrm{~g}$; density of water $=1.0 \mathrm{~g} / \mathrm{mL})$ ?
$\mathbb{H}$ 1.112 A gas company in Massachusetts charges $\$ 1.30$ for $15.0 \mathrm{ft}^{3}$ of natural gas. (a) Convert this rate to dollars per liter of gas. (b) If it takes $0.304 \mathrm{ft}^{3}$ of gas to boil a liter of water, starting at room temperature $\left(25^{\circ} \mathrm{C}\right)$, how much would it cost to boil a $2.1-\mathrm{L}$ kettle of water?
1.113 Pheromones are compounds secreted by females of many insect species to attract mates. Typically, $1.0 \times 10^{-8} \mathrm{~g}$ of a pheromone is sufficient to reach all targeted males within a radius of 0.50 mi . Calculate the density of the pheromone (in grams per liter) in a cylindrical air space having a radius of 0.50 mi and a height of 40 ft (volume of a cylinder of radius $r$ and height $h$ is $\pi r^{2} h$ ).
1.114 A bank teller is asked to assemble $\$ 1$ sets of coins for his clients. Each set is made up of three quarters, one nickel, and two dimes. The masses of the coins are quarter, 5.645 g ; nickel, 4.967 g ; and dime, 2.316 g . What is the maximum number of sets that can be assembled from 33.871 kg of quarters, 10.432 kg of nickels, and 7.990 kg of dimes? What is the total mass (in grams) of the assembled sets of coins?
1.115 A graduated cylinder is filled to the $40.00-\mathrm{mL}$ mark with a mineral oil. The masses of the cylinder before and after the addition of the mineral oil are 124.966 g and 159.446 g , respectively. In a separate experiment, a metal ball bearing of mass 18.713 g is placed in the cylinder and the cylinder is again filled to the $40.00-\mathrm{mL}$ mark with the mineral oil. The combined mass of the ball bearing and mineral oil is 50.952 g . Calculate the density and radius of the ball bearing (volume of a sphere of radius $r$ is $\frac{4}{3} \pi r^{3}$ ).
$\boldsymbol{\Psi}$ 1.116 Bronze is an alloy made of copper $(\mathrm{Cu})$ and tin $(\mathrm{Sn})$. Calculate the mass of a bronze cylinder of radius 6.44 cm and length 44.37 cm . The composition of the bronze is 79.42 percent Cu and 20.58 percent Sn and the densities of Cu and Sn are $8.94 \mathrm{~g} / \mathrm{cm}^{3}$ and $7.31 \mathrm{~g} / \mathrm{cm}^{3}$, respectively. What assumption should you make in this calculation?
1.117 A chemist in the nineteenth century prepared an unknown substance. In general, do you think it would be more difficult to prove that it is an element or a compound? Explain.
1.118 A chemist mixes two liquids $A$ and $B$ to form a homogeneous mixture. The densities of the liquids are $2.0514 \mathrm{~g} / \mathrm{mL}$ for A and $2.6678 \mathrm{~g} / \mathrm{mL}$ for B . When she drops a small object into the mixture, she finds that the object becomes suspended in the liquid; that is, it neither sinks nor floats. If the mixture is made of 41.37 percent A and 58.63 percent $B$ by volume, what is the density of the object? Can this procedure be used in general to determine the densities of solids? What assumptions must be made in applying this method?
1.119 You are given a liquid. Briefly describe the steps you would take to show whether it is a pure substance or a homogeneous mixture.
1.120 TUMS is a popular remedy for acid indigestion. A typical TUMS tablet contains calcium carbonate plus some inert substances. When ingested, it reacts with the gastric juice (hydrochloric acid) in the stomach to give off carbon dioxide gas. When a $1.328-\mathrm{g}$ tablet reacted with 40.00 mL of hydrochloric acid (density $=$ $1.140 \mathrm{~g} / \mathrm{mL}$ ), carbon dioxide gas was given off and the resulting solution weighed 46.699 g . Calculate the number of liters of carbon dioxide gas released if its density is $1.81 \mathrm{~g} / \mathrm{L}$.
1.121 A $250-\mathrm{mL}$ glass bottle was filled with 242 mL of water at $20^{\circ} \mathrm{C}$ and tightly capped. It was then left outdoors overnight, where the average temperature was $-5^{\circ} \mathrm{C}$. Predict what would happen. The density of water at $20^{\circ} \mathrm{C}$ is $0.998 \mathrm{~g} / \mathrm{cm}^{3}$ and that of ice at $-5^{\circ} \mathrm{C}$ is $0.916 \mathrm{~g} / \mathrm{cm}^{3}$.

## Pre-Professional Practice Exam Problems: Verbal Reasoning

English writer and essayist Lady Mary Wortley Montagu (1689-1762) traveled extensively and was fascinated by the customs in other countries. While in Turkey, she observed the practice of "engrafting" wherein people were inoculated against smallpox by intentional exposure to a mild form of the disease. She was so convinced of the efficacy and the safety of engrafting, that she had both of her children inoculated. She herself had survived smallpox as a child. Lady Montagu campaigned for the practice when she returned to England, and despite opposition from doctors and religious leaders, inoculation came into common use. It remained the primary defense against the scourge of smallpox for decades-until Jenner developed the practice of vaccination.

1. The main point of the passage is that
a) Lady Montagu survived smallpox as a child.
b) Lady Montagu brought the practice of engrafting from Turkey to England.
c) Doctors in eighteenth-century England were opposed to the practice of engrafting.
d) Jenner developed the practice of vaccination.
2. Based on the passage, Lady Montagu was most likely
a) a doctor.
b) Turkish.
c) severely scarred by smallpox.
d) a member of a prominent British family.
3. The author refers to Lady Montagu having survived smallpox to
a) explain why Lady Montagu was fascinated by the practice of engrafting.
b) compare Lady Montagu to the doctors and religious leaders in England.
c) explain why Lady Montagu herself did not undergo the engrafting procedure.
d) emphasize Lady Montagu's fascination with other cultures.
4. Based on the passage, the author most likely thinks that Lady Montagu was
a) educated and influential.
b) inconsequential in the prevention of smallpox in England.
c) trained in science and medicine.
d) married to the British ambassador to Turkey.

## Answers to In-Chapter Materials

## How Certain Atoms, Molecules, and Ions Can Affect Human Health

Atoms, molecules, and ions make up the substances we encounter every day. Some of these substances are important components of a balanced diet. An estimated 25 percent of the world's population suffers from iron deficiency, the most common nutritional deficiency in the world. Iron is necessary for the production of hemoglobin, the component in red blood cells responsible for the transport of oxygen. An inadequate supply of iron and the resulting shortage of hemoglobin can cause iron deficiency anemia (IDA). Some of the symptoms of IDA are fatigue, weakness, pale color, poor appetite, headache, and light-headedness.

Although IDA can be caused by loss of blood or by poor absorption of iron, the most common cause is insufficient iron in the diet. Dietary iron comes from such sources as meat, eggs, leafy green vegetables, dried beans, and dried fruits. Some breakfast cereals, such as Total, are fortified with iron in the form of iron metal, also known as elemental or reduced iron. The absorption of dietary iron can be enhanced by the intake of vita$\min \mathrm{C}$ (ascorbic acid). When the diet fails to provide enough iron, a nutritional supplement may be necessary to prevent a deficiency. Many supplements provide iron in the form of a compound called ferrous sulfate.

Elemental iron, ascorbic acid, and the iron in ferrous sulfate are examples of some of the atoms, molecules, and ions that are essential for human health.

Student Annotation: Iron absorption can be diminished by certain disorders, such as Crohn's disease, and by some medications.

At the end of this chapter you will be able to solve a series of problems involving iron, iron sulfate, and ascorbic acid [ $n$ Page 67].

## In This Chapter, You Will Learn:

What atoms are made of and how they are arranged in molecules and ions that make up the substances that we encounter every day. You will also learn how to associate the name of a substance with its chemical formula.

## Before you begin, you should review

- Significant figures [k4 Section 1.5]
- Dimensional analysis [ 14 Section 1.6]

Figure 2.1 (a) John Dalton. (b) In addition to his other work, Dalton devised a system of symbols, which he used to represent the elements. (c) Dalton's only recreation is said to have been a nightly pint of ale and lawn bowling every Thursday afternoon. Note how closely the game balls resemble modern-day molecular models.

### 2.1 The Atomic Theory

In the fifth century b.c. the Greek philosopher Democritus proposed that all matter consists of very small, indivisible particles, which he named atomos (meaning uncuttable or indivisible). Although Democritus's idea was not accepted by many of his contemporaries (notably Plato and Aristotle), somehow it endured. Experimental evidence from early scientific investigations provided support for the notion of "atomism" and gradually gave rise to the modern definitions of elements and compounds. In 1808, an English scientist and schoolteacher, John Dalton ${ }^{1}$ (Figure 2.1), formulated a precise definition of the indivisible building blocks of matter that we call atoms.

Dalton's work marked the beginning of the modern era of chemistry. The hypotheses about the nature of matter on which Dalton's atomic theory is based can be summarized as follows:

1. Elements are composed of extremely small particles called atoms. All atoms of a given element are identical, having the same size, mass, and chemical properties. The atoms of one element are different from the atoms of all other elements.
2. Compounds are composed of atoms of more than one element. In any given compound, the same types of atoms are always present in the same relative numbers.
3. A chemical reaction rearranges atoms in chemical compounds; it does not create or destroy them.
Figure 2.2 is a schematic representation of these hypotheses.
Dalton's concept of an atom was far more detailed and specific than that of Democritus. The first hypothesis states that atoms of one element are different from atoms of all other elements. Dalton made no attempt to describe the structure or composition of atoms-he had no idea what an atom was really like. He did realize, though, that the different properties shown by elements such as hydrogen and oxygen could be explained by assuming that hydrogen atoms were not the same as oxygen atoms.

The second hypothesis suggests that, to form a certain compound, we not only need atoms of the right kinds of elements, but specific numbers of these atoms as well. This idea is an extension of a law published in 1799 by Joseph Proust, a French chemist. According to Proust's law of definite proportions, different samples of a given compound always contain the same elements in the same mass ratio. Thus, if we were to analyze samples of carbon dioxide gas obtained from different sources, such as the exhaust from a car in Mexico City or the air above a pine forest in northern

[^1]

Figure 2.2 This represents a chemical reaction between the elements oxygen and carbon. (a) Oxygen does not exist as isolated atoms under ordinary conditions, but rather as molecules, each of which consists of two oxygen atoms. Note that the oxygen atoms (red spheres) appear all to be identical to one another (hypothesis 1). (b) Likewise, the carbon atoms (black spheres) all appear to be identical to one another. Carbon also exists in the form of molecules that are more varied and complex than those of oxygen. The carbon has been represented as isolated atoms to simplify the figure. (c) The compound $\mathrm{CO}_{2}$ forms when each carbon atom combines with two oxygen atoms (hypothesis 2 ). Finally, the reaction results in the rearrangement of the atoms, but all the atoms present before the reaction (left of the arrow) are also present after the reaction (right of the arrow) (hypothesis 3).

Maine, each sample would contain the same ratio by mass of oxygen to carbon. Consider the following results of the analysis of three samples of carbon dioxide, each from a different source:

| Sample | Mass of O (g) | Mass of C (g) | Ratio (g O : g C) |
| :---: | :---: | :---: | :---: |
| 123 g carbon dioxide | 89.4 | 33.6 | 2.66:1 |
| 50.5 g carbon dioxide | 36.7 | 13.8 | 2.66:1 |
| 88.6 g carbon dioxide | 64.4 | 24.2 | 2.66:1 |

In any sample of pure carbon dioxide, there are 2.66 g of oxygen for every gram of carbon present. This constant mass ratio can be explained by assuming that the elements exist in tiny particles of fixed mass (atoms), and that compounds are formed by the combination of fixed numbers of each type of particle.

Dalton's second hypothesis also supports the law of multiple proportions. According to this law, if two elements can combine to form more than one compound with each other, the masses of one element that combine with a fixed mass of the other element are in ratios of small whole numbers. That is, different compounds made up of the same elements differ in the number of atoms of each kind that combine. For example, carbon combines with oxygen to form carbon dioxide and carbon monoxide. In any sample of pure carbon monoxide, there are 1.33 g of oxygen for every gram of carbon.

| Sample | Mass of O (g) | Mass of C (g) | Ratio (g O : g C) |
| :---: | :---: | :---: | :---: |
| 16.3 g carbon monoxide | 9.31 | 6.99 | 1.33:1 |
| 25.9 g carbon monoxide | 14.8 | 11.1 | 1.33:1 |
| 88.4 g carbon monoxide | 50.5 | 37.9 | 1.33:1 |

Thus, the ratio of oxygen to carbon in carbon dioxide is 2.66; and the ratio of oxygen to carbon in carbon monoxide is 1.33 . According to the law of multiple proportions, the ratio of two such ratios can be expressed as small whole numbers.

$$
\frac{\text { ratio of } \mathrm{O} \text { to } \mathrm{C} \text { in carbon dioxide }}{\text { ratio of } \mathrm{O} \text { to } \mathrm{C} \text { in carbon monoxide }}=\frac{2.66}{1.33}=2: 1
$$

For samples containing equal masses of carbon, the ratio of oxygen in carbon dioxide to oxygen in carbon monoxide is $2: 1$. Modern measurement techniques indicate that one atom of carbon combines with two atoms of oxygen in carbon dioxide and with one atom of oxygen in carbon monoxide. This result is consistent with the law of multiple proportions (Figure 2.3).

Dalton's third hypothesis is another way of stating the law of conservation of mass, ${ }^{2}$ which is that matter can be neither created nor destroyed. Because matter is made up of atoms that are unchanged in a chemical reaction, it follows that mass must be conserved as well.

[^2]Figure 2.3 An illustration of the law of multiple proportions.

Think About lt When the result of such calculations is not a whole number, we must decide whether the result is close enough to round to a whole number as in part (a), or whether to multiply through to get whole numbers as in part (b). Only numbers that are very close to whole can be rounded. For example, numbers ending in approximately $.25, .33$, or .5 should be multiplied by 4,3 , or 2 , respectively, to give a whole number.

Dalton's brilliant insight into the nature of matter was the main stimulus for the rapid progress of chemistry during the nineteenth century.

Sample Problem 2.1 shows how some common compounds obey the law of multiple proportions.

## Sample Problem 2.1

(a) Both water $\left(\mathrm{H}_{2} \mathrm{O}\right)$ and hydrogen peroxide $\left(\mathrm{H}_{2} \mathrm{O}_{2}\right)$ are composed of hydrogen and oxygen. When water is decomposed into its constituent elements, it produces 0.125 g hydrogen for every gram of oxygen. When hydrogen peroxide is decomposed, it produces 0.063 g hydrogen for every gram of oxygen. Determine the whole number ratio of $\mathrm{g} \mathrm{H}: 1.00 \mathrm{~g} \mathrm{O}$ in water to $\mathrm{g} \mathrm{H}: 1.00 \mathrm{~g} \mathrm{O}$ in hydrogen peroxide to show how these data illustrate the law of multiple proportions. (b) Sulfur and oxygen can combine to form several compounds including sulfur dioxide $\left(\mathrm{SO}_{2}\right)$ and sulfur trioxide $\left(\mathrm{SO}_{3}\right)$. Sulfur dioxide contains 0.9978 g oxygen for every gram of sulfur. Sulfur trioxide contains 1.497 g oxygen for every gram of sulfur. Determine the whole number ratio of $\mathrm{g} \mathrm{O}: 1.00 \mathrm{~g} \mathrm{~S}$ in sulfur dioxide to $\mathrm{g} \mathrm{O}: 1.00 \mathrm{~g} \mathrm{~S}$ in sulfur trioxide.

Strategy For two compounds, each consisting of just two different elements, we are given the mass ratio of one element to the other. In each case, to show how the information given illustrates the law of multiple proportions, we divide the larger ratio by the smaller ratio.

Setup (a) The mass ratio of hydrogen to oxygen is higher in water than it is in hydrogen peroxide. Therefore, we divide the number of grams of hydrogen per gram of oxygen given for water by that given for hydrogen peroxide. (b) The mass ratio of oxygen to sulfur is higher in sulfur trioxide than it is in sulfur dioxide. Therefore, we divide the number of grams of oxygen per gram of sulfur given for sulfur trioxide by that given for sulfur dioxide.

## Solution

(a) $\frac{\mathrm{g} \mathrm{H}: 1.00 \mathrm{~g} \mathrm{O} \text { in water }}{\mathrm{g} \mathrm{H}: 1.00 \mathrm{~g} \mathrm{O} \text { in hydrogen peroxide }}=\frac{0.125}{0.063}=1.98: 1 \approx 2: 1$
(b) $\frac{\mathrm{g} \mathrm{O}: 1.00 \mathrm{~g} \mathrm{~S} \text { in sulfur trioxide }}{\mathrm{g} \mathrm{O}: 1.00 \mathrm{~g} \mathrm{~S} \text { in sulfur dioxide }}=\frac{1.497}{0.9978}=1.50: 1$. Multiplying through by 2 gives 3:2 .

Practice Problem A In each case, calculate the appropriate ratio to show that the information given is consistent with the law of multiple proportions. (a) Both ammonia $\left(\mathrm{NH}_{3}\right)$ and hydrazine $\left(\mathrm{N}_{2} \mathrm{H}_{4}\right)$ are composed of nitrogen and hydrogen. Ammonia contains 0.2158 g hydrogen for every gram of nitrogen. Hydrazine contains 0.1439 g hydrogen for every gram of nitrogen. (b) Two of the compounds that consist of nitrogen and oxygen are nitric oxide, also known as nitrogen monoxide (NO) and nitrous oxide $\left(\mathrm{N}_{2} \mathrm{O}\right)$, which is also known as dinitrogen monoxide. Nitric oxide contains 1.142 g oxygen for every gram of nitrogen. Nitrous oxide contains 0.571 g oxygen for every gram of nitrogen.

GPractice Problem B (a) Two of the simplest compounds containing just carbon and hydrogen are methane and ethane. Given that methane contains 0.3357 g hydrogen for every 1.00 g carbon and that the ratio of g hydrogen $/ 1.00 \mathrm{~g}$ carbon in methane to g hydrogen $/ 1.00 \mathrm{~g}$ carbon in ethane is $4: 3$, determine the number of grams of hydrogen per gram of carbon in ethane. (b) Xenon (Xe) and fluorine ( F ) can combine to form several different compounds, including $\mathrm{XeF}_{2}$, which contains 0.2894 g fluorine for every gram of xenon. Use the law of multiple proportions to determine $n$, which represents the number of F atoms in another compound, $\mathrm{XeF}_{n}$, given that it contains 0.8682 g of F for every gram of Xe .

## Checkpoint 2.1 The Atomic Theory

For the two compounds pictured, evaluate the following ratio:

$$
\frac{\mathrm{g} \text { yellow : } 1.00 \mathrm{~g} \text { blue (right) }}{\mathrm{g} \text { yellow }: 1.00 \mathrm{~g} \text { blue }(\mathrm{left})}
$$

a) $2: 1$
b) $3: 2$
c) $3: 4$
d) $5: 2$
e) $5: 4$
2.1.2 For which of the following pairs of compounds is the ratio

$$
\frac{\mathrm{g} \text { yellow }: 1.00 \mathrm{~g} \text { blue }(\mathrm{right})}{\mathrm{g} \text { yellow }: 1.00 \mathrm{~g} \text { blue }(\mathrm{left})}
$$

equal to $4: 1$ ?
a)

d)

### 2.2 The Structure of the Atom

On the basis of Dalton's atomic theory, we can define an atom as the basic unit of an element that can enter into chemical combination. Dalton imagined an atom that was both extremely small and indivisible. However, a series of investigations that began in the 1850s and extended into the twentieth century clearly demonstrated that atoms actually possess internal structure; that is, they are made up of even smaller particles, which are called subatomic particles. This research led to the discovery of electrons, protons, and neutrons.

## Discovery of the Electron

Many scientists in the 1890s studied radiation, the emission and transmission of energy through space in the form of waves. Information gained from this research contributed greatly to our understanding of atomic structure. One device used to investigate this phenomenon was a cathode ray tube, the forerunner of the tubes used in older televisions and computer monitors (Figure 2.4).

Figure 2.5 (a) A cathode ray produced in a discharge tube. The ray itself is invisible, but the fluorescence of a zinc sulfide coating on the glass causes it to appear green. (b) The cathode ray bends toward one pole of a magnet and (c) bends away from the opposite pole.

Student Annotation: Recall that A and s are the SI base units ampere and second, respectively [ 14 Section 1.3, Table 1.2].

Student Annotation: Millikan actually determined the charge on droplets with multiple charges attached. The charges he determined were always multiples of $-1.6022 \times 10^{-19} \mathrm{C}$.

A cathode ray tube consists of two metal plates sealed inside a glass tube from which most of the air has been evacuated. When the metal plates are connected to a high-voltage source, the negatively charged plate, called the cathode, emits an invisible ray. The cathode ray is drawn to the positively charged plate, called the anode, where it passes through a hole and continues traveling to the other end of the tube. When the ray strikes the specially phosphor-coated surface, it produces a bright light.

Because consistent results are observed regardless of the composition of the cathode, cathode rays were presumed to be a component of all matter. Furthermore, because the path of the cathode rays could be deflected by magnetic and electric fields, as shown in Figure 2.4, they must be streams of charged particles. According to electromagnetic theory, a moving charged body behaves like a magnet and can interact with electric and magnetic fields through which it passes. Because the cathode ray is attracted by the plate bearing positive charges and repelled by the plate bearing negative charges, it must consist of negatively charged particles. We know these negatively charged particles as electrons. Figure 2.5 shows the deflection of a stream of electrons away from the south pole of a bar magnet. This effect on the path of electrons is what causes a television picture to become distorted temporarily when a magnet is brought close to the screen.

An English physicist, J. J. Thomson, used a cathode ray tube and his knowledge of electromagnetic theory to determine the ratio of electric charge to the mass of an individual electron. The number he calculated was $1.76 \times 10^{8} \mathrm{C} / \mathrm{g}$, where C stands for coulomb, which is the derived SI unit of electric charge. (In SI base units, $1 \mathrm{C}=1 \mathrm{~A} \cdot \mathrm{~s}$.) Thereafter, in a series of experiments carried out between 1908 and 1917, American R. A. Millikan succeeded in measuring the charge of the electron with great precision. In his experiment, Millikan examined the motion of single tiny drops of oil that picked up static charge from particles in the air. He suspended the charged drops in air by applying an electric field and followed their motions through a microscope (Figure 2.6). His work proved that the charge on each electron was exactly the same: $-1.6022 \times 10^{-19} \mathrm{C}$. Using Thomson's charge-to-mass ratio and the charge from his own experiments, Millikan calculated the mass of an electron as follows:

$$
\text { mass of an electron }=\frac{\text { charge }}{\text { charge } / \mathrm{mass}}=\frac{-1.6022 \times 10^{-19} \mathrm{C}}{-1.76 \times 10^{8} \mathrm{C} / \mathrm{g}}=9.10 \times 10^{-28} \mathrm{~g}
$$

This is an extremely small mass.

## Radioactivity

In 1895 , the German physicist Wilhelm Röntgen noticed that cathode rays caused glass and metals to emit yet another type of ray. This highly energetic radiation penetrated matter, darkened covered photographic plates, and caused a variety of substances to fluoresce (give off light). These rays were not deflected by a magnet, however, so unlike cathode rays, they could not contain charged particles. Röntgen called them X rays because of their mysterious nature.

Not long after Röntgen's discovery, Antoine Becquerel, a professor of physics in Paris, began to study the fluorescent properties of substances. Purely by accident, he found that exposing thickly wrapped photographic plates (so no light could get in) to a uranium compound caused them to darken, even without the stimulation of cathode rays. Like X rays, the rays from the uranium compound were highly energetic and could not be deflected by a magnet, but they differed from

X rays because they arose spontaneously. One of Becquerel's students, Marie Curie, suggested the name radioactivity to describe this spontaneous emission of particles and/or radiation. Today, we use the term radioactive to describe any element that spontaneously emits radiation.

Three types of rays are produced by the breakdown, or decay, of radioactive substances such as uranium. Two of the three are deflected by oppositely charged metal plates (Figure 2.7). Alpha ( $\boldsymbol{\alpha}$ ) rays consist of positively charged particles, called $\boldsymbol{\alpha}$ particles, that are deflected away from the positively charged plate. Beta ( $\boldsymbol{\beta}$ ) rays, or $\boldsymbol{\beta}$ particles, are electrons, so they are deflected away from the negatively charged plate. The third type of radioactive radiation consists of high-energy gamma $(\gamma)$ rays. Like X rays, $\gamma$ rays have no charge and are unaffected by external electric or magnetic fields.

## The Proton and the Nucleus

By the early 1900s, scientists knew that atoms contained electrons but were electrically neutral overall. To be neutral, an atom must contain equal amounts of positive and negative charge. Thomson proposed, therefore, that an atom could be thought of as a sphere of positively charged matter in which negatively charged electrons were embedded uniformly, like the chocolate chips in a scoop of mint chocolate chip ice cream. This so-called plum-pudding model was the accepted theory for a number of years.

Figure 2.7 Three types of rays emitted by radioactive elements. So-called $\beta$ rays actually consist of negatively charged particles (electrons) and are therefore attracted by the positively charged plate. The opposite holds true for so-called $\alpha$ rays-they are actually positively charged particles and are drawn to the negatively charged plate. Because $\gamma$ rays are not particles and have no charge, their path is unaffected by an external electric field.

Figure 2.6 Schematic diagram of Millikan's oil-drop experiment.

Multimedia
Millikan oil-drop experiment.

Figure 2.8 Rutherford's experimental design for measuring the scattering of $\alpha$ particles by a piece of gold foil. The plum-pudding model predicted that the $\alpha$ particles would all pass through the gold foil undeflected. The actual result: Most of the $\alpha$ particles do pass through the gold foil with little or no deflection, but a few are deflected at large angles. Occasionally an $\alpha$ particle bounces off the foil back toward the source. The nuclear model explains the results of Rutherford's experiments.

In 1910 the New Zealand physicist Ernest Rutherford, who had studied with Thomson at Cambridge University, decided to use $\alpha$ particles to probe the structure of atoms. Together with his associate Hans Geiger and an undergraduate named Ernest Marsden, Rutherford carried out a series of experiments using very thin foils of gold and other metals as targets for $\alpha$ particles from a radioactive source. They observed that the majority of particles penetrated the foil either completely undeflected or with only a small angle of deflection. Every now and then, however, an $\alpha$ particle was scattered (or deflected) at a large angle. In some instances, the $\alpha$ particle actually bounced back in the direction from which it had come! This was an extraordinarily surprising finding. In Thomson's model the positive charge of the atom was so diffuse that the relatively massive, positively charged particles should all have passed through the foil with little or no deflection. To quote Rutherford's initial reaction when told of this discovery: "It was as incredible as if you had fired a 15 -inch shell at a piece of tissue paper and it came back and hit you." Figure 2.8 illustrates the results of Rutherford's $\alpha$-scattering experiment.

## Nuclear Model of the Atom

Rutherford later explained the results of the $\alpha$-scattering experiment by proposing a new model for the atom. According to Rutherford, most of the atom must be empty space. This would explain why the majority of $\alpha$ particles passed through the gold foil with little or no deflection. The atom's positive charges, Rutherford proposed, were all concentrated in the nucleus, which is an extremely dense central core within the atom. Whenever an $\alpha$ particle came close to a nucleus in the scattering experiment, it experienced a large repulsive force and therefore a large deflection. Moreover, an $\alpha$ particle traveling directly toward a nucleus would be completely repelled and its direction would be reversed.

The positively charged particles in the nucleus are called protons. In separate experiments, it was found that each proton carried the same quantity of charge as an electron (just opposite in sign) but had a mass of $1.67262 \times 10^{-24} \mathrm{~g}$. Although this is an extremely small value, it is nearly 2000 times the mass of an electron.

Based on these data, the atom was believed to consist of a nucleus that accounted for most of the mass of the atom, but which occupied only a tiny fraction of its volume. We express atomic (and molecular) dimensions using the SI unit picometer (pm), where

$$
1 \mathrm{pm}=1 \times 10^{-12} \mathrm{~m}
$$

A typical atomic radius is about 100 pm , whereas the radius of an atomic nucleus is only about $5 \times 10^{-3} \mathrm{pm}$. You can appreciate the relative sizes of an atom and its nucleus by imagining that if an atom were the size of the New Orleans Superdome, the volume of its nucleus would be comparable to that of a marble. While the protons are confined to the nucleus of the atom, the electrons are distributed around the nucleus at relatively large distances from it.

The concept of atomic radius is useful experimentally, but you should not get the impression that atoms have well-defined boundaries or surfaces. We will learn in Chapter 6 that the outer regions of atoms are relatively "fuzzy," not sharply defined.

## The Neutron

Rutherford's model of atomic structure left one major problem unsolved. It was known that hydrogen, the simplest atom, contained only one proton and that the helium atom contained two protons. Therefore, the ratio of the mass of a helium atom to that of a hydrogen atom should be 2:1. (Because electrons are much lighter than protons, their contribution to atomic mass can be ignored.) In reality, however, the ratio is $4: 1$. Rutherford and others postulated that there must be another type of subatomic particle in the atomic nucleus, the proof of which was provided by James Chadwick, an English physicist, in 1932. When Chadwick bombarded a thin sheet of beryllium with $\alpha$ particles, a very high energy radiation was emitted by the metal that was not deflected by either electric or magnetic fields. Although similar to $\gamma$ rays, later experiments showed that the rays actually consisted of a third type of subatomic particle, which Chadwick named neutrons, because they were electrically neutral particles having a mass slightly greater than that of protons. The mystery of the mass ratio could now be explained. A typical helium nucleus consists of two protons and two neutrons, whereas a typical hydrogen nucleus contains only a proton; the mass ratio, therefore, is $4: 1$.

Figure 2.9 shows the location of the elementary particles (protons, neutrons, and electrons) in an atom. There are other subatomic particles, but the electron, the proton, and the neutron are the three fundamental components of the atom that are important in chemistry. Table 2.1 lists the masses and charges of these three elementary particles.

Student Annotation: Atomic radii are sometimes given in angstroms, where 1 angstrom $(\AA)=1 \times 10^{-10} \mathrm{~m}$. Using angstroms, a typical atomic radius is about $1 \AA$ and a typical nuclear radius is about $5 \times 10^{-5} \AA$.

Figure 2.9 The protons and neutrons in an atom are contained in the tiny volume of the nucleus. Electrons are distributed within the sphere surrounding the nucleus.

Student Annotation: Collectively, protons and neutrons are called nucleons. A nucleon is a particle within the nucleus.

Student Annotation: Because these symbols designate isotopes by specifying numbers of nucleons, they are sometimes referred to as nuclear symbols.

TABLE 2.1 Masses and Charges of Subatomic Particles

| Particle | Mass $(\mathbf{g})$ | Charge (C) | Charge Unit |
| :--- | :---: | :---: | :---: |
| Electron* | $9.10938 \times 10^{-28}$ | $-1.6022 \times 10^{-19}$ | -1 |
| Proton | $1.67262 \times 10^{-24}$ | $+1.6022 \times 10^{-19}$ | +1 |
| Neutron | $1.67493 \times 10^{-24}$ | 0 | 0 |

*More refined measurements have resulted in a small change to Millikan's original value.

### 2.3 Atomic Number, Mass Number, and Isotopes

All atoms can be identified by the number of protons and neutrons they contain. The atomic number ( $Z$ ) is the number of protons in the nucleus of each atom of an element. It also indicates the number of electrons in the atom-because atoms are neutral and contain the same number of protons and electrons. The chemical identity of an atom can be determined solely from its atomic number. For example, the atomic number of nitrogen is 7. Thus, each nitrogen atom has seven protons and seven electrons. Or, viewed another way, every atom in the universe that contains seven protons is a nitrogen atom.

The mass number (A) is the total number of neutrons and protons present in the nucleus of an atom of an element. Except for the most common form of hydrogen, which has one proton and no neutrons, all atomic nuclei contain both protons and neutrons. In general the mass number is given by

$$
\text { mass number }(A)=\text { number of protons }(Z)+\text { number of neutrons }
$$

The number of neutrons in an atom equals the difference between the mass number and the atomic number, or $(A-Z)$. For example, the mass number of fluorine is 19 and the atomic number is 9 (indicating 9 protons in the nucleus). Thus, the number of neutrons in an atom of fluorine is $19-9=10$. The atomic number, number of neutrons, and mass number all must be positive integers (whole numbers).

The accepted way to denote the atomic number and mass number of an atom of an element $(\mathrm{X})$ is as follows:

Contrary to the first hypothesis of Dalton's atomic theory, atoms of a given element do not all have the same mass. Most elements have two or more isotopes, atoms that have the same atomic number $(Z)$ but different mass numbers $(A)$. For example, there are three isotopes of hydrogen, called hydrogen (or protium), deuterium, and tritium. Hydrogen has one proton and no neutrons in its nucleus, deuterium has one proton and one neutron, and tritium has one proton and two neutrons. Thus, to represent the isotopes of hydrogen, we write

| ${ }_{1}^{1} \mathrm{H}$ | ${ }_{1}^{2} \mathrm{H}$ | ${ }_{1}^{3} \mathrm{H}$ |
| :---: | :---: | :---: |
| hydrogen | deuterium | tritium |

Similarly, the two common isotopes of uranium $(Z=92)$, which have mass numbers of 235 and 238, respectively, can be represented as follows:

$$
{ }_{92}^{235} \mathrm{U} \quad{ }_{92}^{238} \mathrm{U}
$$

The first isotope, with $235-92=143$ neutrons in its nucleus, is used in nuclear reactors and atomic bombs, whereas the second isotope, with 146 neutrons, lacks the properties necessary for these applications. With the exception of hydrogen, which has different names for each of its isotopes, the isotopes of other elements are identified by their mass numbers. The two isotopes of uranium are called uranium-235 (pronounced "uranium two thirty-five") and uranium-238 (pronounced "uranium two thirty-eight"). Because the subscripted atomic number can be determined from the elemental sym-
bol, it may be omitted from these representations without the loss of any information. The symbols ${ }^{3} \mathrm{H}$ and ${ }^{235} \mathrm{U}$ are sufficient to specify the isotopes tritium and uranium-235, respectively.

The chemical properties of an element are determined primarily by the protons and electrons in its atoms; neutrons do not take part in chemical changes under normal conditions. Therefore, isotopes of the same element exhibit similar chemical properties, forming the same types of compounds and displaying similar reactivities.

Sample Problem 2.2 shows how to calculate the number of protons, neutrons, and electrons using atomic numbers and mass numbers.

## Sample Problem 2.2

Determine the numbers of protons, neutrons, and electrons in each of the following species: (a) ${ }_{17}^{35} \mathrm{Cl}$, (b) ${ }_{17}^{37} \mathrm{Cl}$, (c) ${ }^{41} \mathrm{~K}$, and (d) carbon-14.

Strategy Recall that the superscript denotes the mass number $(A)$, and the subscript denotes the atomic number ( $Z$ ). In the case where no subscript is shown, as in parts (c) and (d), the atomic number can be deduced from the elemental symbol or name. For the purpose of determining the number of electrons, remember that atoms are neutral, so the number of electrons equals the number of protons.

Setup Number of protons $=Z$, number of neutrons $=A-Z$, and number of electrons $=$ number of protons. Recall that the 14 in carbon-14 is the mass number.

## Solution

(a) The atomic number is 17 , so there are 17 protons. The mass number is 35 , so the number of neutrons is $35-17=18$. The number of electrons equals the number of protons, so there are 17 electrons.
(b) Again, the atomic number is 17 , so there are 17 protons. The mass number is 37 , so the number of neutrons is $37-17=20$. The number of electrons equals the number of protons, so there are 17 electrons, too.
(c) The atomic number of K (potassium) is 19 , so there are 19 protons. The mass number is 41 , so there are 41-19 $=22$ neutrons. There are 19 electrons.
(d) Carbon-14 can also be represented as ${ }^{14} \mathrm{C}$. The atomic number of carbon is 6 , so there are 6 protons and 6 electrons. There are $14-6=8$ neutrons.

Practice Problem A How many protons, neutrons, and electrons are there in an atom of (a) ${ }_{5}^{10} \mathrm{~B}$, (b) ${ }^{36} \mathrm{Ar}$, (c) ${ }_{38}^{85} \mathrm{Sr}$, and (d) carbon-11?

- Practice Problem B Give the correct symbols to identify an atom that contains (a) 4 protons, 4 electrons, and 5 neutrons; (b) 23 protons, 23 electrons, and 28 neutrons; (c) 54 protons, 54 electrons, and 70 neutrons; and (d) 31 protons, 31 electrons, and 38 neutrons.

## Checkpoint 2.3 Atomic Number, Mass Number, and Isotopes

2.3.1 How many neutrons are there in an atom of ${ }^{60} \mathrm{Ni}$ ?
a) 60
b) 30
c) 28
d) 32
e) 29
2.3.2 What is the mass number of an oxygen atom with nine neutrons in its nucleus?
a) 8
b) 9
c) 17
d) 16
e) 18

### 2.4 The Periodic Table

More than half of the elements known today were discovered between 1800 and 1900. During this period, chemists noted that the physical and chemical properties of certain groups of elements were similar to one another. These similarities, together with the need to organize the large volume of available information about the structure and properties of elemental substances, led to the

Think About It Verify that the number of protons and the number of neutrons for each example sum to the mass number that is given. In part (a), for example, there are 17 protons and 18 neutrons, which sum to give a mass number of 35 , the value given in the problem. In part (b), 17 protons +20 neutrons $=37$. In part (c), 19 protons + 22 neutrons $=41$. In part (d), 6 protons +8 neutrons $=14$.

Figure 2.10 The modern periodic table. The elements are arranged according to atomic number, which is shown above each element's symbol. With the exception of hydrogen $(\mathrm{H})$, nonmetals appear at the far right of the table. The two rows of metals beneath the main body of the table are set apart to keep the table from being too wide. Actually, lanthanum (57) should follow barium (56), and actinium (89) should follow radium (88). The $1-18$ group designation has been recommended by the International Union of Pure and Applied Chemistry (IUPAC) but is not yet in wide use. In this text, we generally use the standard U.S. notation for group numbers ( $1 \mathrm{~A}-8 \mathrm{~A}$ and $1 \mathrm{~B}-8 \mathrm{~B}$ ). No names have yet been assigned to elements $112-116$ and 118. As of this writing, the synthesis of element 117 has not yet been reported.

development of the periodic table, a chart in which elements having similar chemical and physical properties are grouped together. Figure 2.10 shows the modern periodic table in which the elements are arranged by atomic number (shown above the element symbol) in horizontal rows called periods and in vertical columns called groups or families. Elements in the same group tend to have similar physical and chemical properties.

The elements can be categorized as metals, nonmetals, or metalloids. A metal is a good conductor of heat and electricity, whereas a nonmetal is usually a poor conductor of heat and electricity. A metalloid has properties that are intermediate between those of metals and nonmetals. Figure 2.10 shows that the majority of known elements are metals; only 17 elements are nonmetals, and fewer than 10 elements are metalloids. Although most sources, including this text, designate the elements $\mathrm{B}, \mathrm{Si}, \mathrm{Ge}, \mathrm{As}, \mathrm{Sb}$, and Te as metalloids, sources vary for the elements Po and At. In this text, we classify both Po and At as metalloids. From left to right across any period, the physical and chemical properties of the elements change gradually from metallic to nonmetallic.

Elements are often referred to collectively by their periodic table group number (Group 1A, Group 2A, and so on). For convenience, however, some element groups have been given special names. The Group 1A elements, with the exception of H (i.e., $\mathrm{Li}, \mathrm{Na}, \mathrm{K}, \mathrm{Rb}, \mathrm{Cs}$, and Fr ), are called alkali metals, and the

Group 2A elements ( $\mathrm{Be}, \mathrm{Mg}, \mathrm{Ca}, \mathrm{Sr}, \mathrm{Ba}$, and Ra ) are called alkaline earth metals. Elements in Group 6A ( $\mathrm{O}, \mathrm{S}, \mathrm{Se}, \mathrm{Te}$, and Po ) are sometimes referred to as the chalcogens. Elements in Group 7A ( $\mathrm{F}, \mathrm{Cl}, \mathrm{Br}, \mathrm{I}$, and At) are known as halogens, and elements in Group 8A ( $\mathrm{He}, \mathrm{Ne}, \mathrm{Ar}, \mathrm{Kr}, \mathrm{Xe}$, and Rn ) are called noble gases, or rare gases. The elements in Group 1B and Groups 3B-8B collectively are called the transition elements or transition metals.

The periodic table is a handy tool that correlates the properties of the elements in a systematic way and helps us to predict chemical behavior. At the turn of the twentieth century, the periodic table was deemed "the most predictive tool in all of science." We will take a more detailed look at this keystone of chemistry in Chapter 7.

The following Bringing Chemistry to Life box describes the distribution of the elements in Earth's crust.

## Bringing Chemistry to Life

## Distribution of Elements on Earth

Earth's crust extends from the surface to a depth of about 40 km (about 25 mi ). Because of technical difficulties, scientists have been unable to study the inner portions of Earth as easily and as thoroughly as the crust. Nevertheless, it is believed that there is a solid core consisting mostly of iron at the center of Earth. Surrounding the core is a layer called the mantle, which consists of hot fluid containing iron, carbon, silicon, and sulfur.

Of the 83 elements that are found in nature, 12 make up 99.7 percent of Earth's crust by mass. They are, in decreasing order of natural abundance, oxygen $(\mathrm{O})$, silicon $(\mathrm{Si})$, aluminum ( Al ), iron $(\mathrm{Fe})$, calcium $(\mathrm{Ca})$, magnesium $(\mathrm{Mg})$, sodium $(\mathrm{Na})$, potassium $(\mathrm{K})$, titanium $(\mathrm{Ti})$, hydrogen $(\mathrm{H})$, phosphorus $(\mathrm{P})$, and manganese $(\mathrm{Mn})$. When discussing the natural abundance of the elements, keep in mind that the elements are unevenly distributed throughout Earth's crust, and most elements are combined chemically with other elements. Some of the elements that can be found in nature in pure form include gold, copper, and sulfur.

## Checkpoint 2.4 The Periodic Table

2.4.1 Which of the following series of elemental symbols lists a nonmetal, a metal, and a metalloid?
a) $\mathrm{Ca}, \mathrm{Cu}, \mathrm{Si}$
b) $\mathrm{K}, \mathrm{Mg}, \mathrm{B}$
c) $\mathrm{Br}, \mathrm{Ba}, \mathrm{Ge}$
d) $\mathrm{O}, \mathrm{Na}, \mathrm{S}$
e) $\mathrm{Ag}, \mathrm{Cr}, \mathrm{As}$
2.4.2 Which of the following elements would you expect to have properties most similar to those of chlorine ( Cl )?
a) Cu
b) F
c) Na
d) Cr
e) S

## You May Be Wondering...

## How Are Atomic Masses Measured?

The most direct and most accurate method for determining atomic and molecular masses is mass spectrometry. In a mass spectrometer, such as that depicted in Figure 2.11, a gaseous sample is bombarded by a stream of high-energy electrons. Collisions between the electrons and the gaseous atoms (or molecules) produce positively charged species, called ions, by dislodging an electron from the atoms or molecules. These positive ions (of mass $m$ and charge $e$ ) are accelerated as they pass through two oppositely charged plates. The emerging ions are deflected into a circular path
by a magnet. The radius of the path depends on the charge-to-mass ratio (i.e., $e / m$ ). Ions with a small $\mathrm{e} / \mathrm{m}$ ratio trace a wider arc than those having a larger $e / m$ ratio, so ions with equal charges but different masses are separated from one another. The mass of each ion (and hence its parent atom or molecule) is determined from the magnitude of its deflection. Eventually the ions arrive at the detector, which registers a current for each type of ion. The amount of current generated is directly proportional to the number of ions, so it enables us to determine the relative abundance of isotopes.

Figure 2.11 Schematic diagram of one type of mass spectrometer.

### 2.5 The Atomic Mass Scale and Average Atomic Mass

In some experimental work it is important to know the masses of individual atoms, which depend on the number of protons, neutrons, and electrons they contain. However, even the smallest speck of dust that our unaided eyes can perceive consists of as many as $1 \times 10^{16}$ atoms! Although we cannot weigh a single atom, it is possible to determine experimentally the mass of one atom relative to another. The first step is to assign a value to the mass of one atom of a given element so that it can be used as a standard.

The first mass spectrometer, developed in the 1920s by the English physicist F. W. Aston, was crude by today's standards. Nevertheless, it provided indisputable evidence of the existence of isotopes, such as neon-20 (natural abundance 90.48 percent) and neon- 22 (natural abundance 9.25 percent). When more sophisticated and sensitive mass spectrometers became available, scientists were surprised to discover that neon has a third stable isotope (neon-21) with natural abundance 0.27 percent (Figure 2.12). This example illustrates how very important experimental accuracy is to a quantitative science like chemistry. Early experiments failed to detect neon- 21 because its natural abundance was so small. Only 27 in $10,000 \mathrm{Ne}$ atoms are neon-21.

Sample Problem 2.3 shows how to calculate the average atomic mass of oxygen.

Figure 2.12 Mass spectrum of neon.

## Sample Problem 2.3

Oxygen is the most abundant element in both Earth's crust and the human body. The atomic masses of its three stable isotopes, ${ }_{8}^{16} \mathrm{O}$ ( 99.757 percent), ${ }_{8}^{17} \mathrm{O}\left(0.038\right.$ percent), and ${ }_{8}^{18} \mathrm{O}(0.205$ percent $)$, are $15.9949,16.9991$, and 17.9992 amu , respectively. Calculate the average atomic mass of oxygen using the relative abundances given in parentheses. Report the result to four significant figures.

Strategy Each isotope contributes to the average atomic mass based on its relative abundance.
Multiplying the mass of each isotope by its fractional abundance (percent value divided by 100) will give its contribution to the average atomic mass.

Setup Each percent abundance must be converted to a fractional abundance: 99.757 percent to $99.757 / 100$ or $0.99757,0.038$ percent to $0.038 / 100$ or 0.00038 , and 0.205 percent to $0.205 / 100$ or 0.00205 . Once we find the contribution to the average atomic mass for each isotope, we can then add the contributions together to obtain the average atomic mass.

## Solution

$(0.99757)(15.9949 \mathrm{amu})+(0.00038)(16.9991 \mathrm{amu})+(0.00205)(17.9992)=15.999 \mathrm{amu}$

Practice Problem A The atomic masses of the two stable isotopes of copper, ${ }_{29}^{63} \mathrm{Cu}$ (69.17 percent)
Think About It The average atomic mass should be closest to the atomic mass of the most abundant isotope (oxygen-16, in this case) and should, to the appropriate number of significant figures, be the same number that appears in the periodic table on the inside front cover of this book ( 16.00 amu , in this case)!

Student Annotation: The atomic masses in the periodic table are average atomic masses. The term atomic weight is sometimes used to mean average atomic mass.
mass of fluorine-19 is 18.9984 amu and that of oxygen-16 is 15.9949 amu . Thus, although we cannot measure the mass of a single oxygen-16 atom, we know that it is approximately 16 times as massive as a hydrogen 1 atom.

When you look up the atomic mass of carbon in a table such as the one on the inside front cover of this book, you will find that its value is 12.01 amu , not 12.00 amu . The difference arises because most naturally occurring elements (including carbon) have more than one isotope. This means that when we measure the atomic mass of an element, we must generally settle for the average mass of the naturally occurring mixture of isotopes. For example, the natural abundances of carbon-12 and carbon-13 are 98.93 percent and 1.07 percent, respectively. The atomic mass of carbon- 13 has been determined to be 13.003355 amu . Thus, the average atomic mass of natural carbon can be calculated as follows:

$$
(0.9893)(12.00000 \mathrm{amu})+(0.0107)(13.003355 \mathrm{amu})=12.01 \mathrm{amu}
$$

In calculations involving percentages, we need to convert each percent abundance to a fractional abundance. For example, 98.93 percent becomes $98.93 / 100$, or 0.9893 . Because there are many more carbon- 12 atoms than carbon-13 atoms in naturally occurring carbon, the average atomic mass is much closer to the mass of carbon-12 than to that of carbon-13.

When we say that the atomic mass of carbon is 12.01 amu , we are referring to the average value. If we could examine an individual atom of naturally occurring carbon, we would find either an atom of atomic mass of exactly 12 amu or one of 13.003355 amu , but never one of 12.01 amu .

The atomic masses of many isotopes have been accurately determined to five or six significant figures. For most purposes, though, we will use average atomic masses, which are generally given to four significant figures (see the table of atomic masses on the inside front cover). For simplicity, we will omit the word average when we discuss the atomic masses of the elements.

## Checkpoint 2.5 The Atomic Mass Scale and Average Atomic Mass

2.5.1 Boron has two naturally occurring isotopes, ${ }^{10} \mathrm{~B}$ and ${ }^{11} \mathrm{~B}$, which have masses 10.0129 and 11.0093 amu , respectively. Given the average atomic mass of boron ( 10.81 amu ), determine the percent abundance of each isotope.
a) $50 \%{ }^{10} \mathrm{~B}, 50 \%{ }^{11} \mathrm{~B}$
b) $20 \%{ }^{10} \mathrm{~B}, 80 \%{ }^{11} \mathrm{~B}$
c) $98 \%{ }^{10} \mathrm{~B}, 2 \%{ }^{11} \mathrm{~B}$
d) $93 \%{ }^{10} \mathrm{~B}, 7 \%{ }^{11} \mathrm{~B}$
e) $22 \%{ }^{10} \mathrm{~B}, 78 \%{ }^{11} \mathrm{~B}$
2.5.2 The two naturally occurring isotopes of antimony, ${ }^{121} \mathrm{Sb}$ ( 57.21 percent) and ${ }^{123} \mathrm{Sb}$ ( 42.79 percent), have masses of 120.904 and 122.904 amu , respectively. What is the average atomic mass of Sb ?
a) 121.90 amu
b) 122.05 amu
c) 121.76 amu
d) 121.34 amu
e) 122.18 amu

### 2.6 Molecules and Molecular Compounds

Out of all the elements, only the six noble gases in Group 8A of the periodic table ( $\mathrm{He}, \mathrm{Ne}, \mathrm{Ar}, \mathrm{Kr}$, Xe , and Rn ) exist in the form of isolated atoms under ordinary conditions. For this reason, they are called monatomic (meaning a single atom) gases. Most matter is composed of molecules, which we discuss in this section, or ions, which we will discuss in Section 2.7.

## Molecules

A molecule is a combination of at least two atoms in a specific arrangement held together by electrostatic forces known as covalent chemical bonds [ $\omega$ Section 8.3]. A molecule may contain atoms of the same element, or it may contain atoms of two or more elements joined in a fixed ratio, in accordance with the law of definite proportions [ 14 Section 2.1]. Thus, a molecule can be an element or it can be a compound, which, by definition, is made up of two or more elements [/I4 Section 1.2]. Hydrogen gas, for example, is an element, but it consists of molecules, each of which is made up of two H atoms. Water, on the other hand, is a compound that consists of molecules, each of which contains two H atoms and one O atom.

The hydrogen molecule, symbolized as $\mathrm{H}_{2}$, is called a diatomic molecule because it contains two atoms. Other elements that normally exist as diatomic molecules are nitrogen $\left(\mathrm{N}_{2}\right)$, oxygen $\left(\mathrm{O}_{2}\right)$, and the Group 7A elements-fluorine $\left(\mathrm{F}_{2}\right)$, chlorine $\left(\mathrm{Cl}_{2}\right)$, bromine $\left(\mathrm{Br}_{2}\right)$, and iodine $\left(\mathrm{I}_{2}\right)$. These are known as homonuclear diatomic molecules because both atoms in each molecule are of the same element. A diatomic molecule can also contain atoms of different elements. Examples of these heteronuclear diatomic molecules include hydrogen chloride $(\mathrm{HCl})$ and carbon monoxide (CO).

Most molecules contain more than two atoms. They can all be atoms of the same element, as in ozone $\left(\mathrm{O}_{3}\right)$ and white phosphorus $\left(\mathrm{P}_{4}\right)$, or they can be combinations of two or more different elements, as in water $\left(\mathrm{H}_{2} \mathrm{O}\right)$ and methane $\left(\mathrm{CH}_{4}\right)$. Molecules containing more than two atoms are called polyatomic molecules.

## Molecular Formulas

A chemical formula denotes the composition of the substance. A molecular formula shows the exact number of atoms of each element in a molecule. In our discussion of molecules, each example was given with its molecular formula in parentheses. Thus, $\mathrm{H}_{2}$ is the molecular formula for hydrogen, $\mathrm{O}_{2}$ is that for oxygen, $\mathrm{O}_{3}$ is that for ozone, and $\mathrm{H}_{2} \mathrm{O}$ is that of water. The subscript numeral indicates the number of atoms of an element present in the molecule. There is no subscript for O in $\mathrm{H}_{2} \mathrm{O}$ because there is only one atom of oxygen in a molecule of water. The number "one" is never used as a subscript in a chemical formula. Oxygen $\left(\mathrm{O}_{2}\right)$ and ozone $\left(\mathrm{O}_{3}\right)$ are allotropes of oxygen. An allotrope is one of two or more distinct forms of an element. Two of the allotropic forms of the element carbon-diamond and graphite-have dramatically different properties (and prices).

We can also represent molecules with structural formulas. The structural formula shows not only the elemental composition, but also the general arrangement of atoms within the molecule. In the case of water, each of the hydrogen atoms is connected to the oxygen atom. Figure 2.13 shows the molecular formula, structural formula, and molecular models (both ball-andstick and space-filling variety) for water. Note that the chemical bond between two atoms can be represented with either a pair of dots or a line.

In Chapters 8 and 9, you will learn how to use the molecular formula to deduce the structural formula and the three-dimensional arrangement of a molecule. We will use all of these methods for representing molecules throughout the book, so you should be familiar with each method and with the information it provides.

Sample Problem 2.4 shows how to write a molecular formula from the corresponding molecular model.

## Sample Problem 2.4

Write the molecular formula of ethanol based on its ball-and-stick model, shown here.

Ethanol

Strategy Refer to the labels on the atoms (or see Table 1.1).
Setup There are two carbon atoms, six hydrogen atoms, and one oxygen atom, so the subscript on C will be 2 and the subscript on H will be 6 , and there will be no subscript on O .

## Solution $\mathrm{C}_{2} \mathrm{H}_{6} \mathrm{O}$

(Continued)

Think About It Often the molecular formula for an organic compound such as ethanol is written so that the formula more closely resembles the actual arrangement of atoms in the molecule. Thus, the molecular formula for ethanol is commonly written as $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$.

Student Annotation: Note that acetone contains a double bond. Multiple bonds between atoms will be discussed in Chapters 8 and 9 .

Student Annotation: The term binary can also refer to ionic compounds, which we discuss in Section 2.7.

Practice Problem A Chloroform was used as an anesthetic for childbirth and surgery during the nineteenth century. Write the molecular formula for chloroform based on the molecular model shown below.

EPractice Problem B Write the molecular formula for acetone based on the molecular model shown below.

Acetone

Chloroform

## Naming Molecular Compounds

When chemistry was a young science, it was possible for practitioners to memorize the names of the relatively small number of known compounds. Often a compound's name was derived from its physical appearance, properties, origin, or application-for example, milk of magnesia, laughing gas, formic acid (formica is the Latin word for ant, and formic acid is the compound responsible for the sting of an ant bite), and baking soda.

Today there are many millions of known compounds, and many more being made every year, so it would be impossible to memorize all their names. Fortunately, it is unnecessary, because over the years chemists have devised a convenient system for naming chemical substances. The rules are the same worldwide, facilitating communication among scientists and providing a useful way of labeling an overwhelming variety of substances. Mastering these rules now will benefit you tremendously as you progress through your chemistry course. You must be able to name a compound, given its chemical formula, and you must be able to write the chemical formula of a compound, given its name.

We begin our discussion of chemical nomenclature, the naming of chemical compounds, with binary molecular compounds, substances that consist of just two different elements. Most are composed of two nonmetals (see Figure 2.10). To name such a compound, we first name the element that appears first in the formula. For HCl that would be hydrogen. We then name the second element, changing the ending of its name to -ide. For HCl , the second element is chlorine, so we would change chlorine to chloride. Thus, the systematic name of HCl is hydrogen chloride. Similarly, HI is hydrogen iodide (iodine $\rightarrow$ iodide) and SiC is silicon carbide (carbon $\rightarrow$ carbide).

It is quite common for one pair of elements to form several different binary molecular compounds. In these cases, confusion in naming the compounds is avoided by the use of Greek prefixes to denote the number of atoms of each element present. Some of the Greek prefixes are listed in Table 2.2, and several compounds named using prefixes are listed in Table 2.3.

The prefix mono- is generally omitted for the first element. $\mathrm{SO}_{2}$, for example, is named sulfur dioxide, not monosulfur dioxide. Thus, the absence of a prefix for the first element usually means there is only one atom of that element present in the molecule. In addition, for ease of pronunciation, we usually eliminate the last letter of a prefix that ends in "o" or "a" when naming an oxide. Thus, $\mathrm{N}_{2} \mathrm{O}_{5}$ is dinitrogen pentoxide, rather than dinitrogen pentaoxide.

Sample Problem 2.5 gives you some practice naming binary molecular compounds from their formulas.

TABLE 2.2

## Greek Prefixes

| Prefix | Meaning | Prefix | Meaning |
| :--- | :---: | :--- | :---: |
| Mono- | 1 | Hexa- | 6 |
| Di- | 2 | Hepta- | 7 |
| Tri- | 3 | Octa- | 8 |
| Tetra- | 4 | Nona- | 9 |
| Penta- | 5 | Deca- | 10 |

TABLE 2.3

Compound
CO
$\mathrm{CO}_{2}$
$\mathrm{SO}_{2}$

Some Compounds Named Using Greek Prefixes

| Name | Compound | Name |
| :--- | :---: | :--- |
| Carbon <br> monoxide | $\mathrm{SO}_{3}$ | Sulfur <br> trioxide |
| Carbon <br> dioxide | $\mathrm{NO}_{2}$ | Nitrogen <br> dioxide |
| Sulfur <br> dioxide | $\mathrm{N}_{2} \mathrm{O}_{5}$ | Dinitrogen <br> pentoxide |

## Sample Problem 2.5

Name the following binary molecular compounds: (a) $\mathrm{NF}_{3}$ and (b) $\mathrm{N}_{2} \mathrm{O}_{4}$.
Strategy Each compound will be named using the systematic nomenclature including, where necessary, appropriate Greek prefixes.

Setup With binary compounds, we start with the name of the element that appears first in the formula, and we change the ending of the second element's name to -ide. We use prefixes, where appropriate, to indicate the number of atoms of each element. In part (a) the molecule contains one nitrogen atom and three fluorine atoms. We will omit the prefix mono- for nitrogen because it is the first element listed in the formula, and we will use the prefix tri- to denote the number of fluorine atoms. In part (b) the molecule contains two nitrogen atoms and four oxygen atoms, so we will use the prefixes $d i-$ and tetra- in naming the compound. Recall that in naming an oxide, the last letter of a prefix that ends in "a" or "o" is omitted.

Solution (a) nitrogen trifluoride and (b) dinitrogen tetroxide

Practice Problem A Name the following binary molecular compounds: (a) $\mathrm{Cl}_{2} \mathrm{O}$ and (b) $\mathrm{SiCl}_{4}$. $\$$ Practice Problem B Name the following binary molecular compounds: (a) $\mathrm{ClO}_{2}$ and (b) $\mathrm{CBr}_{4}$.

Writing the formula for a molecular compound, given its systematic name, is usually straightforward. For instance, the name boron trichloride indicates the presence of one boron atom (no prefix) and three chlorine atoms (tri-), so the corresponding molecular formula is $\mathrm{BCl}_{3}$. Note once again that the order of the elements is the same in both the name and the formula.

Sample Problem 2.6 gives you some practice determining the formulas of binary molecular compounds from their names.

## Sample Problem 2.6

Write the chemical formulas for the following binary molecular compounds: (a) sulfur tetrafluoride and (b) tetraphosphorus decasulfide.

Strategy The formula for each compound will be deduced using the systematic nomenclature guidelines.

Setup In part (a) there is no prefix for sulfur, so there is only one sulfur atom in a molecule of the compound. Therefore, we will use no prefix for the $S$ in the formula. The prefix tetra-means that there are four fluorine atoms. In part (b) the prefixes tetra- and deca-denote four and ten, respectively.

Solution (a) $\mathrm{SF}_{4}$ and (b) $\mathrm{P}_{4} \mathrm{~S}_{10}$

Practice Problem A Give the molecular formula for each of the following compounds: (a) carbon disulfide and (b) dinitrogen trioxide.

HPractice Problem B Give the molecular formula for each of the following compounds: (a) sulfur hexafluoride and (b) disulfur decafluoride.

The names of molecular compounds containing hydrogen do not usually conform to the systematic nomenclature guidelines. Traditionally, many of these compounds are called either by their common, nonsystematic names or by names that do not indicate explicitly the number of H atoms present:

| $\mathrm{B}_{2} \mathrm{H}_{6}$ | Diborane | $\mathrm{PH}_{3}$ | Phosphine |
| :--- | :--- | :--- | :--- |
| $\mathrm{SiH}_{4}$ | Silane | $\mathrm{H}_{2} \mathrm{O}$ | Water |
| $\mathrm{NH}_{3}$ | Ammonia | $\mathrm{H}_{2} \mathrm{~S}$ | Hydrogen sulfide |

Think About It Make sure that the prefixes match the subscripts in the molecular formulas and that the word oxide is not preceded immediately by an "a" or an "o."

Think About It Double-check that the subscripts in the formulas match the prefixes in the compound names: (a) $4=$ tetra and (b) $4=$ tetra and $10=$ deca.

Student Annotation: Binary compounds containing carbon and hydrogen are organic compounds and do not follow the same naming conventions as other molecular compounds. Organic compounds and their nomenclature are discussed in detail in Chapter 10.

| TABLE 2.4 | Some Simple Acids |  |
| :--- | :--- | :--- |
| Formula | Binary Compound Name | Acid Name |
| HF | Hydrogen fluoride | Hydrofluoric acid |
| HCl | Hydrogen chloride | Hydrochloric acid |
| HBr | Hydrogen bromide | Hydrobromic acid |
| HI | Hydrogen iodide | Hydroiodic acid |
| HCN* | Hydrogen cyanide | Hydrocyanic acid |
| * Although HCN is not a binary compound, it is included in this table because it is similar chemically to $\mathrm{HF}, \mathrm{HCl}, \mathrm{HBr}$, and HI. |  |  |

Student Annotation: In Chapter 16 we will explore acids and bases in greater detail; and we will see that there are other ways to define the terms acid and base.

## Student Annotation: An ion is a charged

 species.Student Annotation: Some carboncontaining species such as $\mathrm{CN}^{-}$and $\mathrm{CO}_{3}^{2-}$ are considered inorganic.

Ethanol

Even the order in which the elements are written in these hydrogen-containing compounds is irregular. In water and hydrogen sulfide, H is written first, whereas it is written last in the other compounds.

Acids make up another important class of molecular compounds. One definition of an acid is a substance that produces hydrogen ions $\left(\mathrm{H}^{+}\right)$when dissolved in water. Several binary molecular compounds produce hydrogen ions when dissolved in water and are, therefore, acids. In these cases, two different names can be assigned to the same chemical formula. For example, HCl , hydrogen chloride, is a gaseous compound. When it is dissolved in water, however, we call it hydrochloric acid. The rules for naming simple acids of this type are as follows: remove the -gen ending from hydrogen (leaving hydro-), change the -ide ending on the second element to $-i c$, combine the two words, and add the word acid.

$$
\text { hydrogen chloride }+-i c \text { acid } \longrightarrow \text { hydrochloric acid }
$$

Likewise, hydrogen fluoride (HF) becomes hydrofluoric acid. Table 2.4 lists these and other examples.

For a compound to produce hydrogen ions upon dissolving, it must contain at least one ionizable hydrogen atom. An ionizable hydrogen atom is one that separates from the molecule upon dissolving and becomes a hydrogen ion $\left(\mathrm{H}^{+}\right)$.

So far our discussion of nomenclature has focused on inorganic compounds, which are generally defined as compounds that do not contain carbon. Another important class of molecular substances is organic compounds, which have their own system of nomenclature. Organic compounds contain carbon and hydrogen, sometimes in combination with other elements such as oxygen, nitrogen, sulfur, and the halogens. The simplest organic compounds are those that contain only carbon and hydrogen and are known as hydrocarbons. Among hydrocarbons, the simplest examples are compounds known as alkanes. The name of an alkane depends on the number of carbon atoms in the molecule. Table 2.5 gives the molecular formulas, systematic names of some of the simplest alkanes, and ball-and-stick models.

Many organic compounds are derivatives of alkanes in which one of the H atoms has been replaced by a group of atoms known as a functional group. The functional group determines many of the chemical properties of a compound because it typically is where a chemical reaction occurs. Table 2.6 lists the names and provides space-filling models of several important functional groups.

Ethanol, for example, the alcohol in alcoholic beverages, is ethane $\left(\mathrm{C}_{2} \mathrm{H}_{6}\right)$ with one of the hydrogen atoms replaced by an alcohol $(-\mathrm{OH})$ group. Its name is derived from that of ethane, indicating that it contains two carbon atoms.

The molecular formula of ethanol can also be written $\mathrm{C}_{2} \mathrm{H}_{6} \mathrm{O}$, but $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$ conveys more information about the structure of the molecule. Organic compounds and several functional groups are discussed in greater detail in Chapter 10.

## Empirical Formulas

In addition to the ways we have learned so far, molecular substances can also be represented using empirical formulas. The word empirical means "from experience" or, in the context of chemical formulas, "from experiment." The empirical formula tells what elements are present in a molecule and in what whole-number ratio they are combined. For example, the molecular formula of hydrogen peroxide is $\mathrm{H}_{2} \mathrm{O}_{2}$, but its empirical formula is simply HO . Hydrazine, which has been used as a rocket fuel, has the molecular formula $\mathrm{N}_{2} \mathrm{H}_{4}$, so its empirical formula is $\mathrm{NH}_{2}$. Although the ratio of nitrogen to hydrogen is 1:2 in both the molecular formula $\left(\mathrm{N}_{2} \mathrm{H}_{4}\right)$ and the empirical formula

$\left(\mathrm{NH}_{2}\right)$, only the molecular formula tells us the actual number of N atoms (two) and H atoms (four) present in a hydrazine molecule.

In many cases, the empirical and molecular formulas are identical. In the case of water, for example, there is no combination of smaller whole numbers that can convey the ratio of two H atoms for every one O atom, so the empirical formula is the same as the molecular formula: $\mathrm{H}_{2} \mathrm{O}$. Table 2.7 lists the molecular and empirical formulas for several compounds.

Empirical formulas are the simplest chemical formulas; they are written by reducing the subscripts in molecular formulas to the smallest possible whole numbers (without altering the relative numbers of atoms). Molecular formulas are the true formulas of molecules. As we will see in Chapter 3, when chemists analyze an unknown compound, the first step is usually the determination of the compound's empirical formula.

Sample Problem 2.7 (p. 57) lets you practice determining empirical formulas from molecular formulas.

| TABLE 2.7 | Molecular and Empirical Formulas |
| :--- | :---: | :---: |
| Compound | Molecular Formula |
| Water |  |
| Hydrogen peroxide |  |
| Ethane |  |
| Acetylene | $\mathrm{H}_{2} \mathrm{O}$ |

## Sample Problem 2.7

Write the empirical formulas for the following molecules: (a) glucose $\left(\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}\right)$, a substance known as blood sugar; (b) adenine $\left(\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N}_{5}\right)$, also known as vitamin $\mathrm{B}_{4}$; and (c) nitrous oxide $\left(\mathrm{N}_{2} \mathrm{O}\right)$, a gas that is used as an anesthetic ("laughing gas") and as an aerosol propellant for whipped cream.
Strategy To write the empirical formula, the subscripts in the molecular formula must be reduced to the smallest possible whole numbers (without altering the relative numbers of atoms).

Setup The molecular formulas in parts (a) and (b) each contain subscripts that are divisible by common numbers. Therefore, we will be able to express the formulas with smaller whole numbers than those in the molecular formulas. In part (c), the molecule has only one O atom, so it is impossible to simplify this formula further.

Solution (a) Dividing each of the subscripts in the molecular formula for glucose by 6, we obtain the empirical formula, $\mathrm{CH}_{2} \mathrm{O}$. If we had divided the subscripts by 2 or 3 , we would have obtained the formulas $\mathrm{C}_{3} \mathrm{H}_{6} \mathrm{O}_{3}$ and $\mathrm{C}_{2} \mathrm{H}_{4} \mathrm{O}_{2}$, respectively. Although the ratio of carbon to hydrogen to oxygen atoms in each of these formulas is correct (1:2:1), neither is the simplest formula because the subscripts are not in the smallest possible whole-number ratio.
(b) Dividing each subscript in the molecular formula of adenine by 5 , we get the empirical formula, CHN.
(c) Because the subscripts in the formula for nitrous oxide are already the smallest possible whole numbers, its empirical formula is the same as its molecular formula, $\mathrm{N}_{2} \mathrm{O}$.

Practice Problem A Write empirical formulas for the following molecules: (a) caffeine $\left(\mathrm{C}_{8} \mathrm{H}_{10} \mathrm{~N}_{4} \mathrm{O}_{2}\right)$, a stimulant found in tea and coffee, (b) butane $\left(\mathrm{C}_{4} \mathrm{H}_{10}\right)$, which is used in cigarette lighters, and (c) glycine $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{NO}_{2}\right)$, an amino acid.

Caffeine

Butane

Glycine

PPractice Problem $\mathbf{B}$ For which of the following molecular formulas is the formula shown in parentheses the correct empirical formula? (a) $\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}\left(\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}\right)$, (b) $\mathrm{C}_{8} \mathrm{H}_{12} \mathrm{O}_{4}\left(\mathrm{C}_{4} \mathrm{H}_{6} \mathrm{O}_{2}\right)$, (c) $\mathrm{H}_{2} \mathrm{O}_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)$ ?

## Checkpoint 2.6 Molecules and Molecular Compounds

2.6.1 What is the correct systematic name of $\mathrm{PCl}_{5}$ ?

a) Phosphorus chloride
b) Phosphorus pentachloride
c) Monophosphorus chloride
d) Pentachlorophosphorus
e) Pentaphosphorus chloride

Think About It Make sure that the ratio in each empirical formula is the same as that in the corresponding molecular formula and that the subscripts are the smallest possible whole numbers. In part (a), for example, the ratio of $\mathrm{C}: \mathrm{H}: \mathrm{O}$ in the molecular formula is $6: 12: 6$, which is equal to $1: 2: 1$, the ratio expressed in the empirical formula.
2.6.3 What is the correct formula for the compound carbon tetrachloride?

a) $\mathrm{C}_{4} \mathrm{Cl}_{4}$
b) $\mathrm{C}_{4} \mathrm{Cl}$
c) $\mathrm{CCl}_{4}$
d) $\mathrm{CCl}_{2}$
e) CCl
2.6.4 What is the empirical formula of the compound shown?

a) $\mathrm{C}_{6} \mathrm{H}_{6}$
b) $\mathrm{C}_{4} \mathrm{H}_{4}$
c) $\mathrm{C}_{2} \mathrm{H}_{2}$
d) $\mathrm{CH}_{2}$
e) CH

### 2.7 Ions and Ionic Compounds

The number of positively charged protons in the nucleus of an atom remains the same during ordinary chemical reactions, but negatively charged electrons may be lost or gained-resulting in the formation of ions. An ion is an atom (or a group of atoms) that has a net positive or negative charge. The ions that make up an ionic compound are held together by strong electrostatic forces known as ionic bonds [ $\boldsymbol{\omega}$ Section 8.2].

## Atomic lons

An atomic ion or monatomic ion is one that consists of just one atom with a positive or negative charge. The loss of one or more electrons from an atom yields a cation, an ion with a net positive charge. For example, a sodium atom ( Na ) can readily lose an electron to become a sodium cation, which is represented by $\mathrm{Na}^{+}$:

| $\mathbf{N a}$ Atom | $\mathbf{N a}^{+}$Ion |
| :--- | :--- |
| 11 protons | 11 protons |
| 11 electrons | 10 electrons |

An anion is an ion whose net charge is negative due to an increase in the number of electrons. A chlorine atom $(\mathrm{Cl})$, for instance, can gain an electron to become a chloride ion $\left(\mathrm{Cl}^{-}\right)$:

| Cl Atom | $\mathbf{C l}^{-}$Ion |
| :--- | :--- |
| 17 protons | 17 protons |
| 17 electrons | 18 electrons |

Sodium chloride $(\mathrm{NaCl})$, ordinary table salt, is called an ionic compound because it consists of cations $\left(\mathrm{Na}^{+}\right)$and anions $\left(\mathrm{Cl}^{-}\right)$.

An atom can lose or gain more than one electron. Examples include $\mathrm{Mg}^{2+}, \mathrm{Fe}^{3+}, \mathrm{S}^{2-}$, and

Student Annotation: Note that a multiple charge is denoted with the number followed by the sign; thus, $2+$ not +2 . $\mathrm{N}^{3-}$. Figure 2.14 shows the charges of many more monatomic ions from across the periodic table. With very few exceptions, metals tend to form cations and nonmetals form anions. The charges on monatomic ions of elements in Groups 1A through 7A of the periodic table are fairly predictable. The cations that form from elements of groups $1 \mathrm{~A}, 2 \mathrm{~A}$, and 3 A have charges equal to their respective group numbers. Most of the anions that form from elements of groups 4A through 7A have charges equal to the corresponding group number minus 8 . For example, the monatomic anion formed by oxygen (group 6A) has a charge of $6-8=-2$. You should be able to determine the charges on ions of elements in groups 1A through 7A (for any element that forms only one common ion) using only a periodic table.

A monatomic cation is named simply by adding the word ion to the name of the element. Thus, the ion of potassium $\left(\mathrm{K}^{+}\right)$is known as potassium ion. Similarly, the cations formed by the elements magnesium and aluminum $\left(\mathrm{Mg}^{2+}\right.$ and $\left.\mathrm{Al}^{3+}\right)$ are called magnesium ion and aluminum ion, respectively. It is not necessary for the name to specify the charge on these ions because their charges are equal to their group numbers.

Figure 2.14 Common monatomic ions arranged by their positions in the periodic table. Note that mercury(I), $\mathrm{Hg}_{2}^{2+}$, is actually a polyatomic ion.

Certain metals, especially the transition metals, can form cations of more than one possible charge. Iron, for example, can form $\mathrm{Fe}^{2+}$ and $\mathrm{Fe}^{3+}$. An older nomenclature system that is still in limited use assigns the ending -ous to the cation with the smaller positive charge and the ending $-i c$ to the cation with the greater positive charge:

$$
\begin{aligned}
& \mathrm{Fe}^{2+}: \text { ferrous ion } \\
& \mathrm{Fe}^{3+}: \text { ferric ion }
\end{aligned}
$$

This method of naming ions has some distinct limitations. First, the -ous and -ic suffixes indicate the relative charges of the two cations involved, not the actual charges. Thus, $\mathrm{Fe}^{3+}$ is the ferric ion, but $\mathrm{Cu}^{2+}$ is the cupric ion. In addition, the -ous and -ic endings make it possible to name only two cations with different charges. Some metals, such as manganese (Mn), can form cations with three or more different charges.

Therefore, it has become increasingly common to designate different cations with Roman numerals, using the Stock ${ }^{3}$ system. In this system, the Roman numeral I indicates a positive charge of one, II means a positive charge of two, and so on, as shown for manganese:

$$
\begin{aligned}
& \mathrm{Mn}^{2+}: \text { manganese(II) ion } \\
& \mathrm{Mn}^{3+}: \text { manganese(III) ion } \\
& \mathrm{Mn}^{4+}: \text { manganese(IV) ion }
\end{aligned}
$$

These names are pronounced "manganese-two ion," "manganese-three ion," and "manganese-four ion," respectively. Using the Stock system, the ferrous and ferric ions are iron(II) and iron(III), respectively. To avoid confusion, and in keeping with modern practice, we will use the Stock system to name compounds in this textbook.

A monatomic anion is named by changing the ending of the element's name to -ide, and adding the word ion. Thus, the anion of chlorine $\left(\mathrm{Cl}^{-}\right)$, is called chloride ion. The anions of carbon, nitrogen, and oxygen $\left(\mathrm{C}^{4-}, \mathrm{N}^{3-}\right.$, and $\left.\mathrm{O}^{2-}\right)$ are called carbide, nitride, and oxide, respectively. Because there is only one possible charge for an ion formed from a nonmetal, it is unnecessary for the ion's name to specify its charge. Table 2.8 lists alphabetically a number of common monatomic ions.

## Polyatomic Ions

Ions that consist of a combination of two or more atoms are called polyatomic ions. Because these ions are commonly encountered in general chemistry, you must know the names, formulas, and charges of the polyatomic ions listed in Table 2.9. Although most of the common polyatomic ions are anions, a few are cations.

[^3]| TABLE 2.8 | Names and <br> Formulas of Some Common <br> Monatomic Ions |
| :---: | :---: |
| Name | Formula |
| Cations |  |
| aluminum | $\mathrm{Al}^{3+}$ |
| barium | $\mathrm{Ba}^{2+}$ |
| cadmium | $\mathrm{Cd}^{2+}$ |
| calcium | $\mathrm{Ca}^{2+}$ |
| cesium | Cs ${ }^{+}$ |
| chromium(III) | $\mathrm{Cr}^{3+}$ |
| cobalt(II) | $\mathrm{Co}^{2+}$ |
| copper(I) | $\mathrm{Cu}^{+}$ |
| copper(II) | $\mathrm{Cu}^{2+}$ |
| hydrogen | $\mathrm{H}^{+}$ |
| iron(II) | $\mathrm{Fe}^{2+}$ |
| iron(III) | $\mathrm{Fe}^{3+}$ |
| lead(II) | $\mathrm{Pb}^{2+}$ |
| lithium | $\mathrm{Li}^{+}$ |
| magnesium | $\mathrm{Mg}^{2+}$ |
| manganese(II) | $\mathrm{Mn}^{2+}$ |
| mercury(II) | $\mathrm{Hg}^{2+}$ |
| potassium | $\mathrm{K}^{+}$ |
| silver | $\mathrm{Ag}^{+}$ |
| sodium | $\mathrm{Na}^{+}$ |
| strontium | $\mathrm{Sr}^{2+}$ |
| tin(II) | $\mathrm{Sn}^{2+}$ |
| zinc | $\mathrm{Zn}^{2+}$ |
| Anions |  |
| bromide | $\mathrm{Br}^{-}$ |
| chloride | $\mathrm{Cl}^{-}$ |
| fluoride | $\mathrm{F}^{-}$ |
| hydride | $\mathrm{H}^{-}$ |
| iodide | $\mathrm{I}^{-}$ |
| nitride | $\mathrm{N}^{3-}$ |
| oxide | $\mathrm{O}^{2-}$ |
| sulfide | $\mathrm{S}^{2-}$ |

Student Annotation: Like the atoms in a molecule, the atoms that make up a polyatomic ion are held together by covalent chemical bonds [ $\mathbf{H}$ Section 8.3].

Student Annotation: Some oxoanions occur in series of ions that contain the same central atom and have the same charge, but contain different numbers of oxygen atoms. The FAQ box on page 62 gives more information about how ions in these series are named.

| hypochlorite | $\mathrm{ClO}^{-}$ |
| :---: | :---: |

sulfite $\mathrm{SO}_{3}^{2-}$
thiocyanate $\mathrm{SCN}^{-}$

## Formulas of Ionic Compounds

The formulas of ionic compounds are generally empirical formulas because ionic compounds consist of vast arrays of interspersed cations and anions, not discrete molecular units. For example, solid sodium chloride $(\mathrm{NaCl})$ consists of equal numbers of $\mathrm{Na}^{+}$and $\mathrm{Cl}^{-}$ions arranged in a threedimensional network of alternating cations and anions (Figure 2.15). There is a 1:1 ratio of cations to anions, so the compound is electrically neutral. As a result, the empirical formula of sodium chloride is NaCl . As you can see in Figure 2.15, no $\mathrm{Na}^{+}$ion in NaCl is associated with just one particular $\mathrm{Cl}^{-}$ion. In fact, each $\mathrm{Na}^{+}$ion is surrounded by six $\mathrm{Cl}^{-}$ions and vice versa. In other ionic compounds, the actual structure may be different, but the arrangement of cations and anions is such that the compounds are all electrically neutral. The charges on the cation and anion are not shown in the formula for an ionic compound.

For ionic compounds to be electrically neutral, the sum of the charges on the cation and anion in each formula unit must be zero. If the charges on the cations and anions are numerically

different, you can apply the following guideline to make the formula electrically neutral (and thus obtain the empirical formula): Write a subscript for the cation that is numerically equal to the charge on the anion and a subscript for the anion that is numerically equal to the charge on the cation. If the charges are numerically equal, then no subscripts are necessary.

Let us consider some examples.
Potassium Bromide The potassium ion $\left(\mathrm{K}^{+}\right)$and the bromide ion $\left(\mathrm{Br}^{-}\right)$combine to form the ionic compound potassium bromide. The sum of the charges is $1+(-1)=0$, so no subscripts are necessary. The formula is KBr .
Zinc lodide The zinc ion $\left(\mathrm{Zn}^{2+}\right)$ and the iodide ion $\left(\mathrm{I}^{-}\right)$combine to form zinc iodide. The sum of the charges of one $\mathrm{Zn}^{2+}$ ion and one $\mathrm{I}^{-}$ion is $+2+(-1)=+1$. To make the charges add up to zero, we multiply the -1 charge of the anion by 2 and add the subscript " 2 " to the symbol for iodine. Thus, the formula for zinc iodide is $\mathrm{ZnI}_{2}$.
Ammonium Chloride The cation is $\mathrm{NH}_{4}^{+}$and the anion is $\mathrm{Cl}^{-}$. The sum of the charges is $1+$ $(-1)=0$, so the ions combine in a 1:1 ratio and the resulting formula is $\mathrm{NH}_{4} \mathrm{Cl}$.
Aluminum Oxide The cation is $\mathrm{Al}^{3+}$ and the anion is $\mathrm{O}^{2-}$. The following diagram can be used to determine the subscripts for this compound:

The sum of the charges for aluminum oxide is $2(+3)+3(-2)=0$. Thus, the formula is $\mathrm{Al}_{2} \mathrm{O}_{3}$.
Calcium Phosphate The cation is $\mathrm{Ca}^{2+}$ and the anion is $\mathrm{PO}_{4}^{3-}$. The following diagram can be used to determine the subscripts:

The sum of the charges is $3(+2)+2(-3)=0$. Thus, the formula for calcium phosphate is $\mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}$. When we add a subscript to a polyatomic ion, we must first put parentheses around the ion's formula to indicate that the subscript applies to all the atoms in the polyatomic ion.

## Naming Ionic Compounds

An ionic compound is named using the name of the cation followed by the name of the anion, eliminating the word ion from each. Several examples were given earlier in the Formulas of Ionic Compounds section. Other examples are sodium cyanide $(\mathrm{NaCN})$, potassium permanganate

Figure 2.15 An electron is transferred from the sodium atom to the chlorine atom, giving a sodium ion and a chloride ion. The oppositely charged ions are attracted to each other and form a solid lattice.

You May Be Wondering...

## How Are Oxoanions and Oxoacids Named?

Oxoanions are polyatomic anions that contain one or more oxygen atoms and one atom (the "central atom") of another element. Examples include the chlorate $\left(\mathrm{ClO}_{3}^{-}\right)$, nitrate $\left(\mathrm{NO}_{3}^{-}\right)$, and sulfate ( $\mathrm{SO}_{4}^{2-}$ ) ions. Often, two or more oxoanions have the same central atom but different numbers of O atoms (e.g., $\mathrm{NO}_{3}^{-}$and $\mathrm{NO}_{2}^{-}$). Starting with the oxoanions whose names end in -ate, we can name these ions as follows:

1. The ion with one more O atom than the -ate ion is called the per . . . ate ion. Thus, $\mathrm{ClO}_{3}^{-}$is the chlorate ion, $\mathrm{so} \mathrm{ClO}_{4}^{-}$ is the perchlorate ion.
2. The ion with one less O atom than the -ate anion is called the -ite ion. Thus, $\mathrm{ClO}_{2}^{-}$is the chlorite ion.
3. The ion with two fewer O atoms than the -ate ion is called the hypo . . . ite ion. Thus, $\mathrm{ClO}^{-}$is the hypochlorite ion.
At a minimum, you must commit to memory the formulas and charges of the oxoanions whose names end in -ate so that you can apply these guidelines when necessary.

In addition to the simple acids discussed in Section 2.6, there is another important class of acids known as oxoacids, which ionize to produce hydrogen ions and the corresponding oxoanions. The formula of an oxoacid can be determined by adding enough $\mathrm{H}^{+}$ions to the corresponding oxoanion to yield a formula with no net charge. For example, the formulas of oxoacids based on
the nitrate $\left(\mathrm{NO}_{3}^{-}\right)$and sulfate $\left(\mathrm{SO}_{4}^{2-}\right)$ ions are $\mathrm{HNO}_{3}$ and $\mathrm{H}_{2} \mathrm{SO}_{4}$, respectively. The names of oxoacids are derived from the names of the corresponding oxoanions using the following guidelines:

1. An acid based on an -ate ion is called . . ic acid. Thus, $\mathrm{HClO}_{3}$ is called chloric acid.
2. An acid based on an -ite ion is called . . . ous acid. Thus, $\mathrm{HClO}_{2}$ is called chlorous acid.
3. Prefixes in oxoanion names are retained in the names of the corresponding oxoacids. Thus, $\mathrm{HClO}_{4}$ and HClO are called perchloric acid and hypochlorous acid, respectively.
Many oxoacids, such as $\mathrm{H}_{2} \mathrm{SO}_{4}$ and $\mathrm{H}_{3} \mathrm{PO}_{4}$, are poly-protic-meaning that they have more than one ionizable hydrogen atom. In these cases, the names of anions in which one or more (but not all) of the hydrogen ions have been removed must indicate the number of H ions that remain, as shown for the anions derived from phosphoric acid:

| $\mathrm{H}_{3} \mathrm{PO}_{4}$ | phosphoric acid |
| :--- | :--- |
| $\mathrm{H}_{2} \mathrm{PO}_{4}^{-}$ | dihydrogen phosphate ion |
| $\mathrm{HPO}_{4}^{2-}$ | hydrogen phosphate ion |
| $\mathrm{PO}_{4}^{3-}$ | phosphate ion |

Sample Problems 2.8 and 2.9 test your ability to name and identify oxoanions and oxoacids.

Student Annotation: In general, we determine whether a compound is molecular or ionic by asking these questions: Does the compound consist of only nonmetals? Then it is probably molecular. Does the compound contain either a metal cation or the $\mathrm{NH}_{4}^{+}$ ion? Then it is probably ionic. (Note that it is possible for an ionic compound to contain only nonmetals if it contains the $\mathrm{NH}_{4}^{+}$ion.)
$\left(\mathrm{KMnO}_{4}\right)$, and ammonium sulfate $\left[\left(\mathrm{NH}_{4}\right)_{2} \mathrm{SO}_{4}\right]$. Unlike the naming of molecular compounds, no Greek prefixes are used. For example, $\mathrm{Li}_{2} \mathrm{CO}_{3}$ is lithium carbonate, not dilithium carbonate, even though there are two lithium ions for every carbonate ion. Prefixes are unnecessary because the ions have known charges. Lithium ion always has a charge of +1 , and carbonate ion always has a charge of -2 . The only ratio in which they can combine to form a neutral compound is two $\mathrm{Li}^{+}$ ions for every one $\mathrm{CO}_{3}^{2-}$ ion. Therefore, the name lithium carbonate is sufficient to convey the compound's empirical formula.

In cases where a metal cation may have more than one possible charge, recall that the charge is indicated in the name of the ion with a Roman numeral in parentheses. Thus, the compounds $\mathrm{FeCl}_{2}$ and $\mathrm{FeCl}_{3}$ are named iron(II) chloride and iron(III) chloride, respectively. (These are pronounced "iron-two chloride" and "iron-three chloride.") Figure 2.16 summarizes the steps for naming molecular and ionic compounds.

Sample Problems 2.10 and 2.11 illustrate how to name ionic compounds and write formulas for ionic compounds based on the information given in Figure 2.16 and Tables 2.8 and 2.9.

## Sample Problem 2.8

Name the following species: (a) $\mathrm{BrO}_{4}^{-}$, (b) $\mathrm{HCO}_{3}^{-}$, and (c) $\mathrm{H}_{2} \mathrm{CO}_{3}$.
Strategy Each species is either an oxoanion or an oxoacid. Identify the "reference oxoanion" (the one with the -ate ending) for each, and apply the rules to determine appropriate names.

Setup (a) Chlorine, bromine, and iodine (members of group 7A) all form analogous series of oxoanions with one to four oxygen atoms. Thus, the reference oxoanion is bromate $\left(\mathrm{BrO}_{3}^{-}\right)$, which is analogous to chlorate $\left(\mathrm{ClO}_{3}^{-}\right)$. In parts (b) and (c), $\mathrm{HCO}_{3}^{-}$and $\mathrm{H}_{2} \mathrm{CO}_{3}$ have one and two more hydrogens, respectively, than the carbonate ion $\left(\mathrm{CO}_{3}^{2-}\right)$.

Solution (a) $\mathrm{BrO}_{4}^{-}$has one more O atom than the bromate ion $\left(\mathrm{BrO}_{3}^{-}\right)$, so $\mathrm{BrO}_{4}^{-}$is the perbromate ion. (b) $\mathrm{CO}_{3}^{2-}$ is the carbonate ion. Because $\mathrm{HCO}_{3}^{-}$has one ionizable hydrogen atom, it is called the hydrogen carbonate ion. (c) With two ionizable hydrogen atoms and no charge on the compound, $\mathrm{H}_{2} \mathrm{CO}_{3}$ is carbonic acid.

Practice Problem A Name the following species: (a) HBrO , (b) $\mathrm{HSO}_{4}^{-}$, and (c) $\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}$.
$\$$ Practice Problem B Name the following species: (a) $\mathrm{HIO}_{3}$, (b) $\mathrm{HCrO}_{4}^{-}$, and (c) $\mathrm{HC}_{2} \mathrm{O}_{4}^{-}$.

## Sample Problem 2.9

Determine the formula of sulfurous acid.
Strategy The -ous ending in the name of an acid indicates that the acid is derived from an oxoanion ending in -ite. Determine the formula and charge of the oxoanion, and add enough hydrogens to make a neutral formula.

Setup The sulfite ion is $\mathrm{SO}_{3}^{2-}$.
Solution The formula of sulfurous acid is $\mathrm{H}_{2} \mathrm{SO}_{3}$.

Practice Problem A Determine the formula of perbromic acid. (Refer to the information in Sample Problem 2.8.)
\& Practice Problem B Determine the formula of chromic acid.

Think About It Remembering all these names and formulas is greatly facilitated by memorizing the common ions that end in -ate.

| chlorate | $\mathrm{ClO}_{3}^{-}$ |
| :--- | :--- |
| iodate | $\mathrm{IO}_{3}^{-}$ |
| bromate | $\mathrm{BrO}_{3}^{-}$ |
| sulfate | $\mathrm{SO}_{4}^{2-}$ |
| phosphate | $\mathrm{PO}_{4}^{3-}$ |
| nitrate | $\mathrm{NO}_{3}^{-}$ |
| carbonate | $\mathrm{CO}_{3}^{2-}$ |
| oxalate | $\mathrm{C}_{2} \mathrm{O}_{4}^{2-}$ |
| chromate | $\mathrm{CrO}_{4}^{2-}$ |
| permanganate | $\mathrm{MnO}_{4}^{-}$ |

## Sample Problem 2.10

Name the following ionic compounds: (a) MgO , (b) $\mathrm{Al}(\mathrm{OH})_{3}$, and (c) $\mathrm{Fe}_{2}\left(\mathrm{SO}_{4}\right)_{3}$.
Strategy Begin by identifying the cation and the anion in each compound, and then combine the names for each, eliminating the word ion.

Setup MgO contains $\mathrm{Mg}^{2+}$ and $\mathrm{O}^{2-}$, the magnesium ion and the oxide ion; $\mathrm{Al}(\mathrm{OH})_{3}$ contains $\mathrm{Al}^{3+}$ and $\mathrm{OH}^{-}$, the aluminum ion and the hydroxide ion; and $\mathrm{Fe}_{2}\left(\mathrm{SO}_{4}\right)_{3}$ contains $\mathrm{Fe}^{3+}$ and $\mathrm{SO}_{4}^{2-}$, the iron(III) ion and the sulfate ion. We know that the iron in $\mathrm{Fe}_{2}\left(\mathrm{SO}_{4}\right)_{3}$ is iron(III), $\mathrm{Fe}^{3+}$, because it is combined with the sulfate ion in a $2: 3$ ratio.

Solution (a) Combining the cation and anion names, and eliminating the word ion from each of the individual ions' names, we get magnesium oxide as the name of $\mathrm{MgO} ;(\mathrm{b}) \mathrm{Al}(\mathrm{OH})_{3}$ is aluminum hydroxide; and (c) $\mathrm{Fe}_{2}\left(\mathrm{SO}_{4}\right)_{3}$ is iron(III) sulfate.

Practice Problem A Name the following ionic compounds: (a) $\mathrm{Na}_{2} \mathrm{SO}_{4}$, (b) $\mathrm{Cu}\left(\mathrm{NO}_{3}\right)_{2}$, (c) $\mathrm{Fe}_{2}\left(\mathrm{CO}_{3}\right)_{3}$. $\mathbb{H}$ Practice Problem B Name the following ionic compounds: (a) $\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$, (b) $\mathrm{Li}_{2} \mathrm{C}_{2} \mathrm{O}_{4}$, (c) $\mathrm{CuNO}_{3}$.

Think About It Be careful not to confuse the subscript in a formula with the charge on the metal ion. In part (c), for example, the subscript on Fe is 2 , but this is an iron(III) compound.

Figure 2.16 Steps for naming molecular and ionic compounds.

Think About It Make sure that the charges sum to zero in each compound formula. In part (a), for example, $\mathrm{Hg}_{2}^{2+}+2 \mathrm{Cl}^{-}=$ $(2+)+2(-1)=0$; in part (b), $(+2)+(-2)=0$; and in part (c), $2(+1)+(-2)=0$.

- Name metal first.
- If monatomic anion, add -ide to root of element name.
- If polyatomic anion, use name of anion.
- Name metal first.
- Specify charge of metal cation with Roman numeral in parentheses.
- If monatomic anion, add -ide to root of element name.
- If polyatomic anion, use name of anion.

## Sample Problem 2.11

Deduce the formulas of the following ionic compounds: (a) mercury(I) chloride, (b) lead(II) chromate, and (c) potassium hydrogen phosphate.

Strategy Identify the ions in each compound, and determine their ratios of combination using the charges on the cation and anion in each.

Setup (a) Mercury(I) chloride is a combination of $\mathrm{Hg}_{2}^{2+}$ and $\mathrm{Cl}^{-}$. [Mercury(I) is one of the few cations listed in Table 2.9.] In order to produce a neutral compound, these two ions must combine in a 1:2 ratio. (b) Lead(II) chromate is a combination of $\mathrm{Pb}^{2+}$ and $\mathrm{CrO}_{4}^{2-}$. These ions combine in a $1: 1$ ratio. (c) Potassium hydrogen phosphate is a combination of $\mathrm{K}^{+}$and $\mathrm{HPO}_{4}^{2-}$. These ions combine in a 2:1 ratio.

Solution The formulas are (a) $\mathrm{Hg}_{2} \mathrm{Cl}_{2}$, (b) $\mathrm{PbCrO}_{4}$, and (c) $\mathrm{K}_{2} \mathrm{HPO}_{4}$.

Practice Problem A Deduce the formulas of the following ionic compounds: (a) lead(II) chloride, (b) magnesium carbonate, and (c) ammonium phosphate.

EPractice Problem B Deduce the formulas of the following ionic compounds: (a) iron(III) sulfide, (b) mercury(II) nitrate, and (c) potassium sulfite.

## Hydrates

Hydrates are compounds that have a specific number of water molecules within their solid structure. In its normal state, for example, each unit of copper(II) sulfate has five water molecules associated with it. The systematic name for this compound is copper(II) sulfate pentahydrate, and its formula is written as $\mathrm{CuSO}_{4} \cdot 5 \mathrm{H}_{2} \mathrm{O}$. The water molecules can be driven off by heating. When this

occurs, the resulting compound is $\mathrm{CuSO}_{4}$, which is sometimes called anhydrous copper(II) sulfate; anhydrous means that the compound no longer has water molecules associated with it. Hydrates and the corresponding anhydrous compounds often have distinctly different physical and chemical properties (Figure 2.17).

Some other hydrates are
$\mathrm{BaCl}_{2} \cdot 2 \mathrm{H}_{2} \mathrm{O} \quad$ barium chloride dihydrate
$\mathrm{LiCl} \cdot \mathrm{H}_{2} \mathrm{O} \quad$ lithium chloride monohydrate
$\mathrm{MgSO}_{4} \cdot 7 \mathrm{H}_{2} \mathrm{O}$
$\mathrm{Sr}\left(\mathrm{NO}_{3}\right)_{2} \cdot 4 \mathrm{H}_{2} \mathrm{O}$ magnesium sulfate heptahydrate strontium nitrate tetrahydrate

## Familiar Inorganic Compounds

Some compounds are better known by their common names than by their systematic chemical names. Familiar examples are listed in Table 2.10.

| TABLE 2.10 | Common and Systematic Names of Some Familiar Inorganic <br> Compounds |  |
| :--- | :--- | :--- |
| Formula | Common Name | Systematic Name |
| $\mathrm{H}_{2} \mathrm{O}$ | Water | Dihydrogen monoxide |
| $\mathrm{NH}_{3}$ | Ammonia | Trihydrogen nitride |
| $\mathrm{CO}_{2}$ | Dry ice | Solid carbon dioxide |
| NaCl | Salt | Sodium chloride |
| $\mathrm{N}_{2} \mathrm{O}$ | Nitrous oxide, laughing gas | Dinitrogen monoxide |
| $\mathrm{CaCO}_{3}$ | Marble, chalk, limestone | Calcium carbonate |
| $\mathrm{NaHCO}_{3}$ | Baking soda | Sodium hydrogen carbonate |
| $\mathrm{MgSO}_{4} \cdot 7 \mathrm{H}_{2} \mathrm{O}$ | Epsom salt | Magnesium sulfate heptahydrate |
| $\mathrm{Mg}(\mathrm{OH})_{2}$ | Milk of magnesia | Magnesium hydroxide |

Figure 2.17 $\mathrm{CuSO}_{4}$ is white. The pentahydrate, $\mathrm{CuSO}_{4} \cdot 5 \mathrm{H}_{2} \mathrm{O}$, is blue.

## Checkpoint 2.7 Ions and Ionic Compounds

2.7.1 What is the correct name of the compound $\mathrm{PbSO}_{4}$ ?
a) Lead sulfate
b) Lead(I) sulfate
c) Lead(II) sulfate
d) Monolead sulfate
e) Lead monosulfate
2.7.2 What is the correct formula for the compound iron(III) carbonate?
a) $\mathrm{FeCO}_{3}$
b) $\mathrm{Fe}_{3} \mathrm{CO}_{3}$
c) $\mathrm{Fe}_{2} \mathrm{CO}_{3}$
d) $\mathrm{Fe}_{2}\left(\mathrm{CO}_{3}\right)_{3}$
e) $\mathrm{Fe}_{3}\left(\mathrm{CO}_{3}\right)_{2}$
2.7.3 Which of the following is the correct formula for nitrous acid?
a) HNO
b) $\mathrm{HN}_{2} \mathrm{O}$
c) $\mathrm{N}_{2} \mathrm{O}$
d) $\mathrm{HNO}_{2}$
e) $\mathrm{HNO}_{3}$
2.7.4 What is the formula of nickel(II) nitrate hexahydrate?
a) $\mathrm{NiNO}_{3} \cdot 6 \mathrm{H}_{2} \mathrm{O}$
b) $\mathrm{Ni}_{2} \mathrm{NO}_{3} \cdot 6 \mathrm{H}_{2} \mathrm{O}$
c) $\mathrm{Ni}\left(\mathrm{NO}_{3}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}$
d) $\mathrm{NiNO}_{3} \cdot 12 \mathrm{H}_{2} \mathrm{O}$
e) $\mathrm{Ni}\left(\mathrm{NO}_{3}\right)_{2} \cdot 12 \mathrm{H}_{2} \mathrm{O}$
2.7.5 What is the correct formula for sodium nitride?
a) NaN
b) $\mathrm{NaN}_{3}$
c) $\mathrm{Na}_{3} \mathrm{~N}$
d) $\mathrm{NaNO}_{3}$
e) $\mathrm{NaNO}_{2}$
2.7.6 What is the correct name of the compound $\mathrm{Hg}_{2} \mathrm{CrO}_{4}$ ?
a) Mercury(I) chromate
b) Mercury(II) chromate
c) Mercury dichromate
d) Dimercury chromate
e) Monomercury chromate

## Applying What You've Learned

Although iron is an essential element, it is also a potentially toxic substance. Hemochromatosis is one of the most common hereditary disorders, causing "iron overload" or the storage of excess iron in the tissues and organs. Individuals with hemochromatosis often must undergo periodic phlebotomy (removal of blood) in order to remove excess stored iron, which would otherwise cause irreversible damage to internal organs including the liver and kidneys. Those who have a tendency to store too much iron are advised to avoid combining iron-rich foods with substances that enhance iron absorption, such as ascorbic acid (vitamin C).

Ascorbic acid

Because of iron's toxicity, iron supplements are potentially dangerous, especially to children. In fact, iron poisoning is the most common toxicological emergency in young children-due in part to the resemblance many iron supplements bear to candy. Most vitamins that contain iron are sold with childproof caps to help prevent accidental overdose. The Food and Drug Administration (FDA) requires supplements containing more than 30 mg of iron per dose to be sold in single-dose blister packs to make it more difficult for a child to consume a dangerous amount.

## Problems:

a) Iron has four naturally occurring isotopes: ${ }^{54} \mathrm{Fe}(53.9396 \mathrm{amu}),{ }^{56} \mathrm{Fe}(55.9349 \mathrm{amu})$, ${ }^{57} \mathrm{Fe}(56.9354 \mathrm{amu})$, and ${ }^{58} \mathrm{Fe}(57.9333 \mathrm{amu})$. For each isotope, determine the number of neutrons in the nucleus. [ 14 Sample Problem 2.2]
b) Calculate the average atomic mass of iron given that the natural abundances of the four isotopes are $5.845,91.754,2.119$, and 0.282 percent, respectively. [ ks Sample Problem 2.3]
c) Write the molecular formula for ascorbic acid (see the ball-and-stick model). [ 14 Sample Problem 2.4]
d) Determine the empirical formula of ascorbic acid. [ KA Sample Problem 2.7]
e) Write the formula for ferrous sulfate [iron(II) sulfate]. [k4 Sample Problem 2.11]

## Chapter Summary

## Section 2.1

- Dalton's atomic theory states that all matter is made up of tiny indivisible, immutable particles called atoms. Compounds form, moreover, when atoms of different elements combine in fixed ratios. According to the law of definite proportions, any sample of a given compound will always contain the same elements in the same mass ratio.
- The law of multiple proportions states that if two elements can form more than one compound with one another, the mass ratio of one will be related to the mass ratio of the other by a small whole number.
- The law of conservation of mass states that matter can be neither created nor destroyed.

## Section 2.2

- On the basis of Dalton's atomic theory, the atom is the basic unit of an element. Studies with radiation indicated that atoms contained subatomic particles, one of which was the electron.
- Experiments with radioactivity have shown that some atoms give off different types of radiation, called alpha ( $\alpha$ ) rays, beta $(\beta)$ rays, and gamma $(\gamma)$ rays. Alpha rays are composed of $\alpha$ particles, which are actually helium nuclei. Beta rays are composed of $\boldsymbol{\beta}$ particles, which are actually electrons. Gamma rays are high-energy radiation.
- Most of the mass of an atom resides in a tiny, dense region known as the nucleus. The nucleus contains positively charged particles called protons and electrically neutral particles called neutrons. The charge on a proton is equal in magnitude but opposite in sign to the charge on an electron. The electrons occupy the relatively large volume around the nucleus. A neutron has a slightly greater mass than a proton, but each is almost 2000 times as massive as an electron.

## Section 2.3

- The atomic number $(\boldsymbol{Z})$ is the number of protons in the nucleus of an atom. The atomic number determines the identity of the atom. The mass number $(\boldsymbol{A})$ is the sum of the protons and neutrons in the nucleus.
- Protons and neutrons are referred to collectively as nucleons.
- Atoms with the same atomic number but different mass numbers are called isotopes.

## Section 2.4

- The periodic table arranges the elements in rows (periods) and columns (groups or families). Elements in the same group exhibit similar properties.
- All elements fall into one of three categories: metal, nonmetal, or metalloid.
- Some of the groups have special names including alkali metals (Group 1A, except hydrogen), alkaline earth metals (Group 2A), chalcogens (Group 6A), halogens (Group 7A), noble gases (Group 8A), and transition elements or transition metals (Group 1B and Groups 3B-8B).

## Section 2.5

- Atomic mass is the mass of an atom in atomic mass units. One atomic mass unit (amu), is exactly one-twelfth the mass of a carbon-12 atom.
- The periodic table contains the average atomic mass (sometimes called the atomic weight) of each element.

## Section 2.6

- A molecule is an electrically neutral group of two or more atoms. Molecules consisting of just two atoms are called diatomic. Diatomic molecules may be homonuclear (just one kind of atom) or heteronuclear (two kinds of atoms). In general, molecules containing more than two atoms are called polyatomic.
- A chemical formula denotes the composition of a substance. A molecular formula specifies the exact numbers of atoms in a molecule of a compound. A structural formula shows the arrangement of atoms in a substance.
- An allotrope is one of two or more different forms of an element.
- Molecular compounds are named according to a set of rules, including the use of Greek prefixes to specify the number of each kind of atom in the molecule.
- Binary compounds are those that consist of two elements. An acid is a substance that generates hydrogen ions when it dissolves in water. An ionizable hydrogen atom is one that can be removed in water to become a hydrogen ion $\left(\mathrm{H}^{+}\right)$.
- Inorganic compounds are generally those that do not contain carbon. Organic compounds contain carbon and hydrogen, sometimes in combination with other elements. Hydrocarbons contain only carbon and hydrogen. The simplest hydrocarbons are the alkanes. A functional group is a group of atoms that determines the chemical properties of an organic compound.
- Empirical formulas express, in the smallest possible whole numbers, the ratio of the combination of atoms of the elements in a compound. The empirical and molecular formulas of a compound may or may not be identical.

## Section 2.7

- An ion is an atom or group of atoms with a net charge. An atomic ion or a monatomic ion consists of just one atom.
- An ion with a net positive charge is a cation. An ion with a net negative charge is an anion. An ionic compound is one that consists of cations and anions in an electrically neutral combination. A threedimensional array of alternating cations and anions is called a lattice.
- Ionic compounds are named using rules similar to those for molecular compounds. In general, prefixes are not used to denote the number of ions in the names of ionic compounds.
- Polyatomic ions are those that contain more than one atom chemically bonded together. Oxoanions are polyatomic ions that contain one or more oxygen atoms.
- Oxoacids are acids based on oxoanions. Acids with more than one ionizable hydrogen atom are called polyprotic.
- Hydrates are compounds whose formulas include a specific number of water molecules.

## Questions and Problems

## Section 2.1: The Atomic Theory

## Review Questions

2.1 What are the hypotheses on which Dalton's atomic theory is based?
2.2 State the laws of definite proportions and multiple proportions. Illustrate each with an example.
2.3 The elements nitrogen and oxygen can form a variety of different compounds. Two such compounds, NO and $\mathrm{N}_{2} \mathrm{O}_{4}$, were decomposed into their constituent elements. One produced 0.8756 g N for every gram of O ; the other produced 0.4378 g N for every gram of O . Show that these results are consistent with the law of multiple proportions.
2.4 Two different compounds, each containing only phosphorus and chlorine, were decomposed into their constituent elements. One produced 0.2912 g P for every gram of Cl ; the other produced 0.1747 g P for every gram of Cl . Show that these results are consistent with the law of multiple proportions.
2.5 Sulfur reacts with fluorine to produce three different compounds. The mass ratio of fluorine to sulfur for each compound is given in the following table:

| Compound | mass $\mathbf{F}:$ mass $\mathbf{S}$ |
| :---: | :---: |
| $\mathrm{S}_{2} \mathrm{~F}_{10}$ | 2.962 |
| $\mathrm{SF}_{4}$ | 2.370 |
| $\mathrm{SF}_{6}$ | 3.555 |

Show that these data are consistent with the law of multiple proportions.
2.6 Both FeO and $\mathrm{Fe}_{2} \mathrm{O}_{3}$ contain only iron and oxygen. The mass ratio of oxygen to iron for each compound is given in the following table:

| Compound | mass $\mathbf{O}:$ mass $\mathbf{F e}$ |
| :---: | :---: |
| FeO | 0.2865 |
| $\mathrm{Fe}_{2} \mathrm{O}_{3}$ | 0.4297 |

Show that these data are consistent with the law of multiple proportions.

## Problems

2.7 For the two compounds pictured, evaluate the following ratio:

$$
\frac{\mathrm{g} \text { blue }: 1.00 \mathrm{~g} \text { red (right) }}{\mathrm{g} \text { blue }: 1.00 \mathrm{~g} \text { red (left) }}
$$

2.8 For the two compounds pictured, evaluate the following ratio:

$$
\frac{\mathrm{g} \text { green }: 1.00 \mathrm{~g} \text { yellow (right) }}{\mathrm{g} \text { green }: 1.00 \mathrm{~g} \text { yellow (left) }}
$$

## Section 2.2: The Structure of the Atom

## Review Questions

2.9 Define the following terms: (a) $\alpha$ particle, (b) $\beta$ particle, (c) $\gamma$ ray, (d) X ray.
2.10 Name the types of radiation known to be emitted by radioactive elements.
2.11 Compare the properties of the following: $\alpha$ particles, cathode rays, protons, neutrons, and electrons.
2.12 Describe the contributions of the following scientists to our knowledge of atomic structure: J. J. Thomson, R. A. Millikan, Ernest Rutherford, and James Chadwick.
2.13 Describe the experimental basis for believing that the nucleus occupies a very small fraction of the volume of the atom.

## Problems

2.14 The diameter of a neutral helium atom is about $1 \times 10^{2} \mathrm{pm}$. Suppose that we could line up helium atoms side by side in contact with one another. Approximately how many atoms would it take to make the distance 1 cm from end to end?
2.15 Roughly speaking, the radius of an atom is about 10,000 times greater than that of its nucleus. If an atom were magnified so that the radius of its nucleus became 2.0 cm , about the size of a marble, what would be the radius of the atom in miles $(1 \mathrm{mi}=1609 \mathrm{~m})$ ?

## Section 2.3: Atomic Number, Mass Number, and Isotopes <br> Review Questions

2.16 Use the helium-4 isotope to define atomic number and mass number. Why does knowledge of the atomic number enable us to deduce the number of electrons present in an atom?
2.17 Why do all atoms of an element have the same atomic number, although they may have different mass numbers?
2.18 What do we call atoms of the same elements with different mass numbers?

E2.19 Explain the meaning of each term in the symbol ${ }_{Z}^{A} \mathrm{X}$.

## Problems

E 2.20 What is the mass number of an iron atom that has 28 neutrons?
2.21 Calculate the number of neutrons of ${ }^{239} \mathrm{Pu}$.

E 2.22 For each of the following species, determine the number of protons and the number of neutrons in the nucleus: ${ }_{2}^{3} \mathrm{He},{ }_{2}^{4} \mathrm{He}$, ${ }_{12}^{24} \mathrm{Mg},{ }_{12}^{25} \mathrm{Mg},{ }_{22}^{48} \mathrm{Ti},{ }_{35}^{79} \mathrm{Br},{ }_{78}^{195} \mathrm{Pt}$.
2.23 Indicate the number of protons, neutrons, and electrons in each of the following species: ${ }_{7}^{15} \mathrm{~N},{ }_{16}^{33} \mathrm{~S},{ }_{29}^{63} \mathrm{Cu},{ }_{38}^{84} \mathrm{Sr},{ }_{56}^{130} \mathrm{Ba},{ }_{74}^{186} \mathrm{~W},{ }_{80}^{202} \mathrm{Hg}$.

I 2.24 Write the appropriate symbol for each of the following isotopes:
(a) $Z=11, A=23$; (b) $Z=28, A=64$; (c) $Z=50, A=115$;
(d) $Z=20, A=42$.
2.25 Write the appropriate symbol for each of the following isotopes:
(a) $Z=74, A=186$; (b) $Z=80, A=201$; (c) $Z=34, A=76$;
(d) $Z=94, A=239$.

E 2.26 Determine the mass number of (a) a boron atom with 5 neutrons, (b) a magnesium atom with 14 neutrons, (c) a bromine atom with 46 neutrons, and (d) a mercury atom with 116 neutrons.
2.27 Determine the mass number of (a) a fluorine atom with 10 neutrons, (b) a sulfur atom with 18 neutrons, (c) an arsenic atom with 42 neutrons, and (d) a platinum atom with 114 neutrons.
2.28 The following radioactive isotopes are used in medicine for imaging organs, studying blood circulation, treating cancer, and so on. Give the number of neutrons present in each isotope: ${ }^{198} \mathrm{Au},{ }^{47} \mathrm{Ca},{ }^{60} \mathrm{Co},{ }^{18} \mathrm{~F},{ }^{125} \mathrm{I},{ }^{131} \mathrm{I},{ }^{42} \mathrm{~K},{ }^{43} \mathrm{~K},{ }^{24} \mathrm{Na},{ }^{32} \mathrm{P},{ }^{85} \mathrm{Sr},{ }^{99} \mathrm{Tc}$.

## Section 2.4: The Periodic Table

## Review Questions

2.29 What is the periodic table, and what is its significance in the study of chemistry?
2.30 State two differences between a metal and a nonmetal.
2.31 Write the names and symbols for four elements in each of the following categories: (a) nonmetal, (b) metal, (c) metalloid.
2.32 Give two examples of each of the following: (a) alkali metals, (b) alkaline earth metals, (c) halogens, (d) noble gases, (e) chalcogens, (f) transition metals.
2.33 The explosion of an atomic bomb in the atmosphere releases many radioactive isotopes into the environment. One of the isotopes is ${ }^{90} \mathrm{Sr}$. Via a relatively short food chain, it can enter the human body. Considering the position of strontium in the periodic table, explain why it is particularly harmful to humans.

## Problems

2.34 Elements whose names end with -ium are usually metals; sodium is one example. Identify a nonmetal whose name also ends with -ium.
2.35 Describe the changes in properties (from metals to nonmetals or from nonmetals to metals) as we move (a) down a periodic group and (b) across the periodic table from left to right.
2.36 Consult a handbook of chemical and physical data (ask your instructor where you can locate a copy of the handbook) to find (a) two metals less dense than water, (b) two metals more dense than mercury, (c) the densest known solid metallic element, and (d) the densest known solid nonmetallic element.
$\Psi$ 2.37 Group the following elements in pairs that you would expect to show similar chemical properties: $\mathrm{K}, \mathrm{F}, \mathrm{P}, \mathrm{Na}, \mathrm{Cl}$, and N .
2.38 Group the following elements in pairs that you would expect to show similar chemical properties: $\mathrm{I}, \mathrm{Ba}, \mathrm{O}, \mathrm{Br}, \mathrm{S}$, and Ca .
2.39 Write the symbol for each of the following biologically important elements in the given periodic table: iron (present in hemoglobin for transporting oxygen), iodine (present in the thyroid gland), sodium (present in intracellular and extracellular fluids), phosphorus (present in bones and teeth), sulfur (present in proteins), and magnesium (present in chlorophyll molecules).

## Section 2.5: The Atomic Mass Scale and Average Atomic Mass

## Review Questions

2.40 What is an atomic mass unit? Why is it necessary to introduce such a unit?
2.41 What is the mass (in amu) of a carbon-12 atom? Why is the atomic mass of carbon listed as 12.01 amu in the table on the inside front cover of this book?
2.42 Explain clearly what is meant by the statement "The atomic mass of gold is 197.0 amu."
2.43 What information would you need to calculate the average atomic mass of an element?

## Problems

$\boldsymbol{H} 2.44$ The atomic masses of ${ }_{17}^{35} \mathrm{Cl}$ (75.53 percent) and ${ }_{17}^{37} \mathrm{Cl}$ (24.47 percent) are 34.968 and 36.956 amu , respectively. Calculate the average atomic mass of chlorine. The percentages in parentheses denote the relative abundances.
2.45 The atomic masses of ${ }^{204} \mathrm{~Pb}$ (1.4 percent), ${ }^{206} \mathrm{~Pb}$ (24.1 percent), ${ }^{207} \mathrm{~Pb}$ (22.1 percent), and ${ }^{208} \mathrm{~Pb}$ ( 52.4 percent) are 203.973020 , 205.974440, 206.975872, and 207.976627 amu , respectively. Calculate the average atomic mass of lead. The percentages in parentheses denote the relative abundances.

E 2.46 The atomic masses of ${ }^{203} \mathrm{Tl}$ and ${ }^{205} \mathrm{Tl}$ are 202.972320 and 204.974401 amu , respectively. Calculate the natural abundances of these two isotopes. The average atomic mass of thallium is 204.4 amu .

GI 2.47 The atomic masses of ${ }^{6} \mathrm{Li}$ and ${ }^{7} \mathrm{Li}$ are 6.0151 amu and 7.0160 amu , respectively. Calculate the natural abundances of these two isotopes. The average atomic mass of Li is 6.941 amu .

E 2.48 What is the mass in grams of 13.2 amu ?
El 2.49 How many atomic mass units are there in 8.4 g ?

## Section 2.6: Molecules and Molecular Compounds

## Review Questions

2.50 What is the difference between an atom and a molecule?
2.51 What are allotropes? Give an example. How are allotropes different from isotopes?
2.52 Describe the two commonly used molecular models.
2.53 What does a chemical formula represent? Determine the ratio of the atoms in the following molecular formulas: (a) NO , (b) $\mathrm{NCl}_{3}$, (c) $\mathrm{N}_{2} \mathrm{O}_{4}$, (d) $\mathrm{P}_{4} \mathrm{O}_{6}$.
2.54 Define molecular formula and empirical formula. What are the similarities and differences between the empirical formula and molecular formula of a compound?
2.55 Give an example of a case in which two molecules have different molecular formulas but the same empirical formula.
2.56 What is the difference between inorganic compounds and organic compounds?
2.57 Give one example each for a binary compound and a ternary compound. (A ternary compound is one that contains three different elements.)
2.58 Explain why the formula HCl can represent two different chemical systems.

## Problems

E 2.59 For each of the following diagrams, determine whether it represents diatomic molecules, polyatomic molecules, molecules that are not compounds, molecules that are compounds, or an elemental form of the substance.

(a)

(b)

(c)

E 2.60 For each of the following diagrams, determine whether it represents diatomic molecules, polyatomic molecules, molecules that are not compounds, molecules that are compounds, or an elemental form of the substance.

(a)

(b)

(c)
2.61 Identify the following as elements or compounds: $\mathrm{NH}_{3}, \mathrm{~N}_{2}, \mathrm{~S}_{8}$, $\mathrm{NO}, \mathrm{CO}, \mathrm{CO}_{2}, \mathrm{H}_{2}, \mathrm{SO}_{2}$.
$\boldsymbol{\xi}$ 2.62 Give two examples of each of the following: (a) a diatomic molecule containing atoms of the same element, (b) a diatomic molecule containing atoms of different elements, (c) a polyatomic molecule containing atoms of the same element, (d) a polyatomic molecule containing atoms of different elements.

H2.63 Write the empirical formulas of the following compounds: (a) $\mathrm{C}_{2} \mathrm{~N}_{2}$, (b) $\mathrm{C}_{6} \mathrm{H}_{6}$, (c) $\mathrm{C}_{9} \mathrm{H}_{20}$, (d) $\mathrm{P}_{4} \mathrm{O}_{10}$, (e) $\mathrm{B}_{2} \mathrm{H}_{6}$.

EI 2.64 Write the empirical formulas of the following compounds: (a) $\mathrm{Al}_{2} \mathrm{Br}_{6}$, (b) $\mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{4}$, (c) $\mathrm{N}_{2} \mathrm{O}_{5}$, (d) $\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$, (e) $\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}$.
2.65 Write the molecular formula of alanine, an amino acid used in protein synthesis. The color codes are black (carbon), blue (nitrogen), red (oxygen), and white (hydrogen).

H2.66 Write the molecular formula of ethanol. The color codes are black (carbon), red (oxygen), and white (hydrogen).

2.67 Name the following binary molecular compounds: (a) $\mathrm{NCl}_{3}$, (b) $\mathrm{IF}_{7}$, (c) $\mathrm{P}_{4} \mathrm{O}_{6}$, (d) $\mathrm{S}_{2} \mathrm{Cl}_{2}$.

E 2.68 Write chemical formulas for the following molecular compounds: (a) phosphorus tribromide, (b) dinitrogen tetrafluoride, (c) xenon tetroxide, (d) selenium trioxide.
2.69 Write the molecular formulas and names of the following compounds.

Write the molecular formulas and names of the following compounds.

(a)

(b)

(c)

## Section 2.7: Ions and Ionic Compounds

## Review Questions

2.71 Give an example of each of the following: (a) a monatomic cation, (b) a monatomic anion, (c) a polyatomic cation, (d) a polyatomic anion.
2.72 What is an ionic compound? How is electrical neutrality maintained in an ionic compound?
2.73 Explain why the chemical formulas of ionic compounds are usually the same as their empirical formulas.
2.74 What is the Stock system? What are its advantages over the older system of naming cations?

## Problems

$\boldsymbol{Y}$ 2.75 Give the number of protons and electrons in each of the following common ions: $\mathrm{Na}^{+}, \mathrm{Ca}^{2+}, \mathrm{Al}^{3+}, \mathrm{Fe}^{2+}, \mathrm{I}^{-}, \mathrm{F}^{-}, \mathrm{S}^{2-}, \mathrm{O}^{2-}, \mathrm{N}^{3-}$.
2.76 Give the number of protons and electrons in each of the following common ions: $\mathrm{K}^{+}, \mathrm{Mg}^{2+}, \mathrm{Fe}^{3+}, \mathrm{Br}^{-}, \mathrm{Mn}^{2+}, \mathrm{C}^{4-}, \mathrm{Cu}^{2+}$.

E 2.77 Write the formulas for the following ionic compounds:
(a) sodium oxide, (b) iron sulfide (containing the $\mathrm{Fe}^{2+}$ ion),
(c) cobalt sulfate (containing the $\mathrm{Co}^{3+}$ and $\mathrm{SO}_{4}^{2-}$ ions),
(d) barium fluoride.
$\$ 2.78$ Write the formulas for the following ionic compounds: (a) copper bromide (containing the $\mathrm{Cu}^{+}$ion), (b) manganese oxide (containing the $\mathrm{Mn}^{3+}$ ion), (c) mercury iodide (containing the $\mathrm{Hg}_{2}^{2+}$ ion), (d) magnesium phosphate (containing the $\mathrm{PO}_{4}^{3-}$ ion).

E 2.79 Which of the following compounds are likely to be ionic? Which are likely to be molecular? $\mathrm{SiCl}_{4}, \mathrm{LiF}, \mathrm{BaCl}_{2}, \mathrm{~B}_{2} \mathrm{H}_{6}, \mathrm{KCl}, \mathrm{C}_{2} \mathrm{H}_{4}$

E 2.80 Which of the following compounds are likely to be ionic? Which are likely to be molecular? $\mathrm{CH}_{4}, \mathrm{NaBr}, \mathrm{BaF}_{2}, \mathrm{CCl}_{4}, \mathrm{ICl}, \mathrm{CsCl}, \mathrm{NF}_{3}$

H2.81 Name the following compounds: (a) $\mathrm{KH}_{2} \mathrm{PO}_{4}$, (b) $\mathrm{K}_{2} \mathrm{HPO}_{4}$, (c) HBr (gas), (d) HBr (in water), (e) $\mathrm{Li}_{2} \mathrm{CO}_{3}$, (f) $\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$, (g) $\mathrm{NH}_{4} \mathrm{NO}_{2}$, (h) $\mathrm{HIO}_{3}$, (i) $\mathrm{PF}_{5}$, (j) $\mathrm{P}_{4} \mathrm{O}_{6}$, (k) $\mathrm{CdI}_{2}$, (l) $\mathrm{SrSO}_{4}$, (m) $\mathrm{Al}(\mathrm{OH})_{3}$.

El 2.82 Name the following compounds: (a) KClO , (b) $\mathrm{Ag}_{2} \mathrm{CO}_{3}$, (c) $\mathrm{HNO}_{2}$, (d) $\mathrm{KMnO}_{4}$, (e) $\mathrm{CsClO}_{3}$, (f) $\mathrm{KNH}_{4} \mathrm{SO}_{4}$, (g) FeO , (h) $\mathrm{Fe}_{2} \mathrm{O}_{3}$, (i) $\mathrm{TiCl}_{4}$, (j) NaH , (k) $\mathrm{Li}_{3} \mathrm{~N}$, (l) $\mathrm{Na}_{2} \mathrm{O}$, (m) $\mathrm{Na}_{2} \mathrm{O}_{2}$.

E 2.83 Write the formulas for the following compounds: (a) rubidium nitrite, (b) potassium sulfide, (c) sodium hydrogen sulfide, (d) magnesium phosphate, (e) calcium hydrogen phosphate, (f) lead(II) carbonate, (g) tin(II) fluoride, (h) ammonium sulfate, (i) silver perchlorate, (j) boron trichloride.

EI 2.84 Write the formulas for the following compounds: (a) copper(I) cyanide, (b) strontium chlorite, (c) perbromic acid, (d) hydroiodic acid, (e) disodium ammonium phosphate, (f) potassium dihydrogen
phosphate, (g) iodine heptafluoride, (h) tetraphosphorus decasulfide, (i) mercury(II) oxide, (j) mercury(I) iodide, (k) selenium hexafluoride.
W.85 In the diagrams shown here, match each of the drawings with the following ionic compounds: $\mathrm{Al}_{2} \mathrm{O}_{3}, \mathrm{LiH}, \mathrm{Na}_{2} \mathrm{~S}, \mathrm{Mg}\left(\mathrm{NO}_{3}\right)_{2}$. (Green spheres represent cations and red spheres represent anions.)

(a)

(b)

(c)

(d)
2.86 Given the formulas for the ionic compounds, draw the correct ratio of cations to anions as shown in Problem 2.85: (a) $\mathrm{BaSO}_{4}$, (b) $\mathrm{CaF}_{2}$, (c) $\mathrm{Mg}_{3} \mathrm{~N}_{2}$, (d) $\mathrm{K}_{2} \mathrm{O}$.

## Additional Problems

2.87 Define the following terms: acids, bases, oxoacids, oxoanions, and hydrates.
2.88 A sample of a uranium compound is found to be losing mass gradually. Explain what is happening to the sample.
2.89 In which one of the following pairs do the two species resemble each other most closely in chemical properties: (a) ${ }_{1}^{1} \mathrm{H}$ and ${ }_{1}^{1} \mathrm{H}^{+}$, (b) ${ }_{7}^{14} \mathrm{~N}$ and ${ }_{7}^{14} \mathrm{~N}^{3-}$, (c) ${ }_{6}^{12} \mathrm{C}$ and ${ }_{6}^{13} \mathrm{C}$ ? Explain.
\$2.90 One isotope of a metallic element has mass number 65 and 35 neutrons in the nucleus. The cation derived from the isotope has 28 electrons. Write the symbol for this cation.
2.91 One isotope of a nonmetallic element has mass number 127 and 74 neutrons in the nucleus. The anion derived from the isotope has 54 electrons. Write the symbol for this anion.

E 2.92 The following table gives numbers of electrons, protons, and neutrons in atoms or ions of a number of elements. Answer the following: (a) Which of the species are neutral? (b) Which are negatively charged? (c) Which are positively charged? (d) What are the conventional symbols for all the species?

Atom or Ion of Element

|  | A | B | C | D | E | F | G |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| Number of electrons | 5 | 10 | 18 | 28 | 36 | 5 | 9 |
| Number of protons | 5 | 7 | 19 | 30 | 35 | 5 | 9 |
| Number of neutrons | 5 | 7 | 20 | 36 | 46 | 6 | 10 |

2.93 What is wrong with or ambiguous about the phrase "four molecules of $\mathrm{NaCl} "$ ?
2.94 The following phosphorus sulfides are known: $\mathrm{P}_{4} \mathrm{~S}_{3}, \mathrm{P}_{4} \mathrm{~S}_{7}$, and $\mathrm{P}_{4} \mathrm{~S}_{10}$. Do these compounds obey the law of multiple proportions?
$\boldsymbol{G} 2.95$ Which of the following are elements, which are molecules but not compounds, which are compounds but not molecules, and which are both compounds and molecules? (a) $\mathrm{SO}_{2}$, (b) $\mathrm{S}_{8}$, (c) Cs , (d) $\mathrm{N}_{2} \mathrm{O}_{5}$, (e) O , (f) $\mathrm{O}_{2}$, (g) $\mathrm{O}_{3}$, (h) $\mathrm{CH}_{4}$, (i) KBr , (j) S , (k) $\mathrm{P}_{4}$, (l) LiF.
2.96 What is wrong with the name (given in parentheses or brackets) for each of the following compounds: (a) $\mathrm{BaCl}_{2}$ (barium dichloride), (b) $\mathrm{Fe}_{2} \mathrm{O}_{3}$ [iron(II) oxide], (c) $\mathrm{CsNO}_{2}$ (cesium nitrate), (d) $\mathrm{Mg}\left(\mathrm{HCO}_{3}\right)_{2}$ [magnesium(II) bicarbonate]?
2.97 Discuss the significance of assigning an atomic mass of exactly 12 amu to the carbon- 12 isotope.

EI 2.98 Determine what is wrong with the chemical formula and write the correct chemical formula for each of the following compounds: (a) $\left(\mathrm{NH}_{3}\right)_{2} \mathrm{CO}_{3}$ (ammonium carbonate), (b) CaOH (calcium hydroxide), (c) $\mathrm{CdSO}_{3}$ (cadmium sulfide), (d) $\mathrm{ZnCrO}_{4}$ (zinc dichromate).

E 2.99 Fill in the blanks in the table:

| Symbol |  | ${ }_{26}^{54} \mathrm{Fe}^{2+}$ |  |  |  |
| :--- | :---: | :---: | :---: | ---: | ---: |
| Protons | 5 |  |  | 79 | 86 |
| Neutrons | 6 |  | 16 | 117 | 136 |
| Electrons | 5 |  | 18 | 79 |  |
| Net charge |  |  | -3 |  | 0 |

2.100 (a) Which elements are most likely to form ionic compounds?
(b) Which metallic elements are most likely to form cations with different charges?

G 2.101 Write the formula of the common ion derived from each of the following: (a) Li , (b) S , (c) I, (d) N , (e) Al , (f) Cs , (g) Mg .
2.102 Which of the following symbols provides more information about the atom: ${ }^{23} \mathrm{Na}$ or ${ }_{11} \mathrm{Na}$ ? Explain.

EI2.103 Write the chemical formulas and names of the binary acids and oxoacids that contain Group 7A elements. Do the same for elements in Groups 3A, 4A, 5A, and 6A.

E 2.104 Determine the molecular and empirical formulas of the compounds shown here. (Black spheres are carbon, and white spheres are hydrogen.)

(a)

(b)

(c)

(d)
$\boldsymbol{y} \boldsymbol{2 . 1 0 5}$ For the noble gases (the Group 8A elements) ${ }_{2}^{4} \mathrm{He},{ }_{10}^{20} \mathrm{Ne},{ }_{18}^{40} \mathrm{Ar}$, ${ }_{36}^{84} \mathrm{Kr}$, and ${ }_{54}^{132} \mathrm{Xe}$, (a) determine the number of protons and neutrons in the nucleus of each atom, and (b) determine the ratio of neutrons to protons in the nucleus of each atom. Describe any general trend you discover in the way this ratio changes with increasing atomic number.
$\leftrightarrows$ 2.106 List the elements that exist as gases at room temperature. (Hint: Most of these elements can be found in Groups 5A, 6A, 7A, and 8A.)
2.107 The Group 1B metals, $\mathrm{Cu}, \mathrm{Ag}$, and Au , are called coinage metals. What chemical properties make them especially suitable for making coins and jewelry?
2.108 The elements in Group 8A of the periodic table are called noble gases. Can you suggest what "noble" means in this context?

E 2.109 The formula for calcium oxide is CaO . What are the formulas for magnesium oxide and strontium oxide?
2.110 A common mineral of barium is barytes, or barium sulfate $\left(\mathrm{BaSO}_{4}\right)$. Because elements in the same periodic group have similar chemical properties, we might expect to find some radium sulfate $\left(\mathrm{RaSO}_{4}\right)$ mixed with barytes since radium is the last member of Group 2A. However, the only source of radium compounds in nature is in uranium minerals. Why?
2.111 List five elements each that are (a) named after places, (b) named after people, (c) named after a color. (Consult www.Google.com, www.Wikipedia.com, or www.Webelements.com.)
2.112 Name the only country that is named after an element. (Hint: This country is in South America.)
2.113 Fluorine reacts with hydrogen $(\mathrm{H})$ and deuterium $(\mathrm{D})$ to form hydrogen fluoride (HF) and deuterium fluoride (DF), where deuterium $\left({ }_{1}^{2} \mathrm{H}\right)$ is an isotope of hydrogen. Would a given amount of fluorine react with different masses of the two hydrogen isotopes? Does this violate the law of definite proportion? Explain.

E2.114 Predict the formula and name of a binary compound formed from the following elements: (a) Na and H , (b) B and O , (c) Na and S , (d) Al and F , (e) F and O , (f) Sr and Cl .

E| 2.115 Identify each of the following elements: (a) a halogen whose anion contains 36 electrons, (b) a radioactive noble gas with 86 protons, (c) a Group 6A element whose anion contains 36 electrons, (d) an alkali metal cation that contains 36 electrons, (e) a Group 4A cation that contains 80 electrons.

H2.116 Show the locations of (a) alkali metals, (b) alkaline earth metals, (c) the halogens, and (d) the noble gases in the given outline of a periodic table. Also draw dividing lines between metals and metalloids and between metalloids and nonmetals.

2.117 Fill in the blanks in the table.

| Cation | Anion | Formula | Name |
| :---: | :---: | :---: | :---: |
|  |  |  | Magnesium bicarbonate |
|  |  | $\mathrm{SrCl}_{2}$ |  |
| $\mathrm{Fe}^{3+}$ | $\mathrm{NO}_{2}^{-}$ |  |  |
|  |  |  | Manganese(II) chlorate |
|  |  | $\mathrm{SnBr}_{4}$ |  |
| $\mathrm{Co}^{2+}$ | $\mathrm{PO}_{4}^{3-}$ |  |  |
| $\mathrm{Hg}_{2}^{2+}$ | $\mathrm{I}^{-}$ |  |  |
|  |  | $\mathrm{Cu}_{2} \mathrm{CO}_{3}$ |  |
|  |  |  | Lithium nitride |
| $\mathrm{Al}^{3+}$ | $\mathrm{S}^{2-}$ |  |  |

E 2.118 Some compounds are better known by their common names than by their systematic chemical names. Give the chemical formulas of the following substances: (a) dry ice, (b) salt, (c) laughing gas, (d) marble (chalk, limestone), (e) baking soda, (f) ammonia, (g) water, (h) milk of magnesia, (i) epsom salt.

E 2.119 In the footnote on page 37 it was pointed out that mass and energy are alternate aspects of a single entity called mass-energy. The relationship between these two physical quantities is Einstein's equation, $E=m c^{2}$, where $E$ is energy, $m$ is mass, and $c$ is the
speed of light. In a combustion experiment, it was found that 12.096 g of hydrogen molecules combined with 96.000 g of oxygen molecules to form water and released $1.715 \times 10^{3} \mathrm{~kJ}$ of heat. Use Einstein's equation to calculate the corresponding mass change in this process, and comment on whether or not the law of conservation of mass holds for ordinary chemical processes.
2.120 (a) Describe Rutherford's experiment and how the results revealed the nuclear structure of the atom. (b) Consider the ${ }^{23} \mathrm{Na}$ atom. Given that the radius and mass of the nucleus are $3.04 \times 10^{-15} \mathrm{~m}$ and $3.82 \times 10^{-23} \mathrm{~g}$, respectively, calculate the density of the nucleus in $\mathrm{g} / \mathrm{cm}^{3}$. The radius of a ${ }^{23} \mathrm{Na}$ atom is 186 pm . Calculate the density of the space occupied by the electrons outside the nucleus in the sodium atom. Do your results support Rutherford's model of an atom? [The volume of a sphere of radius $r$ is $\frac{4}{3} \pi r^{3}$.]
2.121 Draw all possible structural formulas of the following hydrocarbons: $\mathrm{CH}_{4}, \mathrm{C}_{2} \mathrm{H}_{6}, \mathrm{C}_{3} \mathrm{H}_{8}, \mathrm{C}_{4} \mathrm{H}_{10}, \mathrm{C}_{5} \mathrm{H}_{12}$.
2.122 Draw two different structural formulas based on the molecular formula $\mathrm{C}_{2} \mathrm{H}_{6} \mathrm{O}$. Is the fact that you can have more than one compound with the same molecular formula consistent with Dalton's atomic theory?

EI 2.123 Ethane and acetylene are two gaseous hydrocarbons. Chemical analyses show that in one sample of ethane, 2.65 g of carbon are combined with 0.665 g of hydrogen, and in one sample of acetylene, 4.56 g of carbon are combined with 0.383 g of hydrogen. (a) Are these results consistent with the law of multiple proportions?
(b) Write reasonable molecular formulas for these compounds.

E 2.124 A cube made of platinum (Pt) has an edge length of 1.0 cm . (a) Calculate the number of Pt atoms in the cube. (b) Atoms are spherical in shape. Therefore, the Pt atoms in the cube cannot fill all the available space. If only 74 percent of the space inside the cube is taken up by Pt atoms, calculate the radius in picometers of a Pt atom. The density Pt is $21.45 \mathrm{~g} / \mathrm{cm}^{3}$, and the mass of a single Pt atom is $3.240 \times 10^{-22} \mathrm{~g}$. [The volume of a sphere of radius $r$ is $\frac{4}{3} \pi r^{3}$.]

H2.125 A monatomic ion has a charge of +2 . The nucleus of the parent atom has a mass number of 55 . If the number of neutrons in the nucleus is 1.2 times that of the number of protons, what is the name and symbol of the element?
2.126 In the following $2 \times 2$ crossword, each letter must be correct in four ways: horizontally, vertically, diagonally, and by itself. When the puzzle is complete, the four spaces will contain the
overlapping symbols of 10 elements. Use capital letters for each square. There is only one correct solution.

## Horizontal

1-2: Two-letter symbol for a metal used in ancient times
3-4: Two-letter symbol for a metal that burns in air and is found in Group 5A

Vertical
1-3: Two-letter symbol for a metalloid
2-4: Two-letter symbol for a metal used in U.S. coins

## Single Square

1: A colorful nonmetal
A colorless gaseous nonmetal
An element that makes fireworks green
An element that has medicinal uses
Diagonal
1-4: Two-letter symbol for an element used in electronics 2-3: Two-letter symbol for a metal used with Zr to make wires for superconducting magnets

EI2.127 Name the given acids.

2.128 (a) Assuming an atomic nucleus is spherical in shape, show that its radius $r$ is proportional to the cube root of the mass number (A). (b) In general, the radius of a nucleus is given by $r=r_{0} A^{1 / 3}$, where $r_{0}$ is a proportionality constant given by $1.2 \times 10^{-15} \mathrm{~m}$. Calculate the volume of the Li nucleus. (c) Given that the radius of a ${ }_{3}{ }^{7} \mathrm{Li}$ atom is 152 pm , calculate what fraction of the atom's volume is occupied by its nucleus. Does your result support Rutherford's model of the atom?

## Pre-Professional Practice Exam Problems: Physical and Biological Sciences

Carbon-14, a radioactive isotope of carbon, is used to determine the ages of fossils in a technique called carbon dating. Carbon-14 is produced in the upper atmosphere when nitrogen-14 atoms are bombarded by neutrons from cosmic rays. ${ }^{14} \mathrm{C}$ undergoes a process called $\beta$ emission in which a neutron in the nucleus decays to form a proton and an electron. The electron, or $\beta$ particle, is ejected from the nucleus. Because the production and decay of ${ }^{14} \mathrm{C}$ occur simultaneously, the total amount of ${ }^{14} \mathrm{C}$ in the atmosphere is constant. Plants absorb ${ }^{14} \mathrm{C}$ in the form of $\mathrm{CO}_{2}$ and animals consume plants and other animals. Thus, all living things contain a constant ratio of ${ }^{12} \mathrm{C}$ to ${ }^{14} \mathrm{C}$. When a living thing dies, the ${ }^{14} \mathrm{C}$ it contains continues to decay but because replenishment ceases, the ratio of ${ }^{12} \mathrm{C}$ to ${ }^{14} \mathrm{C}$ changes over time. Scientists use the ${ }^{12} \mathrm{C}$ to ${ }^{14} \mathrm{C}$ ratio to determine the age of material that was once living.

1. If atmospheric conditions were to change such that ${ }^{14} \mathrm{C}$ were produced at twice the current rate,
a) the world's supply of ${ }^{14} \mathrm{~N}$ would be consumed completely.
b) the ${ }^{12} \mathrm{C}$ to ${ }^{14} \mathrm{C}$ ratio in living things would increase.
c) the ${ }^{12} \mathrm{C}$ to ${ }^{14} \mathrm{C}$ ratio in living things would decrease.
d) the ${ }^{12} \mathrm{C}$ to ${ }^{14} \mathrm{C}$ ratio in living things would not change.
2. When a ${ }^{14} \mathrm{~N}$ nucleus is bombarded by a neutron to produce a ${ }^{14} \mathrm{C}$ nucleus, what else is produced?
a) Nothing
b) Another neutron
c) An electron
d) A proton
3. Based on the description of $\beta$ emission in the passage, what nucleus results from the decay of a ${ }^{14} \mathrm{C}$ nucleus by $\beta$ emission?
a) ${ }^{14} \mathrm{~N}$
b) ${ }^{13} \mathrm{~N}$
c) ${ }^{12} \mathrm{C}$
d) ${ }^{13} \mathrm{C}$
4. The accuracy of carbon dating depends on the assumption that
a) ${ }^{14} \mathrm{C}$ is the only radioactive species in the material being tested.
b) the rate of decay of ${ }^{14} \mathrm{C}$ is constant.
c) ${ }^{12} \mathrm{C}$ and ${ }^{14} \mathrm{C}$ undergo radioactive decay at the same rate.
d) each ${ }^{14} \mathrm{C}$ nucleus decays to give a ${ }^{12} \mathrm{C}$ nucleus.

## Stoichiometry's Importance in the Manufacture of Drugs

Stoichiometry refers to the quantitative relationships between the substances that are consumed and produced by chemical reactions. These quantitative relationships are important in the development of large-scale production of such things as chemotherapeutic drugs for the treatment of cancer.

One of cancer chemotherapy's greatest success stories began with an accidental discovery. In 1964, Barnett Rosenberg and his research group at Michigan State University were studying the effect of an electric field on the growth of bacteria. Using platinum electrodes, they passed an electric current through a bacterial culture. To their surprise, the cells in the culture stopped dividing. The researchers determined that cisplatin, $\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{2} \mathrm{Cl}_{2}$, a compound containing platinum from the electrodes, was responsible. Furthermore, they reasoned that because cancer is the result of the uncontrolled division of abnormal cells, the compound might be useful as an anticancer drug.

Platinol, the name under which cisplatin is marketed, was approved by the FDA in 1978 for the treatment of metastatic testicular and ovarian cancers. Today it is one of the most widely prescribed cancer drugs-being used also for cancers of the bladder, lung, and stomach—and is probably best known for the role it played in seven-time Tour de France winner Lance Armstrong's battle with testicular cancer. Cisplatin works by attaching itself to the DNA of cancer cells and preventing their replication. The damaged cells are then destroyed by the body's immune system. Unfortunately, cisplatin can cause serious side effects, including severe kidney damage. Ongoing research efforts are directed toward finding related compounds that are less toxic.

In 1964, cisplatin was produced accidentally when platinum electrodes reacted with ammonia molecules and chloride ions that were present in a bacterial culture. Today, manufacturers use the principles of stoichiometry to produce cisplatin in the most efficient, economical way possible.

At the end of this chapter, you will be able to solve several problems related to the drug cisplatin.

## In This Chapter, You Will Learn:

How we use chemical equations to represent chemical reactions. You will also learn how balanced chemical equations are used to solve a variety of problems.

Before you begin, you should review

- Average atomic mass [ 14 Section 2.5]
- Molecular formulas [164 Section 2.6]

Caffeine

Think About It Double-check that you have counted the number of atoms correctly for each compound and that you have used the proper atomic masses from the periodic table.

### 3.1 Molecular and Formula Masses

Using atomic masses from the periodic table and a molecular formula, we can determine the molecular mass, which is the mass in atomic mass units (amu) of an individual molecule. The molecular mass is simply the sum of the atomic masses of the atoms that make up the molecule. We multiply the atomic mass of each element by the number of atoms of that element in the molecule and then sum the masses for each element present. For example,

$$
\text { molecular mass of } \begin{aligned}
\mathrm{H}_{2} \mathrm{O} & =2(\text { atomic mass of } \mathrm{H})+\text { atomic mass of } \mathrm{O} \\
& =2(1.008 \mathrm{amu})+16.00 \mathrm{amu}=18.02 \mathrm{amu}
\end{aligned}
$$

Because the atomic masses on the periodic table are average atomic masses, the result of such a determination is an average molecular mass, sometimes referred to as the molecular weight. As with the term atomic mass, we will use the term molecular mass in this text.

Although an ionic compound does not have a molecular mass, we can use its empirical formula to determine its formula mass (the mass of a "formula unit"), sometimes called the formula weight. Sample Problem 3.1 illustrates how to determine molecular mass and formula mass.

## Sample Problem 3.1

Calculate the molecular mass or the formula mass, as appropriate, for each of the following compounds: (a) propane, $\left(\mathrm{C}_{3} \mathrm{H}_{8}\right)$, (b) lithium hydroxide, $(\mathrm{LiOH})$, and (c) barium acetate, $\left[\mathrm{Ba}\left(\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right)_{2}\right]$.

Strategy Determine the molecular mass (for each molecular compound) or formula mass (for each ionic compound) by summing all the atomic masses.

Setup Using the formula for each compound, determine the number of atoms of each element present. A molecule of propane contains three C atoms and eight H atoms. The compounds in parts (b) and (c) are ionic and will therefore have formula masses rather than molecular masses. A formula unit of lithium hydroxide contains one Li atom, one O atom, and one H atom. A formula unit of barium acetate contains one Ba atom, four C atoms, six H atoms, and four O atoms. (Remember that the subscript after the parentheses means that there are two acetate ions, each of which contains two C atoms, three H atoms, and two O atoms.)

Solution For each compound, multiply the number of atoms by the atomic mass of each element and then sum the calculated values.
(a) The molecular mass of propane is $3(12.01 \mathrm{amu})+8(1.008 \mathrm{amu})=44.09 \mathrm{amu}$.
(b) The formula mass of lithium hydroxide is $6.941 \mathrm{amu}+16.00 \mathrm{amu}+1.008 \mathrm{amu}=23.95 \mathrm{amu}$.
(c) The formula mass of barium acetate is $137.3 \mathrm{amu}+4(12.01 \mathrm{amu})+6(1.008 \mathrm{amu})+$ $4(16.00 \mathrm{amu})=255.4 \mathrm{amu}$.

Practice Problem A Calculate the molecular or formula mass of each of the following compounds: (a) magnesium chloride $\left(\mathrm{MgCl}_{2}\right)$, (b) sulfuric acid $\left(\mathrm{H}_{2} \mathrm{SO}_{4}\right)$, and (c) ibuprofen $\left(\mathrm{C}_{13} \mathrm{H}_{18} \mathrm{O}_{2}\right)$.

EPractice Problem B Calculate the molecular or formula mass of each of the following compounds: (a) calcium carbonate $\left(\mathrm{CaCO}_{3}\right)$, (b) nitrous acid $\left(\mathrm{HNO}_{2}\right)$, and (c) caffeine $\left(\mathrm{C}_{8} \mathrm{H}_{10} \mathrm{~N}_{4} \mathrm{O}_{2}\right)$.

## Checkpoint 3.1 Molecular and Formula Masses

Citric acid
3.1.1 What is the molecular mass of citric acid $\left(\mathrm{H}_{3} \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}_{7}\right)$ ?
a) 192.12 amu
b) 189.10 amu
c) 132.07 amu
d) 29.02 amu
e) 89.07 amu
3.1.2 What is the formula mass of calcium citrate $\left[\mathrm{Ca}_{3}\left(\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}_{7}\right)_{2}\right]$ ?
a) 309.34 amu
b) 69.10 amu
c) 229.18 amu
d) 498.44 amu
e) 418.28 amu

### 3.2 Percent Composition of Compounds

The formula of a compound indicates the number of atoms of each element in a unit of the compound. From a molecular or empirical formula, we can calculate what percent of the total mass is contributed by each element in a compound. A list of the percent by mass of each element in a compound is known as the compound's percent composition by mass. One way that the purity of a compound can be verified is by comparing its percent composition by mass, determined experimentally, with its calculated percent composition. Percent composition is calculated by dividing the mass of each element in a unit of the compound by the molecular or formula mass of the compound and then multiplying by 100 percent. Mathematically, the percent by mass of an element in a compound is expressed as
percent by mass of an element $=\frac{n \times \text { atomic mass of element }}{\text { molecular or formula mass of compound }} \times 100 \% \quad$ Equation 3.1
where $n$ is the number of atoms of the element in a molecule or formula unit of the compound. For example, in a molecule of hydrogen peroxide $\left(\mathrm{H}_{2} \mathrm{O}_{2}\right)$, there are two H atoms and two O atoms. The atomic masses of H and O are 1.008 and 16.00 amu , respectively, so the molecular mass of $\mathrm{H}_{2} \mathrm{O}_{2}$ is 34.02 amu . Therefore, the percent composition of $\mathrm{H}_{2} \mathrm{O}_{2}$ is calculated as follows:

$$
\begin{aligned}
& \% \mathrm{H}=\frac{2 \times 1.008 \mathrm{amu} \mathrm{H}}{34.02 \mathrm{amu} \mathrm{H} \mathrm{O}_{2}} \times 100 \%=5.926 \% \\
& \% \mathrm{O}=\frac{2 \times 16.00 \mathrm{amu} \mathrm{O}}{34.02 \mathrm{amu} \mathrm{H} \mathrm{H}_{2} \mathrm{O}_{2}} \times 100 \%=94.06 \%
\end{aligned}
$$

The sum of percentages is $5.296 \%+94.06 \%=99.99 \%$. The small discrepancy from 100 percent is due to rounding of the atomic masses of the elements. We could equally well have used the empirical formula of hydrogen peroxide (HO) for the calculation. In this case, we would have used the empirical formula mass, 17.01 amu , in place of the molecular mass.

$$
\begin{aligned}
& \% \mathrm{H}=\frac{1.008 \mathrm{amu} \mathrm{H}}{17.01 \mathrm{amu}} \times 100 \%=5.926 \% \\
& \% \mathrm{O}=\frac{16.00 \mathrm{amu} \mathrm{O}}{17.01 \mathrm{amu}} \times 100 \%=94.06 \%
\end{aligned}
$$

Because both the molecular formula and the empirical formula tell us the composition of the compound, they both give the same percent composition by mass. Sample Problem 3.2 shows how to calculate percent composition by mass.

## Sample Problem 3.2

Lithium carbonate $\left(\mathrm{Li}_{2} \mathrm{CO}_{3}\right)$ was the first "mood-stabilizing" drug approved by the FDA for the treatment of mania and manic-depressive illness, also known as bipolar disorder. Calculate the percent composition by mass of lithium carbonate.

Strategy Use Equation 3.1 to determine the percent by mass contributed by each element in the compound.

Setup Lithium carbonate is an ionic compound that contains $\mathrm{Li}, \mathrm{C}$, and O . In a formula unit, there are two Li atoms, one C atom, and three O atoms with atomic masses $6.941,12.01$, and 16.00 amu , respectively. The formula mass of $\mathrm{Li}_{2} \mathrm{CO}_{3}$ is $2(6.941 \mathrm{amu})+12.01 \mathrm{amu}+3(16.00 \mathrm{amu})=73.89 \mathrm{amu}$.

## Solution

For each element, multiply the number of atoms by the atomic mass, divide by the formula mass, and multiply by 100 percent.

$$
\begin{aligned}
& \% \mathrm{Li}=\frac{2 \times 6.941 \mathrm{amu} \mathrm{Li}}{73.89 \mathrm{amu} \mathrm{Li}_{2} \mathrm{CO}_{3}} \times 100 \%=18.79 \% \\
& \% \mathrm{C}=\frac{12.01 \mathrm{amu} \mathrm{C}}{73.89 \mathrm{amu} \mathrm{Li}_{2} \mathrm{CO}_{3} \times 100 \%=16.25 \%} \\
& \% \mathrm{O}=\frac{3 \times 16.00 \mathrm{amu} \mathrm{O}}{73.89 \mathrm{amu} \mathrm{Li}_{2} \mathrm{CO}_{3} \times 100 \%=64.96 \%}
\end{aligned}
$$

Think About It Make sure that the percent composition results for a compound sum to approximately 100. (In this case, the results sum to exactly 100 percent- $18.79 \%+$ $16.25 \%+64.96 \%=100.00 \%-$ but remember that because of rounding, the percentages may sum to very slightly more or very slightly less.)

Practice Problem A Determine the percent composition by mass of acetaminophen $\left(\mathrm{C}_{8} \mathrm{H}_{9} \mathrm{NO}_{2}\right)$, the active ingredient in over-the-counter pain relievers such as Tylenol (Figure 3.1).

EPractice Problem B Determine the percent composition by mass of the artificial sweetener aspartame $\left(\mathrm{C}_{14} \mathrm{H}_{18} \mathrm{~N}_{2} \mathrm{O}_{5}\right)$.

Figure 3.1 Acetaminophen is the active ingredient in Tylenol, a nonaspirin pain reliever.

## Checkpoint 3.2 Percent Composition of Compounds

Aspirin
3.2.1 What is the percent composition by mass of aspirin $\left(\mathrm{C}_{9} \mathrm{H}_{8} \mathrm{O}_{4}\right)$ ?
a) $44.26 \% \mathrm{C}, 3.28 \% \mathrm{H}, 52.46 \% \mathrm{O}$
b) $60.00 \% \mathrm{C}, 4.47 \% \mathrm{H}, 35.53 \% \mathrm{O}$
c) $41.39 \% \mathrm{C}, 3.47 \% \mathrm{H}, 55.14 \% \mathrm{O}$
d) $42.86 \% \mathrm{C}, 6.35 \% \mathrm{H}, 50.79 \% \mathrm{O}$
e) $42.86 \% \mathrm{C}, 38.09 \% \mathrm{H}, 19.05 \% \mathrm{O}$
3.2.2 What is the percent composition by mass of sodium bicarbonate $\left(\mathrm{NaHCO}_{3}\right)$ ?
a) $20.89 \% \mathrm{Na}, 2.75 \% \mathrm{H}, 32.74 \% \mathrm{C}$, $43.62 \% \mathrm{O}$
b) $44.20 \% \mathrm{Na}, 1.94 \% \mathrm{H}, 23.09 \% \mathrm{C}$, $30.76 \% \mathrm{O}$
c) $21.28 \% \mathrm{Na}, 0.93 \% \mathrm{H}, 33.35 \% \mathrm{C}$, $44.43 \% \mathrm{O}$
d) $44.20 \% \mathrm{Na}, 1.94 \% \mathrm{H}, 23.09 \% \mathrm{C}$, $30.76 \% \mathrm{O}$
e) $27.37 \% \mathrm{Na}, 1.20 \% \mathrm{H}, 14.30 \% \mathrm{C}$, $57.14 \%$ O

### 3.3 Chemical Equations

A chemical reaction, as described in the third hypothesis of Dalton's atomic theory [ 14 Section 2.1], is the rearrangement of atoms in a sample of matter. Examples include the rusting of iron and the explosive combination of hydrogen and oxygen gases to produce water. A chemical equation uses chemical symbols to denote what occurs in a chemical reaction. We have seen how chemists represent elements and compounds using chemical symbols. Now we will look at how chemists represent chemical reactions using chemical equations.

## Interpreting and Writing Chemical Equations

A chemical equation represents a chemical statement. When you encounter a chemical equation, you may find it useful to read it as though it were a sentence.

Read

$$
\mathrm{NH}_{3}+\mathrm{HCl} \longrightarrow \mathrm{NH}_{4} \mathrm{Cl}
$$

as "Ammonia and hydrogen chloride react to produce ammonium chloride."

Read

$$
\mathrm{CaCO}_{3} \longrightarrow \mathrm{CaO}+\mathrm{CO}_{2}
$$

as "Calcium carbonate reacts to produce calcium oxide and carbon dioxide." Thus, the plus signs can be interpreted simply as the word and, and the arrows can be interpreted as the phrase "react(s) to produce."

In addition to interpreting chemical equations, you must also be able to write chemical equations to represent reactions. For example, the equation for the process by which sulfur and oxygen react to produce sulfur dioxide is written as

$$
\mathrm{S}+\mathrm{O}_{2} \longrightarrow \mathrm{SO}_{2}
$$

Likewise, we write the equation for the reaction of sulfur trioxide and water to produce sulfuric acid as

$$
\mathrm{SO}_{3}+\mathrm{H}_{2} \mathrm{O} \longrightarrow \mathrm{H}_{2} \mathrm{SO}_{4}
$$

Each chemical species that appears to the left of the arrow is called a reactant. Reactants are those substances that are consumed in the course of a chemical reaction. Each species that appears to the right of the arrow is called a product. Products are the substances that form during the course of a chemical reaction.

Chemists usually indicate the physical states of reactants and products with italicized letters in parentheses following each species in the equation. Gases, liquids, and solids are labeled with $(g),(l)$, and $(s)$, respectively. Chemical species that are dissolved in water are said to be aqueous and are labeled $(a q)$. The equation examples given previously can be written as follows:

$$
\begin{gathered}
\mathrm{NH}_{3}(g)+\mathrm{HCl}(g) \longrightarrow \mathrm{NH}_{4} \mathrm{Cl}(s) \quad \mathrm{S}(s)+\mathrm{O}_{2}(g) \longrightarrow \mathrm{SO}_{2}(g) \\
\mathrm{CaCO}_{3}(s) \longrightarrow \mathrm{CaO}(s)+\mathrm{CO}_{2}(g) \quad \mathrm{SO}_{3}(g)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}_{2} \mathrm{SO}_{4}(a q)
\end{gathered}
$$

In some cases, the physical state must be expressed more specifically. Carbon, for example, exists in two different solid forms: diamond and graphite. Rather than simply write $\mathrm{C}(s)$, we must specify the form of solid carbon by writing C (diamond) or C (graphite).

$$
\begin{aligned}
& \mathrm{C}(\text { graphite })+\mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g) \\
& \mathrm{C} \text { (diamond) }+\mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g)
\end{aligned}
$$

Chemical equations are also used to represent physical processes. Sucrose $\left(\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}\right)$ dissolving in water, for example, is a physical process [ $1 / 4$ Section 1.2] that can be represented with the following chemical equation:

$$
\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}(s) \xrightarrow{\mathrm{H}_{2} \mathrm{O}} \mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}(a q)
$$

The $\mathrm{H}_{2} \mathrm{O}$ over the arrow in the equation denotes the process of dissolving a substance in water. Although formulas or symbols often are omitted for simplicity, they can be written over an arrow in a chemical equation to indicate the conditions under which the reaction takes place. For example, in the chemical equation

$$
2 \mathrm{KClO}_{3}(\mathrm{~s}) \xrightarrow{\Delta} 2 \mathrm{KCl}(\mathrm{~s})+3 \mathrm{O}_{2}(\mathrm{~g})
$$

the symbol $\Delta$ indicates that the addition of heat is necessary to make $\mathrm{KClO}_{3}$ react to form KCl and $\mathrm{O}_{2}$.

## Balancing Chemical Equations

Based on what you have learned so far, the chemical equation for the explosive reaction of hydrogen gas with oxygen gas to form liquid water would be

This equation as written violates the law of conservation of mass, however, because four atoms (two H and two O ) react to produce only three atoms (two H and one O ).

Student Annotation: Some problems in later chapters can be solved only if the states of reactants and products are specified. It is a good idea to get in the habit now of including the physical states of reactants and products in the chemical equations that you write.

Student Annotation: Students sometimes fear that they will be asked to determine the products of an unfamiliar chemical reactionand will be unable to do so. In this chapter and in Chapter 4, you will learn how to deduce the products of several different types of reactions.

Student Annotation: When we study electrochemistry in detail, we will learn a method for balancing certain equations that does allow the addition of $\mathrm{H}_{2} \mathrm{O}, \mathrm{H}^{+}$, and $\mathrm{OH}^{-}$ [ 1 Section 19.1].

Student Annotation: Combustion refers to burning in the presence of oxygen. Combustion of a hydrocarbon such as butane produces carbon dioxide and water.

The equation must be balanced so that the same number of each kind of atom appears on both sides of the reaction arrow. Balancing is achieved by writing appropriate stoichiometric coefficients (often referred to simply as coefficients) to the left of the chemical formulas. In this case, we write a coefficient of 2 to the left of both the $\mathrm{H}_{2}(g)$ and the $\mathrm{H}_{2} \mathrm{O}(l)$ :

There are now four H atoms and two O atoms on each side of the arrow. When balancing a chemical equation, we can change only the coefficients that precede the chemical formulas, not the subscripts within the chemical formulas. Changing the subscripts would change the formulas for the species involved in the reaction. For example, changing the product from $\mathrm{H}_{2} \mathrm{O}$ to $\mathrm{H}_{2} \mathrm{O}_{2}$ would result in equal numbers of each kind of atom on both sides of the equation, but the equation we set out to balance represented the combination of hydrogen gas and oxygen gas to form water, not hydrogen peroxide. Additionally, we cannot add reactants or products to the chemical equation for the purpose of balancing it. To do so would result in an equation that represents the wrong reaction. The chemical equation must be made quantitatively correct without changing its qualitative chemical statement.

Balancing a chemical equation requires something of a trial-and-error approach. You may find that you change the coefficient for a particular reactant or product, only to have to change it again later in the process. In general, it will facilitate the balancing process if you do the following:

1. Change the coefficients of compounds (e.g., $\mathrm{CO}_{2}$ ) before changing the coefficients of elements (e.g., $\mathrm{O}_{2}$ ).
2. Treat polyatomic ions that appear on both sides of the equation (e.g., $\mathrm{CO}_{3}^{2-}$ ) as units, rather than counting their constituent atoms individually.
3. Count atoms and/or polyatomic ions carefully, and track their numbers each time you change a coefficient.

To balance the chemical equation for the combustion of butane, we first take an inventory of the numbers of each type of atom on each side of the arrow.

$$
\begin{gathered}
\mathrm{C}_{4} \mathrm{H}_{10}(g)+\mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l) \\
4-\mathrm{C}-1 \\
10-\mathrm{H}-2 \\
2-\mathrm{O}-3
\end{gathered}
$$

Initially, there are four C atoms on the left and one on the right; ten H atoms on the left and two on the right; and two O atoms on the left with three on the right. As a first step, we will place a coefficient of 4 in front of $\mathrm{CO}_{2}(\mathrm{~g})$ on the product side.

$$
\begin{gathered}
\mathrm{C}_{4} \mathrm{H}_{10}(g)+\mathrm{O}_{2}(g) \longrightarrow 4 \mathrm{CO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l) \\
4-\mathrm{C}-4 \\
10-\mathrm{H}-2 \\
2-\mathrm{O}-9
\end{gathered}
$$

This changes the tally of atoms as shown. Thus, the equation is balanced for carbon, but not for hydrogen or oxygen. Next, we place a coefficient of 5 in front of $\mathrm{H}_{2} \mathrm{O}(l)$ on the product side and tally the atoms on both sides again.

$$
\begin{gathered}
\mathrm{C}_{4} \mathrm{H}_{10}(g)+\mathrm{O}_{2}(g) \longrightarrow 4 \mathrm{CO}_{2}(g)+5 \mathrm{H}_{2} \mathrm{O}(l) \\
4-\mathrm{C}-4 \\
10-\mathrm{H}-10 \\
2-\mathrm{O}-13
\end{gathered}
$$

Now the equation is balanced for carbon and hydrogen. Only oxygen remains to be balanced. There are 13 O atoms on the product side of the equation (eight in $\mathrm{CO}_{2}$ molecules and another five in $\mathrm{H}_{2} \mathrm{O}$ molecules), so we need 13 O atoms on the reactant side. Because each oxygen molecule contains two O atoms, we will have to place a coefficient of $\frac{13}{2}$ in front of $\mathrm{O}_{2}(\mathrm{~g})$ :

$$
\begin{gathered}
\mathrm{C}_{4} \mathrm{H}_{10}(g)+\frac{13}{2} \mathrm{O}_{2}(g) \longrightarrow 4 \mathrm{CO}_{2}(g)+5 \mathrm{H}_{2} \mathrm{O}(l) \\
4-\mathrm{C}-4 \\
10-\mathrm{H}-10 \\
13-\mathrm{O}-13
\end{gathered}
$$

With equal numbers of each kind of atom on both sides of the equation, this equation is now balanced. For now, however, you should practice balancing equations with the smallest possible whole number coefficients. Multiplying each coefficient by 2 gives all whole numbers and a final balanced equation:

$$
\begin{gathered}
2 \mathrm{C}_{4} \mathrm{H}_{10}(g)+\mathbf{1 3 O}_{2}(g) \longrightarrow \mathbf{8 \mathrm { CO } _ { 2 } ( g ) + 1 0 \mathrm { H } _ { 2 } \mathrm { O } ( l )} \\
8-\mathrm{C}-8 \\
20-\mathrm{H}-20 \\
26-\mathrm{O}-26
\end{gathered}
$$

Sample Problem 3.3 lets you practice writing and balancing a chemical equation.

## Sample Problem 3.3

Write and balance the chemical equation for the aqueous reaction of barium hydroxide and perchloric acid to produce aqueous barium perchlorate and water.

Strategy Determine the formulas and physical states of all reactants and products, and use them to write a chemical equation that makes the correct chemical statement. Finally, adjust coefficients in the resulting chemical equation to ensure that there are identical numbers of each type of atom on both sides of the reaction arrow.

Setup The reactants are $\mathrm{Ba}(\mathrm{OH})_{2}$ and $\mathrm{HClO}_{4}$, and the products are $\mathrm{Ba}\left(\mathrm{ClO}_{4}\right)_{2}$ and $\mathrm{H}_{2} \mathrm{O}$ [/44 Sections 2.6 and 2.7]. Because the reaction is aqueous, all species except $\mathrm{H}_{2} \mathrm{O}$ will be labeled (aq) in the equation. Being a liquid, $\mathrm{H}_{2} \mathrm{O}$ will be labeled ( $l$ ).

Solution The chemical statement "barium hydroxide and perchloric acid react to produce barium perchlorate and water" can be represented with the following unbalanced equation:

$$
\mathrm{Ba}(\mathrm{OH})_{2}(a q)+\mathrm{HClO}_{4}(a q) \longrightarrow \mathrm{Ba}\left(\mathrm{ClO}_{4}\right)_{2}(a q)+\mathrm{H}_{2} \mathrm{O}(l)
$$

Perchlorate ions $\left(\mathrm{ClO}_{4}^{-}\right)$appear on both sides of the equation, so count them as units, rather than count the individual atoms they contain. Thus, the tally of atoms and polyatomic ions is

$$
\begin{aligned}
& 1-\mathrm{Ba}-1 \\
& 2-\mathrm{O}-1 \\
& 3-\mathrm{H}-2 \\
& 1-\mathrm{ClO}_{4}^{-}-2
\end{aligned}
$$

The barium atoms are already balanced, and placing a coefficient of 2 in front of $\mathrm{HClO}_{4}(\mathrm{aq})$ balances the number of perchlorate ions.

$$
\begin{aligned}
\mathrm{Ba}(\mathrm{OH})_{2}(a q)+2 \mathrm{HClO}_{4}(a q) & \longrightarrow \mathrm{Ba}\left(\mathrm{ClO}_{4}\right)_{2}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \\
& \begin{array}{l}
1-\mathrm{Ba}-1 \\
2-\mathrm{O}-1 \\
4-\mathrm{H}-2 \\
2-\mathrm{ClO}_{4}^{-}-2
\end{array}
\end{aligned} \text { (not including O atoms in } \mathrm{ClO}_{4}^{-} \text {ions) }
$$

Think About It Check to be sure the equation is balanced by counting all the atoms individually.

$$
\begin{gathered}
1-\mathrm{Ba}-1 \\
10-\mathrm{O}-10 \\
4-\mathrm{H}-4 \\
2-\mathrm{Cl}-2
\end{gathered}
$$

Glycerol

Placing a coefficient of 2 in front of $\mathrm{H}_{2} \mathrm{O}(l)$ balances both the O and H atoms, giving us the final balanced equation:

$$
\begin{aligned}
& \mathrm{Ba}(\mathrm{OH})_{2}(a q)+2 \mathrm{HClO}_{4}(a q) \longrightarrow \mathrm{Ba}\left(\mathrm{ClO}_{4}\right)_{2}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l) \\
& 1-\mathrm{Ba}-1 \\
& 2-\mathrm{O}-2 \text { (not including } \mathrm{O} \text { atoms in } \mathrm{ClO}_{4}^{-} \text {ions) } \\
& 4-\mathrm{H}-4 \\
& 2-\mathrm{ClO}_{4}^{-}-2
\end{aligned}
$$

Practice Problem A Write and balance the chemical equation that represents the combustion of propane (i.e., the reaction of propane gas with oxygen gas to produce carbon dioxide gas and liquid water).

EPractice Problem B Write and balance the chemical equation that represents the reaction of sulfuric acid with sodium hydroxide to form water and sodium sulfate.

## Bringing Chemistry to Life

## The Stoichiometry of Metabolism

The carbohydrates and fats we eat are broken down into small molecules in the digestive system. Carbohydrates are broken down into simple sugars such as glucose $\left(\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}\right)$, and fats are broken down into fatty acids (carboxylic acids that contain hydrocarbon chains) and glycerol $\left(\mathrm{C}_{3} \mathrm{H}_{8} \mathrm{O}_{3}\right)$. The small molecules produced in the digestion process are subsequently consumed by a series of complex biochemical reactions. Although the metabolism of simple sugars and fatty acids involves relatively complex processes, the results are essentially the same as that of combustion-that is, simple sugars and fatty acids react with oxygen to produce carbon dioxide, water, and energy. The balanced chemical equation for the metabolism of glucose is

## Sample Problem 3.4

Butyric acid

Butyric acid (also known as butanoic acid, $\mathrm{C}_{4} \mathrm{H}_{8} \mathrm{O}_{2}$ ) is one of many compounds found in milk fat. First isolated from rancid butter in 1869 , butyric acid has received a great deal of attention in recent years as a potential anticancer agent. Assuming that the only products are $\mathrm{CO}_{2}$ and $\mathrm{H}_{2} \mathrm{O}$, write and balance the equation for the metabolism of butyric acid.

Strategy Write an unbalanced equation to represent the combination of reactants and formation of products as stated in the problem, and then balance the equation.

Setup Metabolism in this context refers to the combination of $\mathrm{C}_{4} \mathrm{H}_{8} \mathrm{O}_{2}$ with $\mathrm{O}_{2}$ to produce $\mathrm{CO}_{2}$ and $\mathrm{H}_{2} \mathrm{O}$.

## Solution

$$
\mathrm{C}_{4} \mathrm{H}_{8} \mathrm{O}_{2}(a q)+\mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l)
$$

Balance the number of C atoms by changing the coefficient for $\mathrm{CO}_{2}$ from 1 to 4 .

$$
\mathrm{C}_{4} \mathrm{H}_{8} \mathrm{O}_{2}(a q)+\mathrm{O}_{2}(g) \longrightarrow 4 \mathrm{CO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l)
$$

Balance the number of H atoms by changing the coefficient for $\mathrm{H}_{2} \mathrm{O}$ from 1 to 4 .

$$
\mathrm{C}_{4} \mathrm{H}_{8} \mathrm{O}_{2}(a q)+\mathrm{O}_{2}(g) \longrightarrow 4 \mathrm{CO}_{2}(g)+4 \mathrm{H}_{2} \mathrm{O}(l)
$$

Finally, balance the number of O atoms by changing the coefficient for $\mathrm{O}_{2}$ from 1 to 5 .

$$
\mathrm{C}_{4} \mathrm{H}_{8} \mathrm{O}_{2}(a q)+\mathbf{5} \mathrm{O}_{2}(g) \longrightarrow \mathbf{4} \mathrm{CO}_{2}(g)+\mathbf{4} \mathrm{H}_{2} \mathrm{O}(l)
$$

Practice Problem A Another compound found in milk fat that appears to have anticancer and anti-obesity properties is conjugated linoleic acid (CLA; $\mathrm{C}_{18} \mathrm{H}_{32} \mathrm{O}_{2}$ ). Assuming again that the only products are $\mathrm{CO}_{2}$ and $\mathrm{H}_{2} \mathrm{O}$, write and balance the equation for the metabolism of CLA.

Think About It Count the number of each type of atom on each side of the reaction arrow to verify that the equation is properly balanced. There are $4 \mathrm{C}, 8 \mathrm{H}$, and 12 O in the reactants and in the products, so the equation is balanced.

## Checkpoint 3.3 Chemical Equations

3.3.1 What are the stoichiometric coefficients in the following equation when it is balanced?

$$
\mathrm{CH}_{4}(g)+\mathrm{H}_{2} \mathrm{O}(g) \longrightarrow \mathrm{H}_{2}(g)+\mathrm{CO}_{2}(g)
$$

a) $1,2,2,2$
b) $2,1,1,2$
c) $1,2,2,1$
d) $2,2,2,1$
e) $1,2,4,1$
3.3.2 Which chemical equation represents the reaction shown (blue spheres are nitrogen, and white spheres are hydrogen)?

a) $6 \mathrm{~N}(g)+18 \mathrm{H}(g) \longrightarrow 6 \mathrm{NH}_{3}(g)$
b) $3 \mathrm{~N}_{2}(g)+3 \mathrm{H}_{2}(g) \longrightarrow 2 \mathrm{NH}_{3}(g)$
c) $2 \mathrm{~N}_{2}(g)+3 \mathrm{H}_{2}(g) \longrightarrow 2 \mathrm{NH}_{3}(g)$
d) $\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \longrightarrow 2 \mathrm{NH}_{3}(g)$
e) $3 \mathrm{~N}_{2}(g)+6 \mathrm{H}_{2}(g) \longrightarrow 6 \mathrm{NH}_{3}(g)$

## Checkpoint 3.3 Chemical Equations (continued)

3.3.3 Which is the correctly balanced form of the given equation?
$\mathrm{S}(\mathrm{s})+\mathrm{O}_{3}(\mathrm{~g}) \longrightarrow \mathrm{SO}_{2}(\mathrm{~g})$
a) $\mathrm{S}(\mathrm{s})+\mathrm{O}_{3}(\mathrm{~g}) \longrightarrow \mathrm{SO}_{3}(\mathrm{~g})$
b) $3 \mathrm{~S}(\mathrm{~s})+6 \mathrm{O}_{3}(\mathrm{~g}) \longrightarrow 3 \mathrm{SO}_{2}(\mathrm{~g})$
c) $3 \mathrm{~S}(\mathrm{~s})+\mathrm{O}_{3}(\mathrm{~g}) \longrightarrow 3 \mathrm{SO}_{2}(\mathrm{~g})$
d) $3 \mathrm{~S}(\mathrm{~s})+2 \mathrm{O}_{3}(\mathrm{~g}) \longrightarrow \mathrm{SO}_{2}(\mathrm{~g})$
e) $3 \mathrm{~S}(s)+2 \mathrm{O}_{3}(g) \longrightarrow 3 \mathrm{SO}_{2}(g)$
3.3.4 Carbon monoxide reacts with oxygen to produce carbon dioxide according to the following balanced equation:

$$
2 \mathrm{CO}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{CO}_{2}(g)
$$

A reaction vessel containing the reactants is pictured.

Which of the following represents the contents of the reaction vessel when the reaction is complete?
a)

b)

Student Annotation:
1 dozen = 12
1 gross $=144$
1 mole $=6.022 \times 10^{23}$

Student Annotation: Avogadro's number is almost unimaginably big. If $6.022 \times 10^{23}$ pennies were distributed equally among every inhabitant of the United States, each man, woman, and child would have over 20 trillion dollars! Furthermore, each person's share of pennies, neatly stacked, would occupy approximately the same volume as 760 Empire State Buildings.

### 3.4 The Mole and Molar Masses

A balanced chemical equation tells us not only what species are consumed and produced in a chemical reaction, but also in what relative amounts. In the combination of hydrogen and oxygen to produce water, the balanced chemical equation tells us that two $\mathrm{H}_{2}$ molecules react with one $\mathrm{O}_{2}$ molecule to produce two $\mathrm{H}_{2} \mathrm{O}$ molecules. When carrying out a reaction such as this, however, chemists do not work with individual molecules. Rather, they work with macroscopic quantities that contain enormous numbers of molecules. Regardless of the number of molecules involved, though, the molecules combine in the ratio specified in the balanced equation. Twenty molecules of hydrogen would combine with ten molecules of oxygen, ten million molecules of hydrogen would combine with five million molecules of oxygen, and so on. Clearly it would not be convenient to express the quantities used in the laboratory in terms of the numbers of molecules involved! Instead, chemists use a unit of measurement called the mole.

## The Mole

If you're getting doughnuts for yourself, you probably buy them individually, but if you're getting them for your entire dorm floor, you had better buy them by the dozen. One dozen doughnuts contains exactly 12 doughnuts. In fact, a dozen of anything contains exactly 12 of that thing. Pencils typically come 12 to a box, and 12 such boxes may be shipped to the campus bookstore in a bigger box. The bigger box contains one gross of pencils (144). Whether a dozen or a gross, each is a convenient quantity that contains a reasonable, specific, exact number of items.

Chemists, too, have adopted such a number to make it easy to express the number of molecules (or atoms or ions) in a typical macroscopic sample of matter. Atoms and molecules are so much smaller than doughnuts or pencils, though, that the number used by chemists is significantly bigger than a dozen or a gross. The quantity used by chemists is the mole (mol), which is defined as the amount of a substance that contains as many elementary entities (atoms, molecules, formula units, etc.) as there are atoms in exactly $0.012 \mathrm{~kg}(12 \mathrm{~g})$ of carbon-12. The number of atoms in exactly 12 g of carbon-12, which is determined experimentally, is known as Avogadro's number $\left(N_{\mathrm{A}}\right)$, in honor of the Italian scientist Amedeo Avogadro. ${ }^{1}$ The currently accepted value

[^4]of Avogadro's number is $6.0221418 \times 10^{23}$, although we usually round it to $6.022 \times 10^{23}$. Thus, a dozen doughnuts contains 12 doughnuts; a gross of pencils contains 144 pencils; and a mole of $\mathrm{O}_{2}$ gas, an amount that at room temperature and ordinary pressure would fill slightly more than half of a 10-gallon fish tank, contains $6.022 \times 10^{23} \mathrm{O}_{2}$ molecules. Figure 3.2 shows samples containing one mole each of several common substances.

Consider again the formation of water from hydrogen and oxygen gases. No matter how large the number of molecules involved, the ratio is always two $\mathrm{H}_{2}$ combining with one $\mathrm{O}_{2}$ to form two $\mathrm{H}_{2} \mathrm{O}$. Therefore, just as two molecules of hydrogen combine with one molecule of oxygen to form two molecules of water, two moles of hydrogen molecules ( $2 \times N_{\mathrm{A}}$ or $12.044 \times$ $10^{23} \mathrm{H}_{2}$ molecules) combine with one mole of oxygen molecules ( $6.022 \times 10^{23} \mathrm{O}_{2}$ molecules) to form two moles of water molecules ( $12.044 \times 10^{23} \mathrm{H}_{2} \mathrm{O}$ molecules). Thus, we can now interpret the chemical equation for this reaction in terms of moles. Figure 3.3 depicts this reaction on both the molecular and macroscopic scales.

(c)

Figure 3.2 One mole each of some familiar substances: (left) sulfur, (middle) iron, (right) mercury, and (in balloon) helium.

Figure 3.3 The reaction of $\mathrm{H}_{2}$ and $\mathrm{O}_{2}$ to form $\mathrm{H}_{2} \mathrm{O}$ shown as (a) a balanced chemical equation, (b) molecular models, and (c) an experiment (at $0^{\circ} \mathrm{C}$ and atmospheric pressure) in which 44.8 L of $\mathrm{H}_{2}$ are combined with 22.4 L of $\mathrm{O}_{2}$ to produce 36.0 mL of liquid $\mathrm{H}_{2} \mathrm{O}$.

$N_{\mathrm{A}}=$ Avogadro's number

Think About It Make sure that units cancel properly in each solution and that the result makes sense. In part (a), for example, the number of moles (30) is greater than one, so the number of atoms is greater than Avogadro's number. In part (b), the number of atoms $\left(1 \times 10^{20}\right)$ is less than Avogadro's number, so there is less than a mole of substance.

Student Annotation: Because the number of moles specifies the number of particles (atoms, molecules, or ions), using molar mass as a conversion factor, in effect, allows us to count the particles in a sample of matter by weighing the sample.

Student Annotation: Recall from Section 2.5 that

$$
1 \mathrm{amu}=1.661 \times 10^{-24} \mathrm{~g}
$$

This is the reciprocal of Avogadro's number. Expressed another way:

$$
1 \mathrm{~g}=6.022 \times 10^{23} \mathrm{amu}
$$

In effect, there is 1 mole of atomic mass units in a gram.

Note also that the subscripts in a chemical formula denote the ratio of combination of atoms in a substance. Just as a water molecule contains two H atoms and one O atom, a mole of water molecules contains two moles of H atoms and one mole of O atoms. The ratio of combination stays the same, regardless of the size of the sample.

Sample Problem 3.5 lets you practice converting between moles and atoms.

## Sample Problem 3.5

Calcium is the most abundant metal in the human body. A typical human body contains roughly 30 moles of calcium. Determine (a) the number of Ca atoms in 30.00 moles of calcium and (b) the number of moles of calcium in a sample containing $1.00 \times 10^{20} \mathrm{Ca}$ atoms.

Strategy Use Avogadro's number to convert from moles to atoms and from atoms to moles.
Setup When the number of moles is known, we multiply by Avogadro's number to convert to atoms. When the number of atoms is known, we divide by Avogadro's number to convert to moles.

## Solution

(a) $30.00 \mathrm{molCa} \times \frac{6.022 \times 10^{23} \mathrm{Ca} \text { atoms }}{1 \mathrm{~mol} \mathrm{Ca}}=1.807 \times 10^{25} \mathrm{Ca}$ atoms
(b) $1.00 \times 10^{20} \mathrm{Ca}$-atoms $\times \frac{1 \mathrm{~mol} \mathrm{Ca}}{6.022 \times 10^{23} \mathrm{Ca} \text { atoms }}=1.66 \times 10^{-4} \mathrm{~mol} \mathrm{Ca}$

Practice Problem A Potassium is the second most abundant metal in the human body. Calculate (a) the number of atoms in 7.31 moles of potassium and (b) the number of moles of potassium that contains $8.91 \times 10^{25}$ atoms.
\&Practice Problem B Calculate (a) the number of atoms in $1.05 \times 10^{-6}$ mole of helium and (b) the number of moles of helium that contains $2.33 \times 10^{21}$ atoms.

## Determining Molar Mass

Although chemists often wish to combine substances in specific mole ratios, there is no direct way to measure the number of moles in a sample of matter. Instead, chemists determine how many moles there are of a substance by measuring its mass (usually in grams). The molar mass of the substance is then used to convert from grams to moles.

The molar mass $(\mathcal{M})$ of a substance is the mass in grams of 1 mole of the substance. By definition, the mass of a mole of carbon-12 is exactly 12 g . Note that the molar mass of carbon is numerically equal to its atomic mass. Likewise, the atomic mass of calcium is 40.08 amu and its molar mass is 40.08 g , the atomic mass of sodium is 22.99 amu and its molar mass is 22.99 g , and so on. In general, an element's molar mass in grams is numerically equal to its atomic mass in atomic mass units. The molar mass (in grams) of any compound is numerically equal to its molecular or formula mass (in amu). The molar mass of water, for example, is 18.02 g , and the molar mass of sodium chloride $(\mathrm{NaCl})$ is 58.44 g .

When it comes to expressing the molar mass of elements such as oxygen and hydrogen, we have to be careful to specify what form of the element we mean. For instance, the element oxygen exists predominantly as diatomic molecules $\left(\mathrm{O}_{2}\right)$. Thus, if we say 1 mole of oxygen and by oxygen we mean $\mathrm{O}_{2}$, the molecular mass is 32.00 amu and the molar mass is 32.00 g . If on the other hand we mean a mole of atomic oxygen $(\mathrm{O})$, then the molar mass is only 16.00 g , which is numerically equal to the atomic mass of $\mathrm{O}(16.00 \mathrm{amu})$. You should be able to tell from the context which form of an element is intended, as the following examples illustrate:

| Context | Oxygen Means | Molar Mass |
| :--- | :--- | :---: |
| How many moles of oxygen react with 2 moles of <br> hydrogen to produce water? |  |  |
| How many moles of oxygen are there in 1 mole of water? | $\mathrm{O}_{2}$ | 32.00 g |
| Air is approximately 21\% oxygen. | O | 16.00 g |
| Many organic compounds contain oxygen. | $\mathrm{O}_{2}$ | 32.00 g |
|  | O | 16.00 g |

Figure 3.4 Flowchart for conversions among mass, moles, and number of particles.

Although the term molar mass specifies the mass of 1 mole of a substance, making the appropriate units simply grams (g), we usually express molar masses in units of grams per mole $(\mathrm{g} / \mathrm{mol})$ to facilitate calculations involving moles.

## Interconverting Mass, Moles, and Numbers of Particles

Molar mass is the conversion factor that we use to convert from mass $(m)$ to moles ( $n$ ), and vice versa. We use Avogadro's number to convert from number of moles to number of particles $(N)$, and vice versa. Particles in this context may refer to atoms, molecules, ions, or formula units. Figure 3.4 summarizes the operations involved in these conversions.

Sample Problems 3.6 and 3.7 illustrate how the conversions are done.

## Sample Problem 3.6

Determine (a) the number of moles of C in 10.00 g of naturally occurring carbon and (b) the mass of 0.905 mole of sodium chloride.

Strategy Use molar mass to convert from mass to moles and to convert from moles to mass.
Setup The molar mass of carbon is $12.01 \mathrm{~g} / \mathrm{mol}$. The molar mass of a compound is numerically equal to its formula mass. The molar mass of sodium chloride $(\mathrm{NaCl})$ is $58.44 \mathrm{~g} / \mathrm{mol}$.

## Solution

(a) $10.00 \mathrm{gC} \times \frac{1 \mathrm{~mol} \mathrm{C}}{12.01 \mathrm{gC}}=0.8326 \mathrm{~mol} \mathrm{C}$
(b) $0.905 \mathrm{~mol} \mathrm{NaCl} \times \frac{58.44 \mathrm{~g} \mathrm{NaCl}}{1 \mathrm{~mol} \mathrm{NaCl}}=52.9 \mathrm{~g} \mathrm{NaCl}$

Practice Problem A (a) Determine the mass in grams of 2.75 moles of glucose $\left(\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}\right)$. (b) Determine the number of moles in 59.8 g of sodium nitrate $\left(\mathrm{NaNO}_{3}\right)$.

EPractice Problem B (a) Determine the mass of sodium metal that contains the same number of moles as 87.2 g of copper metal. (b) Determine the number of moles of helium that has the same mass as 4.505 moles of neon.

## Sample Problem 3.7

(a) Determine the number of water molecules and the numbers of H and O atoms in 3.26 g of water.
(b) Determine the mass of $7.92 \times 10^{19}$ carbon dioxide molecules.

Strategy Use molar mass and Avogadro's number to convert from mass to molecules, and vice versa. Use the molecular formula of water to determine the numbers of H and O atoms.

Think About lt Always doublecheck unit cancellations in problems such as these-errors are common when molar mass is used as a conversion factor. Also make sure that the results make sense. In both cases, a mass smaller than the molar mass corresponds to less than a mole of substance.

Think About It Again, check the cancellation of units carefully and make sure that the magnitudes of your results are reasonable.

Setup (a) Starting with mass ( 3.26 g of water), we use molar mass $(18.02 \mathrm{~g} / \mathrm{mol})$ to convert to moles of water. From moles, we use Avogadro's number to convert to number of water molecules. In part (b), we reverse the process in part (a) to go from number of molecules to mass of carbon dioxide.

## Solution

(a) $3.26 \mathrm{~g} \mathrm{H} \mathrm{H}_{2} \mathrm{O} \times \frac{1 \mathrm{moH}_{2} \mathrm{O}}{18.02 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}} \times \frac{6.022 \times 10^{23} \mathrm{H}_{2} \mathrm{O} \text { molecules }}{1 \mathrm{moH}_{2} \mathrm{O}}=1.09 \times 10^{23} \mathrm{H}_{2} \mathrm{O}$ molecules

Using the molecular formula, we can determine the number of H and O atoms in 3.26 g of $\mathrm{H}_{2} \mathrm{O}$ as follows:

$$
\begin{gathered}
1.09 \times 10^{23} \mathrm{H}_{2} \mathrm{O} \text { molecules } \times \frac{2 \mathrm{H} \text { atoms }}{1 \mathrm{H}_{2} \mathrm{O} \text { molecule }}=2.18 \times 10^{23} \mathrm{H} \text { atoms } \\
1.09 \times 10^{23} \mathrm{H}_{2} \mathrm{O} \text { molecules } \times \frac{1 \mathrm{O} \text { atom }}{1 \mathrm{H}_{2} \mathrm{O} \text { molecule }}=1.09 \times 10^{23} \mathrm{O} \text { atoms } \\
\text { (b) } 7.92 \times 10^{19} \mathrm{CO}_{2} \text { molecules } \times \frac{1 \mathrm{moteO}_{2}}{6.022 \times 10^{23} \mathrm{CO}_{2} \text { molecules }} \times \frac{44.01 \mathrm{~g} \mathrm{CO}_{2}}{1 \text { mot } \mathrm{CO}_{2}}=5.79 \times 10^{-3} \mathrm{~g} \mathrm{CO}_{2}
\end{gathered}
$$

Practice Problem A (a) Calculate the number of oxygen molecules and the number of oxygen atoms in 35.5 g of $\mathrm{O}_{2}$. (b) Calculate the mass of $9.95 \times 10^{14} \mathrm{SO}_{3}$ molecules.

HPractice Problem B (a) Determine the number of oxygen atoms and hydrogen atoms in 1.00 kg of water. (b) Calculate the mass of calcium carbonate that contains 1.00 mol of oxygen atoms.

## Empirical Formula from Percent Composition

In Section 3.2, we learned how to use the chemical formula (either molecular or empirical) to determine the percent composition by mass. With the concepts of the mole and molar mass, we can now use the experimentally determined percent composition to determine the empirical formula of a compound. Sample Problem 3.8 shows how to do this.

## Sample Problem 3.8

Determine the empirical formula of a compound that is 30.45 percent nitrogen and 69.55 percent oxygen by mass.

Strategy Assume a 100-g sample so that the mass percentages of nitrogen and oxygen given in the problem statement correspond to the masses of N and O in the compound. Then, using the appropriate molar masses, convert the grams of each element to moles. Use the resulting numbers as subscripts in the empirical formula, reducing them to the lowest possible whole numbers for the final answer.

Setup The empirical formula of a compound consisting of N and O is $\mathrm{N}_{x} \mathrm{O}_{y}$. The molar masses of N and O are 14.01 and $16.00 \mathrm{~g} / \mathrm{mol}$, respectively. One hundred grams of a compound that is 30.45 percent nitrogen and 69.55 percent oxygen by mass contains 30.45 g N and 69.55 g O .

## Solution

$$
\begin{aligned}
& 30.45 \mathrm{gA} \times \frac{1 \mathrm{~mol} \mathrm{~N}}{14.01 \mathrm{gN}}=2.173 \mathrm{~mol} \mathrm{~N} \\
& 69.55 \mathrm{~g} \theta \times \frac{1 \mathrm{~mol} \mathrm{O}}{16.00 \mathrm{~g} \theta}=4.347 \mathrm{~mol} \mathrm{O}
\end{aligned}
$$

This gives a formula of $\mathrm{N}_{2.173} \mathrm{O}_{4.347}$. Dividing both subscripts by the smaller of the two to get the smallest possible whole numbers $(2.173 / 2.173=1,4.347 / 2.173 \approx 2)$ gives an empirical formula of $\mathrm{NO}_{2}$. This may or may not be the molecular formula of the compound because both $\mathrm{NO}_{2}$ and $\mathrm{N}_{2} \mathrm{O}_{4}$ have this empirical formula. Without knowing the molar mass, we cannot be sure which one it is.

Practice Problem A Determine the empirical formula of a compound that is 52.15 percent C, 13.13 percent H , and 34.73 percent O by mass.

FPractice Problem B Determine the empirical formula of a compound that is 85.63 percent $C$ and 14.37 percent H by mass.

## Checkpoint 3.4 The Mole and Molar Masses

3.4.1 How many molecules are in 30.1 g of sulfur dioxide $\left(\mathrm{SO}_{2}\right)$ ?
a) $1.81 \times 10^{25}$
b) $2.83 \times 10^{23}$
c) $6.02 \times 10^{23}$
d) $1.02 \times 10^{24}$
e) $5.00 \times 10^{-23}$
3.4.2 How many moles of hydrogen are there in 6.50 g of ammonia $\left(\mathrm{NH}_{3}\right)$ ?
a) 0.382 mol
b) 1.39 mol
c) 0.215 mol
d) 1.14 mol
e) 2.66 mol
3.4.3 Determine the empirical formula of a compound that has the following composition: 92.3 percent C and 7.7 percent H .
a) CH
b) $\mathrm{C}_{2} \mathrm{H}_{3}$
c) $\mathrm{C}_{4} \mathrm{H}_{6}$
d) $\mathrm{C}_{6} \mathrm{H}_{7}$
e) $\mathrm{C}_{4} \mathrm{H}_{3}$
3.4.4 Determine the empirical formula of a compound that has the following composition: 48.6 percent C, 8.2 percent H , and 43.2 percent O .
a) $\mathrm{C}_{3} \mathrm{H}_{8} \mathrm{O}$
b) $\mathrm{C}_{3} \mathrm{H}_{6} \mathrm{O}$
c) $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{O}_{2}$
d) $\mathrm{C}_{2} \mathrm{H}_{6} \mathrm{O}$
e) $\mathrm{C}_{3} \mathrm{H}_{6} \mathrm{O}_{2}$

### 3.5 Combustion Analysis

As we saw in Section 3.4, knowing the mass of each element contained in a sample of a substance enables us to determine the empirical formula of the substance. One common, practical use of this ability is the experimental determination of empirical formula by combustion analysis.

Combustion analysis of organic compounds (containing carbon, hydrogen, and sometimes oxygen) is carried out using an apparatus like the one shown in Figure 3.5. A sample of known mass is placed in the furnace and heated in the presence of oxygen. The carbon dioxide and water produced from carbon and hydrogen, respectively, in the combustion reaction are collected in "traps," which are weighed before and after the combustion. The difference in mass of each trap before and after the reaction is the mass of the collected product. Knowing the mass of each product, we can determine the percent composition of the compound. And, from percent composition, we can determine the empirical formula.

## Determination of Empirical Formula

When a compound such as glucose is burned in a combustion analysis apparatus, carbon dioxide $\left(\mathrm{CO}_{2}\right)$ and water $\left(\mathrm{H}_{2} \mathrm{O}\right)$ are produced. Because only oxygen gas is added to the reaction, the carbon and hydrogen present in the products must have come from the glucose. The oxygen in the products may have come from the glucose, but it may also have come from the added oxygen. Suppose that in one such experiment the combustion of 18.8 g of glucose produced 27.6 g of $\mathrm{CO}_{2}$ and 11.3 g of $\mathrm{H}_{2} \mathrm{O}$. We can calculate the mass of carbon and hydrogen in the original $18.8-\mathrm{g}$ sample of glucose as follows:

$$
\begin{aligned}
& \text { mass of } \mathrm{C}=27.6 \mathrm{~g} \mathrm{CO}_{2} \times \frac{1 \mathrm{molCO}_{2}}{44.01 \mathrm{gCO}_{2}} \times \frac{1 \mathrm{motC}}{1 \mathrm{molCO}_{2}} \times \frac{12.01 \mathrm{~g} \mathrm{C}}{1 \mathrm{moHC}}=7.53 \mathrm{~g} \mathrm{C} \\
& \text { mass of } \mathrm{H}=11.3 \mathrm{~g} \mathrm{H}_{2} \mathrm{O} \times \frac{1 \mathrm{molH}_{2} \mathrm{O}}{18.02 \mathrm{gH}_{2} \mathrm{O}} \times \frac{2 \mathrm{moHH}^{1 \mathrm{molH}_{2} \mathrm{O}}}{1.008 \mathrm{~g} \mathrm{H}} \frac{1 \mathrm{moHH}}{1.26 \mathrm{~g} \mathrm{H}}
\end{aligned}
$$

Figure 3.5 Schematic of a combustion analysis apparatus. $\mathrm{CO}_{2}$ and $\mathrm{H}_{2} \mathrm{O}$ produced in combustion are trapped and weighed. The amounts of these products are used to determine how much carbon and hydrogen the combusted sample contained. ( CuO is used to ensure complete combustion of all carbon to $\mathrm{CO}_{2}$.)

Student Annotation: Determination of an empirical formula from combustion data can be especially sensitive to rounding error. When solving problems such as these, don't round until the very end.

Glucose

Benzene

Thus, 18.8 g of glucose contains 7.53 g of carbon and 1.26 g of hydrogen. The remaining mass $[18.8 \mathrm{~g}-(7.53 \mathrm{~g}+1.26 \mathrm{~g})=10.0 \mathrm{~g}]$ is oxygen.

The number of moles of each element present in 18.8 g of glucose is

$$
\begin{aligned}
& \text { moles of } \mathrm{C}=7.53 \mathrm{~g} C \times \frac{1 \mathrm{~mol} \mathrm{C}}{12.01 \mathrm{gC}}=0.627 \mathrm{~mol} \mathrm{C} \\
& \text { moles of } \mathrm{H}=1.26 \mathrm{~g} H \times \frac{1 \mathrm{~mol} \mathrm{H}}{1.008 \mathrm{gK}}=1.25 \mathrm{~mol} \mathrm{H} \\
& \text { moles of } \mathrm{O}=10.0 \mathrm{~g} \varnothing \times \frac{1 \mathrm{~mol} \mathrm{O}}{16.00 \mathrm{~g} \varnothing}=0.626 \mathrm{~mol} \mathrm{O}
\end{aligned}
$$

The empirical formula of glucose can therefore be written $\mathrm{C}_{0.627} \mathrm{H}_{1.25} \mathrm{O}_{0.626}$. Because the numbers in an empirical formula must be integers, we divide each of the subscripts by the smallest subscript, $0.626(0.627 / 0.626 \approx 1,1.25 / 0.626 \approx 2$, and $0.626 / 0.626=1)$, and obtain $\mathrm{CH}_{2} \mathrm{O}$ for the empirical formula.

## Determination of Molecular Formula

The empirical formula gives only the ratio of combination of the atoms in a molecule, so there may be numerous compounds with the same empirical formula. If we know the approximate molar mass of the compound, though, we can determine the molecular formula from the empirical formula. For instance, the molar mass of glucose is about 180 g . The empirical-formula mass of $\mathrm{CH}_{2} \mathrm{O}$ is about $30 \mathrm{~g}[12.01 \mathrm{~g}+2(1.008 \mathrm{~g})+16.00 \mathrm{~g}]$. To determine the molecular formula, we first divide the molar mass by the empirical-formula mass: $180 \mathrm{~g} / 30 \mathrm{~g}=6$. This tells us that there are six empirical-formula units per molecule in glucose. Multiplying each subscript by 6 (recall that when none is shown, the subscript is understood to be a 1) gives the molecular formula, $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}$.

Sample Problem 3.9 shows how to determine the molecular formula of a compound from its combustion data and molar mass.

## Sample Problem 3.9

Combustion of a $5.50-\mathrm{g}$ sample of benzene produces $18.59 \mathrm{~g} \mathrm{CO}_{2}$ and $3.81 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}$. Determine the empirical formula and the molecular formula of benzene, given that its molar mass is approximately $78 \mathrm{~g} / \mathrm{mol}$.

Strategy From the product masses, determine the mass of C and the mass of H in the $5.50-\mathrm{g}$ sample of benzene. Sum the masses of C and H ; the difference between this sum and the original sample mass is the mass of $O$ in the sample (if $O$ is in fact present in benzene). Convert the mass of each element to moles, and use the results as subscripts in a chemical formula. Convert the subscripts to whole numbers by dividing each by the smallest subscript. This gives the empirical formula. To calculate the molecular formula, first divide the molar mass given in the problem statement by the empirical-formula mass. Then, multiply the subscripts in the empirical formula by the resulting number to obtain the subscripts in the molecular formula.

Setup The necessary molar masses are $\mathrm{CO}_{2}, 44.01 \mathrm{~g} / \mathrm{mol} ; \mathrm{H}_{2} \mathrm{O}, 18.02 \mathrm{~g} / \mathrm{mol} ; \mathrm{C}, 12.01 \mathrm{~g} / \mathrm{mol} ; \mathrm{H}$, $1.008 \mathrm{~g} / \mathrm{mol}$; and $\mathrm{O}, 16.00 \mathrm{~g} / \mathrm{mol}$.

Solution We calculate the mass of carbon and the mass of hydrogen in the products (and therefore in the original $5.50-\mathrm{g}$ sample) as follows:

$$
\begin{aligned}
& \text { mass of } \mathrm{C}=18.59 \mathrm{~g} \mathrm{CO}_{2} \times \frac{1 \mathrm{~mol} \mathrm{CO}_{2}}{44.01 \mathrm{~g} \mathrm{CO}_{2}} \times \frac{1 \mathrm{motc}}{1 \mathrm{motCO}_{2}} \times \frac{12.01 \mathrm{~g} \mathrm{C}}{1 \mathrm{motC}}=5.073 \mathrm{~g} \mathrm{C} \\
& \text { mass of } \mathrm{H}=3.81 \mathrm{~g} \mathrm{H}_{2} \mathrm{O} \times \frac{1 \mathrm{motH}_{2} \mathrm{O}}{18.02 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}} \times \frac{2 \mathrm{moth}^{1 \mathrm{molH}_{2} \mathrm{O}}}{1.008 \mathrm{~g} \mathrm{H}} \frac{1.026 \mathrm{goth}}{1 \mathrm{~m}}=0.426
\end{aligned}
$$

The total mass of products is $5.073 \mathrm{~g}+0.426 \mathrm{~g}=5.499 \mathrm{~g}$. Because the combined masses of C and H account for the entire mass of the original sample ( $5.499 \mathrm{~g} \approx 5.50 \mathrm{~g}$ ), this compound must not contain O.

Converting mass to moles for each element present in the compound,

$$
\begin{aligned}
& \text { moles of } \mathrm{C}=5.073 \mathrm{~g} C \times \frac{1 \mathrm{~mol} \mathrm{C}}{12.01 \mathrm{gC}}=0.4224 \mathrm{~mol} \mathrm{C} \\
& \text { moles of } \mathrm{H}=0.426 \mathrm{gH} \times \frac{1 \mathrm{~mol} \mathrm{H}}{1.008 \mathrm{gH}}=0.423 \mathrm{~mol} \mathrm{H}
\end{aligned}
$$

gives the formula $\mathrm{C}_{0.4224} \mathrm{H}_{0.423}$. Converting the subscripts to whole numbers ( $0.4224 / 0.4224=1$; $0.423 / 0.4224 \approx 1$ ) gives the empirical formula, CH .

Finally, dividing the approximate molar mass ( $78 \mathrm{~g} / \mathrm{mol}$ ) by the empirical-formula mass $(12.01 \mathrm{~g} / \mathrm{mol}+1.008 \mathrm{~g} / \mathrm{mol}=13.02 \mathrm{~g} / \mathrm{mol})$ gives $78 / 13.02 \approx 6$. Then, multiplying both subscripts in the empirical formula by 6 gives the molecular formula, $\mathrm{C}_{6} \mathrm{H}_{6}$.

Practice Problem A The combustion of a 28.1-g sample of ascorbic acid (vitamin C) produces $42.1 \mathrm{~g} \mathrm{CO}_{2}$ and $11.5 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}$. Determine the empirical and molecular formulas of ascorbic acid. The molar mass of ascorbic acid is approximately $176 \mathrm{~g} / \mathrm{mol}$.
$\boldsymbol{H}$ Practice Problem B Determine the mass of $\mathrm{CO}_{2}$ and the mass of $\mathrm{H}_{2} \mathrm{O}$ produced by the combustion of 1.05 g of a compound with the empirical formula $\mathrm{CH}_{4} \mathrm{O}$.

## Checkpoint 3.5 Combustion Analysis

3.5.1 What is the empirical formula of a compound containing $\mathrm{C}, \mathrm{H}$, and O if combustion of 1.23 g of the compound yields $1.8 \mathrm{~g} \mathrm{CO}_{2}$ and $0.74 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}$ ?
a) $\mathrm{CH}_{3} \mathrm{O}$
b) $\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}$
c) CHO
d) $\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$
e) $\mathrm{CH}_{2} \mathrm{O}$
3.5.2 What are the empirical and molecular formulas of a hydrocarbon if combustion of 2.10 g of the compound yields $6.59 \mathrm{~g} \mathrm{CO}_{2}$ and $2.70 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}$ and its molar mass is about $70 \mathrm{~g} / \mathrm{mol}$ ?
a) $\mathrm{CH}, \mathrm{C}_{6} \mathrm{H}_{6}$
b) $\mathrm{CH}, \mathrm{C}_{5} \mathrm{H}_{5}$
c) $\mathrm{CH}_{2}, \mathrm{C}_{6} \mathrm{H}_{12}$
d) $\mathrm{CH}_{2}, \mathrm{C}_{5} \mathrm{H}_{10}$
e) $\mathrm{CH}_{2}, \mathrm{C}_{3} \mathrm{H}_{6}$
3.5.3 Determine the masses of $\mathrm{CO}_{2}$ and $\mathrm{H}_{2} \mathrm{O}$ produced by the combustion of 0.986 g of a compound with empirical formula $\mathrm{C}_{3} \mathrm{H}_{6} \mathrm{O}_{2}$.
a) $1.76 \mathrm{~g} \mathrm{CO}_{2}, 0.719 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}$
b) $0.480 \mathrm{~g} \mathrm{CO}_{2}, 0.081 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}$
c) $1.76 \mathrm{~g} \mathrm{CO}_{2}, 1.44 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}$
d) $0.329 \mathrm{~g} \mathrm{CO}_{2}, 0.657 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}$
e) $0.657 \mathrm{~g} \mathrm{CO}_{2}, 0.329 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}$
3.5.4 How is it possible for the combined masses of $\mathrm{CO}_{2}$ and $\mathrm{H}_{2} \mathrm{O}$ produced in combustion to be greater than the mass of the compound that is burned?
a) There is experimental error.
b) Different balances are used to determine mass before and after combustion.
c) Combustion violates the law of conservation of mass.
d) Oxygen consumed in the combustion contributes to the mass of products.
e) $\mathrm{CO}_{2}$ and $\mathrm{H}_{2} \mathrm{O}$ have greater molar masses than the compound that is burned.

Think About It Use the molecular formula to determine the molar mass and make sure that the result agrees with the molar mass given in the problem. For $\mathrm{C}_{6} \mathrm{H}_{6}$ the molar mass is $6(12.01 \mathrm{~g} / \mathrm{mol})+$ $6(1.008 \mathrm{~g} / \mathrm{mol})=78.11 \mathrm{~g} / \mathrm{mol}$, which agrees with the $78 \mathrm{~g} / \mathrm{mol}$ given in the problem statement.

## Multimedia

Matter-stoichiometry.

Student Annotation: When reactants are combined in exactly the mole ratio specified by the balanced chemical equation, they are said to be combined in stoichiometric amounts.

### 3.6 Calculations with Balanced Chemical Equations

Often we would like to predict how much of a particular product will form from a given amount of a reactant. Other times, we perform an experiment, measure the amount of product formed, and use this information to deduce the quantity or composition of a reactant. Balanced chemical equations can be powerful tools for this type of problem solving.

## Moles of Reactants and Products

Based on the equation for the reaction of carbon monoxide with oxygen to produce carbon dioxide,

2 moles of CO combine with 1 mole of $\mathrm{O}_{2}$ to produce 2 moles of $\mathrm{CO}_{2}$. In stoichiometric calculations, we say that 2 moles of CO are equivalent to 2 moles of $\mathrm{CO}_{2}$, which can be represented as

$$
2 \mathrm{~mol} \mathrm{CO} \bumpeq 2 \mathrm{~mol} \mathrm{CO}_{2}
$$

where the symbol $\bumpeq$ means "is stoichiometrically equivalent to" or simply "is equivalent to." The ratio of moles of CO consumed to moles of $\mathrm{CO}_{2}$ produced is 2:2 or 1:1. Regardless of the number of moles of CO consumed in the reaction, the same number of moles of $\mathrm{CO}_{2}$ will be produced. We can use this constant ratio as a conversion factor that can be written as

$$
\frac{2 \mathrm{~mol} \mathrm{CO}_{2}}{2 \mathrm{~mol} \mathrm{CO}_{2}} \text { or } \frac{1 \mathrm{~mol} \mathrm{CO}_{1}}{1 \mathrm{~mol} \mathrm{CO}_{2}}
$$

The ratio can also be written as the reciprocal,

$$
\frac{2 \mathrm{~mol} \mathrm{CO}_{2}}{2 \mathrm{~mol} \mathrm{CO}} \text { or } \frac{1 \mathrm{~mol} \mathrm{CO}_{2}}{1 \mathrm{~mol} \mathrm{CO}}
$$

These conversion factors enable us to determine how many moles of $\mathrm{CO}_{2}$ will be produced upon reaction of a given amount of CO , or how much CO is necessary to produce a specific amount of $\mathrm{CO}_{2}$. Consider the complete reaction of 3.82 moles of CO to form $\mathrm{CO}_{2}$. To calculate the number of moles of $\mathrm{CO}_{2}$ produced, we use the conversion factor with moles of $\mathrm{CO}_{2}$ in the numerator and moles of CO in the denominator.

$$
\text { moles } \mathrm{CO}_{2} \text { produced }=3.82 \mathrm{mot} \mathrm{CO} \times \frac{1 \mathrm{~mol} \mathrm{CO}_{2}}{1 \mathrm{motCO}}=3.82 \mathrm{~mol} \mathrm{CO}_{2}
$$

Similarly, we can use other ratios represented in the balanced equation as conversion factors. For example, we have $1 \mathrm{~mol} \mathrm{O}_{2} \bumpeq 2 \mathrm{~mol} \mathrm{CO}_{2}$ and $2 \mathrm{~mol} \mathrm{CO} \bumpeq 1 \mathrm{~mol} \mathrm{O}_{2}$. The corresponding conversion factors allow us to calculate the amount of $\mathrm{CO}_{2}$ produced upon reaction of a given amount of $\mathrm{O}_{2}$, and the amount of one reactant necessary to react completely with a given amount of the other. Using the preceding example, we can determine the stoichiometric amount of $\mathrm{O}_{2}$ (how many moles of $\mathrm{O}_{2}$ are needed to react with 3.82 moles of CO ).

$$
\text { moles } \mathrm{O}_{2} \text { needed }=3.82 \mathrm{mot} \mathrm{CO} \times \frac{1 \mathrm{~mol} \mathrm{O}_{2}}{2 \mathrm{mot} \mathrm{CO}}=1.91 \mathrm{~mol} \mathrm{O}_{2}
$$

Sample Problem 3.10 illustrates how to determine reactant and product amounts using a balanced chemical equation.

## Sample Problem 3.10

Urea $\left[\left(\mathrm{NH}_{2}\right)_{2} \mathrm{CO}\right]$ is a by-product of protein metabolism. This waste product is formed in the liver and then filtered from the blood and excreted in the urine by the kidneys. Urea can be synthesized in the laboratory by the combination of ammonia and carbon dioxide according to the equation

(a) Calculate the amount of urea that will be produced by the complete reaction of 5.25 moles of ammonia. (b) Determine the stoichiometric amount of carbon dioxide required to react with 5.25 moles of ammonia.

Strategy Use the balanced chemical equation to determine the correct stoichiometric conversion factors, and then multiply by the number of moles of ammonia given.

Setup According to the balanced chemical equation, the conversion factor for ammonia and urea is either

$$
\frac{2 \mathrm{~mol} \mathrm{NH}_{3}}{1 \mathrm{~mol}\left(\mathrm{NH}_{2}\right)_{2} \mathrm{CO}} \quad \text { or } \quad \frac{1 \mathrm{~mol}\left(\mathrm{NH}_{2}\right)_{2} \mathrm{CO}}{2 \mathrm{~mol} \mathrm{NH}_{3}}
$$

To multiply by moles of $\mathrm{NH}_{3}$ and have the units cancel properly, we use the conversion factor with moles of $\mathrm{NH}_{3}$ in the denominator.

Similarly, the conversion factor for ammonia and carbon dioxide can be written as

$$
\frac{2 \mathrm{~mol} \mathrm{NH}_{3}}{1 \mathrm{~mol} \mathrm{CO}_{2}} \text { or } \frac{1 \mathrm{~mol} \mathrm{CO}_{2}}{2 \mathrm{~mol} \mathrm{NH}_{3}}
$$

Again, we select the conversion factor with ammonia in the denominator so that moles of $\mathrm{NH}_{3}$ will cancel in the calculation.

## Solution

(a) moles $\left(\mathrm{NH}_{2}\right)_{2} \mathrm{CO}$ produced $=5.25 \mathrm{~mol}_{\mathrm{NH}}^{3}$. $\times \frac{1 \mathrm{~mol}\left(\mathrm{NH}_{2}\right)_{2} \mathrm{CO}}{2 \text { mol } \mathrm{NH}_{3}}=2.63 \mathrm{~mol}\left(\mathrm{NH}_{2}\right)_{2} \mathrm{CO}$

Practice Problem A Nitrogen and hydrogen react to form ammonia according to the following balanced equation: $\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \longrightarrow 2 \mathrm{NH}_{3}(g)$. Calculate the number of moles of hydrogen required to react with 0.0880 mole of nitrogen, and the number of moles of ammonia that will form.

GIPractice Problem B Tetraphosphorus decoxide $\left(\mathrm{P}_{4} \mathrm{O}_{10}\right)$ reacts with water to produce phosphoric acid. Write and balance the equation for this reaction, and determine the number of moles of each reactant required to produce 5.80 moles of phosphoric acid.

## Mass of Reactants and Products

Balanced chemical equations give us the relative amounts of reactants and products in terms of moles. However, because we measure reactants and products in the laboratory by weighing them, most often such calculations start with mass rather than the number of moles. Sample Problem 3.11 illustrates how to determine amounts of reactants and products in terms of grams.

Think About It As always, check to be sure that units cancel properly in the calculation. Also, the balanced equation indicates that there will be fewer moles of urea produced than ammonia consumed. Therefore, your calculated number of moles of urea (2.63) should be smaller than the number of moles given in the problem (5.25). Similarly, the stoichiometric coefficients in the balanced equation are the same for carbon dioxide and urea, so your answers to this problem should also be the same for both species.

Think About It Use the law of conservation of mass to check your answers. Make sure that the combined mass of both products is equal to the mass of reactant you determined in part (a). In this case (rounded to the appropriate number of significant figures), $10.0 \mathrm{~g}+$ $8.18 \mathrm{~g}=18.2 \mathrm{~g}$. Remember that small differences may arise as the result of rounding.

## Sample Problem 3.11

Nitrous oxide $\left(\mathrm{N}_{2} \mathrm{O}\right)$, also known as "laughing gas," is commonly used as an anesthetic in dentistry. It is manufactured by heating ammonium nitrate. The balanced equation is

$$
\mathrm{NH}_{4} \mathrm{NO}_{3}(s) \xrightarrow{\Delta} \mathrm{N}_{2} \mathrm{O}(g)+2 \mathrm{H}_{2} \mathrm{O}(g)
$$

(a) Calculate the mass of ammonium nitrate that must be heated in order to produce 10.0 g of nitrous oxide. (b) Determine the corresponding mass of water produced in the reaction.

Strategy For part (a), use the molar mass of nitrous oxide to convert the given mass of nitrous oxide to moles, use the appropriate stoichiometric conversion factor to convert to moles of ammonium nitrate, and then use the molar mass of ammonium nitrate to convert to grams of ammonium nitrate. For part (b), use the molar mass of nitrous oxide to convert the given mass of nitrous oxide to moles, use the stoichiometric conversion factor to convert from moles of nitrous oxide to moles of water, and then use the molar mass of water to convert to grams of water.

Setup The molar masses are as follows: $80.05 \mathrm{~g} / \mathrm{mol}$ for $\mathrm{NH}_{4} \mathrm{NO}_{3}, 44.02 \mathrm{~g} / \mathrm{mol}$ for $\mathrm{N}_{2} \mathrm{O}$, and $18.02 \mathrm{~g} / \mathrm{mol}$ for $\mathrm{H}_{2} \mathrm{O}$. The conversion factors from nitrous oxide to ammonium nitrate and from nitrous oxide to water are, respectively:

$$
\frac{1 \mathrm{~mol} \mathrm{NH}_{4} \mathrm{NO}_{3}}{1 \mathrm{~mol} \mathrm{~N}_{2} \mathrm{O}} \text { and } \frac{2 \mathrm{~mol} \mathrm{H}_{2} \mathrm{O}}{1 \mathrm{~mol} \mathrm{~N}_{2} \mathrm{O}}
$$

## Solution

(a) $\quad 10.0 \mathrm{~g} \mathrm{~N}_{2} \mathrm{O} \times \frac{1 \mathrm{~mol} \mathrm{~N}_{2} \mathrm{O}}{44.02 \mathrm{~g} \mathrm{~N}_{2} \mathrm{O}}=0.227 \mathrm{~mol} \mathrm{~N}$
$0.227 \mathrm{~mol}_{2} \mathrm{O} \times \frac{1 \mathrm{~mol} \mathrm{NH}_{4} \mathrm{NO}_{3}}{1 \mathrm{~mol} \mathrm{~N}_{2} \mathrm{O}}=0.227 \mathrm{~mol} \mathrm{NH} 4_{4} \mathrm{NO}_{3}$
$0.227 \mathrm{~mol} \mathrm{NH}_{4} \mathrm{NO}_{3} \times \frac{80.05 \mathrm{~g} \mathrm{NH}_{4} \mathrm{NO}_{3}}{1 \mathrm{~mol} \mathrm{NH}_{4} \mathrm{NO}_{3}}=18.2 \mathrm{~g} \mathrm{NH}_{4} \mathrm{NO}_{3}$
Thus, 18.2 g of ammonium nitrate must be heated in order to produce 10.0 g of nitrous oxide.
(b) Starting with the number of moles of nitrous oxide determined in the first step of part (a),

$$
\begin{aligned}
& 0.227 \mathrm{~mol}_{2} \mathrm{O} \times \frac{2 \mathrm{~mol} \mathrm{H}_{2} \mathrm{O}}{1 \mathrm{~mol} \mathrm{~N}_{2} \mathrm{O}}=0.454 \mathrm{~mol} \mathrm{H}_{2} \mathrm{O} \\
& 0.454 \mathrm{~mol}_{2} \mathrm{O} \times \frac{18.02 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}}{1 \mathrm{molH}_{2} \mathrm{O}}=8.18 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}
\end{aligned}
$$

Therefore, 8.18 g of water will also be produced in the reaction.

Practice Problem A Calculate the mass of water produced by the metabolism of 56.8 g of glucose. (See the box on page 84 for the necessary equation.)

HPractice Problem B What mass of glucose must be metabolized in order to produce 175 g of water?

## Checkpoint 3.6 Calculations with Balanced Chemical Equations

3.6.1 How many moles of LiOH will be produced if 0.550 mol Li reacts according to the following equation?

$$
2 \mathrm{Li}(s)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{LiOH}(a q)+\mathrm{H}_{2}(g)
$$

a) 0.550 mol
b) 1.10 mol
c) 0.275 mol
d) 2.20 mol
e) 2.00 mol
3.6.2 Determine the stoichiometric amount (in grams) of $\mathrm{O}_{2}$ necessary to react with 5.71 g Al according to the following equation:

$$
4 \mathrm{Al}(s)+3 \mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{Al}_{2} \mathrm{O}_{3}(s)
$$

a) 5.08 g
b) 9.03 g
c) 2.54 g
d) 4.28 g
e) 7.61 g

### 3.7 Limiting Reactants

When a chemist carries out a reaction, the reactants usually are not present in stoichiometric amounts. Because the goal of a reaction is usually to produce the maximum quantity of a useful compound from the starting materials, an excess of one reactant is commonly supplied to ensure that the more expensive or more important reactant is converted completely to the desired product. Consequently, some of the reactant supplied in excess will be left over at the end of the reaction. The reactant used up first in a reaction is called the limiting reactant, because the amount of this reactant limits the amount of product that can form. When all the limiting reactant has been consumed, no more product can be formed. Excess reactants are those present in quantities greater than necessary to react with the quantity of the limiting reactant.

The concept of a limiting reactant applies to everyday tasks, too, such as making ham sandwiches. Suppose you want to make the maximum number of ham sandwiches possible, each of which will consist of two slices of bread and one slice of ham. If you have eight slices of bread and six slices of ham, how many sandwiches can you make? The answer is four, because after making four sandwiches you will be out of bread. You will have two slices of ham left over, but without additional bread you will be unable to make any more sandwiches. In this case, bread is the limiting reactant and ham is the excess reactant.

## Determining the Limiting Reactant

In problems involving limiting reactants, the first step is to determine which is the limiting reactant. After the limiting reactant has been identified, the rest of the problem can be solved using the approach outlined in Section 3.6. Consider the formation of methanol $\left(\mathrm{CH}_{3} \mathrm{OH}\right)$ from carbon monoxide and hydrogen:

$$
\mathrm{CO}(g)+2 \mathrm{H}_{2}(g) \longrightarrow \mathrm{CH}_{3} \mathrm{OH}(l)
$$

Suppose that initially we have 5 moles of CO and 8 moles of $\mathrm{H}_{2}$, the ratio shown in Figure 3.6(a).
We can use the stoichiometric conversion factors to determine how many moles of $\mathrm{H}_{2}$ are necessary for all the CO to react. From the balanced equation, we have $1 \mathrm{~mol} \mathrm{CO} \bumpeq 2 \mathrm{~mol} \mathrm{H}_{2}$. Therefore, the amount of $\mathrm{H}_{2}$ necessary to react with 5 mol CO is

$$
\text { moles of } \mathrm{H}_{2}=5 \mathrm{mot} \mathrm{CO} \times \frac{2 \mathrm{~mol} \mathrm{H}_{2}}{1 \mathrm{motCO}}=10 \mathrm{~mol} \mathrm{H}_{2}
$$

Because there are only 8 moles of $\mathrm{H}_{2}$ available, there is insufficient $\mathrm{H}_{2}$ to react with all the CO. Therefore, $\mathrm{H}_{2}$ is the limiting reactant and CO is the excess reactant. $\mathrm{H}_{2}$ will be used up first, and when it is gone, the formation of methanol will cease and there will be some CO left over, as shown in Figure 3.6(b). To determine how much CO will be left over when the reaction is complete, we must first calculate the amount of CO that will react with all 8 moles of $\mathrm{H}_{2}$ :

$$
\text { moles of } \mathrm{CO}=8 \underline{\mathrm{~mol}}_{2} \times \frac{1 \mathrm{~mol} \mathrm{CO}}{2 \mathrm{molH}_{2}}=4 \mathrm{~mol} \mathrm{CO}
$$

Thus, there will be 4 moles of CO consumed and 1 mole ( $5 \mathrm{~mol}-4 \mathrm{~mol}$ ) left over. Sample Problem 3.12 illustrates how to combine the concept of a limiting reactant with the conversion between mass and moles. Figure 3.7 (pp. 98-99) illustrates the steps for this type of calculation.

Figure 3.6 The reaction of (a) $\mathrm{H}_{2}$ and CO to form (b) $\mathrm{CH}_{3} \mathrm{OH}$. Each molecule represents 1 mole of substance. In this case, $\mathrm{H}_{2}$ is the limiting reactant and there is 1 mole of CO remaining when the reaction is complete.

Student Annotation: Limiting reactants and excess reactants are also referred to as limiting reagents and excess reagents.

## Multimedia

Limiting reagent in reaction of NO and $\mathrm{O}_{2}$.

Figure 3.7

## Limiting Reactant Problems

Determine what mass of $\mathrm{NH}_{3}$ forms Convert to moles. when $84.06 \mathrm{~g} \mathrm{~N}_{2}$ and $22.18 \mathrm{~g} \mathrm{H}_{2}$ react according to the equation:

$$
\mathrm{N}_{2}+3 \mathrm{H}_{2} \longrightarrow 2 \mathrm{NH}_{3}
$$

$$
\begin{aligned}
& \frac{84.06 \mathrm{~g} \mathrm{~N}_{2}}{28.02 \mathrm{~g} / \mathrm{mol}}=3.000 \mathrm{~mol} \mathrm{~N}_{2} \\
& \frac{22.18 \mathrm{~g} \mathrm{H}_{2}}{2.016 \mathrm{~g} / \mathrm{mol}}=11.00 \mathrm{~mol} \mathrm{H}_{2}
\end{aligned}
$$

Determine moles $\mathrm{NH}_{3}$.

Total mass before reaction:

$$
84.06 \mathrm{~g} \mathrm{~N}_{2}+22.18 \mathrm{~g} \mathrm{H}_{2}=106.24 \mathrm{~g}
$$

Compare the total mass after the reaction with the total mass before the reaction. The small difference between the masses before and after is due to rounding.

$$
\sum \text { after reaction }=102.2 \mathrm{~g} \mathrm{NH}_{3}+4.03 \mathrm{~g} \mathrm{H}_{2}=106.2 \mathrm{~g}
$$

Add the mass of the product and the mass of leftover excess reactant to get the total mass after reaction.

Use coefficients as conversion factors.

Method 1

$$
\begin{aligned}
& 3.000 \mathrm{~mol}_{2} \times \frac{2 \mathrm{~mol} \mathrm{NH}_{3}}{1 \mathrm{molN}_{2}}=6.000 \mathrm{~mol} \mathrm{NH}_{3} \\
& 11.00 \mathrm{moHH}_{2} \times \frac{2 \mathrm{~mol} \mathrm{NH}_{3}}{3 \mathrm{molH}_{2}}=7.333 \mathrm{~mol} \mathrm{NH}_{3}
\end{aligned}
$$

or

## Method 2

Rewrite the balanced equation using actual amounts. According to the balanced equation, $3.667 \mathrm{~mol} \mathrm{~N}_{2}$

Either way, the smaller amount of product is correct.
$6.000 \mathrm{~mol} \mathrm{NH}_{3}$

## What's the point?

There is more than one correct method for solving many types of problems. This limiting reactant problem shows two different routes to the correct answer, and shows how the result can be compared to the information given in the problem to determine whether or not it is reasonable and correct.

The reaction of sodium bicarbonate and citric acid produces Alka-Seltzer's effervescence.

Think About It In a problem such as this, it is a good idea to check your work by calculating the amounts of the other products in the reaction. According to the law of conservation of mass, the combined starting mass of the two reactants $(1.700 \mathrm{~g}+1.000 \mathrm{~g}=$ 2.700 g ) should equal the sum of the masses of products and leftover excess reactant. In this case, the masses of $\mathrm{H}_{2} \mathrm{O}$ and $\mathrm{Na}_{3} \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}_{7}$ produced are 0.2815 g and 1.343 g , respectively. The mass of $\mathrm{CO}_{2}$ produced is 0.6874 g [from part (c)] and the amount of excess $\mathrm{NaHCO}_{3}$ is 0.388 g [from part (b)]. The total, $0.2815 \mathrm{~g}+$ $1.343 \mathrm{~g}+0.6874 \mathrm{~g}+0.388 \mathrm{~g}$, is 2.700 g , identical to the total mass of the reactants.

## Sample Problem 3.12

Alka-Seltzer tablets contain aspirin, sodium bicarbonate, and citric acid. When they come into contact with water, the sodium bicarbonate $\left(\mathrm{NaHCO}_{3}\right)$ and citric acid $\left(\mathrm{H}_{3} \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}_{7}\right)$ react to form carbon dioxide gas, among other products.

$$
3 \mathrm{NaHCO}_{3}(a q)+\mathrm{H}_{3} \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}_{7}(a q) \longrightarrow 3 \mathrm{CO}_{2}(g)+3 \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{Na}_{3} \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}_{7}(a q)
$$

The formation of $\mathrm{CO}_{2}$ causes the trademark fizzing when the tablets are dropped into a glass of water. An Alka-Seltzer tablet contains 1.700 g of sodium bicarbonate and 1.000 g of citric acid. Determine, for a single tablet dissolved in water, (a) which ingredient is the limiting reactant, (b) what mass of the excess reactant is left over when the reaction is complete, and (c) what mass of $\mathrm{CO}_{2}$ forms.

Strategy Convert each of the reactant masses to moles. Use the balanced equation to write the necessary stoichiometric conversion factor and determine which reactant is limiting. Again, using the balanced equation, write the stoichiometric conversion factors to determine the number of moles of excess reactant remaining and the number of moles of $\mathrm{CO}_{2}$ produced. Finally, use the appropriate molar masses to convert moles of excess reactant and moles of $\mathrm{CO}_{2}$ to grams.

Setup The required molar masses are $84.01 \mathrm{~g} / \mathrm{mol}$ for $\mathrm{NaHCO}_{3}, 192.12 \mathrm{~g} / \mathrm{mol}$ for $\mathrm{H}_{3} \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}_{7}$, and $44.01 \mathrm{~g} / \mathrm{mol}$ for $\mathrm{CO}_{2}$. From the balanced equation we have $3 \mathrm{~mol} \mathrm{NaHCO}_{3} \bumpeq 1 \mathrm{~mol} \mathrm{H}_{3} \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}_{7}$, $3 \mathrm{~mol} \mathrm{NaHCO}_{3} \bumpeq 3 \mathrm{~mol} \mathrm{CO} 2$, and $1 \mathrm{~mol}_{3} \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}_{7} \bumpeq 3 \mathrm{~mol} \mathrm{CO}_{2}$. The necessary stoichiometric conversion factors are therefore:

$$
\frac{3 \mathrm{~mol} \mathrm{NaHCO}_{3}}{1 \mathrm{~mol} \mathrm{H}_{3} \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}_{7}} \quad \frac{1 \mathrm{~mol} \mathrm{H}_{3} \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}_{7}}{3 \mathrm{~mol} \mathrm{NaHCO}_{3}} \quad \frac{3 \mathrm{~mol} \mathrm{CO}_{2}}{3 \mathrm{~mol} \mathrm{NaHCO}_{3}} \quad \frac{3 \mathrm{~mol} \mathrm{CO}_{2}}{1 \mathrm{~mol} \mathrm{H}_{3} \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}_{7}}
$$

## Solution

$$
\begin{gathered}
1.700 \mathrm{~g} \mathrm{NaHCO}_{3} \times \frac{1 \mathrm{~mol} \mathrm{NaHCO}_{3}}{84.01 \mathrm{~g} \mathrm{NaHCO}_{3}}=0.02024 \mathrm{~mol} \mathrm{NaHCO}_{3} \\
1.000 \mathrm{~g} \mathrm{H}_{3} \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}_{7} \times \frac{1 \mathrm{~mol} \mathrm{H}_{3} \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}_{7}}{192.12 \mathrm{~g} \mathrm{H}_{3} \mathrm{C}_{6} \mathrm{H}_{5} \Theta_{7}}=0.005205 \mathrm{~mol} \mathrm{H}_{3} \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}_{7}
\end{gathered}
$$

(a) To determine which reactant is limiting, calculate the amount of citric acid necessary to react completely with 0.02024 mol sodium bicarbonate.

$$
0.02024 \mathrm{~mol} \mathrm{NaHeO}_{3} \times \frac{1 \mathrm{~mol} \mathrm{H}_{3} \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}_{7}}{3 \mathrm{~mol} \mathrm{NaHCO}_{3}}=0.006745 \mathrm{~mol} \mathrm{H}_{3} \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}_{7}
$$

The amount of $\mathrm{H}_{3} \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}_{7}$ required to react with 0.02024 mol of $\mathrm{NaHCO}_{3}$ is more than a tablet contains. Therefore, citric acid is the limiting reactant and sodium bicarbonate is the excess reactant.
(b) To determine the mass of excess reactant $\left(\mathrm{NaHCO}_{3}\right)$ left over, first calculate the amount of $\mathrm{NaHCO}_{3}$ that will react:

$$
0.005205 \mathrm{~mol}_{3} \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}_{7} \times \frac{3 \mathrm{~mol} \mathrm{NaHCO}_{3}}{1 \mathrm{~mol} \mathrm{H}_{3} \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}_{7}}=0.01562 \mathrm{~mol} \mathrm{NaHCO} 3
$$

Thus, 0.01562 mole of $\mathrm{NaHCO}_{3}$ will be consumed, leaving 0.00462 mole unreacted. Convert the unreacted amount to grams as follows:

$$
0.00462 \underline{\mathrm{~mol} \mathrm{NaHCO}_{3}} \times \frac{84.01 \mathrm{~g} \mathrm{NaHCO}_{3}}{1 \mathrm{~mol} \mathrm{NaHCO}_{3}}=0.388 \mathrm{~g} \mathrm{NaHCO}_{3}
$$

(c) To determine the mass of $\mathrm{CO}_{2}$ produced, first calculate the number of moles of $\mathrm{CO}_{2}$ produced from the number of moles of limiting reactant $\left(\mathrm{H}_{3} \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}_{7}\right)$ consumed:

$$
0.005205 \mathrm{~mol} \mathrm{H}_{3} \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}_{7} \times \frac{3 \mathrm{~mol} \mathrm{CO}_{2}}{1 \mathrm{~mol} \mathrm{H}_{3} \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}_{7}}=0.01562 \mathrm{~mol} \mathrm{CO}_{2}
$$

Convert this amount to grams as follows:

$$
0.01562 \mathrm{~mol} \mathrm{CO}_{2} \times \frac{44.01 \mathrm{~g} \mathrm{CO}_{2}}{1 \mathrm{molCO}_{2}}=0.6874 \mathrm{~g} \mathrm{CO}_{2}
$$

To summarize the results: (a) citric acid is the limiting reactant, (b) 0.388 g sodium bicarbonate remains unreacted, and (c) 0.6874 g carbon dioxide is produced.

Practice Problem A Ammonia is produced by the reaction of nitrogen and hydrogen according to the equation, $\mathrm{N}_{2}(\mathrm{~g})+3 \mathrm{H}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{NH}_{3}(\mathrm{~g})$. Calculate the mass of ammonia produced when 35.0 g of nitrogen react with 12.5 g of hydrogen. Which is the excess reactant and how much of it will be left over when the reaction is complete?

EPractice Problem B Potassium hydroxide and phosphoric acid react to form potassium phosphate and water according to the equation: $3 \mathrm{KOH}(a q)+\mathrm{H}_{3} \mathrm{PO}_{4}(a q) \longrightarrow \mathrm{K}_{3} \mathrm{PO}_{4}(a q)+3 \mathrm{H}_{2} \mathrm{O}(l)$. Determine the starting mass of each reactant if $55.7 \mathrm{~g} \mathrm{~K}_{3} \mathrm{PO}_{4}$ is produced and $89.8 \mathrm{~g} \mathrm{H}_{3} \mathrm{PO}_{4}$ remains unreacted.

## Reaction Yield

When you use stoichiometry to calculate the amount of product formed in a reaction, you are calculating the theoretical yield of the reaction. The theoretical yield is the amount of product that forms when all the limiting reactant reacts to form the desired product. It is the maximum obtainable yield, predicted by the balanced equation. In practice, the actual yield-the amount of product actually obtained from a reaction-is almost always less than the theoretical yield. There are many reasons for the difference between the actual and theoretical yields. For instance, some of the reactants may not react to form the desired product. They may react to form different products, in something known as side reactions, or they may simply remain unreacted. In addition, it may be difficult to isolate and recover all the product at the end of the reaction. Chemists often determine the efficiency of a chemical reaction by calculating its percent yield, which tells what percentage the actual yield is of the theoretical yield. It is calculated as follows:

$$
\% \text { yield }=\frac{\text { actual yield }}{\text { theoretical yield }} \times 100 \% \quad \text { Equation } 3.2
$$

Percent yields may range from a tiny fraction to 100 percent. (They cannot exceed 100 percent.) Chemists try to maximize percent yield in a variety of ways. Factors that can affect percent yield, including temperature and pressure, are discussed in Chapter 15. Sample Problem 3.13 shows how to calculate the percent yield of a pharmaceutical manufacturing process.

## Sample Problem 3.13

Aspirin, acetylsalicylic acid $\left(\mathrm{C}_{9} \mathrm{H}_{8} \mathrm{O}_{4}\right)$, is the most commonly used pain reliever in the world. It is produced by the reaction of salicylic acid $\left(\mathrm{C}_{7} \mathrm{H}_{6} \mathrm{O}_{3}\right)$ and acetic anhydride $\left(\mathrm{C}_{4} \mathrm{H}_{6} \mathrm{O}_{3}\right)$ according to the following equation:

In a certain aspirin synthesis, 104.8 g of salicylic acid and 110.9 g of acetic anhydride are combined. Calculate the percent yield of the reaction if 105.6 g of aspirin are produced.

Strategy Convert reactant grams to moles, and determine which is the limiting reactant. Use the balanced equation to determine the number of moles of aspirin that can be produced, and convert this number of moles to grams for the theoretical yield. Use the actual yield (given in the problem) and the calculated theoretical yield to calculate the percent yield.

Setup The necessary molar masses are $138.12 \mathrm{~g} / \mathrm{mol}$ for salicylic acid, $102.09 \mathrm{~g} / \mathrm{mol}$ for acetic anhydride, and $180.15 \mathrm{~g} / \mathrm{mol}$ for aspirin.

Think About It Make sure you have used the proper molar masses and remember that percent yield can never exceed 100 percent.

## Solution

$$
\begin{aligned}
& 104.8 \mathrm{~g} \mathrm{C}_{7} \mathrm{H}_{6} \mathrm{O}_{3} \times \frac{1 \mathrm{~mol} \mathrm{C}_{7} \mathrm{H}_{6} \mathrm{O}_{3}}{138.12 \mathrm{~g} \mathrm{C}_{7} \mathrm{H}_{6} \mathrm{O}_{3}}=0.7588 \mathrm{~mol} \mathrm{C}_{7} \mathrm{H}_{6} \mathrm{O}_{3} \\
& 110.9 \mathrm{~g} \mathrm{C}_{4} \mathrm{H}_{6} \mathrm{O}_{3} \times \frac{1 \mathrm{~mol} \mathrm{C}_{4} \mathrm{H}_{6} \mathrm{O}_{3}}{102.09 \mathrm{~g} \mathrm{C}_{4} \mathrm{H}_{6} \mathrm{O}_{3}}=1.086 \mathrm{~mol} \mathrm{C}_{4} \mathrm{H}_{6} \mathrm{O}_{3}
\end{aligned}
$$

Because the two reactants combine in a 1:1 mole ratio, the reactant present in the smallest number of moles (in this case, salicylic acid) is the limiting reactant. According to the balanced equation, one mole of aspirin is produced for every mole of salicylic acid consumed.

$$
1 \mathrm{~mol} \text { salicylic acid }\left(\mathrm{C}_{7} \mathrm{H}_{6} \mathrm{O}_{3}\right) \bumpeq 1 \mathrm{~mol} \text { aspirin }\left(\mathrm{C}_{9} \mathrm{H}_{8} \mathrm{O}_{4}\right)
$$

Therefore, the theoretical yield of aspirin is 0.7588 mol . We convert this to grams using the molar mass of aspirin:

$$
0.7588 \underline{\mathrm{~mol}_{9} \mathrm{H}_{8} \mathrm{O}_{4}} \times \frac{180.15 \mathrm{~g} \mathrm{C}_{9} \mathrm{H}_{8} \mathrm{O}_{4}}{1 \mathrm{molC}_{9} \mathrm{H}_{8} \mathrm{O}_{4}}=136.7 \mathrm{~g} \mathrm{C}_{9} \mathrm{H}_{8} \mathrm{O}_{4}
$$

Thus, the theoretical yield is 136.7 g . If the actual yield is 105.6 g , the percent yield is

$$
\% \text { yield }=\frac{105.6 \mathrm{~g}}{136.7 \mathrm{~g}} \times 100 \%=77.25 \% \text { yield }
$$

Practice Problem A Diethyl ether is produced from ethanol according to the following equation:

$$
2 \mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}(l) \longrightarrow \mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OCH}_{2} \mathrm{CH}_{3}(l)+\mathrm{H}_{2} \mathrm{O}(l)
$$

Calculate the percent yield if 68.6 g of ethanol reacts to produce 16.1 g of ether.
§Practice Problem B What mass of ether will be produced if 221 g of ethanol reacts with a 68.9 percent yield?

## Checkpoint 3.7 Limiting Reactants

3.7.1 What mass of $\mathrm{CaSO}_{4}$ is produced according to the given equation when 5.00 g of each reactant are combined?

$$
\mathrm{CaF}_{2}(s)+\mathrm{H}_{2} \mathrm{SO}_{4}(a q) \longrightarrow \mathrm{CaSO}_{4}(s)+2 \mathrm{HF}(g)
$$

a) 10.0 g
b) 11.6 g
c) 6.94 g
d) 8.72 g
e) 5.02 g
3.7.2 What is the percent yield for a process in which $10.4 \mathrm{~g} \mathrm{CH}_{3} \mathrm{OH}$ reacts and $10.1 \mathrm{~g} \mathrm{CO}_{2}$ forms according to the following equation?

$$
2 \mathrm{CH}_{3} \mathrm{OH}(l)+3 \mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{CO}_{2}(g)+4 \mathrm{H}_{2} \mathrm{O}(l)
$$

a) $97.1 \%$
b) $70.7 \%$
c) $52.1 \%$
d) $103 \%$
e) $37.9 \%$
3.7.3 How many moles of $\mathrm{NH}_{3}$ can be produced by the combination of $3.0 \mathrm{~mol} \mathrm{~N}_{2}$ and $1.5 \mathrm{~mol} \mathrm{H}_{2}$ ?
a) 2.0 mol
b) 1.5 mol
c) 0.50 mol
d) 6.0 mol
e) 1.0 mol
3.7.4 What mass of water is produced by the reaction of $50.0 \mathrm{~g} \mathrm{CH}_{3} \mathrm{OH}$ with an excess of $\mathrm{O}_{2}$ when the yield is $53.2 \%$ ?

$$
2 \mathrm{CH}_{3} \mathrm{OH}(g)+3 \mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{CO}_{2}(g)+4 \mathrm{H}_{2} \mathrm{O}(l)
$$

a) 28.1 g
b) 56.2 g
c) 29.9 g
d) 15.0 g
e) 26.6 g
3.7.5 Reactants A (red) and B (blue) combine to form a single product C (purple) according to the equation $2 \mathrm{~A}+\mathrm{B}$ C. What is the limiting reactant in the reaction vessel shown?

a) A
b) $B$
c) C
d) None. Reactants are present in stoichiometric amounts.
3.7.6 Which of the following represents the contents of the reaction vessel in Checkpoint 3.7.5 after the reaction is complete?

## How Am I Supposed to Remember All These Reactions?

As you continue to study chemistry, you will encounter a wide variety of chemical reactions. The sheer number of different reactions can seem daunting at times, but most of them fall into a relatively small number of categories. Becoming familiar with several reaction types and learning to recognize patterns of reactivity will help you make sense out of the reactions in this book. Three of the most commonly encountered reaction types are combination, decomposition, and combustion.

Combination. A reaction in which two or more reactants combine to form a single product is known as a combination reaction. Examples include the reaction of ammonia and hydrogen chloride to form ammonium chloride,

$$
\mathrm{NH}_{3}(g)+\mathrm{HCl}(g) \longrightarrow \mathrm{NH}_{4} \mathrm{Cl}(s)
$$

and the reaction of nitrogen and hydrogen gases to form ammonia,

Decomposition. A reaction in which two or more products form from a single reactant is known as a decomposition reaction. A decomposition reaction is essentially the opposite of a combination reaction. Examples of this type of reaction include the decomposition of calcium carbonate to produce calcium oxide and carbon dioxide gas,
and the decomposition of hydrogen peroxide to produce water and oxygen gas,

Combustion. As you learned in Section 3.3, a combustion reaction is one in which a substance burns in the presence of oxygen. Combustion of a compound that contains C and H ( or $\mathrm{C}, \mathrm{H}$, and O ) produces carbon dioxide gas and water. By convention, we will consider the water produced in a combustion reaction to be liquid water. Examples of this type of combustion are the combustion of formaldehyde,

$$
\mathrm{CH}_{2} \mathrm{O}(l)+\mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l)
$$

and the combustion of methane,

Although these combustion reactions are shown here as balanced equations, oxygen is generally supplied in excess in such processes to ensure complete combustion.

$$
\mathrm{CaCO}_{3}(s) \xrightarrow{\Delta} \mathrm{CaO}(s)+\mathrm{CO}_{2}(g)
$$

## Sample Problem 3.14

Determine whether each of the following equations represents a combination reaction, a decomposition reaction, or a combustion reaction: (a) $\mathrm{H}_{2}(g)+\mathrm{Br}_{2}(g) \longrightarrow 2 \mathrm{HBr}(g)$, (b) $2 \mathrm{HCO}_{2} \mathrm{H}(\mathrm{l})+\mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{CO}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(l)$, (c) $2 \mathrm{KClO}_{3}(s) \longrightarrow 2 \mathrm{KCl}(s)+3 \mathrm{O}_{2}(g)$.

Strategy Look at the reactants and products in each balanced equation to see if two or more reactants combine into one product (a combination reaction), if one reactant splits into two or more products (a decomposition reaction), or if the main products formed are carbon dioxide gas and water (a combustion reaction).
Setup The equation in part (a) depicts two reactants and one product. The equation in part (b) represents a combination with $\mathrm{O}_{2}$ of a compound containing $\mathrm{C}, \mathrm{H}$, and O to produce $\mathrm{CO}_{2}$ and $\mathrm{H}_{2} \mathrm{O}$. The equation in part (c) represents two products being formed from a single reactant.

Solution These equations represent (a) a combination reaction, (b) a combustion reaction, and (c) a decomposition reaction.

Practice Problem A Identify each of the following as a combination, decomposition, or combustion reaction: (a) $\mathrm{C}_{2} \mathrm{H}_{4} \mathrm{O}_{2}(l)+2 \mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{CO}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(l)$, (b) $2 \mathrm{Na}(s)+$ $\mathrm{Cl}_{2}(g) \longrightarrow 2 \mathrm{NaCl}(s)$, (c) $2 \mathrm{NaH}(s) \longrightarrow 2 \mathrm{Na}(s)+\mathrm{H}_{2}(g)$.

Think About It Make sure that a reaction identified as a combination has only one product [as in part (a)], a reaction identified as a decomposition has only one reactant [as in part (b)], and a reaction identified as a combustion produces only $\mathrm{CO}_{2}$ and $\mathrm{H}_{2} \mathrm{O}$ [as in part (c)].
$\$$ Practice Problem B Using the chemical species $\mathrm{A}_{2}, \mathrm{~B}$, and AB , write a balanced equation for a combination reaction.

## Applying What You've Learned

Cisplatin $\left[\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{2} \mathrm{Cl}_{2}\right]$ is sometimes called "the penicillin of cancer drugs" because it is effective in the treatment of a wide variety of cancers. It is prepared by the reaction of ammonium tetrachloroplatinate(II) with ammonia:

Student Annotation: Note that the equation is not balanced.

This is a very expensive process because $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{PtCl}_{4}$ contains platinum, a precious metal that historically has sold for roughly twice the price of gold. Using a large excess of ammonia helps manufacturers maximize conversion of the high-priced reactant to the desired product.

## Problems:

a) Determine the molecular mass and percent composition by mass for ammonium tetrachloroplatinate(II) and for cisplatin. [14 Sample Problems 3.1 and 3.2]
b) Balance the equation for the production of cisplatin from ammonium tetrachloroplatinate(II) and ammonia. [ $\mathrm{K4}$ Sample Problem 3.3]
c) Determine the number of each type of atom in 50.00 g of cisplatin.
[ 144 Sample Problem 3.7]
d) In a particular process, $172.5 \mathrm{~g}\left(\mathrm{NH}_{4}\right)_{2} \mathrm{PtCl}_{4}$ is combined with an excess of $\mathrm{NH}_{3}$. Assuming all the limiting reactant is converted to product, how many grams of $\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{2} \mathrm{Cl}_{2}$ will be produced? [ KA Sample Problem 3.11]
e) If the actual amount of $\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{2} \mathrm{Cl}_{2}$ produced in part (d) is 129.6 g , what is the percent yield? [14 Sample Problem 3.13]

## Chapter Summary

## Section 3.1

- Molecular mass is calculated by summing the masses of all atoms in a molecule. Molecular weight is another term for molecular mass.
- For ionic compounds, we use the analogous terms formula mass and formula weight.
- Molecular masses, molecular weights, formula masses, and formula weights are expressed in atomic mass units (amu).

## Section 3.2

- Molecular or formula mass can be used to determine percent composition by mass of a compound.

## Section 3.3

- A chemical equation is a written representation of a chemical reaction or a physical process. Chemical species on the left side of the equation are called reactants, while those on the right side of the equation are called products.
- The physical state of each reactant and product is specified in parentheses as $(s),(l),(g)$, or $(a q)$ for solid, liquid, gas, and aqueous (dissolved in water), respectively.
- Chemical equations are balanced only by changing the stoichiometric coefficients of the reactants and/or products, and never by changing the formulas of the reactants and/or products (i.e., by changing their subscripted numbers).

## Section 3.4

- A mole is the amount of a substance that contains $6.022 \times 10^{23}$ [Avogadro's number $\left(N_{\mathrm{A}}\right)$ ] of elementary particles (atoms, molecules, ions, formula units, etc.).
- Molar mass $(\mathcal{M})$ is the mass of one mole of a substance, usually expressed in grams. The molar mass of a substance in grams is numerically equal to the atomic, molecular, or formula mass of the substance in amu.
- Molar mass and Avogadro's number can be used to interconvert among mass, moles, and number of particles (atoms, molecules, ions, formula units, etc.).

## Section 3.5

- Combustion analysis is used to determine the empirical formula of a compound. The empirical formula can be used to calculate percent composition.
- The empirical formula and molar mass can be used to determine the molecular formula.

## Section 3.6

- A balanced chemical equation can be used to determine how much product will form from given amounts of reactants, how much of one reactant is necessary to react with a given amount of another, or how much reactant is required to produce a specified amount of product. Reactants that are combined in exactly the ratio specified by the balanced equation are said to be "combined in stoichiometric amounts."

## Section 3.7

- The limiting reactant is the reactant that is consumed completely in a chemical reaction. An excess reactant is the reactant that is not consumed completely. The maximum amount of product that can form depends on the amount of limiting reactant.
- The theoretical yield of a reaction is the amount of product that will form if all the limiting reactant is consumed by the desired reaction.
- The actual yield is the amount of product actually recovered.
- Percent yield $[($ actual/theoretical $) \times 100 \%$ ] is a measure of the efficiency of a chemical reaction.
- Combustion (in which a substance burns in the presence of oxygen), combination (in which two or more reactants combine to form a single product), and decomposition (in which a reactant splits apart to form two or more products) are three types of reactions that are commonly encountered.

## Key Equations

3.1 percent by mass of an element $=\frac{n \times \text { atomic mass of element }}{\text { molecular or formula mass of compound }} \times 100 \%$
3.2 $\%$ yield $=\frac{\text { actual yield }}{\text { theoretical yield }} \times 100 \%$

## Questions and Problems

## Section 3.1: Molecular and Formula Masses

## Review Questions

3.1 What is meant by the term molecular mass, and why is the molecular mass that we calculate generally an average molecular mass?
3.2 Explain the difference between the terms molecular mass and formula mass. To what type of compound does each term refer?

## Problems

3.3 Calculate the molecular mass (in amu) of each of the following substances: (a) $\mathrm{CH}_{3} \mathrm{Cl}$, (b) $\mathrm{N}_{2} \mathrm{O}_{4}$, (c) $\mathrm{SO}_{2}$, (d) $\mathrm{C}_{6} \mathrm{H}_{12}$, (e) $\mathrm{H}_{2} \mathrm{O}_{2}$, (f) $\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}$, (g) $\mathrm{NH}_{3}$.
3.4 Calculate the molecular mass (in amu) of each of the following substances: (a) $\mathrm{C}_{6} \mathrm{H}_{6} \mathrm{O}$, (b) $\mathrm{H}_{2} \mathrm{SO}_{4}$, (c) $\mathrm{C}_{6} \mathrm{H}_{6}$, (d) $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}$, (e) $\mathrm{BCl}_{3}$, (f) $\mathrm{N}_{2} \mathrm{O}_{5}$, (g) $\mathrm{H}_{3} \mathrm{PO}_{4}$

H3.5 Calculate the molecular mass or formula mass (in amu) of each of the following substances: (a) $\mathrm{CH}_{4}$, (b) $\mathrm{NO}_{2}$, (c) $\mathrm{SO}_{3}$, (d) $\mathrm{C}_{6} \mathrm{H}_{6}$, (e) NaI , (f) $\mathrm{K}_{2} \mathrm{SO}_{4}$, (g) $\mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}$.
3.6 Calculate the molecular mass or formula mass (in amu) of each of the following substances: (a) $\mathrm{Li}_{2} \mathrm{CO}_{3}$, (b) $\mathrm{C}_{2} \mathrm{H}_{6}$, (c) $\mathrm{NF}_{2}$, (d) $\mathrm{Al}_{2} \mathrm{O}_{3}$, (e) $\mathrm{Fe}\left(\mathrm{NO}_{3}\right)_{3}$, (f) $\mathrm{PCl}_{5}$, (g) $\mathrm{Mg}_{3} \mathrm{~N}_{2}$.

## Section 3.2: Percent Composition of Compounds

## Review Questions

3.7 Use ammonia $\left(\mathrm{NH}_{3}\right)$ to explain what is meant by the percent composition by mass of a compound.
3.8 Describe how the knowledge of the percent composition by mass of an unknown compound can help us identify the compound.

## Problems

3.9 Tin ( Sn ) exists in Earth's crust as $\mathrm{SnO}_{2}$. Calculate the percent composition by mass of Sn and O in $\mathrm{SnO}_{2}$.

E3.10 For many years chloroform $\left(\mathrm{CHCl}_{3}\right)$ was used as an inhalation anesthetic in spite of the fact that it is also a toxic substance that may cause severe liver, kidney, and heart damage. Calculate the percent composition by mass of this compound.
3.11 All the substances listed here are fertilizers that contribute nitrogen to the soil. Which of these is the richest source of nitrogen on a mass percentage basis?
(a) Urea $\left[\left(\mathrm{NH}_{2}\right)_{2} \mathrm{CO}\right]$
(b) Ammonium nitrate $\left(\mathrm{NH}_{4} \mathrm{NO}_{3}\right)$
(c) Guanidine $\left[\mathrm{HNC}\left(\mathrm{NH}_{2}\right)_{2}\right]$
(d) Ammonia $\left(\mathrm{NH}_{3}\right)$

E 3.12 The anticaking agent added to Morton salt is calcium silicate $\left(\mathrm{CaSiO}_{3}\right)$. This compound can absorb up to 2.5 times its mass of water and still remain a free-flowing powder. Calculate the percent composition of $\mathrm{CaSiO}_{3}$.
3.13 Tooth enamel is $\mathrm{Ca}_{5}\left(\mathrm{PO}_{4}\right)_{3}(\mathrm{OH})$. Calculate the percent composition of the elements present.

## Section 3.3: Chemical Equations

## Review Questions

3.14 Use the formation of water from hydrogen and oxygen to explain the following terms: chemical reaction, reactant, and product.
3.15 What is the difference between a chemical reaction and a chemical equation?
3.16 Why must a chemical equation be balanced? What law is obeyed by a balanced chemical equation?
3.17 Write the symbols used to represent gas, liquid, solid, and the aqueous phase in chemical equations.

## Problems

3.18 Write an unbalanced equation to represent each of the following reactions: (a) nitrogen and oxygen react to form nitrogen dioxide, (b) dinitrogen pentoxide reacts to form dinitrogen tetroxide and oxygen, (c) ozone reacts to form oxygen, (d) chlorine and sodium iodide react to form iodine and sodium chloride, and (e) magnesium and oxygen react to form magnesium oxide.
3.19 Write an unbalanced equation to represent each of the following reactions: (a) potassium hydroxide and phosphoric acid react to form potassium phosphate and water; (b) zinc and silver chloride react to form zinc chloride and silver; (c) sodium hydrogen carbonate reacts to form sodium carbonate, water, and carbon dioxide; (d) ammonium nitrite reacts to form nitrogen and water; and (e) carbon dioxide and potassium hydroxide react to form potassium carbonate and water.
3.20 For each of the following unbalanced chemical equations, write the corresponding chemical statement.
(a) $\mathrm{S}_{8}+\mathrm{O}_{2} \longrightarrow \mathrm{SO}_{2}$
(b) $\mathrm{CH}_{4}+\mathrm{O}_{2} \longrightarrow \mathrm{CO}_{2}+\mathrm{H}_{2} \mathrm{O}$
(c) $\mathrm{N}_{2}+\mathrm{H}_{2} \longrightarrow \mathrm{NH}_{3}$
(d) $\mathrm{P}_{4} \mathrm{O}_{10}+\mathrm{H}_{2} \mathrm{O} \longrightarrow \mathrm{H}_{3} \mathrm{PO}_{4}$
(e) $\mathrm{S}+\mathrm{HNO}_{3} \longrightarrow \mathrm{H}_{2} \mathrm{SO}_{4}+\mathrm{NO}_{2}+\mathrm{H}_{2} \mathrm{O}$
3.21 For each of the following unbalanced chemical equations, write the corresponding chemical statement.
(a) $\mathrm{K}+\mathrm{H}_{2} \mathrm{O} \longrightarrow \mathrm{KOH}+\mathrm{H}_{2}$
(b) $\mathrm{Ba}(\mathrm{OH})_{2}+\mathrm{HCl} \longrightarrow \mathrm{BaCl}_{2}+\mathrm{H}_{2} \mathrm{O}$
(c) $\mathrm{Cu}+\mathrm{HNO}_{3} \longrightarrow \mathrm{Cu}\left(\mathrm{NO}_{3}\right)_{2}+\mathrm{NO}+\mathrm{H}_{2} \mathrm{O}$
(d) $\mathrm{Al}+\mathrm{H}_{2} \mathrm{SO}_{4} \longrightarrow \mathrm{Al}_{2}\left(\mathrm{SO}_{4}\right)_{3}+\mathrm{H}_{2}$
(e) $\mathrm{HI} \longrightarrow \mathrm{H}_{2}+\mathrm{I}_{2}$
$\leftrightarrows$ 3.22 Balance the following equations using the method outlined in Section 3.3.
(a) $\mathrm{C}+\mathrm{O}_{2} \longrightarrow \mathrm{CO}$
(b) $\mathrm{CO}+\mathrm{O}_{2} \longrightarrow \mathrm{CO}_{2}$
(c) $\mathrm{H}_{2}+\mathrm{Br}_{2} \longrightarrow \mathrm{HBr}$
(d) $\mathrm{K}+\mathrm{H}_{2} \mathrm{O} \longrightarrow \mathrm{KOH}+\mathrm{H}_{2}$
(e) $\mathrm{Mg}+\mathrm{O}_{2} \longrightarrow \mathrm{MgO}$
(f) $\mathrm{O}_{3} \longrightarrow \mathrm{O}_{2}$
(g) $\mathrm{H}_{2} \mathrm{O}_{2} \longrightarrow \mathrm{H}_{2} \mathrm{O}+\mathrm{O}_{2}$
(h) $\mathrm{N}_{2}+\mathrm{H}_{2} \longrightarrow \mathrm{NH}_{3}$
(i) $\mathrm{Zn}+\mathrm{AgCl} \longrightarrow \mathrm{ZnCl}_{2}+\mathrm{Ag}$
(j) $\mathrm{S}_{8}+\mathrm{O}_{2} \longrightarrow \mathrm{SO}_{2}$
(k) $\mathrm{NaOH}+\mathrm{H}_{2} \mathrm{SO}_{4} \longrightarrow \mathrm{Na}_{2} \mathrm{SO}_{4}+\mathrm{H}_{2} \mathrm{O}$
(l) $\mathrm{Cl}_{2}+\mathrm{NaI} \longrightarrow \mathrm{NaCl}+\mathrm{I}_{2}$
(m) $\mathrm{KOH}+\mathrm{H}_{3} \mathrm{PO}_{4} \longrightarrow \mathrm{~K}_{3} \mathrm{PO}_{4}+\mathrm{H}_{2} \mathrm{O}$
(n) $\mathrm{CH}_{4}+\mathrm{Br}_{2} \longrightarrow \mathrm{CBr}_{4}+\mathrm{HBr}$
3.23 Balance the following equations using the method outlined in Section 3.3.
(a) $\mathrm{N}_{2} \mathrm{O}_{5} \longrightarrow \mathrm{~N}_{2} \mathrm{O}_{4}+\mathrm{O}_{2}$
(b) $\mathrm{KNO}_{3} \longrightarrow \mathrm{KNO}_{2}+\mathrm{O}_{2}$
(c) $\mathrm{NH}_{4} \mathrm{NO}_{3} \longrightarrow \mathrm{~N}_{2} \mathrm{O}+\mathrm{H}_{2} \mathrm{O}$
(d) $\mathrm{NH}_{4} \mathrm{NO}_{2} \longrightarrow \mathrm{~N}_{2}+\mathrm{H}_{2} \mathrm{O}$
(e) $\mathrm{NaHCO}_{3} \longrightarrow \mathrm{Na}_{2} \mathrm{CO}_{3}+\mathrm{H}_{2} \mathrm{O}+\mathrm{CO}_{2}$
(f) $\mathrm{P}_{4} \mathrm{O}_{10}+\mathrm{H}_{2} \mathrm{O} \longrightarrow \mathrm{H}_{3} \mathrm{PO}_{4}$
(g) $\mathrm{HCl}+\mathrm{CaCO}_{3} \longrightarrow \mathrm{CaCl}_{2}+\mathrm{H}_{2} \mathrm{O}+\mathrm{CO}_{2}$
(h) $\mathrm{Al}+\mathrm{H}_{2} \mathrm{SO}_{4} \longrightarrow \mathrm{Al}_{2}\left(\mathrm{SO}_{4}\right)_{3}+\mathrm{H}_{2}$
(i) $\mathrm{CO}_{2}+\mathrm{KOH} \longrightarrow \mathrm{K}_{2} \mathrm{CO}_{3}+\mathrm{H}_{2} \mathrm{O}$
(j) $\mathrm{CH}_{4}+\mathrm{O}_{2} \longrightarrow \mathrm{CO}_{2}+\mathrm{H}_{2} \mathrm{O}$
(k) $\mathrm{Be}_{2} \mathrm{C}+\mathrm{H}_{2} \mathrm{O} \longrightarrow \mathrm{Be}(\mathrm{OH})_{2}+\mathrm{CH}_{4}$
(l) $\mathrm{Cu}+\mathrm{HNO}_{3} \longrightarrow \mathrm{Cu}\left(\mathrm{NO}_{3}\right)_{2}+\mathrm{NO}+\mathrm{H}_{2} \mathrm{O}$
(m) $\mathrm{S}+\mathrm{HNO}_{3} \longrightarrow \mathrm{H}_{2} \mathrm{SO}_{4}+\mathrm{NO}_{2}+\mathrm{H}_{2} \mathrm{O}$
(n) $\mathrm{NH}_{3}+\mathrm{CuO} \longrightarrow \mathrm{Cu}+\mathrm{N}_{2}+\mathrm{H}_{2} \mathrm{O}$
3.24 Which of the following equations best represents the reaction shown in the diagram?
(a) $8 \mathrm{~A}+4 \mathrm{~B} \longrightarrow \mathrm{C}+\mathrm{D}$
(b) $4 \mathrm{~A}+8 \mathrm{~B} \longrightarrow 4 \mathrm{C}+4 \mathrm{D}$
(c) $2 \mathrm{~A}+\mathrm{B} \longrightarrow \mathrm{C}+\mathrm{D}$
(d) $4 \mathrm{~A}+2 \mathrm{~B} \longrightarrow 4 \mathrm{C}+4 \mathrm{D}$
(e) $2 \mathrm{~A}+4 \mathrm{~B} \longrightarrow \mathrm{C}+\mathrm{D}$

3.25 Which of the following equations best represents the reaction shown in the diagram?
(a) $\mathrm{A}+\mathrm{B} \longrightarrow \mathrm{C}+\mathrm{D}$
(b) $6 \mathrm{~A}+4 \mathrm{~B} \longrightarrow \mathrm{C}+\mathrm{D}$
(c) $\mathrm{A}+2 \mathrm{~B} \longrightarrow 2 \mathrm{C}+\mathrm{D}$
(d) $3 \mathrm{~A}+2 \mathrm{~B} \longrightarrow 2 \mathrm{C}+\mathrm{D}$
(e) $3 \mathrm{~A}+2 \mathrm{~B} \longrightarrow 4 \mathrm{C}+2 \mathrm{D}$

## Section 3.4: The Mole and Molar Masses

## Review Questions

3.26 Define the term mole. What is the unit for mole in calculations? What does the mole have in common with the pair, the dozen, and the gross? What does Avogadro's number represent?
3.27 What is the molar mass of an atom? What are the commonly used units for molar mass?
3.28 What does the word empirical in empirical formula mean?
3.29 If we know the empirical formula of a compound, what additional information do we need to determine its molecular formula?

## Problems

3.30 Earth's population is about 6.5 billion. Suppose that every person on Earth participates in a process of counting identical particles at the rate of two particles per second. How many years would it
take to count $6.0 \times 10^{23}$ particles? Assume that there are 365 days in a year.
3.31 The thickness of a piece of paper is 0.0036 in . Suppose a certain book has an Avogadro's number of pages; calculate the thickness of the book in light-years. (Hint: See Problem 1.64 for the definition of light-year.)

H3.32 How many atoms are there in 5.10 moles of sulfur (S)?
3.33 How many moles of cobalt $(\mathrm{Co})$ atoms are there in $6.00 \times 10^{9}$ ( 6 billion) Co atoms?
3.34 How many moles of calcium (Ca) atoms are in 77.4 g of Ca ?

Y 3.35 How many grams of gold ( Au ) are there in 15.3 moles of Au ?
3.36 What is the mass in grams of a single atom of each of the following elements: (a) Hg , (b) Ne ?
3.37 What is the mass in grams of a single atom of each of the following elements: (a) As, (b) Ni ?

G3.38 What is the mass in grams of $1.00 \times 10^{12}$ lead $(\mathrm{Pb})$ atoms?
3.39 How many atoms are present in 3.14 g of copper $(\mathrm{Cu})$ ?
3.40 Which of the following has more atoms: 1.10 g of hydrogen atoms or 14.7 g of chromium atoms?
3.41 Which of the following has a greater mass: two atoms of lead or $5.1 \times 10^{-23}$ mole of helium?

H3.42 Calculate the molar mass of the following substances: (a) $\mathrm{Li}_{2} \mathrm{CO}_{3}$, (b) $\mathrm{CS}_{2}$, (c) $\mathrm{CHCl}_{3}$ (chloroform), (d) $\mathrm{C}_{6} \mathrm{H}_{8} \mathrm{O}_{6}$ (ascorbic acid, or vitamin C), (e) $\mathrm{KNO}_{3}$, (f) $\mathrm{Mg}_{3} \mathrm{~N}_{2}$.

H3.43 Calculate the molar mass of a compound if 0.372 mole of it has a mass of 152 g .

EJ 3.44 How many molecules of ethane $\left(\mathrm{C}_{2} \mathrm{H}_{6}\right)$ are present in 0.334 g of $\mathrm{C}_{2} \mathrm{H}_{6}$ ?
$\Psi 3.45$ Calculate the number of $\mathrm{C}, \mathrm{H}$, and O atoms in 1.50 g of glucose $\left(\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}\right)$, a sugar.

H3.46 Urea $\left[\left(\mathrm{NH}_{2}\right)_{2} \mathrm{CO}\right]$ is used for fertilizer and many other things. Calculate the number of $\mathrm{N}, \mathrm{C}, \mathrm{O}$, and H atoms in $1.68 \times 10^{4} \mathrm{~g}$ of urea.

H3.47 Pheromones are a special type of compound secreted by the females of many insect species to attract the males for mating. One pheromone has the molecular formula $\mathrm{C}_{19} \mathrm{H}_{38} \mathrm{O}$. Normally, the amount of this pheromone secreted by a female insect is about $1.0 \times 10^{-12} \mathrm{~g}$. How many molecules are there in this quantity?
$\leftrightarrows 3.48$ The density of water is $1.00 \mathrm{~g} / \mathrm{mL}$ at $4^{\circ} \mathrm{C}$. How many water molecules are present in 2.56 mL of water at this temperature?

H3.49 Cinnamic alcohol is used mainly in perfumery, particularly in soaps and cosmetics. Its molecular formula is $\mathrm{C}_{9} \mathrm{H}_{10} \mathrm{O}$. (a) Calculate the percent composition by mass of $\mathrm{C}, \mathrm{H}$, and O in cinnamic alcohol. (b) How many molecules of cinnamic alcohol are contained in a sample of mass 0.469 g ?
3.50 Allicin is the compound responsible for the characteristic smell of garlic. An analysis of the compound gives the following percent composition by mass: C: 44.4 percent; $\mathrm{H}: 6.21$ percent; $\mathrm{S}: 39.5$ percent; $\mathrm{O}: 9.86$ percent. Calculate its empirical formula. What is its molecular formula given that its molar mass is about 162 g ?
3.51 Peroxyacylnitrate (PAN) is one of the components of smog. It is a compound of $\mathrm{C}, \mathrm{H}, \mathrm{N}$, and O . Determine the percent composition of oxygen and the empirical formula from the following percent composition by mass: 19.8 percent C, 2.50 percent $\mathrm{H}, 11.6$ percent N . What is its molecular formula given that its molar mass is about 120 g ?
3.52 The formula for rust can be represented by $\mathrm{Fe}_{2} \mathrm{O}_{3}$. How many moles of Fe are present in 24.6 g of the compound?
3.53 How many grams of sulfur (S) are needed to react completely with 246 g of mercury $(\mathrm{Hg})$ to form HgS ?

E 3.54 Calculate the mass in grams of iodine $\left(\mathrm{I}_{2}\right)$ that will react completely with 20.4 g of aluminum ( Al ) to form aluminum iodide $\left(\mathrm{AlI}_{3}\right)$.
3.55 Tin(II) fluoride $\left(\mathrm{SnF}_{2}\right)$ is often added to toothpaste as an ingredient to prevent tooth decay. What is the mass of F in grams in 24.6 g of the compound?
3.56 Determine the empirical formulas of the compounds with the following compositions: (a) 2.1 percent $\mathrm{H}, 65.3$ percent $\mathrm{O}, 32.6$ percent S , (b) 20.2 percent $\mathrm{Al}, 79.8$ percent Cl .

E 3.57 Determine the empirical formulas of the compounds with the following compositions: (a) 40.1 percent $\mathrm{C}, 6.6$ percent $\mathrm{H}, 53.3$ percent O , (b) 18.4 percent $\mathrm{C}, 21.5$ percent $\mathrm{N}, 60.1$ percent K .

E3.58 The empirical formula of a compound is CH. If the molar mass of this compound is about 78 g , what is its molecular formula?
3.59 The molar mass of caffeine is 194.19 g . Is the molecular formula of caffeine $\mathrm{C}_{4} \mathrm{H}_{5} \mathrm{~N}_{2} \mathrm{O}$ or $\mathrm{C}_{8} \mathrm{H}_{10} \mathrm{~N}_{4} \mathrm{O}_{2}$ ?

E3.60 Monosodium glutamate (MSG), a food-flavor enhancer, has been blamed for "Chinese restaurant syndrome," the symptoms of which are headaches and chest pains. MSG has the following composition by mass: 35.51 percent $\mathrm{C}, 4.77$ percent $\mathrm{H}, 37.85$ percent $\mathrm{O}, 8.29$ percent N , and 13.60 percent Na . What is its molecular formula if its molar mass is about 169 g ?

Y3.61 Toxicologists use the term $\mathrm{LD}_{50}$ to describe the number of grams of a substance per kilogram of body weight that is a lethal dose for 50 percent of test animals. Calculate the number of arsenic(VI) oxide molecules corresponding to an $\mathrm{LD}_{50}$ value of 0.015 for a 184-lb man, assuming that the test animals and humans have the same $\mathrm{LD}_{50}$.
3.62 Chemical analysis shows that the oxygen-carrying protein hemoglobin is 0.34 percent Fe by mass. What is the minimum possible molar mass of hemoglobin? The actual molar mass of hemoglobin is about $65,000 \mathrm{~g}$. How would you account for the discrepancy between your minimum value and the experimental value?

## Section 3.5: Combustion Analysis

## Review Questions

3.63 In combustion analysis, is the combined mass of the products $\left(\mathrm{CO}_{2}\right.$ and $\left.\mathrm{H}_{2} \mathrm{O}\right)$ less than, equal to, or greater than the combined mass of the compound that is combusted and the $\mathrm{O}_{2}$ that reacts with it? Explain.
3.64 Explain why, in combustion analysis, we cannot determine the amount of oxygen in the sample directly from the amount of oxygen in the products $\mathrm{H}_{2} \mathrm{O}$ and $\mathrm{CO}_{2}$.

## Problems

E3.65 Menthol is a flavoring agent extracted from peppermint oil. It contains $\mathrm{C}, \mathrm{H}$, and O . In one combustion analysis, 10.00 mg of the substance yields $11.53 \mathrm{mg} \mathrm{H}_{2} \mathrm{O}$ and $28.16 \mathrm{mg} \mathrm{CO}_{2}$. What is the empirical formula of menthol?
3.66 Determine the empirical formula of an organic compound containing only C and H given that combustion of a $1.50-\mathrm{g}$ sample of the compound produces $4.71 \mathrm{~g} \mathrm{CO}_{2}$ and $1.93 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}$.
3.67 Lactic acid, which consists of $\mathrm{C}, \mathrm{H}$, and O , has long been thought to be responsible for muscle soreness following strenuous exercise. Determine the empirical formula of lactic acid given that combustion of a $10.0-\mathrm{g}$ sample produces $14.7 \mathrm{~g} \mathrm{CO}_{2}$ and $6.00 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}$.
3.68 Perchloroethylene, also known as "perc," is the solvent used in most dry cleaning. It consists of C and Cl . Determine the empirical formula of perchloroethylene given that a $2.58-\mathrm{g}$ sample yields $1.37 \mathrm{~g} \mathrm{CO}_{2}$ in a combustion analysis experiment.
3.69 Paradichlorobenzene, a common ingredient in solid air fresheners, contains only $\mathrm{C}, \mathrm{H}$, and Cl and has a molar mass of about 147 g . Given that combustion of 1.68 g of this compound produces $3.02 \mathrm{~g} \mathrm{CO}_{2}$ and $0.412 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}$, determine its empirical and molecular formulas.
3.70 Ascorbic acid (vitamin C) contains $\mathrm{C}, \mathrm{H}$, and O . In one combustion analysis, 5.24 g of ascorbic acid yields $7.86 \mathrm{~g} \mathrm{CO}_{2}$ and $2.14 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}$. Calculate the empirical formula and molecular formula of ascorbic acid given that its molar mass is about 176 g .
3.71 The amino acid cysteine plays an important role in the threedimensional structure of proteins by forming "disulfide bridges." The percent composition of cysteine is 29.74 percent $\mathrm{C}, 5.82$ percent $H, 26.41$ percent $O, 11.56$ percent $N$, and 26.47 percent $S$. What is the molecular formula if its molar mass is approximately 121 g ?

## Section 3.6: Calculations with Balanced Chemical Equations

## Review Questions

3.72 On what law is stoichiometry based? Why is it essential to use balanced equations in solving stoichiometric problems?
3.73 Describe the steps involved in balancing a chemical equation.

## Problems

S3.74 Consider the combustion of carbon monoxide ( CO ) in oxygen gas:

$$
2 \mathrm{CO}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{CO}_{2}(g)
$$

Starting with 3.60 moles of CO , calculate the number of moles of $\mathrm{CO}_{2}$ produced if there is enough oxygen gas to react with all the CO .
3.75 Silicon tetrachloride $\left(\mathrm{SiCl}_{4}\right)$ can be prepared by heating Si in chlorine gas:

$$
\mathrm{Si}(s)+2 \mathrm{Cl}_{2}(g) \longrightarrow \mathrm{SiCl}_{4}(l)
$$

In one reaction, 0.507 mole of $\mathrm{SiCl}_{4}$ is produced. How many moles of molecular chlorine were used in the reaction?

Ammonia is a principal nitrogen fertilizer. It is prepared by the reaction between hydrogen and nitrogen:

$$
3 \mathrm{H}_{2}(g)+\mathrm{N}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{NH}_{3}(\mathrm{~g})
$$

In a particular reaction, 6.0 moles of $\mathrm{NH}_{3}$ were produced. How many moles of $\mathrm{H}_{2}$ and how many moles of $\mathrm{N}_{2}$ were consumed to produce this amount of $\mathrm{NH}_{3}$ ?
3.77 Consider the combustion of butane $\left(\mathrm{C}_{4} \mathrm{H}_{10}\right)$ :

$$
2 \mathrm{C}_{4} \mathrm{H}_{10}(g)+13 \mathrm{O}_{2}(g) \longrightarrow 8 \mathrm{CO}_{2}(g)+10 \mathrm{H}_{2} \mathrm{O}(l)
$$

In a particular reaction, 5.0 moles of $\mathrm{C}_{4} \mathrm{H}_{10}$ react with an excess of $\mathrm{O}_{2}$. Calculate the number of moles of $\mathrm{CO}_{2}$ formed.
\& 3.78 The annual production of sulfur dioxide from burning coal and fossil fuels, auto exhaust, and other sources is about 26 million tons. The equation for the reaction is

$$
\mathrm{S}(s)+\mathrm{O}_{2}(g) \longrightarrow \mathrm{SO}_{2}(g)
$$

How much sulfur (in tons), present in the original materials, would result in that quantity of $\mathrm{SO}_{2}$ ?
3.79 When baking soda (sodium bicarbonate or sodium hydrogen carbonate, $\mathrm{NaHCO}_{3}$ ) is heated, it releases carbon dioxide gas, which is responsible for the rising of cookies, doughnuts, and bread. (a) Write a balanced equation for the decomposition of the compound (one of the products is $\mathrm{Na}_{2} \mathrm{CO}_{3}$ ). (b) Calculate the mass of $\mathrm{NaHCO}_{3}$ required to produce 20.5 g of $\mathrm{CO}_{2}$.
\& 3.80 When potassium cyanide (KCN) reacts with acids, a deadly poisonous gas, hydrogen cyanide (HCN), is given off. Here is the equation:

$$
\mathrm{KCN}(a q)+\mathrm{HCl}(a q) \longrightarrow \mathrm{KCl}(a q)+\mathrm{HCN}(g)
$$

If a sample of 0.140 g of KCN is treated with an excess of HCl , calculate the amount of HCN formed, in grams.
3.81 Fermentation is a complex chemical process of winemaking in which glucose is converted into ethanol and carbon dioxide:

$$
\underset{\text { glucose }}{\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}} \longrightarrow \underset{\text { ethanol }}{2 \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}}+2 \mathrm{CO}_{2}
$$

Starting with 500.4 g of glucose, what is the maximum amount of ethanol in grams and in liters that can be obtained by this process (density of ethanol $=0.789 \mathrm{~g} / \mathrm{mL})$ ?
3.82 Each copper(II) sulfate unit is associated with five water molecules in crystalline copper(II) sulfate pentahydrate $\left(\mathrm{CuSO}_{4} \cdot 5 \mathrm{H}_{2} \mathrm{O}\right)$. When this compound is heated in air above $100^{\circ} \mathrm{C}$, it loses the water molecules and also its blue color:

$$
\mathrm{CuSO}_{4} \cdot 5 \mathrm{H}_{2} \mathrm{O} \longrightarrow \mathrm{CuSO}_{4}+5 \mathrm{H}_{2} \mathrm{O}
$$

If 9.60 g of $\mathrm{CuSO}_{4}$ is left after heating 15.01 g of the blue compound, calculate the number of moles of $\mathrm{H}_{2} \mathrm{O}$ originally present in the compound.
\& 3.83 For many years the extraction of gold-that is, the separation of gold from other materials-involved the use of potassium cyanide:

$$
4 \mathrm{Au}+8 \mathrm{KCN}+\mathrm{O}_{2}+2 \mathrm{H}_{2} \mathrm{O} \longrightarrow 4 \mathrm{KAu}(\mathrm{CN})_{2}+4 \mathrm{KOH}
$$

What is the minimum amount of KCN in moles needed to extract 29.0 g (about an ounce) of gold?
3.84 Limestone $\left(\mathrm{CaCO}_{3}\right)$ is decomposed by heating to quicklime $(\mathrm{CaO})$ and carbon dioxide. Calculate how many grams of quicklime can be produced from 1.0 kg of limestone.
3.85 Nitrous oxide $\left(\mathrm{N}_{2} \mathrm{O}\right)$ is also called "laughing gas." It can be prepared by the thermal decomposition of ammonium nitrate $\left(\mathrm{NH}_{4} \mathrm{NO}_{3}\right)$. The other product is $\mathrm{H}_{2} \mathrm{O}$. (a) Write a balanced
equation for this reaction. (b) How many grams of $\mathrm{N}_{2} \mathrm{O}$ are formed if 0.46 mole of $\mathrm{NH}_{4} \mathrm{NO}_{3}$ is used in the reaction?
\& 3.86 The fertilizer ammonium sulfate $\left[\left(\mathrm{NH}_{4}\right)_{2} \mathrm{SO}_{4}\right]$ is prepared by the reaction between ammonia $\left(\mathrm{NH}_{3}\right)$ and sulfuric acid:

$$
2 \mathrm{NH}_{3}(g)+\mathrm{H}_{2} \mathrm{SO}_{4}(a q) \longrightarrow\left(\mathrm{NH}_{4}\right)_{2} \mathrm{SO}_{4}(a q)
$$

How many kilograms of $\mathrm{NH}_{3}$ are needed to produce $1.00 \times 10^{5} \mathrm{~kg}$ of $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{SO}_{4}$ ?
3.87 A common laboratory preparation of oxygen gas is the thermal decomposition of potassium chlorate $\left(\mathrm{KClO}_{3}\right)$. Assuming complete decomposition, calculate the number of grams of $\mathrm{O}_{2}$ gas that can be obtained from 46.0 g of $\mathrm{KClO}_{3}$. (The products are KCl and $\mathrm{O}_{2}$.)

## Section 3.7: Limiting Reactants

## Review Questions

3.88 Define limiting reactant and excess reactant. What is the significance of the limiting reactant in predicting the amount of the product obtained in a reaction? Can there be a limiting reactant if only one reactant is present?
3.89 Give an everyday example that illustrates the limiting reactant concept.
3.90 Why is the theoretical yield of a reaction determined only by the amount of the limiting reactant?
3.91 Why is the actual yield of a reaction almost always smaller than the theoretical yield?

## Problems

3.92 Consider the reaction

$$
2 \mathrm{~A}+\mathrm{B} \longrightarrow \mathrm{C}
$$

(a) In the diagram here that represents the reaction, which reactant, A or B , is the limiting reactant? (b) Assuming a complete reaction, draw a molecular-model representation of the amounts of reactants and products left after the reaction. The atomic arrangement in C is ABA.

3.93 Consider the reaction

$$
\mathrm{N}_{2}+3 \mathrm{H}_{2} \longrightarrow 2 \mathrm{NH}_{3}
$$

Assuming each model represents one mole of the substance, show the number of moles of the product and the excess reactant left after the complete reaction.

\$3.94 Nitric oxide (NO) reacts with oxygen gas to form nitrogen dioxide $\left(\mathrm{NO}_{2}\right)$, a dark-brown gas:

$$
2 \mathrm{NO}(g)+\mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{NO}_{2}(\mathrm{~g})
$$

In one experiment, 0.886 mole of NO is mixed with 0.503 mole of $\mathrm{O}_{2}$. Determine which of the two reactants is the limiting reactant. Calculate also the number of moles of $\mathrm{NO}_{2}$ produced.
3.95 Consider the reaction pictured, where each red sphere represents an oxygen atom and each blue sphere represents a nitrogen atom. Write the balanced equation and identify the limiting reactant.

3.96 Products of the combustion analysis of a hydrocarbon are represented as shown. Determine the empirical formula of the hydrocarbon.

3.97 Consider the reaction

$$
\mathrm{MnO}_{2}+4 \mathrm{HCl} \longrightarrow \mathrm{MnCl}_{2}+\mathrm{Cl}_{2}+2 \mathrm{H}_{2} \mathrm{O}
$$

If 0.86 mole of $\mathrm{MnO}_{2}$ and 48.2 g of HCl react, which reactant will be used up first? How many grams of $\mathrm{Cl}_{2}$ will be produced?
3.98 Hydrogen fluoride is used in the manufacture of Freons (which destroy ozone in the stratosphere) and in the production of aluminum metal. It is prepared by the reaction

$$
\mathrm{CaF}_{2}+\mathrm{H}_{2} \mathrm{SO}_{4} \longrightarrow \mathrm{CaSO}_{4}+2 \mathrm{HF}
$$

In one process, 6.00 kg of $\mathrm{CaF}_{2}$ is treated with an excess of $\mathrm{H}_{2} \mathrm{SO}_{4}$ and yields 2.86 kg of HF. Calculate the percent yield of HF.
3.99 Nitroglycerin $\left(\mathrm{C}_{3} \mathrm{H}_{5} \mathrm{~N}_{3} \mathrm{O}_{9}\right)$ is a powerful explosive. Its decomposition may be represented by

$$
4 \mathrm{C}_{3} \mathrm{H}_{5} \mathrm{~N}_{3} \mathrm{O}_{9} \longrightarrow 6 \mathrm{~N}_{2}+12 \mathrm{CO}_{2}+10 \mathrm{H}_{2} \mathrm{O}+\mathrm{O}_{2}
$$

This reaction generates a large amount of heat and gaseous products. It is the sudden formation of these gases, together with their rapid expansion, that produces the explosion. (a) What is the maximum amount of $\mathrm{O}_{2}$ in grams that can be obtained from 2.00 $\times 10^{2} \mathrm{~g}$ of nitroglycerin? (b) Calculate the percent yield in this reaction if the amount of $\mathrm{O}_{2}$ generated is found to be 6.55 g .
3.100 Titanium(IV) oxide $\left(\mathrm{TiO}_{2}\right)$ is a white substance produced by the action of sulfuric acid on the mineral ilmenite $\left(\mathrm{FeTiO}_{3}\right)$ :

$$
\mathrm{FeTiO}_{3}+\mathrm{H}_{2} \mathrm{SO}_{4} \longrightarrow \mathrm{TiO}_{2}+\mathrm{FeSO}_{4}+\mathrm{H}_{2} \mathrm{O}
$$

Its opaque and nontoxic properties make it suitable as a pigment in plastics and paints. In one process, $8.00 \times 10^{3} \mathrm{~kg}$ of $\mathrm{FeTiO}_{3}$ yielded $3.67 \times 10^{3} \mathrm{~kg}$ of $\mathrm{TiO}_{2}$. What is the percent yield of the reaction?
3.101 Ethylene $\left(\mathrm{C}_{2} \mathrm{H}_{4}\right)$, an important industrial organic chemical, can be prepared by heating hexane $\left(\mathrm{C}_{6} \mathrm{H}_{14}\right)$ at $800^{\circ} \mathrm{C}$ :

$$
\mathrm{C}_{6} \mathrm{H}_{14} \xrightarrow{\Delta} \mathrm{C}_{2} \mathrm{H}_{4}+\text { other products }
$$

If the yield of ethylene production is 42.5 percent, what mass of hexane must be used to produce 481 g of ethylene?

E3.102 When heated, lithium reacts with nitrogen to form lithium nitride:

$$
6 \mathrm{Li}(s)+\mathrm{N}_{2}(g) \longrightarrow 2 \mathrm{Li}_{3} \mathrm{~N}(s)
$$

What is the theoretical yield of $\mathrm{Li}_{3} \mathrm{~N}$ in grams when 12.3 g of Li is heated with 33.6 g of $\mathrm{N}_{2}$ ? If the actual yield of $\mathrm{Li}_{3} \mathrm{~N}$ is 5.89 g , what is the percent yield of the reaction?
3.103 Disulfide dichloride $\left(\mathrm{S}_{2} \mathrm{Cl}_{2}\right)$ is used in the vulcanization of rubber, a process that prevents the slippage of rubber molecules past one another when stretched. It is prepared by heating sulfur in an atmosphere of chlorine:

$$
\mathrm{S}_{8}(l)+4 \mathrm{Cl}_{2}(g) \longrightarrow 4 \mathrm{~S}_{2} \mathrm{Cl}_{2}(l)
$$

What is the theoretical yield of $\mathrm{S}_{2} \mathrm{Cl}_{2}$ in grams when 4.06 g of $\mathrm{S}_{8}$ is heated with 6.24 g of $\mathrm{Cl}_{2}$ ? If the actual yield of $\mathrm{S}_{2} \mathrm{Cl}_{2}$ is 6.55 g , what is the percent yield?
3.104 Determine whether each of the following equations represents a combination reaction, a decomposition reaction, or a combustion reaction: (a) $2 \mathrm{NaHCO}_{3} \longrightarrow \mathrm{Na}_{2} \mathrm{CO}_{3}+\mathrm{CO}_{2}+\mathrm{H}_{2} \mathrm{O}$, (b) $\mathrm{NH}_{3}+$ $\mathrm{HCl} \longrightarrow \mathrm{NH}_{4} \mathrm{Cl}$, (c) $2 \mathrm{CH}_{3} \mathrm{OH}+3 \mathrm{O}_{2} \longrightarrow 2 \mathrm{CO}_{2}+4 \mathrm{H}_{2} \mathrm{O}$.
3.105 Determine whether each of the following equations represents a combination reaction, a decomposition reaction, or a combustion reaction: (a) $\mathrm{C}_{3} \mathrm{H}_{8}+5 \mathrm{O}_{2} \longrightarrow 3 \mathrm{CO}_{2}+4 \mathrm{H}_{2} \mathrm{O}$, (b) $2 \mathrm{NF}_{2} \longrightarrow$ $\mathrm{N}_{2} \mathrm{~F}_{4}$, (c) $\mathrm{CuSO}_{4} \cdot 5 \mathrm{H}_{2} \mathrm{O} \longrightarrow \mathrm{CuSO}_{4}+5 \mathrm{H}_{2} \mathrm{O}$.

## Additional Problems

E 3.106 The diagram represents the products $\left(\mathrm{CO}_{2}\right.$ and $\left.\mathrm{H}_{2} \mathrm{O}\right)$ formed after the combustion of a hydrocarbon (a compound containing only C and H atoms). Write an equation for the reaction. (Hint: The molar mass of the hydrocarbon is about 30 g .)

3.107 Consider the reaction of hydrogen gas with oxygen gas:

Assuming a complete reaction, which of the diagrams (a-d) shown here represents the amounts of reactants and products left after the reaction?

3.108 Cysteine, shown here, is one of the 20 amino acids found in proteins in humans. Write the molecular formula of cysteine, and calculate its molar mass.

3.109 Isoflurane, shown here, is a common inhalation anesthetic. Write its molecular formula, and calculate its molar mass.

E3.110 Industrially, nitric acid is produced by the Ostwald process represented by the following equations:

$$
\begin{aligned}
4 \mathrm{NH}_{3}(g)+5 \mathrm{O}_{2}(g) & \longrightarrow 4 \mathrm{NO}(g)+6 \mathrm{H}_{2} \mathrm{O}(l) \\
2 \mathrm{NO}(g)+\mathrm{O}_{2}(g) & \longrightarrow 2 \mathrm{NO}_{2}(g) \\
2 \mathrm{NO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l) & \longrightarrow \mathrm{HNO}_{3}(a q)+\mathrm{HNO}_{2}(a q)
\end{aligned}
$$

What mass of $\mathrm{NH}_{3}$ (in grams) must be used to produce 1.00 ton of $\mathrm{HNO}_{3}$ by the Ostwald process, assuming an 80 percent yield in each step ( 1 ton $=2000 \mathrm{lb} ; 1 \mathrm{lb}=453.6 \mathrm{~g}$ ) ?
3.111 A sample of a compound of Cl and O reacts with an excess of $\mathrm{H}_{2}$ to give 0.233 g of HCl and 0.403 g of $\mathrm{H}_{2} \mathrm{O}$. Determine the empirical formula of the compound.

E 3.112 The atomic mass of element $X$ is 33.42 amu . A 27.22-g sample of X combines with 84.10 g of another element Y to form a compound XY. Calculate the atomic mass of Y.
3.113 How many moles of O are needed to combine with 0.212 mole of C to form (a) CO and (b) $\mathrm{CO}_{2}$ ?
3.114 The aluminum sulfate hydrate $\left[\mathrm{Al}_{2}\left(\mathrm{SO}_{4}\right)_{3} \cdot x \mathrm{H}_{2} \mathrm{O}\right]$ contains 8.10 percent Al by mass. Calculate $x$, that is, the number of water molecules associated with each $\mathrm{Al}_{2}\left(\mathrm{SO}_{4}\right)_{3}$ unit.
3.115 The explosive nitroglycerin $\left(\mathrm{C}_{3} \mathrm{H}_{5} \mathrm{~N}_{3} \mathrm{O}_{9}\right)$ has also been used as a drug to treat heart patients to relieve pain (angina pectoris). We now know that nitroglycerin produces nitric oxide (NO), which causes muscles to relax and allows the arteries to dilate. If each nitroglycerin molecule releases one NO per atom of N , calculate the mass percent of NO in nitroglycerin.

H3.116 The compound 2,3-dimercaptopropanol $\left(\mathrm{HSCH}_{2} \mathrm{CHSHCH}_{2} \mathrm{OH}\right)$, commonly known as British Anti-Lewisite (BAL), was developed during World War I as an antidote to arsenic-containing poison gas. (a) If each BAL molecule binds one arsenic (As) atom, how many As atoms can be removed by 1.0 g of BAL? (b) BAL can also be used to remove poisonous heavy metals like mercury $(\mathrm{Hg})$ and lead $(\mathrm{Pb})$. If each BAL binds one Hg atom, calculate the mass percent of Hg in a BAL-Hg complex. (An H atom is removed when a BAL molecule binds an Hg atom.)
3.117 Mustard gas $\left(\mathrm{C}_{4} \mathrm{H}_{8} \mathrm{Cl}_{2} \mathrm{~S}\right)$ is a poisonous gas that was used in World War I and banned afterward. It causes general destruction of body tissues, resulting in the formation of large water blisters. There is no effective antidote. Calculate the percent composition by mass of the elements in mustard gas.
3.118 The carat is the unit of mass used by jewelers. One carat is exactly 200 mg . How many carbon atoms are present in a 2 -carat diamond?
3.119 An iron bar weighed 664 g . After the bar had been standing in moist air for a month, exactly one-eighth of the iron turned to rust $\left(\mathrm{Fe}_{2} \mathrm{O}_{3}\right)$. Calculate the final mass of the iron bar and rust.
3.120 A certain metal oxide has the formula MO where M denotes the metal. A 39.46-g sample of the compound is strongly heated in an atmosphere of hydrogen to remove oxygen as water molecules. At the end, 31.70 g of the metal is left over. If O has an atomic mass of 16.00 amu , calculate the atomic mass of $M$ and identify the element.

H3.121 An impure sample of $\operatorname{zinc}(\mathrm{Zn})$ is treated with an excess of sulfuric acid $\left(\mathrm{H}_{2} \mathrm{SO}_{4}\right)$ to form zinc sulfate $\left(\mathrm{ZnSO}_{4}\right)$ and molecular hydrogen $\left(\mathrm{H}_{2}\right)$. (a) Write a balanced equation for the reaction. (b) If 0.0764 g of $\mathrm{H}_{2}$ is obtained from 3.86 g of the sample, calculate the percent purity of the sample. (c) What assumptions must you make in part (b)?

H3.122 One of the reactions that occurs in a blast furnace, where iron ore is converted to cast iron, is

$$
\mathrm{Fe}_{2} \mathrm{O}_{3}+3 \mathrm{CO} \longrightarrow 2 \mathrm{Fe}+3 \mathrm{CO}_{2}
$$

Suppose that $1.64 \times 10^{3} \mathrm{~kg}$ of Fe is obtained from a $2.62 \times 10^{3}-\mathrm{kg}$ sample of $\mathrm{Fe}_{2} \mathrm{O}_{3}$. Assuming that the reaction goes to completion, what is the percent purity of $\mathrm{Fe}_{2} \mathrm{O}_{3}$ in the original sample?
3.123 Carbon dioxide $\left(\mathrm{CO}_{2}\right)$ is the gas that is mainly responsible for global warming (the greenhouse effect). The burning of fossil fuels is a major cause of the increased concentration of $\mathrm{CO}_{2}$ in the atmosphere. Carbon dioxide is also the end product of metabolism (see Sample Problem 3.4). Using glucose as an example of food, calculate the annual human production of $\mathrm{CO}_{2}$ in grams, assuming that each person consumes $5.0 \times 10^{2} \mathrm{~g}$ of glucose per day, that the world's population is 6.5 billion, and that there are 365 days in a year.
3.124 Carbohydrates are compounds containing carbon, hydrogen, and oxygen in which the hydrogen to oxygen ratio is $2: 1$. A certain carbohydrate contains 40.0 percent carbon by mass. Calculate the empirical and molecular formulas of the compound if the approximate molar mass is 178 g .
3.125 Which of the following has the greater mass: 0.72 g of $\mathrm{O}_{2}$ or 0.0011 mole of chlorophyll $\left(\mathrm{C}_{55} \mathrm{H}_{72} \mathrm{MgN}_{4} \mathrm{O}_{5}\right)$ ?
3.126 Analysis of a metal chloride $\mathrm{XCl}_{3}$ shows that it contains 67.2 percent Cl by mass. Calculate the molar mass of X , and identify the element.
3.127 Hemoglobin $\left(\mathrm{C}_{2952} \mathrm{H}_{4664} \mathrm{~N}_{812} \mathrm{O}_{832} \mathrm{~S}_{8} \mathrm{Fe}_{4}\right)$ is the oxygen carrier in blood. (a) Calculate its molar mass. (b) An average adult has about 5.0 L of blood. Every milliliter of blood has approximately $5.0 \times 10^{9}$ erythrocytes, or red blood cells, and every red blood cell has about $2.8 \times 10^{8}$ hemoglobin molecules. Calculate the mass of hemoglobin molecules in grams in an average adult.
3.128 Myoglobin stores oxygen for metabolic processes in muscle. Chemical analysis shows that it contains 0.34 percent Fe by mass. What is the molar mass of myoglobin? (There is one Fe atom per molecule.)

H3.129 Calculate the number of cations and anions in each of the following compounds: (a) 8.38 g of KBr , (b) 5.40 g of $\mathrm{Na}_{2} \mathrm{SO}_{4}$, (c) 7.45 g of $\mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}$.
3.130 A mixture of NaBr and $\mathrm{Na}_{2} \mathrm{SO}_{4}$ contains 29.96 percent Na by mass. Calculate the percent by mass of each compound in the mixture.

E13.131 Aspirin or acetylsalicylic acid is synthesized by combining salicylic acid with acetic anhydride:
$\underset{\text { salicylic acid acetic anhydride }}{\mathrm{C}_{7} \mathrm{H}_{6} \mathrm{O}_{3}}+\underset{\text { aspirin }}{\mathrm{C}_{4} \mathrm{H}_{6} \mathrm{O}_{3}} \underset{\text { acetic acid }}{\mathrm{C}_{9} \mathrm{H}_{8} \mathrm{O}_{4}}+\underset{\mathrm{H}_{2}}{\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}}$
(a) How much salicylic acid is required to produce 0.400 g of aspirin (about the content in a tablet), assuming acetic anhydride is present in excess? (b) Calculate the amount of salicylic acid needed if only 74.9 percent of salicylic is converted to aspirin. (c) In one experiment, 9.26 g of salicylic acid reacts with 8.54 g of acetic anhydride. Calculate the theoretical yield of aspirin and the percent yield if only 10.9 g of aspirin is produced.

G3
3.132 Calculate the percent composition by mass of all the elements in calcium phosphate $\left[\mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}\right]$, a major component of bone.
3.133 Lysine, an essential amino acid in the human body, contains C, $\mathrm{H}, \mathrm{O}$, and N . In one experiment, the complete combustion of 2.175 g of lysine gave $3.94 \mathrm{~g} \mathrm{CO}_{2}$ and $1.89 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}$. In a separate experiment, 1.873 g of lysine gave $0.436 \mathrm{~g} \mathrm{NH}_{3}$. (a) Calculate the empirical formula of lysine. (b) The approximate molar mass of lysine is 150 g . What is the molecular formula of the compound?
3.134 Does 1 g of hydrogen molecules contain as many H atoms as 1 g of hydrogen atoms?
3.135 Avogadro's number has sometimes been described as a conversion factor between amu and grams. Use the fluorine atom (19.00 amu) as an example to show the relationship between the atomic mass unit and the gram.

E 3.136 The natural abundances of the two stable isotopes of hydrogen (hydrogen and deuterium) are 99.99 percent ${ }_{1}^{1} \mathrm{H}$ and 0.01 percent ${ }_{1}^{2} \mathrm{H}$. Assume that water exists as either $\mathrm{H}_{2} \mathrm{O}$ or $\mathrm{D}_{2} \mathrm{O}$. Calculate the number of $\mathrm{D}_{2} \mathrm{O}$ molecules in exactly 400 mL of water (density $1.00 \mathrm{~g} / \mathrm{mL}$ ).
3.137 In the formation of carbon monoxide, CO , it is found that 2.445 g of carbon combine with 3.257 g of oxygen. What is the atomic mass of oxygen if the atomic mass of carbon is 12.01 amu ?
3.138 What mole ratio of molecular chlorine $\left(\mathrm{Cl}_{2}\right)$ to molecular oxygen $\left(\mathrm{O}_{2}\right)$ would result from the breakup of the compound $\mathrm{Cl}_{2} \mathrm{O}_{7}$ into its constituent elements?
3.139 Which of the following substances contains the greatest mass of chlorine: (a) $5.0 \mathrm{~g} \mathrm{Cl}_{2}$, (b) $60.0 \mathrm{~g} \mathrm{NaClO}_{3}$, (c) 0.10 mol KCl , (d) $30.0 \mathrm{~g} \mathrm{MgCl}_{2}$, (e) $0.50 \mathrm{~mol} \mathrm{Cl}_{2}$ ?
3.140 A compound made up of $\mathrm{C}, \mathrm{H}$, and Cl contains 55.0 percent Cl by mass. If 9.00 g of the compound contain $4.19 \times 10^{23} \mathrm{H}$ atoms, what is the empirical formula of the compound?
3.141 Platinum forms two different compounds with chlorine. One contains 26.7 percent Cl by mass, and the other contains 42.1 percent Cl by mass. Determine the empirical formulas of the two compounds.
3.142 Heating 2.40 g of the oxide of metal X (molar mass of $\mathrm{X}=$ $55.9 \mathrm{~g} / \mathrm{mol}$ ) in carbon monoxide ( CO ) yields the pure metal and carbon dioxide. The mass of the metal product is 1.68 g . From the data given, show that the simplest formula of the oxide is $\mathrm{X}_{2} \mathrm{O}_{3}$ and write a balanced equation for the reaction.
3.143 A compound $X$ contains 63.3 percent manganese ( Mn ) and 36.7 percent O by mass. When X is heated, oxygen gas is evolved and a new compound Y containing 72.0 percent Mn and 28.0 percent O is formed. (a) Determine the empirical formulas of X and Y . (b) Write a balanced equation for the conversion of X to Y .
3.144 The formula of a hydrate of barium chloride is $\mathrm{BaCl}_{2} \cdot x \mathrm{H}_{2} \mathrm{O}$. If 1.936 g of the compound gives 1.864 g of anhydrous $\mathrm{BaSO}_{4}$ upon treatment with sulfuric acid, calculate the value of $x$.
3.145 It is estimated that the day Mt. St. Helens erupted (May 18, 1980), about $4.0 \times 10^{5}$ tons of $\mathrm{SO}_{2}$ were released into the atmosphere. If all the $\mathrm{SO}_{2}$ were eventually converted to sulfuric acid, how many tons of $\mathrm{H}_{2} \mathrm{SO}_{4}$ were produced?
3.146 A mixture of $\mathrm{CuSO}_{4} \cdot 5 \mathrm{H}_{2} \mathrm{O}$ and $\mathrm{MgSO}_{4} \cdot 7 \mathrm{H}_{2} \mathrm{O}$ is heated until all the water is lost. If 5.020 g of the mixture gives 2.988 g of the anhydrous salts, what is the percent by mass of $\mathrm{CuSO}_{4} \cdot 5 \mathrm{H}_{2} \mathrm{O}$ in the mixture?
3.147 When 0.273 g of Mg is heated strongly in a nitrogen $\left(\mathrm{N}_{2}\right)$ atmosphere, a chemical reaction occurs. The product of the reaction weighs 0.378 g . Calculate the empirical formula of the compound containing Mg and N . Name the compound.
3.148 A mixture of methane $\left(\mathrm{CH}_{4}\right)$ and ethane $\left(\mathrm{C}_{2} \mathrm{H}_{6}\right)$ of mass 13.43 g is completely burned in oxygen. If the total mass of $\mathrm{CO}_{2}$ and $\mathrm{H}_{2} \mathrm{O}$ produced is 64.84 g , calculate the fraction of $\mathrm{CH}_{4}$ in the mixture.
3.149 Leaded gasoline contains an additive to prevent engine "knocking." On analysis, the additive compound is found to contain carbon, hydrogen, and lead (Pb) (hence, "leaded gasoline"). When 51.36 g of this compound is burned in an apparatus such as that shown in Figure 3.5, 55.90 g of $\mathrm{CO}_{2}$ and 28.61 g of $\mathrm{H}_{2} \mathrm{O}$ are produced. Determine the empirical formula of the gasoline additive.
3.150 Because of its detrimental effect on the environment, the lead compound described in Problem 3.149 has been replaced in recent years by methyl tert-butyl ether (a compound of $\mathrm{C}, \mathrm{H}$, and O ) to enhance the performance of gasoline. (As of 1999, this compound is also being phased out because of its contamination of drinking water.) When 12.1 g of the compound is burned in an apparatus like the one shown in Figure 3.5, 30.2 g of $\mathrm{CO}_{2}$ and 14.8 g of $\mathrm{H}_{2} \mathrm{O}$ are formed. What is the empirical formula of the compound?
3.151 Suppose you are given a cube made of magnesium ( Mg ) metal of edge length 1.0 cm . (a) Calculate the number of Mg atoms in the cube. (b) Atoms are spherical in shape. Therefore, the Mg atoms in the cube cannot fill all the available space. If only 74 percent of the space inside the cube is taken up by Mg atoms, calculate the radius in picometers of an Mg atom. (The density of Mg is $1.74 \mathrm{~g} / \mathrm{cm}^{3}$, and the volume of a sphere of radius $r$ is $\frac{4}{3} \pi r^{3}$.)

E3.152 A certain sample of coal contains 1.6 percent sulfur by mass. When the coal is burned, the sulfur is converted to sulfur dioxide. To prevent air pollution, this sulfur dioxide is treated with calcium oxide $(\mathrm{CaO})$ to form calcium sulfite $\left(\mathrm{CaSO}_{3}\right)$. Calculate the daily mass (in kilograms) of CaO needed by a power plant that uses $6.60 \times 10^{6} \mathrm{~kg}$ of coal per day.

E3.153 Air is a mixture of many gases. However, in calculating its molar mass we need consider only the three major components: nitrogen, oxygen, and argon. Given that one mole of air at sea level is made up of 78.08 percent nitrogen, 20.95 percent oxygen, and 0.97 percent argon, what is the molar mass of air?
3.154 A die has an edge length of 1.5 cm . (a) What is the volume of one mole of such dice? (b) Assuming that the mole of dice could be packed in such a way that they were in contact with one another, forming stacking layers covering the entire surface of Earth, calculate the height in meters the layers would extend outward. [The radius $(r)$ of Earth is 6371 km , and the area of a sphere is $4 \pi r^{2}$.]
3.155 The following is a crude but effective method for estimating the order of magnitude of Avogadro's number using stearic acid $\left(\mathrm{C}_{18} \mathrm{H}_{36} \mathrm{O}_{2}\right)$. When stearic acid is added to water, its molecules collect at the surface and form a monolayer; that is, the layer is only one molecule thick. The cross-sectional area of each stearic acid molecule has been measured to be $0.21 \mathrm{~nm}^{2}$. In one experiment it is found that $1.4 \times 10^{-4} \mathrm{~g}$ of stearic acid is needed to form a monolayer over water in a dish of diameter 20 cm . Based on these measurements, what is Avogadro's number? (The area of a circle of radius $r$ is $\pi r^{2}$.)
3.156 Octane $\left(\mathrm{C}_{8} \mathrm{H}_{18}\right)$ is a component of gasoline. Complete combustion of octane yields $\mathrm{H}_{2} \mathrm{O}$ and $\mathrm{CO}_{2}$. Incomplete combustion produces $\mathrm{H}_{2} \mathrm{O}$ and CO , which not only reduces the efficiency of the engine using the fuel but is also toxic. In a certain test run, 1.000 gallon (gal) of octane is burned in an engine. The total mass of $\mathrm{CO}, \mathrm{CO}_{2}$, and $\mathrm{H}_{2} \mathrm{O}$ produced is 11.53 kg . Calculate the efficiency of the process; that is, calculate the fraction of octane converted to $\mathrm{CO}_{2}$. The density of octane is $2.650 \mathrm{~kg} / \mathrm{gal}$.
3.157 Industrially, hydrogen gas can be prepared by combining propane gas $\left(\mathrm{C}_{3} \mathrm{H}_{8}\right)$ with steam at about $400^{\circ} \mathrm{C}$. The products are carbon monoxide $(\mathrm{CO})$ and hydrogen gas $\left(\mathrm{H}_{2}\right)$. (a) Write a balanced equation for the reaction. (b) How many kilograms of $\mathrm{H}_{2}$ can be obtained from $2.84 \times 10^{3} \mathrm{~kg}$ of propane?
3.158 A reaction having a 90 percent yield may be considered a successful experiment. However, in the synthesis of complex molecules such as chlorophyll and many anticancer drugs, a chemist often has to carry out multiple-step syntheses. What is the overall percent yield for such a synthesis, assuming it is a 30 -step reaction with a 90 percent yield at each step?
3.159 Potash is any potassium mineral that is used for its potassium content. Most of the potash produced in the United States goes into fertilizer. The major sources of potash are potassium chloride $(\mathrm{KCl})$ and potassium sulfate $\left(\mathrm{K}_{2} \mathrm{SO}_{4}\right)$. Potash production is often reported as the potassium oxide $\left(\mathrm{K}_{2} \mathrm{O}\right)$ equivalent or the amount of $\mathrm{K}_{2} \mathrm{O}$ that could be made from a given mineral. (a) If KCl costs $\$ 0.55$ per kg , for what price (dollar per kg ) must $\mathrm{K}_{2} \mathrm{SO}_{4}$ be sold to supply the same amount of potassium on a per dollar basis? (b) What mass (in kg ) of $\mathrm{K}_{2} \mathrm{O}$ contains the same number of moles of K atoms as 1.00 kg of KCl ?

E3.160 A 21.496-g sample of magnesium is burned in air to form magnesium oxide and magnesium nitride. When the products are treated with water, 2.813 g of gaseous ammonia is generated. Calculate the amounts of magnesium nitride and magnesium oxide formed.
3.161 A certain metal M forms a bromide containing 53.79 percent Br by mass. What is the chemical formula of the compound?
3.162 A sample of iron weighing 15.0 g was heated with potassium chlorate $\left(\mathrm{KClO}_{3}\right)$ in an evacuated container. The oxygen generated from the decomposition of $\mathrm{KClO}_{3}$ converted some of the Fe to $\mathrm{Fe}_{2} \mathrm{O}_{3}$. If the combined mass of Fe and $\mathrm{Fe}_{2} \mathrm{O}_{3}$ was 17.9 g , calculate the mass of $\mathrm{Fe}_{2} \mathrm{O}_{3}$ formed and the mass of $\mathrm{KClO}_{3}$ decomposed.
3.163 A sample containing $\mathrm{NaCl}, \mathrm{Na}_{2} \mathrm{SO}_{4}$, and $\mathrm{NaNO}_{3}$ gives the following elemental analysis: 32.08 percent $\mathrm{Na}, 36.01$ percent $\mathrm{O}, 19.51$ percent Cl . Calculate the mass percent of each compound in the sample.
3.164 A sample of 10.0 g of sodium reacts with oxygen to form 13.83 g of sodium oxide $\left(\mathrm{Na}_{2} \mathrm{O}\right)$ and sodium peroxide $\left(\mathrm{Na}_{2} \mathrm{O}_{2}\right)$. Calculate the percent composition of the product mixture.
3.165 The depletion of ozone $\left(\mathrm{O}_{3}\right)$ in the stratosphere has been a matter of great concern among scientists in recent years. It is believed that ozone can react with nitric oxide (NO) that is discharged from high-altitude jet planes. The reaction is

$$
\mathrm{O}_{3}+\mathrm{NO} \longrightarrow \mathrm{O}_{2}+\mathrm{NO}_{2}
$$

If 0.740 g of $\mathrm{O}_{3}$ reacts with 0.670 g of NO , how many grams of $\mathrm{NO}_{2}$ will be produced? Which compound is the limiting reactant? Calculate the number of moles of the excess reactant remaining at the end of the reaction.
3.166 Propane $\left(\mathrm{C}_{3} \mathrm{H}_{8}\right)$ is a minor component of natural gas and is used in domestic cooking and heating. (a) Balance the following equation representing the combustion of propane in air:

$$
\mathrm{C}_{3} \mathrm{H}_{8}+\mathrm{O}_{2} \longrightarrow \mathrm{CO}_{2}+\mathrm{H}_{2} \mathrm{O}
$$

(b) How many grams of carbon dioxide can be produced by burning 3.65 moles of propane? Assume that oxygen is the excess reactant in this reaction.
3.167 What is wrong or ambiguous with each of the following statements? (a) $\mathrm{NH}_{4} \mathrm{NO}_{2}$ is the limiting reactant in the reaction

$$
\mathrm{NH}_{4} \mathrm{NO}_{2}(s) \longrightarrow \mathrm{N}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(l)
$$

(b) The limiting reactants for the reaction shown here are $\mathrm{NH}_{3}$ and NaCl .
$\mathrm{NH}_{3}(a q)+\mathrm{NaCl}(a q)+\mathrm{H}_{2} \mathrm{CO}_{3}(a q) \longrightarrow \mathrm{NaHCO}_{3}(a q)+\mathrm{NH}_{4} \mathrm{Cl}(a q)$

## Pre-Professional Practice Exam Problems: Physical and Biological Sciences

The first step in producing phosphorus fertilizer is the treatment of fluorapatite, a phosphate rock, with sulfuric acid to yield calcium dihydrogen phosphate, calcium sulfate, and hydrogen fluoride gas. In one experiment, a chemist combines 1.00 kg of each reactant.

1. Select the correct balanced equation to represent the reaction.

$$
\begin{aligned}
& \text { a) } 2 \mathrm{CaPO}_{4} \mathrm{~F}(s)+2 \mathrm{H}_{2} \mathrm{SO}_{4}(a q) \\
& \text { b) } 2 \mathrm{CaPO}_{4} \mathrm{~F}(s)+\mathrm{H}_{2} \mathrm{SO}_{4}(a q) \\
& \xrightarrow{\longrightarrow} \mathrm{CaH}_{2} \mathrm{PO}_{4}(a q)+\mathrm{CaSO}_{4}(a q)+\mathrm{HF}(g) \\
& \text { c) } \mathrm{Ca}_{5}\left(\mathrm{PO}_{4}\right)_{3} \mathrm{~F}(s)+3 \mathrm{CaH}_{2} \mathrm{PO}_{4}(a q)+\mathrm{CaSO}_{4}(a q)+\mathrm{HF}(g) \\
& \xrightarrow{3 q}(\mathrm{Saq}) \\
& \text { d) } 2 \mathrm{Ca}_{5}\left(\mathrm{PO}_{4}\right)_{3} \mathrm{~F}(s)+7 \mathrm{H}_{2} \mathrm{SO}_{4}(a q) \\
& \xrightarrow{3}\left(\mathrm{H}_{2} \mathrm{PO}_{4}\right)_{2}(a q)+2 \mathrm{CaSO}_{4}(a q)+\mathrm{HF}(g) \\
&
\end{aligned}
$$

2. Assuming that all the limiting reactant is converted to products, what mass of calcium dihydrogen phosphate is produced?
a) 464 g
b) 696 g
c) 92.8 g
d) 199 g
3. What mass of the excess reactant remains unreacted?
a) 319 g
b) 681 g
c) 406 g
d) 490 g
4. What is the percent yield of the reaction if 197 g of calcium dihydrogen phosphate is produced?
a) 99.0 percent
b) 42.5 percent
c) 28.3 percent
d) 212 percent

A traditional sobriety test for a driver suspected of being intoxicated may have included instructing the driver to walk a straight line or touch his or her own nose. Today it is common for the more quantitative method of the Breathalyzer test to be used.

## How An Aqueous Reaction Is Used to Prosecute Drunk Drivers

Chemical reactions can be used to verify the presence of a substance or to measure the amount of a substance present. This type of analysis can be used to determine the amount of alcohol in a person's blood.
Every year in the United States tens of thousands of people are killed and half a million more are injured as a result of drunk driving. In recent years, most states have lowered the legal limit of blood alcohol concentration (BAC) from 0.10 to 0.08 percent. Despite stiffer penalties for drunk-driving offenses and high-profile campaigns to educate the public about the dangers of driving while intoxicated, law enforcement agencies still must devote a great deal of work to removing drunk drivers from America's roads.

The police often use a device called a Breathalyzer to test drivers suspected of being drunk. In one type of device the breath of a driver suspected of driving under the influence of alcohol is bubbled through an orange solution containing potassium dichromate $\left(\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}\right)$ and sulfuric acid $\left(\mathrm{H}_{2} \mathrm{SO}_{4}\right)$. The alcohol in the driver's breath reacts with the dichromate ion to produce acetic acid $\left(\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right)$, which is colorless, and green chromium(III) sulfate $\left[\mathrm{Cr}_{2}\left(\mathrm{SO}_{4}\right)_{3}\right]$. The degree of color change from orange to green indicates the alcohol concentration in the breath sample, which is used to estimate the BAC.

The basis for the Breathalyzer test is a relatively simple chemical reaction called an oxidation-reduction reaction. This is one of several important types of reactions that can occur in aqueous solution.

Student Annotation: A blood alcohol concentration of 0.08 percent means that 100 mL of blood contains 0.08 g of ethanol.

Student Annotation: A Breathalyzer has two ampoules containing identical solutions. The driver's breath is bubbled through the solution in one ampoule, and the solution in the other ampoule remains unchanged. The device contains a calibrated meter that compares the colors in the two ampoules.

At the end of this chapter, you will be able to solve several problems related to the aqueous reaction used in the Breathalyzer test. [ $\|$ Page 159].

## In This Chapter, You Will Learn:

About some of the properties of aqueous solutions and about several different types of reactions that can occur between dissolved substances. You will also learn how to express the concentration of a solution and how concentration can be useful in solving quantitative problems.

## Before you begin, you should review

- Identifying compounds as either molecular or ionic [ 144 Sections 2.6 and 2.7]
- Names, formulas, and charges of the common polyatomic ions [/4 Table 2.9]

Student Annotation: A substance that dissolves in a particular solvent is said to be "soluble" in that solvent. In this chapter, we will use the word soluble to mean "watersoluble."

Student Annotation: Bases may be molecular, like ammonia $\left(\mathrm{NH}_{3}\right)$, or ionic, like sodium hydroxide $(\mathrm{NaOH})$.

### 4.1 General Properties of Aqueous Solutions

A solution is a homogeneous mixture [ 144 Section 1.2] of two or more substances. Solutions may be gaseous (such as air), solid (such as brass), or liquid (such as saltwater). Usually, the substance present in the largest amount is referred to as the solvent and any substance present in a smaller amount is called the solute. For example, if we dissolve a teaspoon of sugar in a glass of water, water is the solvent and sugar is the solute. In this chapter we will focus on the properties of aqueous solutions-those in which water is the solvent. Throughout the remainder of this chapter, unless otherwise noted, solution will refer specifically to an aqueous solution.

## Electrolytes and Nonelectrolytes

You have probably heard of electrolytes in the context of sports drinks such as Gatorade. Electrolytes in body fluids are necessary for the transmission of electrical impulses, which are critical to physiological processes such as nerve impulses and muscle contractions. In general, an electrolyte is a substance that dissolves in water to yield a solution that conducts electricity. By contrast, a nonelectrolyte is a substance that dissolves in water to yield a solution that does not conduct electricity. Every water-soluble substance fits into one of these two categories.

The difference between an aqueous solution that conducts electricity and one that does not is the presence or absence of ions. As an illustration, consider solutions of sugar and salt. The physical processes of sugar (sucrose, $\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}$ ) dissolving in water and salt (sodium chloride, NaCl ) dissolving in water can be represented with the following chemical equations:

$$
\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}(s) \xrightarrow{\mathrm{H}_{2} \mathrm{O}} \mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}(a q) \quad \text { and } \quad \mathrm{NaCl}(s) \xrightarrow{\mathrm{H}_{2} \mathrm{O}} \mathrm{Na}^{+}(a q)+\mathrm{Cl}^{-}(a q)
$$

Note that while the sucrose molecules remain intact upon dissolving, becoming aqueous sucrose molecules, the sodium chloride dissociates, producing aqueous sodium ions and aqueous chloride ions. Dissociation is the process by which an ionic compound, upon dissolution, breaks apart into its constituent ions. It is the presence of ions that allows the solution of sodium chloride to conduct electricity. Thus, sodium chloride is an electrolyte and sucrose is a nonelectrolyte.

Like sucrose, which is a molecular compound [ 1 H Section 2.6], many water-soluble molecular compounds are nonelectrolytes. Some molecular compounds are electrolytes, however, because they ionize on dissolution. Ionization is the process by which a molecular compound forms ions when it dissolves. Recall from Chapter 2 that acids are compounds that dissolve in water to produce hydrogen ions $\left(\mathrm{H}^{+}\right)\left[\mathrm{K}\right.$ Section 2.6]. HCl , for example, ionizes to produce $\mathrm{H}^{+}$ ions and $\mathrm{Cl}^{-}$ions.

$$
\mathrm{HCl}(g) \xrightarrow{\mathrm{H}_{2} \mathrm{O}} \mathrm{H}^{+}(a q)+\mathrm{Cl}^{-}(a q)
$$

Acids constitute one of two important classes of molecular compounds that are electrolytes. Molecular bases constitute the other one. A base is a compound that dissolves in water to produce hydroxide ions $\left(\mathrm{OH}^{-}\right)$. Ammonia $\left(\mathrm{NH}_{3}\right)$, for example, ionizes in water to produce ammonium $\left(\mathrm{NH}_{4}^{+}\right)$and hydroxide $\left(\mathrm{OH}^{-}\right)$ions.

$$
\mathrm{NH}_{3}(g)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{NH}_{4}^{+}(a q)+\mathrm{OH}^{-}(a q)
$$

## Strong Electrolytes and Weak Electrolytes

In a solution of sodium chloride, all the dissolved compound exists in the form of ions. Thus, NaCl , which is an ionic compound [ 14 Section 2.7], is said to have dissociated completely. An electrolyte that dissociates completely is known as a strong electrolyte. All water-soluble ionic compounds dissociate completely upon dissolving, so all water-soluble ionic compounds are strong electrolytes.

The list of molecular compounds that are strong electrolytes is fairly short. It comprises the seven strong acids, which are listed in Table 4.1. A strong acid ionizes completely, resulting in a solution that contains hydrogen ions and the corresponding anions but essentially no acid molecules.

Most of the molecular compounds that are electrolytes are weak electrolytes. A weak electrolyte is a compound that produces ions upon dissolving but exists in solution predominantly as molecules that are not ionized. Most acids (except those listed in Table 4.1) are weak electrolytes. Acetic acid $\left(\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right)$ is not one of the strong acids listed in Table 4.1, so it is a weak acid. Its ionization in water is represented by the following chemical equation:

$$
\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}(l) \rightleftarrows \mathrm{H}^{+}(a q)+\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}(a q)
$$

## TABLE 4.1

## Ionization Equation

$$
\begin{aligned}
\mathrm{HCl}(a q) & \longrightarrow \mathrm{H}^{+}(a q)+\mathrm{Cl}^{-}(a q) \\
\mathrm{HBr}(a q) & \longrightarrow \mathrm{H}^{+}(a q)+\mathrm{Br}^{-}(a q) \\
\mathrm{HI}(a q) & \longrightarrow \mathrm{H}^{+}(a q)+\mathrm{I}^{-}(a q) \\
\mathrm{HNO}_{3}(a q) & \longrightarrow \mathrm{H}^{+}(a q)+\mathrm{NO}_{3}^{-}(a q) \\
\mathrm{HClO}_{3}(a q) & \longrightarrow \mathrm{H}^{+}(a q)+\mathrm{ClO}_{3}^{-}(a q) \\
\mathrm{HClO}_{4}(a q) & \longrightarrow \mathrm{H}^{+}(a q)+\mathrm{ClO}_{4}^{-}(a q) \\
\mathrm{H}_{2} \mathrm{SO}_{4}(a q) & \longrightarrow \mathrm{H}^{+}(a q)+\mathrm{HSO}_{4}^{-}(a q) \\
\mathrm{HSO}_{4}^{-}(a q) & \longrightarrow \mathrm{H}^{+}(a q)+\mathrm{SO}_{4}^{2-}(a q)
\end{aligned}
$$

*Note that although each sulfuric acid molecule has two ionizable hydrogen atoms, it only undergoes the first ionization completely, effectively producing one $\mathrm{H}^{+}$ion and one $\mathrm{HSO}_{4}^{-}$ion per $\mathrm{H}_{2} \mathrm{SO}_{4}$ molecule. The second ionization happens only to a very small extent.

Note the use of the double arrow, $\rightleftarrows$, in this equation and in two earlier equations, including one in Table 4.1. This denotes a reaction that occurs in both directions and does not result in all the reactant(s) (e.g., acetic acid) being converted permanently to product(s) (e.g., hydrogen ions and acetate ions). Instead, forward and reverse reactions both occur, and a state of dynamic chemical equilibrium is established.

Although acetic acid molecules ionize, the resulting ions have a strong tendency to recombine to form acetic acid molecules again. Eventually, the ions produced by the ionization will be recombining at the same rate at which they are produced, and there will be no further change in the numbers of acetic acid molecules, hydrogen ions, or acetate ions. Because there is a stronger tendency for the ions to recombine than for the molecules to ionize, at any given point in time, most of the dissolved acetic acid exists as molecules that are not ionized (reactant). Only a very small percentage exists in the form of hydrogen ions and acetate ions (products).

The ionization of a weak base, while similar in many ways to the ionization of a weak acid, requires some additional explanation. Ammonia $\left(\mathrm{NH}_{3}\right)$ is a common weak base. The ionization of ammonia in water is represented by the equation

$$
\mathrm{NH}_{3}(g)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{NH}_{4}^{+}(a q)+\mathrm{OH}^{-}(a q)
$$

Note that the ammonia molecule does not ionize by breaking apart into ions. Rather, it does so by ionizing a water molecule. The $\mathrm{H}^{+}$ion from a water molecule attaches to an ammonia molecule, producing an ammonium ion $\left(\mathrm{NH}_{4}^{+}\right)$and leaving what remains of the water molecule, the $\mathrm{OH}^{-}$ ion, in solution.

As with the ionization of a weak acid, the reverse process predominates and at any given point in time, there will be far more $\mathrm{NH}_{3}$ molecules present than there will be $\mathrm{NH}_{4}^{+}$and $\mathrm{OH}^{-}$ions.

We can distinguish between electrolytes and nonelectrolytes experimentally using an apparatus like the one pictured in Figure 4.1. A lightbulb is connected to a battery using a circuit that includes the contents of the beaker. For the bulb to light, electric current must flow from one electrode to the other. Pure water is a very poor conductor of electricity because $\mathrm{H}_{2} \mathrm{O}$ ionizes to only a minute extent. There are virtually no ions in pure water to conduct the current, so $\mathrm{H}_{2} \mathrm{O}$ is considered a nonelectrolyte. If we add a small amount of salt (sodium chloride), however, the lightbulb will begin to glow as soon as the salt dissolves in the water. Sodium chloride dissociates completely in water to give $\mathrm{Na}^{+}$and $\mathrm{Cl}^{-}$ions. Because the NaCl solution conducts electricity, we say that NaCl is an electrolyte.

If the solution contains a nonelectrolyte, as it does in Figure 4.1(a), the bulb will not light. If the solution contains an electrolyte, as it does in Figure 4.1(b) and (c), the bulb will light. The

Student Annotation: In a state of dynamic chemical equilibrium, or simply equilibrium, both forward and reverse reactions continue to occur. However, because they are occurring at the same rate, no net change is observed over time in the amounts of reactants or products. Chemical equilibrium is the subject of Chapters 15 to 17.

Figure 4.1 An apparatus for distinguishing between electrolytes and nonelectrolytes and between weak electrolytes and strong electrolytes. A solution's ability to conduct electricity depends on the number of ions it contains. (a) Pure water contains almost no ions and does not conduct electricity; therefore the lightbulb is not lit. (b) A weak electrolyte solution such as $\mathrm{HF}(\mathrm{aq})$ contains a small number of ions, and the lightbulb is dimly lit. (c) A strong electrolyte solution such as $\mathrm{NaCl}(a q)$ contains a large number of ions, and the lightbulb is brightly lit. The molar amounts of dissolved substances in the beakers in (b) and (c) are equal.
cations in solution are attracted to the negative electrode, and the anions are attracted to the positive electrode. This movement sets up an electric current that is equivalent to the flow of electrons along a metal wire. How brightly the bulb burns depends upon the number of ions in solution. In Figure 4.1(b), the solution contains a weak electrolyte and therefore a relatively small number of ions, so the bulb lights only weakly. The solution in Figure 4.1(c) contains a strong electrolyte, which produces a relatively large number of ions, so the bulb lights brightly.

## Bringing Chemistry to Life

## The Invention of Gatorade

In 1965, University of Florida (UF) assistant coach Dwayne Douglas was concerned about the health of Gators football players. He noted that during practices and games in hot weather the players (1) lost a great deal of weight, (2) seldom needed to urinate, and (3) had limited stamina, especially during the second half of a practice or game. He consulted Dr. Robert Cade, researcher and kidney-disease specialist at UF's medical college, who embarked on a project to identify the cause of the athletes' lack of endurance. It was found that after a period of intense activity accompanied by profuse sweating, the players had low blood sugar, low blood volume, and an imbalance of electrolytes - all of which contributed to heat exhaustion. Cade and his research fellows theorized that the depletion of sugar, water, and electrolytes might be remedied by having the athletes drink a solution containing just the right amounts of each. Using this theory, they developed a beverage containing water, sugar, and sodium and potassium salts similar to those present in sweat. By all accounts, the beverage tasted so bad that no one would drink it. Mary Cade, Robert Cade's wife, suggested adding lemon juice to make the concoction more palatable-and the drink
that would become Gatorade was born. In their 1966 season the Gators earned a reputation as the "second-half" team, often coming from behind in the third or fourth quarter. Gators coach Ray Graves attributed his team's newfound late-in-the-game strength to the newly developed sideline beverage that replenished blood sugar, blood volume, and electrolyte balance. Sports drinks are now a multibillion dollar industry, and there are several popular brands, although Gatorade still maintains a large share of the market.

## Sample Problem 4.1

Sports drinks typically contain sucrose $\left(\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}\right)$, fructose $\left(\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}\right)$, sodium citrate $\left(\mathrm{Na}_{3} \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}_{7}\right)$, potassium citrate $\left(\mathrm{K}_{3} \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}_{7}\right)$, and ascorbic acid $\left(\mathrm{H}_{2} \mathrm{C}_{6} \mathrm{H}_{6} \mathrm{O}_{6}\right)$, among other ingredients. Classify each of these ingredients as a nonelectrolyte, a weak electrolyte, or a strong electrolyte.

Strategy Identify each compound as ionic or molecular; identify each molecular compound as acid, base, or neither; and identify each acid as strong or weak.

Setup Sucrose and fructose contain no cations and are therefore molecular compounds-neither is an acid or a base. Sodium citrate and potassium citrate contain metal cations and are therefore ionic compounds. Ascorbic acid is an acid that does not appear on the list of strong acids in Table 4.1, so ascorbic acid is a weak acid.

Solution Sucrose and fructose are nonelectrolytes. Sodium citrate and potassium citrate are strong electrolytes. Ascorbic acid is a weak electrolyte.

Practice Problem A A so-called enhanced water contains citric acid $\left(\mathrm{H}_{3} \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}_{7}\right)$, magnesium lactate $\left[\mathrm{Mg}\left(\mathrm{C}_{3} \mathrm{H}_{5} \mathrm{O}_{3}\right)_{2}\right]$, calcium lactate $\left[\mathrm{Ca}\left(\mathrm{C}_{3} \mathrm{H}_{5} \mathrm{O}_{3}\right)_{2}\right]$, and potassium phosphate $\left(\mathrm{K}_{3} \mathrm{PO}_{4}\right)$. Classify each of these compounds as a nonelectrolyte, a weak electrolyte, or a strong electrolyte.

Think About It Remember that any soluble ionic compound is a strong electrolyte, whereas most molecular compounds are nonelectrolytes or weak electrolytes. The only molecular compounds that are strong electrolytes are the strong acids listed in Table 4.1.

## Checkpoint 4.1 General Properties of Aqueous Solutions

d) NaI
e) $\mathrm{HNO}_{3}$
4.1.4 Which of the following compounds is a strong electrolyte?
a) HF
b) $\mathrm{H}_{2} \mathrm{CO}_{3}$
c) NaF
d) $\mathrm{NH}_{3}$
e) $\mathrm{H}_{2} \mathrm{O}$

## You May Be Wondering...

## How Can I Tell if a Compound Is an Electrolyte?

While the experimental method described in Figure 4.1 can be useful, often you will have to characterize a compound as a nonelectrolyte, a weak electrolyte, or a strong electrolyte just by looking at its formula. A good first step is to determine whether the compound is ionic or molecular.

An ionic compound contains a cation (which is either a metal ion or the ammonium ion) and an anion (which may be atomic or polyatomic). A binary compound that contains a metal and a nonmetal is almost always ionic. This is a good time to review the polyatomic anions in Table 2.8 [ 144 Section 2.7]. You will need to be able to recognize them in the formulas of compounds. Any ionic compound that dissolves in water is a strong electrolyte.

If a compound does not contain a metal cation or the ammonium cation, it is molecular. In this case, you will need to determine whether or not the compound is an acid. Acids generally can be recognized by the way their formulas are written, with the ionizable hydrogens written first. $\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}, \mathrm{H}_{2} \mathrm{CO}_{3}$, and $\mathrm{H}_{3} \mathrm{PO}_{4}$ are acetic acid, carbonic acid, and phosphoric acid, respectively. Formulas of carboxylic acids, such as acetic acid, often are written with their ionizable hydrogen atoms last to keep the functional group together in the formula. Thus, either $\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$ or $\mathrm{CH}_{3} \mathrm{COOH}$ is correct for acetic acid. To make it easier to identify compounds as acids, in this chapter we will write all acid formulas with the ionizable H atom(s) first. If a compound is an acid, it is an electrolyte. If it is one of the acids listed in Table 4.1, it is a strong acid and therefore a strong electrolyte. Any acid not listed in Table 4.1 is a weak acid and therefore a weak electrolyte.

If a molecular compound is not an acid, you must then consider whether or not it is a weak base. Many weak bases are relat-
ed to ammonia in that they consist of a nitrogen atom bonded to hydrogen and/or carbon atoms. Examples include methylamine $\left(\mathrm{CH}_{3} \mathrm{NH}_{2}\right)$, pyridine $\left(\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N}\right)$, and hydroxylamine $\left(\mathrm{NH}_{2} \mathrm{OH}\right)$. Weak bases are weak electrolytes.

If a molecular compound is neither an acid nor a weak base, it is a nonelectrolyte. The flowchart in Figure 4.2 can be useful for classification of water-soluble compounds.

Figure 4.2 Flowchart for determining if a compound is a strong electrolyte, a weak electrolyte, or a nonelectrolyte.

### 4.2 Precipitation Reactions

When an aqueous solution of lead(II) nitrate $\left[\mathrm{Pb}\left(\mathrm{NO}_{3}\right)_{2}\right]$ is added to an aqueous solution of sodium iodide ( NaI ), a yellow insoluble solid—lead(II) iodide $\left(\mathrm{PbI}_{2}\right)$ —forms. Sodium nitrate $\left(\mathrm{NaNO}_{3}\right)$, the other reaction product, remains in solution. Figure 4.3 (page 124) shows this reaction in progress. An insoluble solid product that separates from a solution is called a precipitate, and a chemical reaction in which a precipitate forms is called a precipitation reaction.

Precipitation reactions usually involve ionic compounds, but a precipitate does not form every time two solutions of electrolytes are combined. Instead, whether or not a precipitate forms when two solutions are mixed depends on the solubility of the products.

## Solubility Guidelines for Ionic Compounds in Water

When an ionic substance such as sodium chloride dissolves in water, the water molecules remove individual ions from the three-dimensional solid structure and surround them. This process, called

## Sample Problem 4.2

Classify each of the following compounds as a nonelectrolyte, a weak electrolyte, or a strong electrolyte: (a) methanol $\left(\mathrm{CH}_{3} \mathrm{OH}\right)$, (b) sodium hydroxide $(\mathrm{NaOH})$, (c) ethylamine $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{NH}_{2}\right)$, and (d) hydrofluoric acid (HF).

Strategy Classify each compound as ionic or molecular. Soluble ionic compounds are strong electrolytes. Classify each molecular compound as an acid, base, or neither. Molecular compounds that are neither acids nor bases are nonelectrolytes. Molecular compounds that are bases are weak electrolytes. Finally, classify acids as either strong or weak. Strong acids are strong electrolytes, and weak acids are weak electrolytes.

Setup (a) Methanol contains neither a metal cation nor the ammonium ion. It is therefore molecular. Its formula does not begin with H , so it is probably not an acid, and it does not contain a nitrogen atom, so it is not a weak base. Molecular compounds that are neither acids nor bases are nonelectrolytes.
(b) Sodium hydroxide contains a metal cation $\left(\mathrm{Na}^{+}\right)$and is therefore ionic. It is also one of the strong bases.
(c) Ethylamine contains no cations and is therefore molecular. It is also a nitrogen-containing base, similar to ammonia.
(d) Hydrofluoric acid is, as its name suggests, an acid. However, it is not on the list of strong acids in Table 4.1 and is, therefore, a weak acid.

Solution (a) Nonelectrolyte
(b) Strong electrolyte
(c) Weak electrolyte
(d) Weak electrolyte

Practice Problem A Identify the following compounds as nonelectrolytes, weak electrolytes, or strong electrolytes: ethanol $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right)$, nitrous acid $\left(\mathrm{HNO}_{2}\right)$, and sodium hydrogen carbonate $\left(\mathrm{NaHCO}_{3}\right.$, also known as bicarbonate).

EPPractice Problem B Identify the following compounds as nonelectrolytes, weak electrolytes, or strong electrolytes: phosphorous acid $\left(\mathrm{H}_{3} \mathrm{PO}_{3}\right)$, hydrogen peroxide $\left(\mathrm{H}_{2} \mathrm{O}_{2}\right)$, and ammonium sulfate $\left[\left(\mathrm{NH}_{4}\right)_{2} \mathrm{SO}_{4}\right]$.

Think About It Make sure that you have correctly identified compounds that are ionic and compounds that are molecular. Remember that strong acids are strong electrolytes, weak acids and weak bases are weak electrolytes, and strong bases are strong electrolytes (by virtue of their being soluble ionic compounds). Molecular compounds, with the exceptions of acids and weak bases, are nonelectrolytes.
hydration, is shown in Figure 4.4 (page 124). Water is an excellent solvent for ionic compounds because $\mathrm{H}_{2} \mathrm{O}$ is a polar molecule; that is, its electrons are distributed such that there is a partial negative charge on the oxygen atom, denoted by the $\delta-$ symbol, and partial positive charges, denoted by the $\delta+$ symbol, on each of the hydrogen atoms. The oxygen atoms in the surrounding water molecules are attracted to the cations, while the hydrogen atoms are attracted to the anions. These attractions explain the orientation of water molecules around each of the ions in solution. The surrounding water molecules prevent the cations and anions from recombining.

Solubility is defined as the maximum amount of solute that will dissolve in a given quantity of solvent at a specific temperature. Not all ionic compounds dissolve in water. Whether or not an ionic compound is water soluble depends on the relative magnitudes of the water molecules' attraction to the ions, and the ions' attraction for each other. We will learn more about the magnitudes of attractive forces in ionic compounds in Chapter 8, but for now it is useful to learn some guidelines that enable us to predict the solubility of ionic compounds. Table 4.2 lists groups of compounds that are soluble and shows the insoluble exceptions. Table 4.3 lists groups of compounds that are insoluble and shows the soluble exceptions.

Sample Problem 4.3 gives you some practice applying the solubility guidelines.

Student Annotation: The partial charges on the oxygen atom and the hydrogen atoms sum to zero. Water molecules, although polar, have no net charge. You will learn more about partial charges and molecular polarity in Chapters 8 and 9.

Student Annotation: If the water molecules' attraction for the ions exceeds the ions' attraction to one another, then the ionic compound will dissolve. If the ions' attraction to each other exceeds the water molecules' attraction to the ions, then the compound won't dissolve.

Chemical reactions-predicting precipitation reactions (interactive).

Figure 4.3 A colorless aqueous solution of NaI is added to a colorless aqueous solution of $\mathrm{Pb}\left(\mathrm{NO}_{3}\right)_{2}$. A yellow precipitate, $\mathrm{PbI}_{2}$, forms. $\mathrm{Na}^{+}$and $\mathrm{NO}_{3}^{-}$ions remain in solution.

Figure 4.4 Hydration of anions and cations of a soluble ionic compound. Water molecules surround each anion with their partial positive charges (H atoms) oriented toward the negatively charged anion; and they surround each cation with their partial negative charges ( O atoms) oriented toward the positively charged cation.

## TABLE 4.2

## Solubility Guidelines: Soluble Compounds

## Water-Soluble Compounds

Compounds containing an alkali metal cation ( $\mathrm{Li}^{+}$, $\left.\mathrm{Na}^{+}, \mathrm{K}^{+}, \mathrm{Rb}^{+}, \mathrm{Cs}^{+}\right)$or the ammonium ion $\left(\mathrm{NH}_{4}^{+}\right)$
Compounds containing the nitrate ion $\left(\mathrm{NO}_{3}^{-}\right)$, acetate ion $\left(\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}\right)$, or chlorate ion $\left(\mathrm{ClO}_{3}^{-}\right)$
Compounds containing the chloride ion $\left(\mathrm{Cl}^{-}\right)$, bromide ion $\left(\mathrm{Br}^{-}\right)$, or iodide ion ( $\mathrm{I}^{-}$)
Compounds containing the sulfate ion $\left(\mathrm{SO}_{4}^{2-}\right)$

## Insoluble Exceptions

Compounds containing $\mathrm{Ag}^{+}, \mathrm{Hg}_{2}^{2+}$, or $\mathrm{Pb}^{2+}$
Compounds containing $\mathrm{Ag}^{+}, \mathrm{Hg}_{2}^{2+}$, $\mathrm{Pb}^{2+}, \mathrm{Ca}^{2+}, \mathrm{Sr}^{2+}$, or $\mathrm{Ba}^{2+}$

## TABLE 4.3

## Solubility Guidelines: Insoluble Compounds

## Water-Insoluble Compounds

Compounds containing the carbonate ion $\left(\mathrm{CO}_{3}^{2-}\right)$, phosphate ion $\left(\mathrm{PO}_{4}^{3-}\right)$, chromate ion $\left(\mathrm{CrO}_{4}^{2-}\right)$, or sulfide ion ( $\mathrm{S}^{2-}$ )
Compounds containing the hydroxide ion $\left(\mathrm{OH}^{-}\right)$

## Soluble Exceptions

Compounds containing $\mathrm{Li}^{+}, \mathrm{Na}^{+}$, $\mathrm{K}^{+}, \mathrm{Rb}^{+}, \mathrm{Cs}^{+}$, or $\mathrm{NH}_{4}^{+}$

Compounds containing $\mathrm{Li}^{+}, \mathrm{Na}^{+}$, $\mathrm{K}^{+}, \mathrm{Rb}^{+}, \mathrm{Cs}^{+}$, or $\mathrm{Ba}^{2+}$

## Sample Problem 4.3

Classify each of the following compounds as soluble or insoluble in water: (a) $\mathrm{AgNO}_{3}$, (b) $\mathrm{CaSO}_{4}$, (c) $\mathrm{K}_{2} \mathrm{CO}_{3}$.

Strategy Use the guidelines in Tables 4.2 and 4.3 to determine whether or not each compound is expected to be water soluble.

Setup (a) $\mathrm{AgNO}_{3}$ contains the nitrate ion $\left(\mathrm{NO}_{3}^{-}\right)$. According to Table 4.2, all compounds containing the nitrate ion are soluble.
(b) $\mathrm{CaSO}_{4}$ contains the sulfate ion $\left(\mathrm{SO}_{4}^{2-}\right)$. According to Table 4.2, compounds containing the sulfate ion are soluble unless the cation is $\mathrm{Ag}^{+}, \mathrm{Hg}_{2}^{2+}, \mathrm{Pb}^{2+}, \mathrm{Ca}^{2+}, \mathrm{Sr}^{2+}$, or $\mathrm{Ba}^{2+}$. Thus, the $\mathrm{Ca}^{2+}$ ion is one of the insoluble exceptions.
(c) $\mathrm{K}_{2} \mathrm{CO}_{3}$ contains an alkali metal cation $\left(\mathrm{K}^{+}\right)$for which, according to Table 4.2, there are no insoluble exceptions. Alternatively, Table 4.3 shows that most compounds containing the carbonate ion $\left(\mathrm{CO}_{3}^{2-}\right)$ are insoluble-but compounds containing a Group 1 A cation such as $\mathrm{K}^{+}$are soluble exceptions.

Solution (a) Soluble, (b) insoluble, (c) soluble.

Practice Problem A Classify each of the following compounds as soluble or insoluble in water: (a) $\mathrm{PbCl}_{2}$, (b) $\left(\mathrm{NH}_{4}\right)_{3} \mathrm{PO}_{4}$, (c) $\mathrm{Fe}(\mathrm{OH})_{3}$.

HPractice Problem B Classify each of the following compounds as soluble or insoluble in water: (a) $\mathrm{MgBr}_{2}$, (b) $\mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}$, (c) $\mathrm{KClO}_{3}$.

## Molecular Equations

The reaction shown in Figure 4.3 can be represented with the chemical equation

$$
\mathrm{Pb}\left(\mathrm{NO}_{3}\right)_{2}(a q)+2 \mathrm{NaI}(a q) \longrightarrow 2 \mathrm{NaNO}_{3}(a q)+\mathrm{PbI}_{2}(s)
$$

Based on this chemical equation, the metal cations seem to exchange anions. That is, the $\mathrm{Pb}^{2+}$ ion, originally paired with $\mathrm{NO}_{3}^{-}$ions, ends up paired with $\mathrm{I}^{-}$ions; similarly, each $\mathrm{Na}^{+}$ion, originally paired with an $\mathrm{I}^{-}$ion, ends up paired with an $\mathrm{NO}_{3}^{-}$ion. This equation, as written, is called a molecular equation, which is a chemical equation written with all compounds represented

Student Annotation: Some books list fewer exceptions to these solubility rules. In fact, ionic compounds listed here as "insoluble" are actually very slightly soluble. It is how soluble a compound must be to be called "soluble" that may vary from book to book.

Student Annotation: lonic compounds often are classified according to the anions they contain. Compounds that contain the chloride ion are called chlorides, compounds containing the nitrate ion are called nitrates, and so on.

Student Annotation: Note the reoccurrence of the same three groups of ions in the exceptions columns in Tables 4.2 and 4.3: Group 1A or the ammonium cation; $\mathrm{Ag}^{+}$, $\mathrm{Hg}_{2}^{2+}$, or $\mathrm{Pb}^{2+}$; and the heavier Group 2A cations.

Think About It Check the ions in each compound against the information in Tables 4.2 and 4.3 to confirm that you have drawn the right conclusions.

Student Annotation: Reactions in which compounds exchange ions are sometimes called metathesis or double replacement reactions.
by their chemical formulas, making it look as though they exist in solution as molecules or formula units.

You now know enough chemistry to predict the products of this type of chemical reaction! Simply write the formulas for the reactants, and then write formulas for the compounds that would form if the cations in the reactants were to trade anions. For example, if you want to write the equation for the reaction that occurs when solutions of sodium sulfate and barium hydroxide are combined, you would first write the formulas of the reactants [ $1 / 4$ Section 2.7]:

$$
\mathrm{Na}_{2} \mathrm{SO}_{4}(a q)+\mathrm{Ba}(\mathrm{OH})_{2}(a q) \longrightarrow
$$

Then you would write the formula for one product by combining the cation from the first reactant $\left(\mathrm{Na}^{+}\right)$with the anion from the second $\left(\mathrm{OH}^{-}\right)$; and write the formula for the other product by combining the cation from the second reactant $\left(\mathrm{Ba}^{2+}\right)$ with the anion from the first $\left(\mathrm{SO}_{4}^{2-}\right)$. Thus, the equation is

$$
\mathrm{Na}_{2} \mathrm{SO}_{4}(a q)+\mathrm{Ba}(\mathrm{OH})_{2}(a q) \longrightarrow 2 \mathrm{NaOH}+\mathrm{BaSO}_{4}
$$

Although we have balanced the equation [ $1 \mathrm{KA}_{\mathrm{A}}$ Section 3.3], we have not yet put phases in parentheses for the products.

The final step in predicting the outcome of such a reaction is to determine which of the products, if any, will precipitate from solution. We do this using the solubility guidelines for ionic compounds (Tables 4.2 and 4.3). The first product $(\mathrm{NaOH})$ contains a Group 1A cation $\left(\mathrm{Na}^{+}\right)$and will therefore be soluble. We indicate its phase as $(a q)$. The second product $\left(\mathrm{BaSO}_{4}\right)$ contains the sulfate ion $\left(\mathrm{SO}_{4}^{2-}\right)$. Sulfate compounds are soluble unless the cation is $\mathrm{Ag}^{+}, \mathrm{Hg}_{2}^{2+}, \mathrm{Pb}^{2+}, \mathrm{Ca}^{2+}$, $\mathrm{Sr}^{2+}$, or $\mathrm{Ba}^{2+}$. $\mathrm{BaSO}_{4}$ is therefore insoluble and will precipitate. We indicate its phase as $(s)$ :

$$
\mathrm{Na}_{2} \mathrm{SO}_{4}(a q)+\mathrm{Ba}(\mathrm{OH})_{2}(a q) \longrightarrow 2 \mathrm{NaOH}(a q)+\mathrm{BaSO}_{4}(s)
$$

## Ionic Equations

Although molecular equations are useful, especially from the standpoint of knowing which solutions to combine in the laboratory, they are in a sense unrealistic. Soluble ionic compounds are strong electrolytes [ 14 Section 4.1]. As such, they exist in solution as hydrated ions, rather than as formula units. Thus, it would be more realistic to represent the aqueous species in the reaction of $\mathrm{Na}_{2} \mathrm{SO}_{4}(a q)$ with $\mathrm{Ba}(\mathrm{OH})_{2}(a q)$ as follows:

$$
\begin{aligned}
\mathrm{Na}_{2} \mathrm{SO}_{4}(a q) & \longrightarrow 2 \mathrm{Na}^{+}(a q)+\mathrm{SO}_{4}^{2-}(a q) \\
\mathrm{Ba}(\mathrm{OH})_{2}(a q) & \longrightarrow \mathrm{Ba}^{2+}(a q)+2 \mathrm{OH}^{-}(a q) \\
\mathrm{NaOH}(a q) & \longrightarrow \mathrm{Na}^{+}(a q)+\mathrm{OH}^{-}(a q)
\end{aligned}
$$

If we were to rewrite the equation, representing the dissolved compounds as hydrated ions, it would be

$$
2 \mathrm{Na}^{+}(a q)+\mathrm{SO}_{4}^{2-}(a q)+\mathrm{Ba}^{2+}(a q)+2 \mathrm{OH}^{-}(a q) \longrightarrow 2 \mathrm{Na}^{+}(a q)+2 \mathrm{OH}^{-}(a q)+\mathrm{BaSO}_{4}(s)
$$

This version of the equation is called an ionic equation, a chemical equation in which any compound that exists completely or predominantly as ions in solution is represented as those ions. Species that are insoluble or that exist in solution completely or predominantly as molecules are represented with their chemical formulas, as they were in the molecular equation.

## Net Ionic Equations

$\mathrm{Na}^{+}(a q)$ and $\mathrm{OH}^{-}(a q)$ both appear as reactants and products in the ionic equation for the reaction of $\mathrm{Na}_{2} \mathrm{SO}_{4}(a q)$ with $\mathrm{Ba}(\mathrm{OH})_{2}(a q)$. Ions that appear on both sides of the equation arrow are called spectator ions because they do not participate in the reaction. Spectator ions cancel one another, just as identical terms on both sides of an algebraic equation cancel one another, so we need not show spectator ions in chemical equations.

$$
2 \mathrm{Na}^{+}(a q)+\mathrm{SO}_{4}^{2-}(a q)+\mathrm{Ba}^{2+}(a q)+2 \mathrm{OH}^{-}(a q) \longrightarrow 2 \mathrm{Na}^{+}(a q)+2 \mathrm{OH}^{-}(a q)+\mathrm{BaSO}_{4}(s)
$$

Eliminating the spectator ions yields the following equation:

$$
\mathrm{Ba}^{2+}(a q)+\mathrm{SO}_{4}^{2-}(a q) \longrightarrow \mathrm{BaSO}_{4}(s)
$$

This version of the equation is called a net ionic equation, which is a chemical equation that includes only the species that are actually involved in the reaction. The net ionic equation, in effect, tells us what actually happens when we combine solutions of sodium sulfate and barium hydroxide.

The steps necessary to determine the molecular, ionic, and net ionic equations for a precipitation reaction are as follows:

1. Write and balance the molecular equation, predicting the products by assuming that the cations trade anions.
2. Write the ionic equation by separating strong electrolytes into their constituent ions.
3. Write the net ionic equation by identifying and canceling spectator ions on both sides of the equation.

If both products of a reaction are strong electrolytes, all the ions in solution are spectator ions. In this case, there is no net ionic equation and no reaction takes place.

Sample Problem 4.4 illustrates the stepwise determination of molecular, ionic, and net ionic equations.

## Sample Problem 4.4

Write the molecular, ionic, and net ionic equations for the reaction that occurs when aqueous solutions of lead acetate $\left[\mathrm{Pb}\left(\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right)_{2}\right]$, and calcium chloride $\left(\mathrm{CaCl}_{2}\right)$, are combined.

Strategy Predict the products by exchanging ions and balance the equation. Determine which product will precipitate based on the solubility guidelines in Tables 4.2 and 4.3. Rewrite the equation showing strong electrolytes as ions. Identify and cancel spectator ions.

Setup The products of the reaction are $\mathrm{PbCl}_{2}$ and $\mathrm{Ca}\left(\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right)_{2} . \mathrm{PbCl}_{2}$ is insoluble, because $\mathrm{Pb}^{2+}$ is one of the insoluble exceptions for chlorides, which are generally soluble. $\mathrm{Ca}\left(\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right)_{2}$ is soluble because all acetates are soluble.

Solution Molecular equation:

$$
\mathrm{Pb}\left(\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right)_{2}(a q)+\mathrm{CaCl}_{2}(a q) \longrightarrow \mathrm{PbCl}_{2}(s)+\mathrm{Ca}\left(\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right)_{2}(a q)
$$

Ionic equation:

$$
\mathrm{Pb}^{2+}(a q)+2 \mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}(a q)+\mathrm{Ca}^{2+}(a q)+2 \mathrm{Cl}^{-}(a q) \longrightarrow \mathrm{PbCl}_{2}(s)+\mathrm{Ca}^{2+}(a q)+2 \mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}(a q)
$$

Net ionic equation:

$$
\mathrm{Pb}^{2+}(a q)+2 \mathrm{Cl}^{-}(a q) \longrightarrow \mathrm{PbCl}_{2}(s)
$$

Practice Problem A Write the molecular, ionic, and net ionic equations for the combination of $\mathrm{Sr}\left(\mathrm{NO}_{3}\right)_{2}(a q)$ and $\mathrm{Li}_{2} \mathrm{SO}_{4}(a q)$.

Think About It Remember that the charges on ions in a compound must sum to zero. Make sure that you have written correct formulas for the products and that each of the equations you have written is balanced. If you find that you are having trouble balancing an equation, check to make sure you have correct formulas for the products.

HPactice Problem B Write the molecular, ionic, and net ionic equations for the combination of $\mathrm{KNO}_{3}(a q)$ and $\mathrm{BaCl}_{2}(a q)$.

## Checkpoint 4.2 Precipitation Reactions

4.2.1 Which of the following are water soluble? (Choose all that apply.)
a) $\mathrm{Na}_{2} \mathrm{~S}$
b) $\mathrm{Ba}\left(\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right)_{2}$
c) $\mathrm{CaCO}_{3}$
d) $\mathrm{CuBr}_{2}$
e) $\mathrm{Hg}_{2} \mathrm{Cl}_{2}$
4.2.2 Which of the following are water insoluble? (Choose all that apply.)
a) $\mathrm{Ag}_{2} \mathrm{CrO}_{4}$
b) $\mathrm{Li}_{2} \mathrm{CO}_{3}$
c) $\mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}$
d) $\mathrm{BaSO}_{4}$
e) $\mathrm{ZnCl}_{2}$

## Checkpoint 4.2 Precipitation Reactions (continued)

4.2.3 What are the spectator ions in the ionic equation for the combination of $\mathrm{Li}_{2} \mathrm{CO}_{3}(a q)$ and $\mathrm{Ba}(\mathrm{OH})_{2}(a q)$ ?
a) $\mathrm{CO}_{3}^{2-}$ and $\mathrm{OH}^{-}$
b) $\mathrm{Li}^{+}$and $\mathrm{OH}^{-}$
c) $\mathrm{Li}^{+}$and $\mathrm{Ba}^{2+}$
d) $\mathrm{Ba}^{2+}$ and $\mathrm{OH}^{-}$
e) $\mathrm{Ba}^{2+}$ and $\mathrm{CO}_{3}^{2-}$
4.2.4 Select the correct net ionic equation for the combination of $\mathrm{Fe}\left(\mathrm{NO}_{3}\right)_{2}(a q)$ and $\mathrm{Na}_{2} \mathrm{CO}_{3}(\mathrm{aq})$.
a) $\mathrm{Na}^{+}(a q)+\mathrm{CO}_{3}^{2-}(a q) \longrightarrow \mathrm{NaCO}_{3}(s)$
b) $\mathrm{Fe}^{2+}(a q)+\mathrm{CO}_{3}^{2-}(a q) \longrightarrow \mathrm{FeCO}_{3}(s)$
c) $2 \mathrm{Na}^{+}(a q)+\mathrm{CO}_{3}^{2-}(a q) \longrightarrow \mathrm{Na}_{2} \mathrm{CO}_{3}(s)$
d) $\mathrm{Fe}^{2+}(a q)+2 \mathrm{NO}_{3}^{-}(a q) \longrightarrow \mathrm{Fe}\left(\mathrm{NO}_{3}\right)_{2}(s)$
e) $\mathrm{Na}^{+}(a q)+\mathrm{NO}_{3}^{-}(a q) \longrightarrow \mathrm{NaNO}_{3}(s)$
4.2.5 Which reaction is represented by the net ionic equation for the combination of aqueous solutions of LiOH and $\mathrm{Cu}\left(\mathrm{NO}_{3}\right)_{2}$ ?
(a)

(b)
(c)
(d)

4.2.6 Which reaction is represented by the net ionic equation for the combination of aqueous solutions of $\mathrm{LiNO}_{3}$ and $\mathrm{NaC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$ ?
(e) There is no net ionic equation. No reaction occurs.

$$
\mathrm{Li}^{+}=\bigcirc \quad \mathrm{NO}_{3}^{-}=\bigcirc \quad \mathrm{Na}^{+}=\bigcirc \quad \mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}=
$$

(e) There is no net ionic equation. No reaction occurs.

### 4.3 Acid-Base Reactions

Another type of reaction occurs when two solutions, one containing an acid and one containing a base, are combined. We frequently encounter acids and bases in everyday life (Figure 4.5). Ascorbic acid, for instance, is also known as vitamin C; acetic acid is the component responsible for the sour taste and characteristic smell of vinegar; and hydrochloric acid is the acid in muriatic acid and is also the principal ingredient in gastric juice (stomach acid). Ammonia, found in many cleaning products, and sodium hydroxide, found in drain cleaner, are common bases. Acid-base chemistry is extremely important to biological processes. Let's look again at the properties of acids and bases, and then look at acid-base reactions.

Media Player/ MPEG Content
Acids and bases-dissociation of strong and weak acids.

## Strong Acids and Bases

As we saw in Section 4.1, the seven strong acids-those that ionize completely in solution-are listed in Table 4.1. All other acids are weak acids. The strong bases are the hydroxides of Group 1A and heavy Group 2A metals. These are soluble ionic compounds, which dissociate completely

TABLE 4.4
Strong Acids and Strong Bases

| Strong Acids | Strong Bases |
| :--- | :--- |
| HCl | LiOH |
| HBr | NaOH |
| HI | KOH |
| $\mathrm{HNO}_{3}$ | RbOH |
| $\mathrm{HClO}_{3}$ | CsOH |
| $\mathrm{HClO}_{4}$ | $\mathrm{Ca}(\mathrm{OH})_{2}$ |
| $\mathrm{H}_{2} \mathrm{SO}_{4}$ | $\mathrm{Sr}(\mathrm{OH})_{2}$ |
|  | $\mathrm{Ba}(\mathrm{OH})_{2}$ |

and exist entirely as ions in solution. Thus, both strong acids and strong bases are strong electrolytes. Table 4.4 lists the strong acids and strong bases. It is important that you know these compounds.

## Brønsted Acids and Bases

In Section 2.6 we defined an acid as a substance that ionizes in water to produce $\mathrm{H}^{+}$ions, and a base as a substance that ionizes (or dissociates, in the case of an ionic base) in water to produce $\mathrm{OH}^{-}$ions. These definitions are attributed to the Swedish chemist Svante Arrhenius. ${ }^{1}$ Although

[^5]Figure 4.5 Some common acids and bases. From left to right: Sodium hydroxide ( NaOH ), ascorbic acid $\left(\mathrm{C}_{6} \mathrm{H}_{8} \mathrm{O}_{6}\right.$ or, with its ionizable hydrogens written first, $\mathrm{H}_{2} \mathrm{C}_{6} \mathrm{H}_{6} \mathrm{O}_{6}$ ), hydrochloric acid $(\mathrm{HCl})$, acetic acid $\left(\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right)$, and ammonia $\left(\mathrm{NH}_{3}\right)$. HCl and NaOH are both strong electrolytes and exist in solution entirely as ions. Water molecules are not shown.

Student Annotation: Although three of the Group 2A hydroxides $\left[\mathrm{Ca}(\mathrm{OH})_{2}, \mathrm{Sr}(\mathrm{OH})_{2}\right.$, and $\mathrm{Ba}(\mathrm{OH})_{2}$ ] are typically classified as strong bases, only $\mathrm{Ba}(\mathrm{OH})_{2}$ is sufficiently soluble to be used commonly in the laboratory. For any ionic compound, what does dissolve - even if it is only a tiny amount-dissociates completely.

Student Annotation: The H atom consists of a proton and an electron. When the electron is lost, all that remains is the proton-hence the use of the term proton in this context.

Student Annotation: In reality, aqueous protons are surrounded by water molecules, just as other ions are. We use $\mathrm{H}_{3} \mathrm{O}^{+}$in chemical equations, showing just one of the water molecules involved, to emphasize that the proton is hydrated in solution.

Student Annotation: The terms and symbols hydrogen ion, proton, hydronium ion, $\mathrm{H}^{+}$, and $\mathrm{H}_{3} \mathrm{O}^{+}$all refer to the same aqueous species and are used interchangeably.
the Arrhenius acid and Arrhenius base definitions are useful, they are restricted to the behavior of compounds in aqueous solution. More inclusive definitions were proposed by the Danish chemist Johannes Brønsted ${ }^{2}$ in 1932. A Brønsted acid is a proton donor, and a Brønsted base is a proton acceptor. In this context, the word proton refers to a hydrogen atom that has lost its electron-also known as a hydrogen ion $\left(\mathrm{H}^{+}\right)$. Consider the ionization of the weak base ammonia $\left(\mathrm{NH}_{3}\right)$.

$$
\mathrm{NH}_{3}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{NH}_{4}^{+}(a q)+\mathrm{OH}^{-}(a q)
$$

This equation shows that $\mathrm{NH}_{3}$ is a base in the Arrhenius sense; that is, it produces $\mathrm{OH}^{-}$in solution. It is also a base in the Brønsted sense because it accepts a proton $\left(\mathrm{H}^{+}\right)$from the water molecule to become the ammonium ion $\left(\mathrm{NH}_{4}^{+}\right)$.

Now consider the ionization of hydrofluoric acid (HF), a weak acid.

$$
\mathrm{HF}(a q) \rightleftarrows \mathrm{H}^{+}(a q)+\mathrm{F}^{-}(a q)
$$

HF is an acid in the Arrhenius sense because it produces $\mathrm{H}^{+}$in solution. It is also an acid in the Brønsted sense because it donates a proton to the aqueous solution. An aqueous proton ( $\mathrm{H}^{+}$), however, does not exist as an isolated species in solution. Rather, it is hydrated just as other aqueous ions are [ 1 Wd Section 4.2]. The proton, being positively charged, is strongly attracted to the partial negative charge on the oxygen atom in a water molecule. Thus, it is convenient and more realistic for us to represent the ionization of HF with the equation

$$
\mathrm{HF}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{F}^{-}(a q)
$$

where we include the water molecule to which the proton becomes attached, both before and after the ionization. (We could show $\mathrm{H}_{3} \mathrm{O}^{+}$as $\mathrm{H}_{2} \mathrm{O} \cdot \mathrm{H}^{+}$to emphasize that it is a water molecule attached to a proton.) With the equation written this way, we show that HF donates a proton to $\mathrm{H}_{2} \mathrm{O}$, thus converting the $\mathrm{H}_{2} \mathrm{O}$ molecule to the hydronium ion $\left(\mathrm{H}_{3} \mathrm{O}^{+}\right)$.

Both $\mathrm{H}^{+}$and $\mathrm{H}_{3} \mathrm{O}^{+}$will be used in chemical equations throughout the text. You should be aware that they refer to the same aqueous species.

The Brønsted definitions of acids and bases are not restricted to species in aqueous solution. In fact, Brønsted acid-base reactions sometimes take place in the gas phase. For example, in the reaction between HCl and $\mathrm{NH}_{3}$ gases, HCl acts as the Brønsted acid, donating its proton to $\mathrm{NH}_{3}$, which, by accepting the proton, acts as a Brønsted base. The products of this proton transfer are the chloride ion $\left(\mathrm{Cl}^{-}\right)$and the ammonium ion $\left(\mathrm{NH}_{4}^{+}\right)$, which subsequently combine to form the ionic solid ammonium chloride.

$$
\mathrm{HCl}(g)+\mathrm{NH}_{3}(g) \longrightarrow \mathrm{NH}_{4} \mathrm{Cl}(s)
$$

Most of the strong acids are monoprotic acids, meaning that each acid molecule has one proton to donate. One of the strong acids, $\mathrm{H}_{2} \mathrm{SO}_{4}$, is a diprotic acid, meaning that each acid molecule has two protons that it can donate. Other diprotic acids include oxalic acid $\left(\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}\right)$ and carbonic acid $\left(\mathrm{H}_{2} \mathrm{CO}_{3}\right)$. There are also triprotic acids, those with three protons, although they are relatively less common than mono- or diprotic acids. Examples include phosphoric acid $\left(\mathrm{H}_{3} \mathrm{PO}_{4}\right)$ and citric acid $\left(\mathrm{H}_{3} \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}_{7}\right)$. In general, acids with more than one proton are called polyprotic acids.

Of the polyprotic acids, only sulfuric acid is a strong acid. Recall from Table 4.1, though, that $\mathrm{H}_{2} \mathrm{SO}_{4}$ is strong only in its first ionization in water. Although $\mathrm{H}_{2} \mathrm{SO}_{4}$ ionizes completely to

[^6]yield $\mathrm{H}^{+}$and $\mathrm{HSO}_{4}^{-}$, the subsequent ionization of the hydrogen sulfate ion $\left(\mathrm{HSO}_{4}^{-}\right)$happens only to a very small extent. Note the single and double arrows in the following two equations.
\[

$$
\begin{aligned}
& \mathrm{H}_{2} \mathrm{SO}_{4}(a q) \longleftrightarrow \mathrm{H}^{+}(a q)+\mathrm{HSO}_{4}^{-}(a q) \\
& \mathrm{HSO}_{4}^{-}(a q) \rightleftarrows \mathrm{H}^{+}(a q)+\mathrm{SO}_{4}^{2-}(a q)
\end{aligned}
$$
\]

For all other polyprotic acids, each ionization is incomplete and is represented by an equation with a double arrow. The first, second, and third ionizations of phosphoric acid are represented as

$$
\begin{aligned}
\mathrm{H}_{3} \mathrm{PO}_{4}(a q) & \rightleftarrows \mathrm{H}^{+}(a q)+\mathrm{H}_{2} \mathrm{PO}_{4}^{-}(a q) \\
\mathrm{H}_{2} \mathrm{PO}_{4}^{-}(a q) & \rightleftarrows \mathrm{H}^{+}(a q)+\mathrm{HPO}_{4}^{2-}(a q) \\
\mathrm{HPO}_{4}^{2-}(a q) & \rightleftarrows \mathrm{H}^{+}(a q)+\mathrm{PO}_{4}^{3-}(a q)
\end{aligned}
$$

Some of each of the species shown is present in a solution of phosphoric acid. Because each successive ionization happens to a smaller and smaller extent, the relative concentrations of species in solution are as follows:

$$
\left[\mathrm{H}_{3} \mathrm{PO}_{4}\right]>\left[\mathrm{H}^{+}\right] \approx\left[\mathrm{H}_{2} \mathrm{PO}_{4}^{-}\right]>\left[\mathrm{HPO}_{4}^{2-}\right]>\left[\mathrm{PO}_{4}^{3-}\right]
$$

Just as some acids produce more than one $\mathrm{H}^{+}$ion, some strong bases produce more than one $\mathrm{OH}^{-}$ion. Barium hydroxide, for example, dissociates to produce 2 moles of hydroxide ion for every mole of $\mathrm{Ba}(\mathrm{OH})_{2}$ dissolved.

$$
\mathrm{Ba}(\mathrm{OH})_{2}(s) \xrightarrow{\mathrm{H}_{2} \mathrm{O}} \mathrm{Ba}^{2+}(a q)+2 \mathrm{OH}^{-}(a q)
$$

Compounds such as this are referred to as dibasic bases, indicating that they produce 2 moles of hydroxide per mole of compound. Those that produce only 1 mole of hydroxide per mole of compound, such as NaOH , are called monobasic bases.

## Acid-Base Neutralization

A neutralization reaction is a reaction between an acid and a base. In general, an aqueous acidbase reaction produces water and a salt, which is an ionic compound made up of the cation from a base and the anion from an acid. The substance we know as table salt, NaCl, is a familiar example. It is a product of the following acid-base reaction:

$$
\mathrm{HCl}(a q)+\mathrm{NaOH}(a q) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{NaCl}(a q)
$$

However, because the acid, base, and salt are all strong electrolytes, they exist entirely as ions in solution. The ionic equation is

$$
\mathrm{H}^{+}(a q)+\mathrm{Cl}^{-}(a q)+\mathrm{Na}^{+}(a q)+\mathrm{OH}^{-}(a q) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{Na}^{+}(a q)+\mathrm{Cl}^{-}(a q)
$$

The net ionic equation is

$$
\mathrm{H}^{+}(a q)+\mathrm{OH}^{-}(a q) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)
$$

Both $\mathrm{Na}^{+}$and $\mathrm{Cl}^{-}$are spectator ions. If we were to carry out the preceding reaction using stoichiometric amounts [ 14 Section 3.6] of HCl and NaOH , the result would be neutral saltwater with no leftover acid or base.

The following are also examples of acid-base neutralization reactions, represented by molecular equations:

$$
\begin{aligned}
\mathrm{HNO}_{3}(a q)+\mathrm{KOH}(a q) & \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{KNO}_{3}(a q) \\
\mathrm{H}_{2} \mathrm{SO}_{4}(a q)+2 \mathrm{NaOH}(a q) & \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{Na}_{2} \mathrm{SO}_{4}(a q) \\
2 \mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}(a q)+\mathrm{Ba}(\mathrm{OH})_{2}(a q) & \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{Ba}\left(\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right)_{2}(a q) \\
\mathrm{HCl}(a q)+\mathrm{NH}_{3}(a q) & \longrightarrow \mathrm{NH}_{4} \mathrm{Cl}(a q)
\end{aligned}
$$

The last equation looks different because it does not show water as a product. Recall, however, that $\mathrm{NH}_{3}(a q)$ ionizes to give $\mathrm{NH}_{4}^{+}(a q)$ and $\mathrm{OH}^{-}(a q)$. If we include these two species as reactants in place of $\mathrm{NH}_{3}(a q)$, the equation becomes

$$
\mathrm{HCl}(a q)+\mathrm{NH}_{4}^{+}(a q)+\mathrm{OH}^{-}(a q) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{NH}_{4} \mathrm{Cl}(a q)
$$

Sample Problem 4.5 involves an acid-base neutralization reaction.

Student Annotation: These relative concentrations are true only in an aqueous solution of phosphoric acid that contains no other dissolved compounds. We will look in detail at how to determine concentrations in aqueous solutions of polyprotic acids in Chapter 16.

## Multimedia

Acids and bases-neutralization reaction of NaOH and HCl .

Student Annotation: A compound in which the anion is oxide $\left(\mathrm{O}^{2-}\right)$ or hydroxide $\left(\mathrm{OH}^{-}\right)$is not considered a salt.

Student Annotation: Acid-base neutralization reactions, like precipitation reactions [ 14 Section 4.2], are metathesis reactions, where two species exchange ions.

Student Annotation: Most suspended solids will settle to the bottom of the bottle, making it necessary to "shake well before using." Shaking redistributes the solid throughout the liquid.

Think About It Make sure your equation is balanced and that you only show strong electrolytes as ions. $\mathrm{Mg}(\mathrm{OH})_{2}$ is not shown as aqueous ions because it is insoluble.

## Sample Problem 4.5

Milk of magnesia, an over-the-counter laxative, is a mixture of magnesium hydroxide $\left[\mathrm{Mg}(\mathrm{OH})_{2}\right]$ and water. Because $\mathrm{Mg}(\mathrm{OH})_{2}$ is insoluble in water (see Table 4.3), milk of magnesia is a suspension rather than a solution. The undissolved solid is responsible for the milky appearance of the product. When acid such as HCl is added to milk of magnesia, the suspended $\mathrm{Mg}(\mathrm{OH})_{2}$ dissolves, and the result is a clear, colorless solution. Write and balance the molecular equation, and then give the ionic and net ionic equations for this reaction.

Strategy Determine the products of the reaction; then write and balance the equation. Remember that one of the reactants, $\mathrm{Mg}(\mathrm{OH})_{2}$, is a solid. Identify any strong electrolytes and rewrite the equation showing strong electrolytes as ions. Identify and cancel the spectator ions.

Setup Because this is an acid-base neutralization reaction, one of the products is water. The other product is a salt comprising the cation from the base, $\mathrm{Mg}^{2+}$, and the anion from the acid, $\mathrm{Cl}^{-}$. For the formula to be neutral, these ions combine in a 1:2 ratio, giving $\mathrm{MgCl}_{2}$ as the formula of the salt.

## Solution

$$
\operatorname{Mg}(\mathrm{OH})_{2}(s)+2 \mathrm{HCl}(a q) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{MgCl}_{2}(a q)
$$

Of the species in the molecular equation, only HCl and $\mathrm{MgCl}_{2}$ are strong electrolytes. Therefore, the ionic equation is

$$
\mathrm{Mg}(\mathrm{OH})_{2}(s)+2 \mathrm{H}^{+}(a q)+2 \mathrm{Cl}^{-}(a q) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{Mg}^{2+}(a q)+2 \mathrm{Cl}^{-}(a q)
$$

$\mathrm{Cl}^{-}$is the only spectator ion. The net ionic equation is

$$
\mathrm{Mg}(\mathrm{OH})_{2}(s)+2 \mathrm{H}^{+}(a q) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{Mg}^{2+}(a q)
$$

Practice Problem A Write and balance the molecular equation and then give the ionic and net ionic equations for the neutralization reaction between $\mathrm{Ba}(\mathrm{OH})_{2}(a q)$ and $\mathrm{HF}(a q)$.

EPPractice Problem B Write and balance the molecular equation and then give the ionic and net ionic equations for the neutralization reaction between $\mathrm{NH}_{3}(a q)$ and $\mathrm{H}_{2} \mathrm{SO}_{4}(a q)$.

## Checkpoint 4.3 Acid-Base Reactions

4.3.1 Identify the Brønsted acid in the following equation:

$$
\mathrm{H}_{2} \mathrm{SO}_{4}(a q)+2 \mathrm{NH}_{3}(a q) \longrightarrow\left(\mathrm{NH}_{4}\right)_{2} \mathrm{SO}_{4}(a q)
$$

a) $\mathrm{H}_{2} \mathrm{SO}_{4}(\mathrm{aq})$
b) $\mathrm{NH}_{3}(a q)$
c) $\mathrm{H}_{2} \mathrm{O}(l)$
d) $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{SO}_{4}$
e) This equation does not contain a Brønsted acid.
4.3.2 Identify the Brønsted base in the following equation:

$$
\mathrm{HCl}(a q)+\mathrm{NO}_{2}^{-}(a q) \longrightarrow \mathrm{HNO}_{2}(a q)+\mathrm{Cl}^{-}(a q)
$$

a) $\mathrm{HCl}(a q)$
b) $\mathrm{NO}_{2}^{-}(\mathrm{aq})$
c) $\mathrm{HNO}_{2}(a q)$
d) $\mathrm{Cl}^{-}(a q)$
e) $\mathrm{H}_{2} \mathrm{O}(l)$
4.3.3 Which of the following is the correct net ionic equation for the reaction of $\mathrm{H}_{2} \mathrm{SO}_{4}$ and KOH ?
a) $\mathrm{H}_{2}(a q)+2 \mathrm{OH}^{-}(a q) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l)$
b) $2 \mathrm{H}^{+}(a q)+2 \mathrm{OH}^{-}(a q) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l)$
c) $2 \mathrm{H}^{+}(a q)+\mathrm{OH}^{-}(a q) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)$
d) $\mathrm{H}_{2} \mathrm{SO}_{4}(a q)+2 \mathrm{OH}^{-}(a q) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{SO}_{4}^{2-}(a q)$
e) $\mathrm{H}^{+}(a q)+\mathrm{HSO}_{4}^{-}(a q)+2 \mathrm{OH}^{-}(a q) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{SO}_{4}^{2-}(a q)$
4.3.4 Which of the following is the correct net ionic equation for the reaction of HF and LiOH ?
a) $\mathrm{HF}(a q)+\mathrm{LiOH}(a q) \longrightarrow \mathrm{H}_{2} \mathrm{O}(a q)+\mathrm{LiF}(a q)$
b) $\mathrm{H}^{+}(a q)+\mathrm{F}^{-}(a q)+\mathrm{Li}^{+}(a q)+\mathrm{OH}^{-}(a q) \longrightarrow$ $\mathrm{H}_{2} \mathrm{O}(a q)+\mathrm{Li}^{+}(a q)+\mathrm{F}^{-}(a q)$
c) $\mathrm{H}^{+}(a q)+\mathrm{OH}^{-}(a q) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)$
d) $\mathrm{HF}(a q)+\mathrm{OH}^{-}(a q) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{F}^{-}(a q)$
e) $\mathrm{H}^{+}(a q)+\mathrm{Li}^{+}(a q)+\mathrm{OH}^{-}(a q) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{Li}^{+}(a q)$

### 4.4 Oxidation-Reduction Reactions

In Sections 4.2 and 4.3 we encountered two types of chemical reactions that can occur when two electrolyte solutions are combined: precipitation, in which ionic compounds exchange ions, and acid-base neutralization, in which a proton is transferred from an acid to a base. In this section, we will learn about oxidation-reduction reactions, commonly called redox reactions. A redox reaction is a chemical reaction in which electrons are transferred from one reactant to another. For example, if we place a piece of zinc metal into a solution that contains copper ions, the following reaction will occur:

$$
\mathrm{Zn}(s)+\mathrm{Cu}^{2+}(a q) \longrightarrow \mathrm{Zn}^{2+}(a q)+\mathrm{Cu}(s)
$$

This reaction is shown in Figure 4.6. In this process, zinc atoms are oxidized (they lose electrons) and copper ions are reduced (they gain electrons). Each zinc atom loses two electrons to become a zinc ion,

$$
\mathrm{Zn}(s) \longrightarrow \mathrm{Zn}^{2+}(a q)+2 e^{-}
$$

and each copper ion gains two electrons to become a copper atom.

$$
\mathrm{Cu}^{2+}(a q)+2 e^{-} \longrightarrow \mathrm{Cu}(s)
$$

Figure 4.6 Oxidation of zinc in a solution of copper(II) sulfate.

Student Annotation: The term oxidation originally was used by chemists to mean "reaction with oxygen." Like definitions of acids and bases, though, it has been redefined to include any reaction in which electrons are lost.

Multimedia
Chemical reactions-formation of $\mathrm{Ag}_{2} \mathrm{~S}$ by oxidation reduction.

Student Annotation: The number in a circle under each element's symbol contains the oxidation state of the element. The number in a square contains the total contribution to charge by that element. For more on the use of this convention, see the "You May Be Wondering" box on page 137.

These two equations show electrons as a product in the zinc reaction and as a reactant in the copper reaction. Each of these two equations represents a half-reaction, the oxidation or the reduction reaction in a redox reaction. The sum of the two half-reaction equations is the overall equation for the redox reaction:

$$
\begin{aligned}
\mathrm{Zn}(s) & \longrightarrow \mathrm{Zn}^{2+}(a q)+2 e^{-} \\
+\mathrm{Cu}^{2+}(a q)+2 e^{-} & \longrightarrow \mathrm{Cu}(s) \\
\mathrm{Zn}(s)+\mathrm{Cu}^{2+}(a q)+2 e^{-} & \mathrm{Zn}^{2+}(a q)+\mathrm{Cu}(s)+2 e^{-}
\end{aligned}
$$

Although these two processes can be represented by separate equations, they cannot occur separately. For one species to gain electrons, another must lose them, and vice versa.

Oxidation is the loss of electrons. The opposite process, the gain of electrons, is called reduction. In the reaction of Zn with $\mathrm{Cu}^{2+}, \mathrm{Zn}$ is called the reducing agent because it donates electrons, causing $\mathrm{Cu}^{2+}$ to be reduced. $\mathrm{Cu}^{2+}$ is called the oxidizing agent, on the other hand, because it accepts electrons, causing Zn to be oxidized.

Another example of a redox reaction is the formation of calcium oxide $(\mathrm{CaO})$ from its constituent elements.

$$
2 \mathrm{Ca}(s)+\mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{CaO}(s)
$$

In this reaction, each calcium atom loses two electrons (is oxidized) and each oxygen atom gains two electrons (is reduced). The corresponding half-reactions are

$$
\begin{aligned}
2 \mathrm{Ca} & \longrightarrow 2 \mathrm{Ca}^{2+}+4 e^{-} \\
\mathrm{O}_{2}+4 e^{-} & \longrightarrow 2 \mathrm{O}^{2-}
\end{aligned}
$$

The resulting $\mathrm{Ca}^{2+}$ and $\mathrm{O}^{2-}$ ions combine to form CaO .
Redox reactions take place because atoms of different elements have different tendencies to gain electrons. Oxygen, for instance, has a much greater tendency to gain electrons than does calcium. Calcium, being a metal, has a significant tendency to lose electrons. Compounds that form between elements with significantly different tendencies to gain electrons generally are ionic. By knowing the charges on the monatomic ions in such compounds, we can keep track of the electrons that have been lost and gained.

## Oxidation Numbers

When elements of similar abilities to gain electrons combine, they tend to form molecular compounds, as in the formation of HF and $\mathrm{NH}_{3}$ from their respective elements:

$$
\begin{gathered}
\mathrm{H}_{2}(g)+\mathrm{F}_{2}(g) \longrightarrow 2 \mathrm{HF}(g) \\
\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \longrightarrow 2 \mathrm{NH}_{3}(g)
\end{gathered}
$$

In the formation of hydrogen fluoride (HF), therefore, fluorine does not gain an electron per seand hydrogen does not lose one. Experimental evidence shows, however, that there is a partial transfer of electrons from H to F. Oxidation numbers provide us with a way to "balance the books" with regard to electrons in a chemical equation. The oxidation number, also called the oxidation state, is the charge an atom would have if electrons were transferred completely. For example, we can rewrite the preceding equations for the formation of HF and $\mathrm{NH}_{3}$ as follows:

The numbers in circles below each element are the oxidation numbers, and the numbers in the boxes are each atom's contribution to overall charge. In both of the reactions shown, the reactants are all homonuclear diatomic molecules. Thus, we would expect no transfer of electrons from one atom to the other and the oxidation number of each is zero. For the product molecules, however,
for the sake of determining oxidation numbers, we assume that complete electron transfer has taken place and that each atom has either gained or lost one or more electrons. The oxidation numbers reflect the number of electrons assumed to have been transferred.

Oxidation numbers enable us to identify elements that are oxidized and reduced at a glance. The elements that show an increase in oxidation number-hydrogen in the preceding examplesare oxidized, whereas the elements that show a decrease in oxidation number-fluorine and nitrogen-are reduced.

In a sense, each atom's oxidation number makes a contribution to the overall charge on the species. Note that the oxidation numbers in both HF $[(+1)+(-1)=0]$ and $\mathrm{NH}_{3}[(-3)+$ $3(+1)=0$ ] sum to zero. Because compounds are electrically neutral, the oxidation numbers in any compound will sum to zero. For a polyatomic ion, oxidation numbers must sum to the charge on the ion. (The oxidation number of a monatomic ion is equal to its charge.)

## Oxidation of Metals in Aqueous Solutions

Recall from the beginning of this section that zinc metal reacts with aqueous copper ions to form aqueous zinc ions and copper metal. One way that this reaction might be carried out is for zinc metal to be immersed in a solution of copper(II) sulfate $\left(\mathrm{CuSO}_{4}\right)$, as depicted in Figure 4.6. The molecular equation for this reaction is

This is an example of a displacement reaction. Zinc displaces, or replaces, copper in the dissolved salt by being oxidized from Zn to $\mathrm{Zn}^{2+}$. Copper is displaced from the salt (and removed from solution) by being reduced from $\mathrm{Cu}^{2+}$ to Cu . Chloride ( $\mathrm{Cl}^{-}$), which is neither oxidized nor reduced, is a spectator ion in this reaction.

What would happen, then, if we placed copper metal into a solution containing zinc chloride $\left(\mathrm{ZnCl}_{2}\right)$ ? Would $\mathrm{Cu}(s)$ be oxidized to $\mathrm{Cu}^{2+}(a q)$ by $\mathrm{Zn}^{2+}(a q)$ the way $\mathrm{Zn}(s)$ is oxidized to $\mathrm{Zn}^{2+}(a q)$ by $\mathrm{Cu}^{2+}(a q)$ ? The answer is no. In fact, no reaction would occur if we were to immerse copper metal into an aqueous solution of $\mathrm{ZnCl}_{2}$.

$$
\mathrm{Cu}(s)+\mathrm{ZnCl}_{2}(a q) \longrightarrow \text { no reaction }
$$

No reaction occurs between $\mathrm{Cu}(s)$ and $\mathrm{Zn}^{2+}(a q)$, whereas a reaction does occur between $\mathrm{Zn}(s)$ and $\mathrm{Cu}^{2+}(a q)$ because zinc is more easily oxidized than copper.

The activity series (Table 4.5) is a list of metals (and hydrogen) arranged from top to bottom in order of decreasing ease of oxidation. The second column shows the oxidation half-reaction corresponding to each element in the first column. Note the positions of zinc and copper in the table. Zinc appears higher in the table and is therefore oxidized more easily. In fact, an element in the series will be oxidized by the ions of any element that appears below it. According to Table 4.5, therefore, zinc metal will be oxidized by a solution containing any of the following ions: $\mathrm{Cr}^{3+}$, $\mathrm{Fe}^{2+}, \mathrm{Cd}^{2+}, \mathrm{Co}^{2+}, \mathrm{Ni}^{2+}, \mathrm{Sn}^{2+}, \mathrm{H}^{+}, \mathrm{Cu}^{2+}, \mathrm{Ag}^{+}, \mathrm{Hg}^{2+}, \mathrm{Pt}^{2+}$, or $\mathrm{Au}^{3+}$. On the other hand, zinc will not be oxidized by a solution containing $\mathrm{Mn}^{2+}, \mathrm{Al}^{3+}, \mathrm{Mg}^{2+}, \mathrm{Na}^{+}, \mathrm{Ca}^{2+}, \mathrm{Ba}^{2+}, \mathrm{K}^{+}$, or $\mathrm{Li}^{+}$ions.

Metals listed at the top of the activity series are called the active metals. These include the alkali and alkaline earth metals. These metals are so reactive that they are not found in nature in their elemental forms. Metals at the bottom of the series, such as copper, silver, platinum, and gold, are called the noble metals because they have very little tendency to react. These are the metals most often used for jewelry and coins.

## Balancing Simple Redox Equations

To learn how to balance redox equations, let's revisit the practice of balancing equations. In Chapter 3 , you learned to balance equations by counting the number of each kind of atom on each side of the equation arrow. For the purpose of balancing redox equations, it is also necessary to count electrons. For example, consider the net ionic equation for the reaction of chromium metal with nickel ion:

$$
\mathrm{Cr}(s)+\mathrm{Ni}^{2+}(a q) \longrightarrow \mathrm{Cr}^{3+}(a q)+\mathrm{Ni}(s)
$$

Although this equation has equal numbers of each type of atom on both sides, it is not balanced because there is a charge of +2 on the reactant side and a charge of +3 on the product side. To balance it, we can separate it into its half-reactions.

Some metals such as copper are so unreactive that they are found in nature in the uncombined state.

Student Annotation: When a metal is oxidized by an aqueous solution, it becomes an aqueous ion.

?

## Multimedia

Sodium, lithium, and potassium reaction series.

TABLE 4.5
Activity Series

|  | Element | Oxidation Half-Reaction |
| :---: | :---: | :---: |
|  | Lithium | $\mathrm{Li} \longrightarrow \mathrm{Li}^{+}+e^{-}$ |
|  | Potassium | $\mathrm{K} \longrightarrow \mathrm{K}^{+}+e^{-}$ |
|  | Barium | $\mathrm{Ba} \longrightarrow \mathrm{Ba}^{2+}+2 e^{-}$ |
|  | Calcium | $\mathrm{Ca} \longrightarrow \mathrm{Ca}^{2+}+2 e^{-}$ |
|  | Sodium | $\mathrm{Na} \longrightarrow \mathrm{Na}^{+}+e^{-}$ |
|  | Magnesium | $\mathrm{Mg} \longrightarrow \mathrm{Mg}^{2+}+2 e^{-}$ |
|  | Aluminum | $\mathrm{Al} \longrightarrow \mathrm{Al}^{3+}+3 e^{-}$ |
|  | Manganese | $\mathrm{Mn} \longrightarrow \mathrm{Mn}^{2+}+2 e^{-}$ |
|  | Zinc | $\mathrm{Zn} \longrightarrow \mathrm{Zn}^{2+}+2 e^{-}$ |
|  | Chromium | $\mathrm{Cr} \longrightarrow \mathrm{Cr}^{3+}+3 e^{-}$ |
|  | Iron | $\mathrm{Fe} \longrightarrow \mathrm{Fe}^{2+}+2 e^{-}$ |
|  | Cadmium | $\mathrm{Cd} \longrightarrow \mathrm{Cd}^{2+}+2 e^{-}$ |
|  | Cobalt | $\mathrm{Co} \longrightarrow \mathrm{Co}^{2+}+2 e^{-}$ |
|  | Nickel | $\mathrm{Ni} \longrightarrow \mathrm{Ni}^{2+}+2 e^{-}$ |
|  | Tin | $\mathrm{Sn} \longrightarrow \mathrm{Sn}^{2+}+2 e^{-}$ |
|  | Lead | $\mathrm{Pb} \longrightarrow \mathrm{Pb}^{2+}+2 e^{-}$ |
|  | Hydrogen | $\mathrm{H}_{2} \longrightarrow 2 \mathrm{H}^{+}+2 e^{-}$ |
|  | Copper | $\mathrm{Cu} \longrightarrow \mathrm{Cu}^{2+}+2 e^{-}$ |
|  | Silver | $\mathrm{Ag} \longrightarrow \mathrm{Ag}^{+}+e^{-}$ |
|  | Mercury | $\mathrm{Hg} \longrightarrow \mathrm{Hg}^{2+}+2 e^{-}$ |
|  | Platinum | $\mathrm{Pt} \longrightarrow \mathrm{Pt}^{2+}+2 e^{-}$ |
|  | Gold | $\mathrm{Au} \longrightarrow \mathrm{Au}^{3+}+3 e^{-}$ |

$$
\begin{aligned}
\mathrm{Cr}(s) & \longrightarrow \mathrm{Cr}^{3+}(a q)+3 e^{-} \\
\mathrm{Ni}^{2+}(a q)+2 e^{-} & \longrightarrow \mathrm{Ni}(s)
\end{aligned}
$$

When we add half-reactions to get the overall reaction, the electrons must cancel. Because any electrons lost by one species must be gained by the other, electrons may not appear in an overall chemical equation. Therefore, prior to adding these two half-reactions, we must multiply the chromium half-reaction by 2

$$
2\left[\mathrm{Cr}(s) \longrightarrow \mathrm{Cr}^{3+}(a q)+3 e^{-}\right]
$$

and the nickel half-reaction by 3 .

$$
3\left[\mathrm{Ni}^{2+}(a q)+2 e^{-} \longrightarrow \mathrm{Ni}(s)\right]
$$

Then when we add the half-reactions, the electrons cancel and we get the balanced overall equation.

$$
\begin{aligned}
& 2 \mathrm{Cr}(s) \longrightarrow 2 \mathrm{Cr}^{3+}(a q)+6 e^{-} \\
&+3 \mathrm{Ni}^{2+}(a q)+6 e^{-} \longrightarrow 3 \mathrm{Ni}(s) \\
& \hline 2 \mathrm{Cr}(s)+3 \mathrm{Ni}^{2+}(a q) \longrightarrow 2 \mathrm{Cr}^{3+}(a q)+3 \mathrm{Ni}(s)
\end{aligned}
$$

This is known as the half-reaction method of balancing redox equations. We will use this method extensively when we examine more complex redox reactions in Chapter 19.

The activity series enables us to predict whether or not a metal will be oxidized by a solution containing a particular salt or by an acid. Sample Problems 4.7 and 4.8 on page 139 give you more practice making such predictions and balancing redox equations.

## FAQ You May Be Wondering...

## How Do I Assign Oxidation Numbers?

The following guidelines will help you assign oxidation numbers. There are essentially two rules:

1. The oxidation number of any element, in its elemental form, is zero.
2. The oxidation numbers in any chemical species must sum to the overall charge on the species. That is, oxidation numbers must sum to zero for any molecule and must sum to the charge on any polyatomic ion. The oxidation number of a monatomic ion is equal to the charge on the ion.
In addition to these two rules, it is necessary to know the elements that always, or nearly always, have the same oxidation number. Table 4.6 lists elements whose oxidation numbers are "reliable," in order of decreasing reliability.

To determine oxidation numbers in a compound or a polyatomic ion, you must use a stepwise, systematic approach. Draw a circle under each element's symbol in the chemical formula. Then draw a square under each circle. In the circle, write the oxidation number of the element; in the square, write the total contribution to charge by that element. Start with the oxidation numbers you know, and use them to figure out the ones you don't know. Here is an example:

|  | $\mathrm{KMnO}_{4}$ |
| :--- | ---: |
| Oxidation number | $\square$ |
| Total contribution to charge | $\square \square$ |

Fill in the oxidation number first for the element that appears highest on the list in Table 4.6. Potassium (K) is a Group 1A
metal. In its compounds, it always has the oxidation number +1 . We write +1 in the circle beneath the K. Because there is only one K atom in this formula, the total contribution to charge is also +1 , so we also write +1 in the square beneath the K .

|  | $\mathrm{KMnO}_{4}$ |
| :--- | ---: |
| Oxidation number | $+1-\square$ |
| Total contribution to charge | $+1 \square \square$ |

Next on the list is oxygen (O). In compounds, O usually has the oxidation number -2 , so we assign it -2 . Because there are four O atoms in the formula, the total contribution to charge by O atoms is $4(-2)=-8$.

|  | $\mathrm{KMnO}_{4}$ |
| :---: | :---: |
| Oxidation number | (+1) -2 |
| Total contribution to charge |  |

The numbers in the squares, all the contributions to overall charge, must sum to zero. This requires putting +7 in the box beneath the Mn atom. Because there is just one Mn atom in this formula, the contribution to charge is the same as the oxidation number. Thus, $(+1)+(+7)+(-8)=0$.

|  | $\mathrm{KMnO}_{4}$ |
| :--- | ---: |
| Oxidation number | $+1+7-2$ |
| Total contribution to charge | $+1+7-8$ |
| $+1+7-8$ |  |

Sample Problem 4.6 lets you determine oxidation numbers in three more compounds and a polyatomic ion.

## TABLE 4.6 Elements with Reliable Oxidation Numbers in Compounds or Polyatomic Ions

| Element | Oxidation Number | Exceptions |
| :---: | :---: | :---: |
| Fluorine | -1 |  |
| Group 1A or 2A metal | +1 or +2 , respectively |  |
| Hydrogen | +1 | Any combination with a Group 1A or 2A metal to form a metal hydride. Examples: LiH and $\mathrm{CaH}_{2}$-the oxidation number of H is -1 in both examples. |
| Oxygen | -2 | Any combination with something higher on the list that necessitates its having a different oxidation number (see rule 2 for assigning oxidation numbers). Examples: $\mathrm{H}_{2} \mathrm{O}_{2}$ and $\mathrm{KO}_{2}$-the oxidation number of O for $\mathrm{H}_{2} \mathrm{O}_{2}$ is -1 and for $\mathrm{KO}_{2}$ is $-\frac{1}{2}$. |
| Group 7A <br> (other than fluorine) | -1 | Any combination with something higher on the list that necessitates its having a different oxidation number (see rule 2 for assigning oxidation numbers). Examples: $\mathrm{ClF}, \mathrm{BrO}_{4}^{-}$, and $\mathrm{IO}_{3}^{-}$-the oxidation numbers of $\mathrm{Cl}, \mathrm{Br}$, and I are $+1,+7$, and +5 , respectively. Remember that these exceptions do not apply to fluorine, which always has an oxidation state of -1 when it is part of a compound. |

You May Be Wondering...(continued)

## Sample Problem 4.6

Determine the oxidation number of each atom in the following compounds and ion: (a) $\mathrm{SO}_{2}$, (b) NaH , (c) $\mathrm{CO}_{3}^{2-}$, (d) $\mathrm{N}_{2} \mathrm{O}_{5}$.

Strategy For each compound, assign an oxidation number first to the element that appears higher in Table 4.6 (page 137). Then use rule 2 to determine the oxidation number of the other element.

Setup (a) O appears in Table 4.6 but S does not, so we assign oxidation number -2 to O . Because there are two O atoms in the molecule, the total contribution to charge by O is $2(-2)=-4$. The lone $S$ atom must therefore contribute +4 to the overall charge.
(b) Both Na and H appear in Table 4.6, but Na appears higher in the table, so we assign the oxidation number +1 to Na . This means that H must contribute -1 to the overall charge.
(c) We assign the oxidation number -2 to O . Because there are three O atoms in the carbonate ion, the total contribution to charge by O is -6 . To have the contributions to charge sum to the charge on the ion $(-2)$, the C atom must contribute +4 .
(d) We assign the oxidation number -2 to O . Because there are five O atoms in the $\mathrm{N}_{2} \mathrm{O}_{5}$ molecule, the total contribution to charge by O is -10 . To have the contributions to charge sum to zero, the contribution by N must be +10 , and because there are two N atoms, each one must contribute +5 . Therefore, the oxidation number of N is +5 .

## Solution

(a) In $\mathrm{SO}_{2}$, the oxidation numbers of S and O are +4 and -2 , respectively.
$\mathrm{SO}_{2}$

| +4 | -2 |
| ---: | ---: |
| +4 | -4 |

(b) In NaH , the oxidation numbers of Na and H are +1 and -1 , respectively.

NaH

| +1 | -1 |
| :--- | :--- | :--- |
| +1 | -1 |

(c) In $\mathrm{CO}_{3}^{2-}$, the oxidation numbers of C and O are +4 and -2 , respectively.

(d) In $\mathrm{N}_{2} \mathrm{O}_{5}$, the oxidation numbers of N and O are +5 and -2 , respectively.

$$
\begin{aligned}
& \mathrm{N}_{2} \mathrm{O}_{5} \\
& +5 \\
& +5 \\
& +-2 \\
& +10-10
\end{aligned}
$$

Practice Problem A Assign oxidation numbers to each atom in the following compounds and ion: $\mathrm{H}_{2} \mathrm{O}_{2}, \mathrm{ClO}_{3}^{-}, \mathrm{H}_{2} \mathrm{SO}_{4}$.

HPractice Problem B Assign oxidation numbers to each atom in the following species: $\mathrm{O}_{2}^{2-}$, $\mathrm{ClO}^{-}, \mathrm{MnO}_{2}$.

## Sample Problem 4.7

Predict which of the following reactions will occur, and for those that will occur, write the net ionic equation and indicate which element is oxidized and which is reduced: (a) $\mathrm{Fe}(s)+\mathrm{PtCl}_{2}(a q) \longrightarrow$ ? (b) $\mathrm{Cr}(s)+\mathrm{AuCl}_{3}(a q) \longrightarrow$ ? (c) $\mathrm{Pb}(s)+\mathrm{Zn}\left(\mathrm{NO}_{3}\right)_{2}(a q) \longrightarrow$ ?

Strategy Recognize that the salt in each equation (the compound on the reactant side) is a strong electrolyte. What is important is the identity of the metal cation in the salt. For each equation, compare the positions in Table 4.5 (page 136) of the solid metal and the metal cation from the salt to determine whether or not the solid metal will be oxidized. If the cation appears lower in the table, the solid metal will be oxidized (i.e., the reaction will occur). If the cation appears higher in the table, the solid metal will not be oxidized (i.e., no reaction will occur).

Setup (a) The cation in $\mathrm{PtCl}_{2}$ is $\mathrm{Pt}^{2+}$. Platinum appears lower in Table 4.5 than iron, so $\mathrm{Pt}^{2+}(a q)$ will oxidize $\mathrm{Fe}(s)$.
(b) The cation in $\mathrm{AuCl}_{3}$ is $\mathrm{Au}^{3+}$. Gold appears lower in Table 4.5 than chromium, so $\mathrm{Au}^{3+}(a q)$ will oxidize $\mathrm{Cr}(\mathrm{s})$.
(c) The cation in $\mathrm{Zn}\left(\mathrm{NO}_{3}\right)_{2}$ is $\mathrm{Zn}^{2+}$. Zinc appears higher in Table 4.5 than lead, so $\mathrm{Zn}^{2+}(a q)$ will not oxidize $\mathrm{Pb}(s)$.

Solution $(\mathrm{a}) \mathrm{Fe}(s)+\mathrm{Pt}^{2+}(a q) \longrightarrow \mathrm{Fe}^{2+}(a q)+\mathrm{Pt}(s)$; iron is oxidized $(0$ to +2$)$ and platinum is reduced ( +2 to 0 ).
(b) $\mathrm{Cr}(s)+\mathrm{Au}^{3+}(a q) \longrightarrow \mathrm{Cr}^{3+}(a q)+\mathrm{Au}(s)$; chromium is oxidized $(0$ to +3$)$ and gold is reduced ( +3 to 0 ).
(c) No reaction.

Practice Problem A Predict which of the following reactions will occur, and for those that will occur, write the net ionic equation and indicate which element is oxidized and which is reduced:
(a) $\mathrm{Co}(s)+\mathrm{BaI}_{2}(a q) \longrightarrow$ ? (b) $\mathrm{Sn}(s)+\mathrm{CuBr}_{2}(a q) \longrightarrow$ ? (c) $\mathrm{Ag}(s)+\mathrm{NaCl}(a q) \longrightarrow$ ?

Think About lt Check your conclusions by working each problem backward. For part (b), for example, write the net ionic equation in reverse, using the products as the reactants: $\mathrm{Au}(s)+\mathrm{Cr}^{3+}(a q) \longrightarrow$ ? Now compare the positions of gold and chromium in Table 4.5 again. Chromium is higher, so chromium(III) ions cannot oxidize gold. This confirms your conclusion that the forward reaction (the oxidation of chromium by gold ions) will occur.

## Sample Problem 4.8

Predict which of the following reactions will occur, and for those that will occur, balance the equation and indicate which element is oxidized and which is reduced: (a) $\mathrm{Al}(s)+\mathrm{CaCl}_{2}(a q) \longrightarrow$ ?
(b) $\mathrm{Cr}(s)+\mathrm{Pb}\left(\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right)_{2}(a q)$ $\longrightarrow$ ? (c) $\mathrm{Sn}(s)+\mathrm{HI}(a q) \longrightarrow$ ?

Strategy As in Sample Problem 4.7, identify the cation in the aqueous species and for each equation, compare the positions in Table 4.5 of the solid metal and the cation to determine whether or not the solid metal will be oxidized. If the cation appears lower in the table, the reaction will occur.

Setup (a) The cation in $\mathrm{CaCl}_{2}$ is $\mathrm{Ca}^{2+}$. Calcium appears higher in Table 4.5 than aluminum, so $\mathrm{Ca}^{2+}(a q)$ will not oxidize $\mathrm{Al}(s)$. (b) The cation in $\mathrm{Pb}\left(\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right)_{2}$ is $\mathrm{Pb}^{2+}$. Lead appears lower in Table 4.5 than chromium, so $\mathrm{Pb}^{2+}(a q)$ will oxidize $\mathrm{Cr}(s)$. (c) The cation in HI is $\mathrm{H}^{+}$. Hydrogen appears lower in Table 4.5 than tin, so $\mathrm{H}^{+}(a q)$ will oxidize $\mathrm{Sn}(s)$.

Solution (a) No reaction.
(b) The two half-reactions are represented by the following:

$$
\begin{aligned}
& \text { Oxidation: } \mathrm{Cr}(s) \longrightarrow \mathrm{Cr}^{3+}(a q)+3 e^{-} \\
& \text {Reduction: } \mathrm{Pb}^{2+}(a q)+2 e^{-} \longrightarrow \mathrm{Pb}(s)
\end{aligned}
$$

To balance the charges, we must multiply the oxidation half-reaction by 2 and the reduction halfreaction by 3 :

$$
\begin{aligned}
& 2 \times\left[\mathrm{Cr}(s) \longrightarrow \mathrm{Cr}^{3+}(a q)+3 e^{-}\right]=2 \mathrm{Cr}(s) \longrightarrow 2 \mathrm{Cr}^{3+}(a q)+6 e^{-} \\
& 3 \times\left[\mathrm{Pb}^{2+}(a q)+2 e^{-} \longrightarrow \mathrm{Pb}(s)\right]=3 \mathrm{~Pb}^{2+}(a q)+6 e^{-} \longrightarrow 3 \mathrm{~Pb}(s)
\end{aligned}
$$

Student Annotation: Reactions in which hydrogen ion is reduced to hydrogen gas are known as hydrogen displacement reactions.

We can then add the two half-reactions, canceling the electrons on both sides to get

$$
2 \mathrm{Cr}(s)+3 \mathrm{~Pb}^{2+}(a q) \longrightarrow 2 \mathrm{Cr}^{3+}(a q)+3 \mathrm{~Pb}(s)
$$

The overall, balanced molecular equation is

$$
2 \mathrm{Cr}(s)+3 \mathrm{~Pb}\left(\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right)_{2}(a q) \longrightarrow 2 \mathrm{Cr}\left(\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right)_{3}(a q)+3 \mathrm{~Pb}(s)
$$

Chromium is oxidized $(0$ to +3$)$ and lead is reduced $(+2$ to 0$)$.
(c) The two half-reactions are as follows:

Oxidation: $\mathrm{Sn}(s) \longrightarrow \mathrm{Sn}^{2+}(a q)+2 e^{-}$
Reduction: $2 \mathrm{H}^{+}(a q)+2 e^{-} \longrightarrow \mathrm{H}_{2}(g)$
Adding the two half-reactions and canceling the electrons on both sides yields

$$
\mathrm{Sn}(s)+2 \mathrm{H}^{+}(a q) \longrightarrow \mathrm{Sn}^{2+}(a q)+\mathrm{H}_{2}(g)
$$

The overall, balanced molecular equation is

$$
\mathrm{Sn}(s)+2 \mathrm{HI}(a q) \longrightarrow \operatorname{SnI}_{2}(a q)+\mathrm{H}_{2}(g)
$$

Tin is oxidized $(0$ to +2$)$ and hydrogen is reduced $(+1$ to 0$)$.

Practice Problem A Predict which of the following reactions will occur, and for those that will occur, give the overall, balanced molecular equation and indicate which element is oxidized and which is reduced. (a) $\mathrm{Mg}(s)+\mathrm{Cr}\left(\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right)_{3}(a q) \longrightarrow$ ? (b) $\mathrm{Cu}(s)+\mathrm{HBr}(a q) \longrightarrow$ ? (c) $\mathrm{Cd}(s)+\mathrm{AgNO}_{3}(a q) \longrightarrow$ ?
\&Practice Problem B Predict which of the following reactions will occur, and for those that will occur, indicate which element is oxidized and which is reduced. (a) $\mathrm{Pt}(s)+\mathrm{Cu}\left(\mathrm{NO}_{3}\right)_{2}(a q) \longrightarrow$ ? (b) $\mathrm{Ag}(s)+\mathrm{AuCl}_{3}(a q) \longrightarrow$ ? (c) $\mathrm{Sn}(s)+\mathrm{HNO}_{3}(a q) \longrightarrow$ ?

## Other Types of Redox Reactions

Several of the reaction types that you have already encountered are also redox reactions.

## Combination Reactions

Combination reactions such as the formation of ammonia from its constituent elements can involve oxidation and reduction.

In this reaction, nitrogen is reduced from 0 to -3 , while hydrogen is oxidized from 0 to +1 . Other examples of combination reactions include those shown in Figure 4.7.

## Decomposition

Decomposition can also be a redox reaction, as illustrated by the following examples:

Figure 4.7 (a) Reaction between sodium and chlorine to form sodium chloride, and (b) reaction between hydrogen and oxygen to form water. For each element, the oxidation number appears in the circle and the total contribution to charge appears in the square below it.

The decomposition of hydrogen peroxide, shown in the preceding equation, is an example of a disproportionation reaction, in which one element undergoes both oxidation and reduction. In the case of $\mathrm{H}_{2} \mathrm{O}_{2}$, the oxidation number of O is initially -1 . In the products of the decomposition, O has an oxidation number of -2 in $\mathrm{H}_{2} \mathrm{O}$ and of 0 in $\mathrm{O}_{2}$.

Finally, combustion [ 14 Section 3.3] is a redox process.

Figure 4.8 shows the known oxidation numbers of elements in compounds-arranged according to their positions in the periodic table.

## Checkpoint 4.4 Oxidation-Reduction Reactions

4.4.1 Determine the oxidation number of sulfur in each of the following species: $\mathrm{H}_{2} \mathrm{~S}, \mathrm{HSO}_{3}^{-}, \mathrm{SCl}_{2}$, and $\mathrm{S}_{8}$.
a) $+2,+6,-2,+\frac{1}{4}$
b) $-2,+3,+2,0$
c) $-2,+5,+2,-\frac{1}{4}$
d) $-1,+4,+2,0$
e) $-2,+4,+2,0$
4.4.2 What species is the reducing agent in the following equation?

$$
\mathrm{Mg}(s)+2 \mathrm{HCl}(a q) \longrightarrow \mathrm{MgCl}_{2}(a q)+\mathrm{H}_{2}(g)
$$

a) $\mathrm{Mg}(s)$
b) $\mathrm{H}^{+}(a q)$
c) $\mathrm{Cl}^{-}(a q)$
d) $\mathrm{Mg}^{2+}(a q)$
e) $\mathrm{H}_{2}(\mathrm{~g})$
4.4.3 Which of the following equations represents a redox reaction? (Choose all that apply.)
a) $2 \mathrm{Mg}(s)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{MgO}(s)$
b) $\mathrm{Cu}(s)+\mathrm{PtCl}_{2}(a q) \longrightarrow \mathrm{CuCl}_{2}(a q)+\mathrm{Pt}(s)$
c) $\mathrm{NH}_{4} \mathrm{Cl}(a q)+\mathrm{AgNO}_{3}(a q) \longrightarrow \mathrm{NH}_{4} \mathrm{NO}_{3}(a q)+\mathrm{AgCl}(s)$
d) $2 \mathrm{NaN}_{3}(s) \longrightarrow 2 \mathrm{Na}(s)+3 \mathrm{~N}_{2}(g)$
e) $\mathrm{CaCO}_{3}(s) \longrightarrow \mathrm{CaO}(s)+\mathrm{CO}_{2}(g)$
4.4.4 According to the activity series, which of the following redox reactions will occur? (Choose all that apply.)
a) $\mathrm{Fe}(s)+\mathrm{NiBr}_{2}(a q) \longrightarrow \mathrm{FeBr}_{2}(a q)+\mathrm{Ni}(s)$
b) $\mathrm{Sn}(\mathrm{s})+\mathrm{Pb}\left(\mathrm{NO}_{3}\right)_{2}(a q) \longrightarrow \mathrm{Sn}\left(\mathrm{NO}_{3}\right)_{2}(a q)+\mathrm{Pb}(s)$
c) $\mathrm{Mg}(s)+\mathrm{BaI}_{2}(a q) \longrightarrow \mathrm{MgI}_{2}(a q)+\mathrm{Ba}(s)$
d) $\mathrm{Pb}(s)+\mathrm{PtCl}_{2}(a q) \longrightarrow \mathrm{PbCl}_{2}(a q)+\mathrm{Pt}(s)$
e) $\mathrm{Zn}(s)+\mathrm{CaBr}_{2}(a q) \longrightarrow \mathrm{ZnBr}_{2}(a q)+\mathrm{Ca}(s)$

Figure 4.8 Periodic table showing oxidation numbers for each element. The most common oxidation numbers are shown in red.

Student Annotation: The qualitative terms concentrated and dilute are relative terms, like expensive and cheap.

Student Annotation: Molarity can equally well be defined as millimoles per milliliter ( $\mathrm{mmol} / \mathrm{mL}$ ), which can simplify some calculations.

### 4.5 Concentration of Solutions

One of the factors that can influence reactions in aqueous solution is concentration. The concentration of a solution is the amount of solute dissolved in a given quantity of solvent or solution. Consider the two solutions of iodine pictured in Figure 4.9. The solution on the left is more concentrated than the one on the right-that is, it contains a higher ratio of solute to solvent. By contrast, the solution on the right is more dilute. The color is more intense in the more concentrated solution. Often the concentrations of reactants determine how fast a chemical reaction occurs. For example, the reaction of magnesium metal and acid [1/4 Section 4.4] happens faster if the concentration of acid is greater. As we will see in Chapter 13, there are several different ways to express the concentration of a solution. In this chapter, we introduce only molarity, which is one of the most commonly used units of concentration.

## Molarity

Molarity, or molar concentration, symbolized $M$, is defined as the number of moles of solute per liter of solution. Thus, 1 L of a 1.5 molar solution of glucose $\left(\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}\right)$, written as $1.5 \mathrm{M} \mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}$, contains 1.5 moles of dissolved glucose. Half a liter of the same solution would contain 0.75 mole

of dissolved glucose, a milliliter of the solution would contain $1.5 \times 10^{-3}$ mole of dissolved glucose, and so on.

$$
\text { molarity }=\frac{\text { moles solute }}{\text { liters solution }}
$$

Equation 4.1
To calculate the molarity of a solution, we divide the number of moles of solute by the volume of the solution in liters.

Equation 4.1 can be rearranged in three ways to solve for any of the three variables: molarity $(M)$, moles of solute (mol), or volume of solution in liters (L).
(1) $M=\frac{\mathrm{mol}}{\mathrm{L}}$
(2) $\mathrm{L}=\frac{\mathrm{mol}}{M}$
(3) $\mathrm{mol}=M \times \mathrm{L}$

Sample Problem 4.9 illustrates how to use these equations to solve for molarity, volume of solution, and moles of solute.

## Sample Problem 4.9

For an aqueous solution of glucose $\left(\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}\right)$, determine (a) the molarity of 2.00 L of a solution that contains 50.0 g of glucose, (b) the volume of this solution that would contain 0.250 mole of glucose, and (c) the number of moles of glucose in 0.500 L of this solution.
Strategy Convert the mass of glucose given to moles, and use the equations for interconversions of $M$, liters, and moles to calculate the answers.

Setup The molar mass of glucose is 180.2 g .

$$
\text { moles of glucose }=\frac{50.0 \mathrm{~g}}{180.2 \mathrm{~g} / \mathrm{mol}}=0.277 \mathrm{~mol}
$$

Solution (a) molarity $=\frac{0.277 \mathrm{~mol} \mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}}{2.00 \mathrm{~L} \text { solution }}=0.139 \mathrm{M}$
(b) volume $=\frac{0.250 \mathrm{~mol} \mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}}{0.139 \mathrm{M}}=1.80 \mathrm{~L}$
(c) moles of $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}$ in $0.500 \mathrm{~L}=0.500 \mathrm{~L} \times 0.139 M=0.0695 \mathrm{~mol}$

Figure 4.9 Two solutions of iodine in benzene. The solution on the left is more concentrated. The solution on the right is more dilute.

Student Annotation: Students sometimes have difficulty seeing how units cancel in these equations. It may help to write $M$ as mol/L until you become completely comfortable with these equations.

Student Annotation: A common way to state the concentration of this solution is to say, "This solution is 0.139 M in glucose."

Think About It Check to see that the magnitudes of your answers are logical. For example, the mass given in the problem corresponds to 0.277 mole of solute. If you are asked, as in part (b), for the volume that contains a number of moles smaller than 0.277 , make sure your answer is smaller than the original volume.

Media Player/MPEG Animation: Figure 4.10, Preparing a Solution from a Solid, pp. 146-147.

Student Annotation: It is important to remember that molarity is defined in terms of the volume of solution, not the volume of solvent. In many cases, these two are not the same.

Practice Problem A For an aqueous solution of sucrose $\left(\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}\right)$, determine (a) the molarity of 5.00 L of a solution that contains 235 g of sucrose, (b) the volume of this solution that would contain 1.26 mole of sucrose, and (c) the number of moles of sucrose in 1.89 L of this solution.
$\leftrightarrows$ Practice Problem B For an aqueous solution of sodium chloride $(\mathrm{NaCl})$, determine (a) the molarity of 3.75 L of a solution that contains 155 g of sodium chloride, (b) the volume of this solution that would contain 4.58 moles of sodium chloride, and (c) the number of moles of sodium chloride in 22.75 L of this solution.

The procedure for preparing a solution of known molarity is shown in Figure 4.10 (pp. 146147). First, the solute is weighed accurately and transferred, often with a funnel, to a volumetric flask of the desired volume. Next, water is added to the flask, which is then swirled to dissolve the solid. After all the solid has dissolved, more water is added slowly to bring the level of solution exactly to the volume mark. Finally, the flask is capped and inverted to ensure thorough mixing. Knowing the volume of the solution in the flask and the quantity of compound dissolved, we can determine the molarity of the solution using Equation 4.1. Note that this procedure does not require that we know the exact amount of water added. Because of the way molarity is defined, it is important only that we know the final volume of the solution.

## Dilution

Concentrated "stock" solutions of commonly used substances typically are kept in the laboratory stockroom. Often we need to dilute these stock solutions before using them. Dilution is the process of preparing a less concentrated solution from a more concentrated one. Suppose that we want to prepare 1.00 L of a $0.400 \mathrm{M} \mathrm{KMO}_{4}$ solution from a solution of $1.00 \mathrm{M} \mathrm{KMnO}_{4}$. For this purpose we need 0.400 mole of $\mathrm{KMnO}_{4}$. Because there is 1.00 mole of $\mathrm{KMnO}_{4}$ in 1.00 L of a $1.00 \mathrm{M} \mathrm{KMnO}_{4}$ solution, there is 0.400 mole of $\mathrm{KMnO}_{4}$ in 0.400 L of the same solution:

$$
\frac{1.00 \mathrm{~mol} \mathrm{KMnO}_{4}}{1.00 \mathrm{~L} \text { of solution }}=\frac{0.400 \mathrm{~mol} \mathrm{KMnO}_{4}}{0.400 \mathrm{~L} \text { of solution }}
$$

Therefore, we must withdraw 400 mL from the $1.00 \mathrm{M}_{\mathrm{KMnO}}^{4}$ solution and dilute it to 1.00 L by adding water (in a $1.00-\mathrm{L}$ volumetric flask). This method gives us 1.00 L of the desired 0.400 M $\mathrm{KMnO}_{4}$.

In carrying out a dilution process, it is useful to remember that adding more solvent to a given amount of the stock solution changes (decreases) the concentration of the solution without changing the number of moles of solute present in the solution (Figure 4.11, p. 148).

Equation 4.2 moles of solute before dilution $=$ moles of solute after dilution
Using arrangement (3) of Equation 4.1, we can calculate the number of moles of solute:

$$
\text { moles of solute }=\frac{\text { moles of solute }}{\text { liters of solution }} \times \text { liters of solution }
$$

Because the number of moles of solute before the dilution is the same as that after dilution, we can write

$$
\text { Equation 4.3 } \quad M_{\mathrm{c}} \times \mathrm{L}_{\mathrm{c}}=M_{\mathrm{d}} \times \mathrm{L}_{\mathrm{d}}
$$

where the subscripts c and d stand for concentrated and dilute, respectively. Thus, by knowing the molarity of the concentrated stock solution $\left(M_{\mathrm{c}}\right)$ and the desired final molarity $\left(M_{\mathrm{d}}\right)$ and volume $\left(\mathrm{L}_{\mathrm{d}}\right)$ of the dilute solution, we can calculate the volume of stock solution required for the dilution $\left(\mathrm{L}_{\mathrm{c}}\right)$.

Because most volumes measured in the laboratory are in milliliters rather than liters, it is worth pointing out that Equation 4.3 can also be written with volumes of the concentrated and dilute solutions in milliliters.

$$
M_{\mathrm{c}} \times \mathrm{mL}_{\mathrm{c}}=M_{\mathrm{d}} \times \mathrm{mL}_{\mathrm{d}}
$$

Equation 4.4
In this form of the equation, the product of each side is in millimoles (mmol) rather than moles. We apply Equation 4.4 in Sample Problem 4.10.

## Sample Problem 4.10

What volume of 12.0 M HCl , a common laboratory stock solution, must be used to prepare 250.0 mL of 0.125 M HCl ?

Strategy Use Equation 4.4 to determine the volume of 12.0 M HCl required for the dilution.
Setup $M_{\mathrm{c}}=12.0 M, M_{\mathrm{d}}=0.125 M, \mathrm{~mL}_{\mathrm{d}}=250.0 \mathrm{~mL}$.
Solution

$$
\begin{aligned}
12.0 M \times \mathrm{mL}_{\mathrm{c}} & =0.125 M \times 250.0 \mathrm{~mL} \\
\mathrm{~mL}_{\mathrm{c}} & =\frac{0.125 M \times 250.0 \mathrm{~mL}}{12.0 M}=2.60 \mathrm{~mL}
\end{aligned}
$$

Practice Problem A What volume of $6.0 \mathrm{M} \mathrm{H}_{2} \mathrm{SO}_{4}$ is needed to prepare 500.0 mL of a solution that is $0.25 M$ in $\mathrm{H}_{2} \mathrm{SO}_{4}$ ?

HPractice Problem B What volume of $0.20 \mathrm{M} \mathrm{H}_{2} \mathrm{SO}_{4}$ can be prepared by diluting 125 mL of 6.0 M $\mathrm{H}_{2} \mathrm{SO}_{4}$ ?

## Serial Dilution

A series of dilutions may be used in the laboratory to prepare a number of increasingly dilute solutions from a stock solution. The method involves preparing a solution as described on page 146 and diluting a portion of the prepared solution to make a more dilute solution. For example, we could use the $0.400 M \mathrm{KMnO}_{4}$ solution described on page 144 to prepare a series of five increasingly dilute solutions, with the concentration decreasing by a factor of 10 at each stage. Using a volumetric pipette, we withdraw 10.00 mL of the 0.400 M solution and deliver it into a $100.00-\mathrm{mL}$ volumetric flask as shown in Figure 4.12(a). We then dilute to the volumetric mark and cap and invert the flask to ensure complete mixing. The concentration of the newly prepared solution is determined using Equation 4.4 , where $M_{\mathrm{c}}$ is 0.400 M , and $\mathrm{mL}_{\mathrm{c}}$ and $\mathrm{mL}_{\mathrm{d}}$ are 10.00 mL and 100.00 mL , respectively.

$$
\begin{gathered}
0.400 M \times 10.00 \mathrm{~mL}=M_{\mathrm{d}} \times 100.00 \mathrm{~mL} \\
M_{\mathrm{d}}=0.0400 \mathrm{M}
\end{gathered} \text { or } 4.00 \times 10^{-2} \mathrm{M}
$$

Repeating this process four more times, each time using the most recently prepared solution as the "concentrated" solution and diluting 10.00 mL to 100.00 mL , we get five $\mathrm{KMnO}_{4}$ solutions with concentrations $4.00 \times 10^{-2} \mathrm{M}, 4.00 \times 10^{-3} \mathrm{M}, 4.00 \times 10^{-4} \mathrm{M}, 4.00 \times 10^{-5} \mathrm{M}$, and $4.00 \times 10^{-6} \mathrm{M}$ [Figure 4.12(b)]. This type of serial dilution is commonly used to prepare "standard" solutions with precisely known concentrations, for quantitative analysis.

Student Annotation: Students sometimes resist using the unit millimole. However, using the $M_{c} \times \mathrm{mL}_{\mathrm{c}}=M_{\mathrm{d}} \times \mathrm{mL} L_{\mathrm{d}}$ form in Equation 4.4 often reduces the number of steps in a problem, thereby reducing the number of opportunities to make calculation errors.

Student Annotation: It is very important to note that, for safety, when diluting a concentrated acid, the acid must be added to the water, and not the other way around.

Think About It Plug the answer into Equation 4.4, and make sure that the product of concentration and volume is the same on both sides of the equation.

## Figure 4.10

## Preparing a Solution from a Solid

Add water sufficient to dissolve the $\mathrm{KMnO}_{4}$.

Swirl the flask to dissolve the solid.

Add more water.

Fill exactly to the calibration mark using a wash bottle or eye dropper.

After capping and inverting the flask to ensure complete mixing, we calculate the actual concentration of the prepared solution.
$3.896 \mathrm{~g} \mathrm{KMnO}_{4} \times \frac{1 \mathrm{~mol}}{158.04 \mathrm{~g}}=0.024652 \mathrm{~mol}$
$\frac{0.024652 \mathrm{~mol}}{0.2500 \mathrm{~L}}=0.09861 \mathrm{M}$

## What's the point?

The goal is to prepare a solution of precisely known concentration, with that concentration being very close to the target concentration of 0.1 M . Note that because 0.1 is a specified number, it does not limit the number of significant figures in our calculations.

Figure 4.11 Dilution changes the concentration of a solution; it does not change the number of moles of solute in the solution.

(a)

Figure 4.12 Serial dilution. (a) A solution of precisely known concentration is prepared in a volumetric flask. A precise volume of the solution is transferred to a second volumetric flask and subsequently diluted. (b) A precise volume of the second solution is transferred to a third volumetric flask and diluted. The process is repeated several times, each time producing more dilute solution. In this example, the concentration is reduced by a factor of 10 at each stage.

(b)

Sample Problem 4.11 illustrates the method of serial dilution to prepare a series of standard HCl solutions.

## Sample Problem 4.11

Starting with a 2.00 M stock solution of hydrochloric acid, four standard solutions (1 to 4) are prepared by sequentially diluting 10.00 mL of each solution to 250.00 mL . Determine (a) the concentrations of all four standard solutions and (b) the number of moles of HCl in each solution.

Strategy In part (a), because the volumes are all given in milliliters, we will use Equation 4.4, rearranged to solve for $M_{\mathrm{d}}$, to determine the molar concentration of each standard solution. In part (b), Equation 4.1, rearranged to solve for moles, can be used to calculate the number of moles in each. We must remember to convert each solution's volume to liters so that units will cancel properly.

Setup (a) $M_{\mathrm{d}}=\frac{M_{\mathrm{c}} \times \mathrm{mL}_{\mathrm{c}}}{\mathrm{mL}_{\mathrm{d}}}$; (b) $\mathrm{mol}=M \times \mathrm{L}, 250.00 \mathrm{~mL}=2.500 \times 10^{-1} \mathrm{~L}$.
Solution (a) $M_{\mathrm{d} 1}=\frac{2.00 \mathrm{M} \times 10.00 \mathrm{~mL}}{250.00 \mathrm{~mL}}=8.00 \times 10^{-2} M$

$$
\begin{aligned}
& M_{\mathrm{d} 2}=\frac{8.00 \times 10^{-2} M \times 10.00 \mathrm{~mL}}{250.00 \mathrm{~mL}}=3.20 \times 10^{-3} M \\
& M_{\mathrm{d} 3}=\frac{3.20 \times 10^{-3} M \times 10.00 \mathrm{~mL}}{250.00 \mathrm{~mL}}=1.28 \times 10^{-4} M \\
& M_{\mathrm{d} 4}=\frac{1.28 \times 10^{-4} M \times 10.00 \mathrm{~mL}}{250.00 \mathrm{~mL}}=5.12 \times 10^{-6} M
\end{aligned}
$$

(b) $\mathrm{mol}_{1}=8.00 \times 10^{-2} M \times 2.500 \times 10^{-1} \mathrm{~L}=2.00 \times 10^{-2} \mathrm{~mol}$
$\mathrm{mol}_{2}=3.20 \times 10^{-3} M \times 2.500 \times 10^{-1} \mathrm{~L}=8.00 \times 10^{-4} \mathrm{~mol}$
$\operatorname{mol}_{3}=1.28 \times 10^{-4} M \times 2.500 \times 10^{-1} \mathrm{~L}=3.20 \times 10^{-5} \mathrm{~mol}$
$\mathrm{mol}_{4}=5.12 \times 10^{-6} M \times 2.500 \times 10^{-1} \mathrm{~L}=1.28 \times 10^{-6} \mathrm{~mol}$

Practice Problem A Starting with a $6.552 M$ stock solution of $\mathrm{HNO}_{3}$, five standard solutions are prepared via serial dilution. At each stage, 25.00 mL of solution is diluted to 100.00 mL . Determine (a) the concentration of and (b) the number of moles of $\mathrm{HNO}_{3}$ in each standard solution.
$\oiint$ Practice Problem B Five standard solutions of HBr are prepared by serial dilution in which, at each stage, 10.00 mL is diluted to 150.00 mL . Given that the concentration of the most dilute solution is $3.22 \times 10^{-6} M$, determine the concentration of the original HBr stock solution.

## Solution Stoichiometry

Soluble ionic compounds such as $\mathrm{KMnO}_{4}$ are strong electrolytes, so they undergo complete dissociation upon dissolution and exist in solution entirely as ions. $\mathrm{KMnO}_{4}$ dissociates, for example, to give 1 mole of potassium ion and 1 mole of permanganate ion for every mole of potassium permanganate. Thus, a 0.400 M solution of $\mathrm{KMnO}_{4}$ will be 0.400 M in $\mathrm{K}^{+}$and $0.400 \mathrm{M} \mathrm{in}_{\mathrm{MnO}}^{4}-$.

In the case of a soluble ionic compound with other than a $1: 1$ combination of constituent ions, we must use the subscripts in the chemical formula to determine the concentration of each ion in solution. Sodium sulfate $\left(\mathrm{Na}_{2} \mathrm{SO}_{4}\right)$ dissociates, for example, to give twice as many sodium ions as sulfate ions.

$$
\mathrm{Na}_{2} \mathrm{SO}_{4}(s) \xrightarrow{\mathrm{H}_{2} \mathrm{O}} 2 \mathrm{Na}^{+}(a q)+\mathrm{SO}_{4}^{2-}(a q)
$$

Therefore, a solution that is $0.35 M$ in $\mathrm{Na}_{2} \mathrm{SO}_{4}$ is actually $0.70 M$ in $\mathrm{Na}^{+}$and 0.35 M in $\mathrm{SO}_{4}^{2-}$. Frequently, molar concentrations of dissolved species are expressed using square brackets. Thus, the concentrations of species in a 0.35 M solution of $\mathrm{Na}_{2} \mathrm{SO}_{4}$ can be expressed as follows: $\left[\mathrm{Na}^{+}\right]=$ 0.70 M and $\left[\mathrm{SO}_{4}^{2-}\right]=0.35 \mathrm{M}$.

Sample Problem 4.13 (page 152) lets you practice relating concentrations of compounds and concentrations of individual ions using solution stoichiometry.

Think About It Serial dilution is one of the fundamental practices of homeopathy. Some remedies undergo so many serial dilutions that very few (if any) molecules of the original substance still exist in the final preparation.

Student Annotation: If we only need to express the concentration of the compound, rather than the concentrations of the individual ions, we could express the concentration of this solution as $\left[\mathrm{Na}_{2} \mathrm{SO}_{4}\right]=0.35 \mathrm{M}$.

Student Annotation: Square brackets around a chemical species can be read as "the concentration of" that species. For example, $\left[\mathrm{Na}^{+}\right]$is read as "the concentration of sodium ion."

## FAQ You May Be Wondering...

## How Can We Measure Solution Concentrations?

As you may know, white light is actually composed of all the colors of the rainbow. In fact, a rainbow results from the separation of white light by water droplets into the colors or wavelengths that make up the visible spectrum [ $\|$ Section 6.1]. Selective absorption of visible light is what makes some solutions appear colored; and, for a solution that is colored, the intensity of color is related to the solution's concentration (see Figure 4.9). This effect gives rise to a type of analysis known as visible spectrophotometry. A visible spectrophotometer compares the intensity of light that enters a sample (called the incident light) $I_{0}$, with the intensity of the light that is transmitted through the sample, $I$. Transmittance $(T)$ is the ratio of $I$ to $I_{0}$.

Equation 4.5

$$
T=\frac{I}{I_{0}}
$$

Absorbance (A) measures how much light is absorbed by the solution and is defined as the negative logarithm of transmittance.

Equation 4.6

$$
A=-\log T=-\log \frac{I}{I_{0}}
$$

Plotting absorbance as a function of wavelength gives an absorption spectrum. The absorption spectrum, that is, the characteristic absorption over a range of wavelengths, can serve as a sort of fingerprint for the identification of a compound in solution.

The quantitative relationship between absorbance and a solution's concentration is called the Beer-Lambert law and is expressed as

Equation 4.7

$$
A=\varepsilon b c
$$

where $\quad \varepsilon=$ proportionality constant called the molar absorptivity
$b=$ path length of solution (in cm ) through which light travels
$c=$ molar concentration of solution
The molar absorptivity is specific to a chemical species and is a measure of how strongly the species absorbs light at a particular wavelength. Figure 4.13 shows how absorbance depends on path length and concentration. Quantitative analysis using visible spectrophotometry generally requires selection of the appropriate wavelength for analysis (usually the wavelength at which absorbance is highest), determination of absorbance for a series of solutions of known concentration (the standards), construction of a calibration curve (Figure 4.14), and calculation of an unknown concentration using the calibration curve.

Sample Problem 4.12 shows how visible spectrophotometry is used to determine the concentration of a colored solution.

Figure 4.13 (a) A colored solution absorbs some of the incident visible light, diminishing the light's intensity from $I_{0}$ to $I$. (b) The intensity is reduced more when the light travels through a longer path length of the same solution or (c) when the light travels through the same path length of a more concentrated solution.

Figure 4.14 A calibration curve with absorbance $(A)$ on the $y$ axis and molar concentration on the $x$ axis. Linear regression is done using a spreadsheet or graphing calculator to generate the line that best fits all the calibration data. An unknown concentration can be determined by drawing a dashed line from the point on the calibration line corresponding to the measured absorbance to the $x$ axis, as shown. In this case, a measured absorbance of 0.83 corresponds to a concentration of 1.1 M .

## Sample Problem 4.12

Absorbance values for five standard $\mathrm{KMnO}_{4}$ solutions were determined at a wavelength of 528 nm . The data are tabulated here.

| $\left[\mathrm{KMnO}_{4}\right](\boldsymbol{M})$ | $\boldsymbol{A}$ |
| :---: | :---: |
| 0.0500 | 0.172 |
| 0.100 | 0.310 |
| 0.150 | 0.502 |
| 0.200 | 0.680 |
| 0.250 | 0.822 |

The absorbance of a $\mathrm{KMnO}_{4}$ solution with unknown concentration, analyzed under the same conditions, was 0.550 . Determine the concentration of the unknown solution.

Strategy Using either a graphing calculator or an Excel spreadsheet, we graph the tabulated data to verify that the relationship between absorbance and concentration is linear and that the line goes through the origin. We then use the line and the measured absorbance to determine the concentration of the unknown solution.

Setup Graphing the tabulated data with Excel gives the following plot:

Solution Solving for the unknown concentration gives 0.165 M .

Practice Problem A Absorbance values for five standard solutions of a colored solute were determined at 410 nm with a $1.00-\mathrm{cm}$ path length, giving the following table of data:

| Solute concentration $(\boldsymbol{M})$ | $\mathbf{A}$ |
| :---: | :---: |
| 0.250 | 0.165 |
| 0.500 | 0.317 |
| 0.750 | 0.510 |
| 1.000 | 0.650 |
| 1.250 | 0.837 |

The absorbance of a solution of unknown concentration containing the same solute was 0.400 . What is the concentration of the unknown solution?

EPractice Problem B Referring to Practice Problem A, (a) determine the absorbance values you would expect for solutions with the following concentrations: $0.4 \mathrm{M}, 0.6 \mathrm{M}, 0.8 \mathrm{M}, 1.1 \mathrm{M}$. (b) Using the data in the table in Practice Problem A, calculate the average molar absorptivity of the compound and determine the units of molar absorptivity.

## Sample Problem 4.13

Using square-bracket notation, express the concentration of (a) chloride ion in a solution that is 1.02 M in $\mathrm{AlCl}_{3}$, (b) nitrate ion in a solution that is 0.451 M in $\mathrm{Ca}\left(\mathrm{NO}_{3}\right)_{2}$, and (c) $\mathrm{Na}_{2} \mathrm{CO}_{3}$ in a solution in which $\left[\mathrm{Na}^{+}\right]=0.124 \mathrm{M}$.

Strategy Use the concentration given in each case and the stoichiometry indicated in the corresponding chemical formula to determine the concentration of the specified ion or compound.

Setup (a) There are 3 moles of $\mathrm{Cl}^{-}$ion for every 1 mole of $\mathrm{AlCl}_{3}$,

$$
\mathrm{AlCl}_{3}(s) \xrightarrow{\mathrm{H}_{2} \mathrm{O}} \mathrm{Al}^{3+}(a q)+3 \mathrm{Cl}^{-}(a q)
$$

so the concentration of $\mathrm{Cl}^{-}$will be three times the concentration of $\mathrm{AlCl}_{3}$.
(b) There are 2 moles of nitrate ion for every 1 mole of $\mathrm{Ca}\left(\mathrm{NO}_{3}\right)_{2}$,

$$
\mathrm{Ca}\left(\mathrm{NO}_{3}\right)_{2}(s) \xrightarrow{\mathrm{H}_{2} \mathrm{O}} \mathrm{Ca}^{2+}(a q)+2 \mathrm{NO}_{3}^{-}(a q)
$$

so $\left[\mathrm{NO}_{3}^{-}\right]$will be twice $\left[\mathrm{Ca}\left(\mathrm{NO}_{3}\right)_{2}\right]$.
(c) There is 1 mole of $\mathrm{Na}_{2} \mathrm{CO}_{3}$ for every 2 moles of sodium ion,

$$
\mathrm{Na}_{2} \mathrm{CO}_{3}(s) \xrightarrow{\mathrm{H}_{2} \mathrm{O}} 2 \mathrm{Na}^{+}(a q)+\mathrm{CO}_{3}^{2-}(a q)
$$

so $\left[\mathrm{Na}_{2} \mathrm{CO}_{3}\right]$ will be half of $\left[\mathrm{Na}^{+}\right]$. (Assume that $\mathrm{Na}_{2} \mathrm{CO}_{3}$ is the only source of $\mathrm{Na}^{+}$ions in this solution.)

## Solution

(a) $\left[\mathrm{Cl}^{-}\right]=\left[\mathrm{AlCl}_{3}\right] \times \frac{3 \mathrm{~mol} \mathrm{Cl}^{-}}{1 \mathrm{~mol} \mathrm{AlCl}_{3}}$

$$
\begin{aligned}
& =\frac{1.02 \mathrm{~mol} \mathrm{AlC}_{3}}{\mathrm{~L}} \times \frac{3 \mathrm{~mol} \mathrm{Cl}^{-}}{1 \mathrm{~mol} \mathrm{AlCl}_{3}} \\
& =\frac{3.06 \mathrm{~mol} \mathrm{Cl}^{-}}{\mathrm{L}} \\
& =3.06 \mathrm{M}
\end{aligned}
$$

(b) $\left[\mathrm{NO}_{3}^{-}\right]=\left[\mathrm{Ca}\left(\mathrm{NO}_{3}\right)_{2}\right] \times \frac{2 \mathrm{~mol} \mathrm{NO}}{3}-\frac{-}{1 \mathrm{~mol} \mathrm{Ca}\left(\mathrm{NO}_{3}\right)_{2}}$

$$
\begin{aligned}
& =\frac{0.451 \mathrm{~mol} \mathrm{Ca}\left(\mathrm{NO}_{3}\right)_{2}}{\mathrm{~L}} \times \frac{2 \mathrm{~mol} \mathrm{NO}_{3}^{-}}{1 \mathrm{~mol} \mathrm{Ca}\left(\mathrm{NO}_{3}\right)_{2}} \\
& =\frac{0.902 \mathrm{~mol} \mathrm{NO}_{3}^{-}}{\mathrm{L}} \\
& =0.902 \mathrm{M}
\end{aligned}
$$

(c) $\left[\mathrm{Na}_{2} \mathrm{CO}_{3}\right]=\left[\mathrm{Na}^{+}\right] \times \frac{1 \mathrm{~mol} \mathrm{Na}_{2} \mathrm{CO}_{3}}{2 \mathrm{~mol} \mathrm{Na}^{+}}$

$$
\begin{aligned}
& =\frac{0.124 \mathrm{molNa}}{\mathrm{~L}} \times \frac{1 \mathrm{~mol} \mathrm{Na}_{2} \mathrm{CO}_{3}}{2 \mathrm{molNa}} \\
& =\frac{0.0620 \mathrm{~mol} \mathrm{Na}_{2} \mathrm{CO}_{3}}{\mathrm{~L}} \\
& =0.0620 \mathrm{M}
\end{aligned}
$$

Practice Problem A Using the square-bracket notation, express the concentrations of ions in a solution that is 0.750 M in aluminum sulfate $\left[\mathrm{Al}_{2}\left(\mathrm{SO}_{4}\right)_{3}\right]$.

ElPractice Problem B Using the square-bracket notation, express the concentration of chloride ions in a solution that is 0.250 M in sodium chloride $(\mathrm{NaCl})$ and 0.25 M in magnesium chloride $\left(\mathrm{MgCl}_{2}\right)$.

## Checkpoint 4.5 Concentration of Solutions

4.5.1 Calculate the molar concentration of a solution prepared by dissolving 58.5 g NaOH in enough water to yield 1.25 L of solution.
a) 1.46 M
b) 46.8 M
c) $2.14 \times 10^{-2} \mathrm{M}$
d) 1.17 M
e) 0.855 M
4.5.2 What mass of glucose $\left(\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}\right)$ in grams must be used in order to prepare 500 mL of a solution that is 2.50 M in glucose?
a) 225 g
b) 125 g
c) 200 g
d) 1.25 g
e) 625 g
4.5.3 What volume in mL of a 1.20 M HCl solution must be diluted in order to prepare 1.00 L of 0.0150 M HCl ?
a) 15.0 mL
b) 12.5 mL
c) 12.0 mL
d) 85.0 mL
e) 115 mL
4.5.4 A solution that is 0.18 M in $\mathrm{Na}_{2} \mathrm{CO}_{3}$ is also $\qquad$ . (Choose all that apply.)
a) 0.18 M in $\mathrm{CO}_{3}^{2-}$
b) 0.18 M in $\mathrm{Na}^{+}$
c) 0.09 M in $\mathrm{Na}^{+}$
d) 0.09 M in $\mathrm{CO}_{3}^{2-}$
e) 0.36 M in $\mathrm{Na}^{+}$
4.5.5 Which best represents the before-and-after molecular-level view of the dilution of a concentrated stock solution?

4.5.6 Which best represents an aqueous solution of sodium sulfate?

(c)

Student Annotation: Experiments that measure the amount of a substance present are called quantitative analysis.

Student Annotation: According to the information in Table 4.2, AgCl is an insoluble exception to the chlorides, which typically are soluble.

Think About It Pay close attention to which numbers correspond to which quantities. It is easy in this type of problem to lose track of which mass is the precipitate and which is the original sample. Dividing by the wrong mass at the end will result in an incorrect answer.

### 4.6 Aqueous Reactions and Chemical Analysis

Certain aqueous reactions are useful for determining how much of a particular substance is present in a sample. For example, if we want to know the concentration of lead in a sample of water, or if we need to know the concentration of an acid, knowledge of precipitation reactions, acidbase reactions, and solution stoichiometry will be useful. Two common types of such quantitative analyses are gravimetric analysis and acid-base titration.

## Gravimetric Analysis

Gravimetric analysis is an analytical technique based on the measurement of mass. One type of gravimetric analysis experiment involves the formation and isolation of a precipitate, such as $\mathrm{AgCl}(s)$ :

$$
\mathrm{AgNO}_{3}(a q)+\mathrm{NaCl}(a q) \longrightarrow \mathrm{NaNO}_{3}(a q)+\mathrm{AgCl}(s)
$$

This reaction is often used in gravimetric analysis because the reactants can be obtained in pure form. The net ionic equation is

$$
\mathrm{Ag}^{+}(a q)+\mathrm{Cl}^{-}(a q) \longrightarrow \mathrm{AgCl}(s)
$$

Suppose, for example, that we wanted to test the purity of a sample of NaCl by determining the percent by mass of Cl . First, we would accurately weigh out some NaCl and dissolve it in water. To this mixture, we would add enough $\mathrm{AgNO}_{3}$ solution to cause the precipitation of all the $\mathrm{Cl}^{-}$ ions present in solution as AgCl . (In this procedure NaCl is the limiting reagent and $\mathrm{AgNO}_{3}$ is the excess reagent.) We would then separate, dry, and weigh the AgCl precipitate. From the measured mass of AgCl , we would be able to calculate the mass of Cl using the percent by mass of Cl in AgCl . Because all the Cl in the precipitate came from the dissolved NaCl , the amount of Cl that we calculate is the amount that was present in the original NaCl sample. We could then calculate the percent by mass of Cl in the NaCl and compare it to the known composition of NaCl to determine its purity.

Gravimetric analysis is a highly accurate technique, because the mass of a sample can be measured accurately. However, this procedure is applicable only to reactions that go to completion or have nearly 100 percent yield. In addition, if AgCl were soluble to any significant degree, it would not be possible to remove all the $\mathrm{Cl}^{-}$ions from the original solution, and the subsequent calculation would be in error. Sample Problem 4.14 shows the calculations involved in a gravimetric experiment.

## Sample Problem 4.14

A 0.8633-g sample of an ionic compound containing chloride ions and an unknown metal cation is dissolved in water and treated with an excess of $\mathrm{AgNO}_{3}$. If 1.5615 g of AgCl precipitate forms, what is the percent by mass of Cl in the original compound?

Strategy Using the mass of AgCl precipitate and the percent composition of AgCl , determine what mass of chloride the precipitate contains. The chloride in the precipitate was originally in the unknown compound. Using the mass of chloride and the mass of the original sample, determine the percent Cl in the compound.

Setup To determine the percent Cl in AgCl , divide the molar mass of Cl by the molar mass of AgCl :

$$
\frac{35.45 \mathrm{~g}}{35.45 \mathrm{~g}+107.9 \mathrm{~g}} \times 100 \%=24.73 \%
$$

The mass of Cl in the precipitate is $0.2473 \times 1.5615 \mathrm{~g}=0.3862 \mathrm{~g}$.
Solution The percent Cl in the unknown compound is the mass of Cl in the precipitate divided by the mass of the original sample:

$$
\frac{0.3862 \mathrm{~g}}{0.8633 \mathrm{~g}} \times 100 \%=44.73 \% \mathrm{Cl}
$$

Practice Problem A A $0.5620-\mathrm{g}$ sample of an ionic compound containing the bromide ion $\left(\mathrm{Br}^{-}\right)$ is dissolved in water and treated with an excess of $\mathrm{AgNO}_{3}$. If the mass of the AgBr precipitate that forms is 0.8868 g , what is the percent by mass of Br in the original compound?

HPractice Problem B A sample that is 63.9 percent chloride by mass is dissolved in water and treated with an excess of $\mathrm{AgNO}_{3}$. If the mass of the AgCl precipitate that forms is 1.085 g , what was the mass of the original sample?

Gravimetric analysis is a quantitative method, not a qualitative one, so it does not establish the identity of the unknown substance. Thus, the results in Sample Problem 4.14 do not identify the cation. However, knowing the percent by mass of Cl greatly helps us narrow the possibilities. Because no two compounds containing the same anion (or cation) have the same percent composition by mass, comparison of the percent by mass obtained from gravimetric analysis with that calculated from a series of known compounds could reveal the identity of the unknown compounds.

## Acid-Base Titrations

Quantitative studies of acid-base neutralization reactions are most conveniently carried out using a technique known as titration. In titration, a solution of accurately known concentration, called a standard solution, is added gradually to another solution of unknown concentration, until the chemical reaction between the two solutions is complete, as shown in Figure 4.15. If we know the volumes of the standard and unknown solutions used in the titration, along with the concentration of the standard solution, we can calculate the concentration of the unknown solution.

A solution of the strong base sodium hydroxide can be used as the standard solution in a titration, but it must first be standardized, because sodium hydroxide in solution reacts with carbon dioxide in the air, making its concentration unstable over time. We can standardize the sodium hydroxide solution by titrating it against an acid solution of accurately known concentration. The acid often chosen for this task is a monoprotic acid called potassium hydrogen phthalate (KHP), for which the molecular formula is $\mathrm{KHC}_{8} \mathrm{H}_{4} \mathrm{O}_{4}$. KHP is a white, soluble solid that is commercially available in highly pure form. The reaction between KHP and sodium hydroxide is

and the net ionic equation is

$$
\mathrm{HC}_{8} \mathrm{H}_{4} \mathrm{O}_{4}^{-}(a q)+\mathrm{OH}^{-}(a q) \longrightarrow \mathrm{C}_{8} \mathrm{H}_{4} \mathrm{O}_{4}^{2-}(a q)+\mathrm{H}_{2} \mathrm{O}(l)
$$

To standardize a solution of NaOH with KHP, a known amount of KHP is transferred to an Erlenmeyer flask and some distilled water is added to make up a solution. $\mathrm{Next}, \mathrm{NaOH}$ solution is carefully added to the KHP solution from a burette until all the acid has reacted with the base. This point in the titration, where the acid has been completely neutralized, is called the equivalence point. It is usually signaled by the endpoint, where an indicator causes a sharp change in the color of the solution. In acid-base titrations, indicators are substances that have distinctly different colors in acidic and basic media. One commonly used indicator is phenolphthalein, which is colorless in acidic and neutral solutions but reddish pink in basic solutions. At the equivalence point, all the KHP present has been neutralized by the added NaOH and the solution is still colorless. However, if we add just one more drop of NaOH solution from the buret, the solution will be basic and will immediately turn pink. Sample Problem 4.15 illustrates just such a titration.

Multimedia
Chemical reactions-titrations.

Student Annotation: Standardization in this context is the meticulous determination of concentration.

Student Annotation: Note that KHP is a monoprotic acid, so it reacts in a 1:1 ratio with hydroxide ion

Student Annotation: The endpoint in a titration is used to approximate the equivalence point. A careful choice of indicators, which we will discuss in Chapter 16, helps make this approximation reasonable. Phenolphthalein, although very common, is not appropriate for every acid-base titration.

Figure 4.15 Apparatus for titration.

Think About It Remember that molarity can also be defined as $\mathrm{mmol} / \mathrm{mL}$. Try solving the problem again using millimoles and make sure you get the same answer.
$0.003495 \mathrm{~mol}=3.495 \times 10^{-3} \mathrm{~mol}$

$$
=3.495 \mathrm{mmol}
$$

and
$\frac{3.495 \mathrm{mmol}}{25.49 \mathrm{~mL}}=0.1371 \mathrm{M}$

## Sample Problem 4.15

In a titration experiment, a student finds that 25.49 mL of an NaOH solution is needed to neutralize 0.7137 g of KHP. What is the concentration (in $M$ ) of the NaOH solution?

Strategy Using the mass given and the molar mass of KHP, determine the number of moles of KHP. Recognize that the number of moles of NaOH in the volume given is equal to the number of moles of KHP. Divide moles of NaOH by volume (in liters) to get molarity.

Setup The molar mass of $\operatorname{KHP}\left(\mathrm{KHC}_{8} \mathrm{H}_{4} \mathrm{O}_{4}\right)=[39.1 \mathrm{~g}+5(1.008 \mathrm{~g})+8(12.01 \mathrm{~g})+4(16.00 \mathrm{~g})]=$ $204.2 \mathrm{~g} / \mathrm{mol}$.

## Solution

$$
\text { moles of KHP }=\frac{0.7137 \mathrm{~g}}{204.2 \mathrm{~g} / \mathrm{mol}}=0.003495 \mathrm{~mol}
$$

Because moles of $\mathrm{KHP}=$ moles of NaOH , then moles of $\mathrm{NaOH}=0.003495 \mathrm{~mol}$.

$$
\text { molarity of } \mathrm{NaOH}=\frac{0.003495 \mathrm{~mol}}{0.02549 \mathrm{~L}}=0.1371 \mathrm{M}
$$

Practice Problem A How many grams of KHP are needed to neutralize 22.36 mL of a 0.1205 M NaOH solution?

GPractice Problem B What volume (in mL ) of a 0.2550 M NaOH solution can be neutralized by 10.75 g of KHP?

The reaction between NaOH and KHP is a relatively simple acid-base neutralization. Suppose, though, that instead of KHP, we wanted to use a diprotic acid such as $\mathrm{H}_{2} \mathrm{SO}_{4}$ for the titration. The reaction is represented by

$$
2 \mathrm{NaOH}(a q)+\mathrm{H}_{2} \mathrm{SO}_{4}(a q) \longrightarrow \mathrm{Na}_{2} \mathrm{SO}_{4}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l)
$$

Because $2 \mathrm{~mol} \mathrm{NaOH} \bumpeq 1 \mathrm{~mol} \mathrm{H}_{2} \mathrm{SO}_{4}$, we need twice as much NaOH to react completely with an $\mathrm{H}_{2} \mathrm{SO}_{4}$ solution of the same molar concentration and volume as a monoprotic acid such as HCl . On the other hand, we would need twice the amount of HCl to neutralize a $\mathrm{Ba}(\mathrm{OH})_{2}$ solution compared to an NaOH solution having the same concentration and volume because 1 mole of $\mathrm{Ba}(\mathrm{OH})_{2}$ yields 2 moles of $\mathrm{OH}^{-}$ions:

$$
2 \mathrm{HCl}(a q)+\mathrm{Ba}(\mathrm{OH})_{2}(a q) \longrightarrow \mathrm{BaCl}_{2}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l)
$$

In any acid-base titration, regardless of what acid and base are reacting, the total number of moles of $\mathrm{H}^{+}$ions that have reacted at the equivalence point must be equal to the total number of moles of $\mathrm{OH}^{-}$ions that have reacted. Sample Problem 4.16 explores the titration of an NaOH solution with a diprotic acid.

## Sample Problem 4.16

What volume (in mL ) of a 0.203 M NaOH solution is needed to neutralize 25.0 mL of a 0.188 M $\mathrm{H}_{2} \mathrm{SO}_{4}$ solution?

Strategy First, write and balance the chemical equation that corresponds to the neutralization reaction:

$$
2 \mathrm{NaOH}(a q)+\mathrm{H}_{2} \mathrm{SO}_{4}(a q) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{Na}_{2} \mathrm{SO}_{4}(a q)
$$

The base and the diprotic acid combine in a $2: 1$ ratio: $2 \mathrm{NaOH} \bumpeq \mathrm{H}_{2} \mathrm{SO}_{4}$. Use the molarity and the volume given to determine the number of millimoles of $\mathrm{H}_{2} \mathrm{SO}_{4}$. Use the number of millimoles of $\mathrm{H}_{2} \mathrm{SO}_{4}$ to determine the number of millimoles of NaOH . Using millimoles of NaOH and the concentration given, determine the volume of NaOH that will contain the correct number of millimoles.

Setup The necessary conversion factors are:
From the balanced equation: $\frac{2 \mathrm{mmol} \mathrm{NaOH}}{1 \mathrm{mmol} \mathrm{H}_{2} \mathrm{SO}_{4}}$
From the molarity of the NaOH given: $\frac{1 \mathrm{~mL} \mathrm{NaOH}}{0.203 \mathrm{mmol} \mathrm{NaOH}}$

## Solution

$$
\begin{gathered}
\text { millimoles of } \mathrm{H}_{2} \mathrm{SO}_{4}=0.188 \mathrm{M} \times 25.0 \mathrm{~mL}=4.70 \mathrm{mmol} \\
\text { millimoles of } \mathrm{NaOH} \text { required }=4.70 \underline{\mathrm{mmol}_{2} \mathrm{H}_{2} \mathrm{SO}_{4}} \times \frac{2 \mathrm{mmol} \mathrm{NaOH}}{1 \mathrm{mmol} \mathrm{H}_{2} \mathrm{SO}_{4}}=9.40 \mathrm{mmol} \mathrm{NaOH} \\
\text { volume of } 0.203 \mathrm{M} \mathrm{NaOH}=9.40 \underline{\mathrm{mmol} \mathrm{NaOH}} \times \frac{1 \mathrm{~mL} \mathrm{NaOH}}{0.203 \mathrm{mmol} \mathrm{NaOH}}=46.3 \mathrm{~mL}
\end{gathered}
$$

Practice Problem A How many milliliters of a $1.42 \mathrm{M} \mathrm{H}_{2} \mathrm{SO}_{4}$ solution are needed to neutralize 95.5 mL of a 0.336 M KOH solution?

GPractice Problem B How many milliliters of a 0.211 M HCl solution are needed to neutralize 275 mL of a $0.0350 \mathrm{M} \mathrm{Ba}(\mathrm{OH})_{2}$ solution?

Sample Problem 4.17 shows how titration with a standard base can be used to determine the molar mass of an unknown acid.

## Sample Problem 4.17

A $0.1216-\mathrm{g}$ sample of a monoprotic acid is dissolved in 25 mL water, and the resulting solution is titrated with $0.1104 M \mathrm{NaOH}$ solution. A $12.5-\mathrm{mL}$ volume of the base is required to neutralize the acid. Calculate the molar mass of the acid.

Strategy Using the concentration and volume of the base, we can determine the number of moles of base required to neutralize the acid. We then determine the number of moles of acid and divide the mass of the acid by the number of moles to get molar mass.

Setup Because the acid is monoprotic, it will react in a $1: 1$ ratio with the base; therefore, the number of moles of acid will be equal to the number of moles of base. The volume of base in liters is 0.0125 L .

## Student Annotation:

Remember: molarity $\times \mathrm{mL}=$ millimoles This saves steps in titration problems.

Think About It Notice that the two concentrations 0.203 M and $0.188 M$ are similar. Both round to the same value $(\sim 0.20 \mathrm{M})$ to two significant figures. Therefore, the titration of a diprotic acid with a monobasic base of roughly equal concentration should require roughly twice as much base as the beginning volume of acid: $2 \times 25.0 \mathrm{~mL} \approx 46.3 \mathrm{~mL}$.

## Solution

## Think About It For this

 technique to work, we must know whether the acid is monoprotic, diprotic, or polyprotic. A diprotic acid, for example, would combine in a 1:2 ratio with the base, and the result would have been a molar mass twice as large.$$
\text { moles of base }=0.0125 \mathrm{~L} \times 0.1104 \mathrm{~mol} / \mathrm{L}=0.00138
$$

Because moles of base $=$ moles of acid, the moles of acid $=0.00138$ mol. Therefore,

$$
\text { molar mass of the acid }=\frac{0.1216 \mathrm{~g}}{0.00138 \mathrm{~mol}}=88.1 \mathrm{~g} / \mathrm{mol}
$$

Practice Problem A What is the molar mass of a monoprotic acid if 28.1 mL of 0.0788 M NaOH is required to neutralize a $0.205-\mathrm{g}$ sample?

EPractice Problem B What is the molar mass of a diprotic acid if 30.5 mL of 0.1112 M NaOH is required to neutralize a $0.1365-\mathrm{g}$ sample?

## Checkpoint 4.6 Aqueous Reactions and Chemical Analysis

4.6.1 What mass of AgCl will be recovered if a solution containing 5.00 g of NaCl is treated with enough $\mathrm{AgNO}_{3}$ to precipitate all the chloride ion?
a) 12.3 g
b) 5.00 g
c) 3.03 g
d) 9.23 g
e) 10.0 g
4.6.2 A 10.0-g sample of an unknown ionic compound is dissolved, and the solution is treated with enough $\mathrm{AgNO}_{3}$ to precipitate all the chloride ion. If 30.1 g of AgCl is recovered, which of the following compounds could be the unknown?
a) NaCl
b) $\mathrm{NaNO}_{3}$
c) $\mathrm{BaCl}_{2}$
d) $\mathrm{MgCl}_{2}$
e) KCl
4.6.3 Which of the following best represents the contents of a beaker in which equal volumes of $0.10 \mathrm{M} \mathrm{BaCl}_{2}$ and $0.10{\mathrm{M} \mathrm{AgNO}_{3} \text { were }}^{\text {w }}$ combined?

4.6.4 If 25.0 mL of an $\mathrm{H}_{2} \mathrm{SO}_{4}$ solution requires 39.9 mL of 0.228 M NaOH to neutralize, what is the concentration of the $\mathrm{H}_{2} \mathrm{SO}_{4}$ solution?
a) 0.728 M
b) 0.364 M
c) 0.182 M
d) 0.228 M
e) 0.910 M
4.6.5 What volume of $0.144 \mathrm{M} \mathrm{H}_{2} \mathrm{SO}_{4}$ is required to neutralize 25.0 mL of $0.0415 \mathrm{M} \mathrm{Ba}(\mathrm{OH})_{2}$ ?
a) 7.20 mL
b) 3.60 mL
c) 14.4 mL
d) 50.0 mL
e) 12.5 mL
4.6.6 Which of the following best represents the contents of a beaker in which equal volumes of 0.10 M NaCl and $0.10 \mathrm{M} \mathrm{Pb}\left(\mathrm{NO}_{3}\right)_{2}$ were combined?

(b)

(d)

## Applying What You've Learned

The balanced overall equation for the Breathalyzer reaction is

$$
\begin{aligned}
3 \mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}(g)+2 \mathrm{~K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}(a q) & +8 \mathrm{H}_{2} \mathrm{SO}_{4}(a q) \longrightarrow \\
& 3 \mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}(a q)+2 \mathrm{Cr}_{2}\left(\mathrm{SO}_{4}\right)_{3}(a q)+2 \mathrm{~K}_{2} \mathrm{SO}_{4}(a q)+11 \mathrm{H}_{2} \mathrm{O}(l)
\end{aligned}
$$

## Problems:

a) Classify each of the species in the Breathalyzer reaction as a strong electrolyte, weak electrolyte, or nonelectrolyte. [144 Sample Problem 4.2]
b) Write the ionic and net ionic equations for the Breathalyzer reaction.
[ FA Sample Problem 4.4]
c) Determine the oxidation number of each element in the overall equation.
[ 14 Sample Problem 4.6]
d) One manufacturer of Breathalyzers specifies a potassium dichromate concentration of 0.025 percent weight per volume ( $0.025 \mathrm{~g} \mathrm{~K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$ per 100 mL of solution). Express this concentration in terms of molarity. [ 1 kt Sample Problem 4.9]
e) What volume of 0.014 M stock solution of $\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$ would have to be diluted to 250 mL to make a solution of the specified concentration?
[ 1 Kt Sample Problem 4.10]
f) Using square-bracket notation, express the molarity of each ion in a $\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$ solution of the specified concentration. [14 Sample Problem 4.13]

## Chapter Summary

## Section 4.1

- A solution is a homogeneous mixture consisting of a solvent and one or more dissolved species called solutes.
- An electrolyte is a compound that dissolves in water to give an electrically conducting solution. Nonelectrolytes dissolve to give nonconducting solutions. Acids and bases are electrolytes.
- Electrolytes may be ionic or molecular. Ionic electrolytes undergo dissociation in solution; molecular electrolytes undergo ionization. Strong electrolytes dissociate (or ionize) completely. Weak electrolytes ionize only partially.

## Section 4.2

- A precipitation reaction results in the formation of an insoluble product called a precipitate. From general guidelines about solubilities of ionic compounds, we can predict whether a precipitate will form in a reaction.
- Hydration is the process in which water molecules surround solute particles.
- Solubility is the amount of solute that will dissolve in a specified amount of a given solvent at a specified temperature.
- A molecular equation represents a reaction as though none of the reactants or products has dissociated or ionized.
- An ionic equation represents the strong electrolytes in a reaction as ions.
- A spectator ion is one that is not involved in the reaction. Spectator ions appear on both sides of the ionic equation. A net ionic equation is an ionic equation from which spectator ions have been eliminated.

## Section 4.3

- The hydrogen ion in solution is more realistically represented as the hydronium ion $\left(\mathrm{H}_{3} \mathrm{O}^{+}\right)$. The terms hydrogen ion, hydronium ion, and proton are used interchangeably in the context of acid-base reactions.
- Arrhenius acids ionize in water to give $\mathrm{H}^{+}$ions, whereas Arrhenius bases ionize (or dissociate) in water to give $\mathrm{OH}^{-}$ions. Brønsted acids donate protons ( $\mathrm{H}^{+}$ions), whereas Brønsted bases accept protons.
- Brønsted acids may be monoprotic, diprotic, or triprotic, depending on the number of ionizable hydrogen atoms they have. In general, an acid with more than one ionizable hydrogen atom is called polyprotic.
- The reaction of an acid and a base is a neutralization reaction. The products of a neutralization reaction are water and a salt.

## Section 4.4

- Oxidation-reduction, or redox, reactions are those in which electrons are exchanged. Oxidation and reduction always occur simultaneously. You cannot have one without the other.
- Oxidation is the loss of electrons; reduction is the gain of electrons. In a redox reaction, the oxidizing agent is the reactant that gets reduced and the reducing agent is the reactant that gets oxidized.
- Oxidation numbers or oxidation states help us keep track of charge distribution and are assigned to all atoms in a compound or ion according to specific rules.
- Many redox reactions can be further classified as combination, decomposition, displacement, hydrogen displacement, combustion, or disproportionation reactions. The activity series can be used to determine whether or not a displacement reaction will occur.
- A half-reaction is a chemical equation representing only the oxidation or only the reduction of an oxidation-reduction reaction. Redox equations, which must be balanced for both mass and charge, can be balanced using the half-reaction method.

## Section 4.5

- The concentration of a solution is the amount of solute dissolved in a given amount of solution. Molarity $(M)$ or molar concentration expresses concentration as the number of moles of solute in 1 L of solution.
- Adding a solvent to a solution, a process known as dilution, decreases the concentration (molarity) of the solution without changing the total number of moles of solute present in the solution.
- Visible spectrophotometry can be used to measure the concentration of a colored solution. Transmittance $(T)$ is the ratio of transmitted light $(I)$ to incident light $\left(I_{0}\right)$. Absorbance $(A)$ is the negative log of transmittance. A plot of absorbance against wavelength is an absorption spectrum. The Beer-Lambert law relates the absorbance of a solution to its concentration and the path length through which the light passes. The molar absorptivity is the proportionality constant in the Beer-Lambert law.

## Section 4.6

- Gravimetric analysis often involves a precipitation reaction.
- Acid-base titration involves an acid-base reaction. Typically, a solution of known concentration (a standard solution) is added gradually to a solution of unknown concentration with the goal of determining the unknown concentration.
- The point at which the reaction in the titration is complete is called the equivalence point. An indicator is a substance that changes color at or near the equivalence point of a titration. The point at which the indicator changes color is called the endpoint of the titration.

## Questions and Problems

## Section 4.1: General Properties of Aqueous Solutions

## Review Questions

4.1 Define solute, solvent, and solution by describing the process of dissolving a solid in a liquid.
4.2 What is the difference between a nonelectrolyte and an electrolyte? Between a weak electrolyte and a strong electrolyte?
4.3 What is the difference between the symbols $\longrightarrow$ and $\rightleftarrows$ in chemical equations?
4.4 Water is an extremely weak electrolyte and therefore cannot conduct electricity. Why are we often cautioned not to operate electrical appliances when our hands are wet?
4.5 Lithium fluoride (LiF) is a strong electrolyte. What species are present in $\operatorname{LiF}(a q)$ ?

## Problems

E14.6 The aqueous solutions of three compounds are shown in the diagrams. Identify each compound as a nonelectrolyte, a weak electrolyte, or a strong electrolyte.

(a)

(b)

(c)
4.7 Which of the following diagrams best represents the hydration of NaCl when dissolved in water? The $\mathrm{Cl}^{-}$ion is larger in size than the $\mathrm{Na}^{+}$ion.

E4.8 Identify each of the following substances as a strong electrolyte, weak electrolyte, or nonelectrolyte: (a) $\mathrm{H}_{2} \mathrm{O}$, (b) KCl , (c) $\mathrm{HNO}_{3}$, (d) $\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$, (e) $\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}$.
§4.9 Identify each of the following substances as a strong electrolyte, weak electrolyte, or nonelectrolyte: (a) $\mathrm{Ba}\left(\mathrm{NO}_{3}\right)_{2}$, (b) Ne , (c) $\mathrm{NH}_{3}$, (d) NaOH .
4.10 The passage of electricity through an electrolyte solution is caused by the movement of (a) electrons only, (b) cations only, (c) anions only, (d) both cations and anions.
4.11 Predict and explain which of the following systems are electrically conducting: (a) solid NaCl , (b) molten NaCl , (c) an aqueous solution of NaCl .
4.12 You are given a water-soluble compound X. Describe how you would determine whether it is an electrolyte or a nonelectrolyte. If it is an electrolyte, how would you determine whether it is strong or weak?
4.13 Explain why a solution of HCl in benzene does not conduct electricity but in water it does.

## Section 4.2: Precipitation Reactions

## Review Questions

4.14 Describe hydration. What properties of water enable its molecules to interact with ions in solution?
4.15 What is the difference between an ionic equation and a molecular equation?
4.16 What is the advantage of writing net ionic equations?

## Problems

El 4.17 Two aqueous solutions of $\mathrm{AgNO}_{3}$ and NaCl are mixed. Which of the following diagrams best represents the mixture?

(a)

(b)

(c)

|  |
| :---: |
|  |
|  |
| $\mathrm{AgCl}(s)$ |
| $\mathrm{NaNO}_{3}(s)$ |

(d)

- 4.18 Two aqueous solutions of KOH and $\mathrm{MgCl}_{2}$ are mixed. Which of the following diagrams best represents the mixture?

| $\mathrm{Mg}^{2+}(a q)$ |
| :---: |
| $\mathrm{OH}^{+}(a q)$ |
|  |
| $\mathrm{KCl}(s)$ |

(a)

| $\mathrm{K}^{+}(a q)$ |
| :---: |
| $\mathrm{Cl}^{-}(a q)$ |
| $\mathrm{Mg}(\mathrm{OH})_{2}(s)$ |

(b)

(c)

(d)

E4.19 Characterize the following compounds as soluble or insoluble in water: (a) $\mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}$, (b) $\mathrm{Mn}(\mathrm{OH})_{2}$, (c) $\mathrm{AgClO}_{3}$, (d) $\mathrm{K}_{2} \mathrm{~S}$.

G4.20 Characterize the following compounds as soluble or insoluble in water: (a) $\mathrm{CaCO}_{3}$, (b) $\mathrm{ZnSO}_{4}$, (c) $\mathrm{Hg}\left(\mathrm{NO}_{3}\right)_{2}$, (d) $\mathrm{HgSO}_{4}$, (e) $\mathrm{NH}_{4} \mathrm{ClO}_{4}$.
4.21 Write ionic and net ionic equations for the following reactions:
(a) $\mathrm{AgNO}_{3}(a q)+\mathrm{Na}_{2} \mathrm{SO}_{4}(a q) \longrightarrow$
(b) $\mathrm{BaCl}_{2}(a q)+\mathrm{ZnSO}_{4}(a q) \longrightarrow$
(c) $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{CO}_{3}(a q)+\mathrm{CaCl}_{2}(a q) \longrightarrow$

E4.22 Write ionic and net ionic equations for the following reactions:
(a) $\mathrm{Na}_{2} \mathrm{~S}(a q)+\mathrm{ZnCl}_{2}(a q) \longrightarrow$
(b) $\mathrm{K}_{3} \mathrm{PO}_{4}(a q)+3 \mathrm{Sr}\left(\mathrm{NO}_{3}\right)_{2}(a q)$
(c) $\mathrm{Mg}\left(\mathrm{NO}_{3}\right)_{2}(a q)+2 \mathrm{NaOH}(a q) \longrightarrow$

EJ4.23 Which of the following processes will likely result in a precipitation reaction? (a) Mixing an $\mathrm{NaNO}_{3}$ solution with a $\mathrm{CuSO}_{4}$ solution. (b) Mixing a $\mathrm{BaCl}_{2}$ solution with a $\mathrm{K}_{2} \mathrm{SO}_{4}$ solution. Write a net ionic equation for the precipitation reaction.

## Section 4.3: Acid-Base Reactions

## Review Questions

4.24 List the general properties of acids and bases.
4.25 Give Arrhenius's and Brønsted's definitions of an acid and a base. Why are Brønsted's definitions more useful in describing acidbase properties?
4.26 Give an example of a monoprotic acid, a diprotic acid, and a triprotic acid.
4.27 What are the characteristics of an acid-base neutralization reaction?
4.28 What factors qualify a compound as a salt? Specify which of the following compounds are salts: $\mathrm{CH}_{4}, \mathrm{NaF}, \mathrm{NaOH}, \mathrm{CaO}, \mathrm{BaSO}_{4}$, $\mathrm{HNO}_{3}, \mathrm{NH}_{3}, \mathrm{KBr}$.
4.29 Identify the following as a weak or strong acid or base: (a) $\mathrm{NH}_{3}$, (b) $\mathrm{H}_{3} \mathrm{PO}_{4}$, (c) LiOH , (d) HCOOH (formic acid), (e) $\mathrm{H}_{2} \mathrm{SO}_{4}$, (f) $\mathrm{HF},(\mathrm{g}) \mathrm{Ba}(\mathrm{OH})_{2}$.

## Problems

$\$ 4.30$ Identify each of the following species as a Brønsted acid, base, or both: (a) HI , (b) $\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}$, (c) $\mathrm{H}_{2} \mathrm{PO}_{4}^{-}$, (d) $\mathrm{HSO}_{4}^{-}$.
4.31 Identify each of the following species as a Brønsted acid, base, or both: (a) $\mathrm{PO}_{4}^{3-}$, (b) $\mathrm{ClO}_{2}^{-}$, (c) $\mathrm{NH}_{4}^{+}$, (d) $\mathrm{HCO}_{3}^{-}$.

EY 4.32 Balance the following equations and write the corresponding ionic and net ionic equations (if appropriate):
(a) $\mathrm{HBr}(a q)+\mathrm{NH}_{3}(a q) \longrightarrow$
(b) $\mathrm{Ba}(\mathrm{OH})_{2}(a q)+\mathrm{H}_{3} \mathrm{PO}_{4}(a q) \longrightarrow$
(c) $\mathrm{HClO}_{4}(a q)+\mathrm{Mg}(\mathrm{OH})_{2}(s)$

E4.33 Balance the following equations and write the corresponding ionic and net ionic equations (if appropriate):
(a) $\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}(a q)+\mathrm{KOH}(a q) \longrightarrow$
(b) $\mathrm{H}_{2} \mathrm{CO}_{3}(a q)+\mathrm{NaOH}(a q) \longrightarrow$
(c) $\mathrm{HNO}_{3}(a q)+\mathrm{Ba}(\mathrm{OH})_{2}(a q)$

## Section 4.4: Oxidation-Reduction Reactions

## Review Questions

4.34 Give an example of a combination redox reaction, a decomposition redox reaction, and a displacement redox reaction.
4.35 All combustion reactions are redox reactions. True or false? Explain.
4.36 What is an oxidation number? How is it used to identify redox reactions? Explain why, except for ionic compounds, the oxidation number does not have any physical significance.
4.37 (a) Without referring to Figure 4.8 , give the oxidation numbers of the alkali and alkaline earth metals in their compounds. (b) Give the highest oxidation numbers that the Groups 3A-7A elements can have.
4.38 How is the activity series organized? How is it used in the study of redox reactions?
4.39 Use the following reaction to define the terms redox reaction, half-reaction, oxidizing agent, and reducing agent: $4 \mathrm{Na}(s)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{Na}_{2} \mathrm{O}(s)$.
4.40 Is it possible to have a reaction in which oxidation occurs and reduction does not? Explain.

## Problems

G4.41 For the complete redox reactions given here, break down each reaction into its half-reactions, identify the oxidizing agent, and identify the reducing agent.
(a) $2 \mathrm{Sr}+\mathrm{O}_{2} \longrightarrow 2 \mathrm{SrO}$
(b) $2 \mathrm{Li}+\mathrm{H}_{2} \longrightarrow 2 \mathrm{LiH}$
(c) $2 \mathrm{Cs}+\mathrm{Br}_{2} \longrightarrow 2 \mathrm{CsBr}$
(d) $3 \mathrm{Mg}+\mathrm{N}_{2} \longrightarrow \mathrm{Mg}_{3} \mathrm{~N}_{2}$
4.42 For the complete redox reactions given here, write the halfreactions and identify the oxidizing and reducing agents:
(a) $4 \mathrm{Fe}+3 \mathrm{O}_{2} \longrightarrow 2 \mathrm{Fe}_{2} \mathrm{O}_{3}$
(b) $\mathrm{Cl}_{2}+2 \mathrm{NaBr} \longrightarrow 2 \mathrm{NaCl}+\mathrm{Br}_{2}$
(c) $\mathrm{Si}+2 \mathrm{~F}_{2} \longrightarrow \mathrm{SiF}_{4}$
(d) $\mathrm{H}_{2}+\mathrm{Cl}_{2} \longrightarrow 2 \mathrm{HCl}$

G4.43 Arrange the following species in order of increasing oxidation number of the sulfur atom: (a) $\mathrm{H}_{2} \mathrm{~S}$, (b) $\mathrm{S}_{8}$, (c) $\mathrm{H}_{2} \mathrm{SO}_{4}$, (d) $\mathrm{S}^{2-}$, (e) $\mathrm{HS}^{-}$, (f) $\mathrm{SO}_{2}$, (g) $\mathrm{SO}_{3}$.

E4.44 Phosphorus forms many oxoacids. Indicate the oxidation number of phosphorus in each of the following acids: (a) $\mathrm{HPO}_{3}$, (b) $\mathrm{H}_{3} \mathrm{PO}_{2}$, (c) $\mathrm{H}_{3} \mathrm{PO}_{3}$, (d) $\mathrm{H}_{3} \mathrm{PO}_{4}$, (e) $\mathrm{H}_{4} \mathrm{P}_{2} \mathrm{O}_{7}$, (f) $\mathrm{H}_{5} \mathrm{P}_{3} \mathrm{O}_{10}$.

E\$4.45 Give the oxidation numbers for the underlined atoms in the following molecules and ions: (a) $\underline{\mathrm{ClF}}$, (b) $\underline{\mathrm{IF}}_{7}$, (c) $\underline{\mathrm{CH}}_{4}$, (d) $\underline{\mathrm{C}}_{2} \mathrm{H}_{2}$, (e) $\underline{\mathrm{C}}_{2} \mathrm{H}_{4}$, (f) $\mathrm{K}_{2} \mathrm{CrO}_{4}$, (g) $\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{4}$, (h) $\mathrm{KMnO}_{4}$, (i) $\mathrm{NaHCO}_{3}$, (j) $\underline{\mathrm{Li}}_{2}$, (k) $\mathrm{NaIO}_{3}$, (l) $\mathrm{KO}_{2}$, (m) $\underline{\mathrm{PF}}_{6}^{-}$, (n) $\mathrm{KAuCl}_{4}$.
4.46 Give the oxidation number for the following species: $\mathrm{H}_{2}, \mathrm{Se}_{8}, \mathrm{P}_{4}$, $\mathrm{O}, \mathrm{U}, \mathrm{As}_{4}, \mathrm{~B}_{12}$.

G4.47 Give the oxidation numbers for the underlined atoms in the following molecules and ions: (a) $\mathrm{Cs}_{2} \mathrm{O}$, (b) $\mathrm{CaI} \underline{I}_{2}$, (c) $\mathrm{Al}_{2} \mathrm{O}_{3}$, (d) $\mathrm{H}_{3} \underline{\mathrm{AsO}}_{3}$, (e) $\mathrm{TiO}_{2}$, (f) $\mathrm{MoO}_{4}^{2-}$, (g) $\mathrm{PtCl}_{4}^{2-}$, (h) $\underline{\mathrm{PtCl}_{6}^{2-}}$, (i) $\underline{\mathrm{SnF}}_{2}$, (j) $\underline{\mathrm{ClF}}_{3}$, (k) $\underline{\mathrm{SbF}}_{6}^{-}$.

E4.48 Give the oxidation numbers for the underlined atoms in the following molecules and ions: (a) $\mathrm{Mg}_{3} \underline{\mathrm{~N}}_{2}$, (b) $\mathrm{CsO}_{2}$, (c) $\mathrm{CaC}_{2}$, (d) $\mathrm{CO}_{3}^{2-}$, (e) $\underline{\mathrm{C}}_{2} \mathrm{O}_{4}^{2-}$, (f) $\mathrm{ZnO}_{2}^{2-}$, (g) NaBH 4 , (h) $\underline{\mathrm{WO}}_{4}^{2-}$.
4.49 Nitric acid is a strong oxidizing agent. State which of the following species is least likely to be produced when nitric acid reacts with a strong reducing agent such as zinc metal, and explain why: $\mathrm{N}_{2} \mathrm{O}, \mathrm{NO}, \mathrm{NO}_{2}, \mathrm{~N}_{2} \mathrm{O}_{4}, \mathrm{~N}_{2} \mathrm{O}_{5}, \mathrm{NH}_{4}^{+}$.
4.50 Determine which of the following metals can react with acid: (a) Au , (b) Ni , (c) Zn , (d) Ag , (e) Pt.
4.51 One of the following oxides does not react with molecular oxygen: $\mathrm{NO}, \mathrm{N}_{2} \mathrm{O}, \mathrm{SO}_{2}, \mathrm{SO}_{3}, \mathrm{P}_{4} \mathrm{O}_{6}$. Based on oxidation numbers, which one is it? Explain.
4.52 Predict the outcome of the reactions represented by the following equations by using the activity series, and balance the equations.
(a) $\mathrm{Cu}(s)+\mathrm{HCl}(a q) \longrightarrow$
(b) $\mathrm{Au}(s)+\mathrm{NaBr}(a q)$
(c) $\mathrm{Mg}(s)+\mathrm{CuSO}_{4}(a q)$
(d) $\mathrm{Zn}(s)+\mathrm{KBr}(a q) \longrightarrow$

EJ 4.53 Classify the following redox reactions as combination, decomposition, or displacement:
(a) $2 \mathrm{H}_{2} \mathrm{O}_{2} \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}+\mathrm{O}_{2}$
(b) $\mathrm{Mg}+2 \mathrm{AgNO}_{3} \longrightarrow \mathrm{Mg}\left(\mathrm{NO}_{3}\right)_{2}+2 \mathrm{Ag}$
(c) $\mathrm{NH}_{4} \mathrm{NO}_{2} \longrightarrow \mathrm{~N}_{2}+2 \mathrm{H}_{2} \mathrm{O}$
(d) $\mathrm{H}_{2}+\mathrm{Br}_{2} \longrightarrow 2 \mathrm{HBr}$

E4.54 Classify the following redox reactions as combination, decomposition, or displacement:
(a) $\mathrm{P}_{4}+10 \mathrm{Cl}_{2} \longrightarrow 4 \mathrm{PCl}_{5}$
(b) $2 \mathrm{NO} \longrightarrow \mathrm{N}_{2}+\mathrm{O}_{2}$
(c) $\mathrm{Cl}_{2}+2 \mathrm{KI} \longrightarrow 2 \mathrm{KCl}+\mathrm{I}_{2}$
(d) $3 \mathrm{HNO}_{2} \longrightarrow \mathrm{HNO}_{3}+\mathrm{H}_{2} \mathrm{O}+2 \mathrm{NO}$

## Section 4.5: Concentration of Solutions

## Visualizing Chemistry

Figure 4.10 Preparing a Solution from a Solid
VC 4.1 Which of the following would result in the actual concentration of the prepared solution being higher than the final, calculated value?
a) Loss of some of the solid during transfer to the volumetric flask.
b) Neglecting to add the last bit of water with the wash bottle to fill to the volumetric mark.
c) Neglecting to tare the balance with the weigh paper on the pan.
VC 4.2 Why can't we prepare the solution by first filling the volumetric flask to the mark and then adding the solid?
a) The solid would not all dissolve.
b) The solid would not all fit into the flask.
c) The final volume would not be correct.

VC 4.3 What causes the concentration of the prepared solution not to be exactly $0.1 M$ ?
a) Rounding error in the calculations.
b) The volume of the flask is not exactly 250 mL .
c) The amount of solid weighed out is not exactly the calculated mass.
VC 4.4 The volumetric flask used to prepare a solution from a solid is shown before and after the last of the water has been added.

Which of the following statements is true?
a) The concentration of solute is greater in ithan in ii.
b) The concentration of solute is smaller in i than in ii.
c) The concentration of solute in i is equal to the concentration of solute in ii.

## Review Questions

4.55 Write the equation for calculating molarity. Why is molarity a convenient concentration unit in chemistry?
4.56 Describe the steps involved in preparing a solution of known molar concentration using a volumetric flask.
4.57 Describe the basic steps involved in diluting a solution of known concentration.
4.58 Write the equation that enables us to calculate the concentration of a diluted solution. Give units for all the terms.

## Problems

4.59 Calculate the mass of KI in grams required to prepare $5.00 \times$ $10^{2} \mathrm{~mL}$ of a 2.80 M solution.
4.60 Describe how you would prepare 250 mL of a $0.707 \mathrm{M} \mathrm{NaNO}_{3}$ solution.

EJ 4.61 How many moles of $\mathrm{MgCl}_{2}$ are present in 60.0 mL of a 0.100 M $\mathrm{MgCl}_{2}$ solution?
4.62 How many grams of KOH are present in 35.0 mL of a 5.50 M KOH solution?

E44.63 Calculate the molarity of each of the following solutions:
(a) 29.0 g of ethanol $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right)$ in 545 mL of solution,
(b) 15.4 g of sucrose $\left(\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}\right)$ in 74.0 mL of solution,
(c) 9.00 g of sodium chloride $(\mathrm{NaCl})$ in 86.4 mL of solution.
4.64 Calculate the molarity of each of the following solutions: (a) 6.57 g of methanol $\left(\mathrm{CH}_{3} \mathrm{OH}\right)$ in $1.50 \times 10^{2} \mathrm{~mL}$ of solution, (b) 10.4 g of calcium chloride $\left(\mathrm{CaCl}_{2}\right)$ in $2.20 \times 10^{2} \mathrm{~mL}$ of solution, (c) 7.82 g of naphthalene $\left(\mathrm{C}_{10} \mathrm{H}_{8}\right)$ in 85.2 mL of benzene solution.

E4.65 Calculate the volume in milliliters of a solution required to provide the following: (a) 2.14 g of sodium chloride from a 0.270 M solution, (b) 4.30 g of ethanol from a 1.50 M solution, (c) 0.85 g of acetic acid $\left(\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right)$ from a 0.30 M solution.

E4.66 Determine how many grams of each of the following solutes would be needed to make $2.50 \times 10^{2} \mathrm{~mL}$ of a 0.100 M solution: (a) cesium iodide ( CsI ), (b) sulfuric acid $\left(\mathrm{H}_{2} \mathrm{SO}_{4}\right)$, (c) sodium carbonate $\left(\mathrm{Na}_{2} \mathrm{CO}_{3}\right)$, (d) potassium dichromate $\left(\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}\right)$, (e) potassium permanganate $\left(\mathrm{KMnO}_{4}\right)$.
4.67 Describe how to prepare 1.00 L of a 0.646 M HCl solution, starting with a 2.00 M HCl solution.
$\leftrightarrows 4.68$ Water is added to 25.0 mL of a $0.866 \mathrm{M} \mathrm{KO}_{3}$ solution until the volume of the solution is exactly 500 mL . What is the concentration of the final solution?
4.69 How would you prepare 60.0 mL of $0.200 M \mathrm{HNO}_{3}$ from a stock solution of $4.00 \mathrm{M} \mathrm{HNO}_{3}$ ?

E4.70 You have 505 mL of a 0.125 M HCl solution and you want to dilute it to exactly 0.100 M . How much water should you add?

E 4.71 (a) Determine the chloride ion concentration in each of the following solutions: $0.150 \mathrm{MaCl}_{2}, 0.566 \mathrm{M} \mathrm{NaCl}, 1.202 \mathrm{M}$ $\mathrm{AlCl}_{3}$. (b) What is the concentration of a $\mathrm{Sr}\left(\mathrm{NO}_{3}\right)_{2}$ solution that is 2.55 M in nitrate ion?
4.72 (a) What is the $\mathrm{Na}^{+}$concentration in each of the following solutions: $3.25 M$ sodium sulfate, $1.78 M$ sodium carbonate, $0.585 M$ sodium bicarbonate? (b) What is the concentration of a lithium carbonate solution that is 0.595 M in $\mathrm{Li}^{+}$?

E4.73 Determine the resulting nitrate ion concentration when 95.0 mL of 0.992 M potassium nitrate and 155.5 mL of 1.570 M calcium nitrate are combined.

G4.74 What volume of 0.112 M ammonium sulfate contains 5.75 g of ammonium ion?

## Section 4.6: Aqueous Reactions and Chemical Analysis

 Review Questions4.75 Describe the basic steps involved in gravimetric analysis. How does this procedure help us determine the identity of a compound or the purity of a compound if its formula is known?
4.76 Distilled water must be used in the gravimetric analysis of chlorides. Why?
4.77 Describe the basic steps involved in an acid-base titration. Why is this technique of great practical value?
4.78 How does an acid-base indicator work?
4.79 A student carried out two titrations using an NaOH solution of unknown concentration in the burette. In one titration she weighed out 0.2458 g of KHP (see page 155) and transferred it to an Erlenmeyer flask. She then added 20.00 mL of distilled water to dissolve the acid. In the other titration she weighed out 0.2507 g of KHP but added 40.00 mL of distilled water to dissolve the acid. Assuming no experimental error, would she obtain the same result for the concentration of the NaOH solution?
4.80 Would the volume of a 0.10 M NaOH solution needed to titrate 25.0 mL of a $0.10 \mathrm{M} \mathrm{HNO}_{2}$ (a weak acid) solution be different from that needed to titrate 25.0 mL of a 0.10 M HCl (a strong acid) solution?

## Problems

E 4.81 If 30.0 mL of $0.150 \mathrm{M} \mathrm{CaCl}_{2}$ is added to 15.0 mL of 0.100 M $\mathrm{AgNO}_{3}$, what is the mass in grams of AgCl precipitate?
4.82 A sample of 0.6760 g of an unknown compound containing barium ions $\left(\mathrm{Ba}^{2+}\right)$ is dissolved in water and treated with an excess of $\mathrm{Na}_{2} \mathrm{SO}_{4}$. If the mass of the $\mathrm{BaSO}_{4}$ precipitate formed is 0.4105 g , what is the percent by mass of Ba in the original unknown compound?
4.83 How many grams of NaCl are required to precipitate most of the Ag ions from $2.50 \times 10^{2} \mathrm{~mL}$ of a 0.0113 M AgNO 3 solution? Write the net ionic equation for the reaction.

E4.84 Diagram (a) shows a solution of a base and an acid before the neutralization reaction. Each of the after-reaction diagrams, (b)-(d), shows the products of reaction with one of the following acids: $\mathrm{HCl}, \mathrm{H}_{2} \mathrm{SO}_{4}, \mathrm{H}_{3} \mathrm{PO}_{4}$. Determine which diagram corresponds to which acid. Blue spheres $=\mathrm{OH}^{-}$ions, red spheres $=$acid molecules, green spheres $=$ anions of the acids. Assume all the acid-base neutralization reactions go to completion.

4.85 Diagram (a) shows a mixture of HCl and a base before the neutralization reaction. Of diagrams (b)-(d), which represents the products of reaction when the base is sodium hydroxide and which represents the products when the base is barium hydroxide?

Blue spheres $=$ base, red spheres $=\mathrm{H}^{+}$, grey spheres $=$cations of the bases. Assume all the acid-base neutralization reactions go to completion.

(a)

(b)

(c)

(d)

EI 4.86 Calculate the concentration (in molarity) of an NaOH solution if 25.0 mL of the solution is needed to neutralize 17.4 mL of a 0.312 M HCl solution.

G4.87 Calculate the volume in milliliters of a 1.420 M NaOH solution required to titrate the following solutions:
(a) 25.00 mL of a 2.430 M HCl solution
(b) 25.00 mL of a $4.500 \mathrm{M} \mathrm{H}_{2} \mathrm{SO}_{4}$ solution
(c) 25.00 mL of a $1.500 \mathrm{M} \mathrm{H}_{3} \mathrm{PO}_{4}$ solution

E 4.88 What volume of a 0.500 M HCl solution is needed to neutralize each of the following:
(a) 10.0 mL of a 0.300 M NaOH solution
(b) 10.0 mL of a $0.200 \mathrm{M} \mathrm{Ba}(\mathrm{OH})_{2}$ solution

## Additional Problems

G4.89 Classify the following reactions according to the types discussed in the chapter:
(a) $\mathrm{Cl}_{2}+2 \mathrm{OH}^{-} \longrightarrow \mathrm{Cl}^{-}+\mathrm{ClO}^{-}+\mathrm{H}_{2} \mathrm{O}$
(b) $\mathrm{Ca}^{2+}+\mathrm{CO}_{3}^{2-} \longrightarrow \mathrm{CaCO}_{3}$
(c) $\mathrm{NH}_{3}+\mathrm{H}^{+} \longrightarrow \mathrm{NH}_{4}^{+}$
(d) $2 \mathrm{CCl}_{4}+\mathrm{CrO}_{4}^{2-} \longrightarrow 2 \mathrm{COCl}_{2}+\mathrm{CrO}_{2} \mathrm{Cl}_{2}+2 \mathrm{Cl}^{-}$
(e) $\mathrm{Ca}+\mathrm{F}_{2} \longrightarrow \mathrm{CaF}_{2}$
(f) $2 \mathrm{Li}+\mathrm{H}_{2} \longrightarrow 2 \mathrm{LiH}$
(g) $\mathrm{Ba}\left(\mathrm{NO}_{3}\right)_{2}+\mathrm{Na}_{2} \mathrm{SO}_{4} \longrightarrow 2 \mathrm{NaNO}_{3}+\mathrm{BaSO}_{4}$
(h) $\mathrm{CuO}+\mathrm{H}_{2} \longrightarrow \mathrm{Cu}+\mathrm{H}_{2} \mathrm{O}$
(i) $\mathrm{Zn}+2 \mathrm{HCl} \longrightarrow \mathrm{ZnCl}_{2}+\mathrm{H}_{2}$
(j) $2 \mathrm{FeCl}_{2}+\mathrm{Cl}_{2} \longrightarrow 2 \mathrm{FeCl}_{3}$
4.90 Oxygen $\left(\mathrm{O}_{2}\right)$ and carbon dioxide $\left(\mathrm{CO}_{2}\right)$ are colorless and odorless gases. Suggest two chemical tests that would allow you to distinguish between these two gases.
4.91 Which of the following aqueous solutions would you expect to be the best conductor of electricity at $25^{\circ} \mathrm{C}$ ? Explain your answer.
(a) 0.20 M NaCl
(b) $0.60 M \mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$
(c) 0.25 M HCl
(d) $0.20 \mathrm{M} \mathrm{Mg}\left(\mathrm{NO}_{3}\right)_{2}$
$\$ 4.92$ A $5.00 \times 10^{2} \mathrm{~mL}$ sample of 2.00 M HCl solution is treated with 4.47 g of magnesium. Calculate the concentration of the acid solution after all the metal has reacted. Assume that the volume remains unchanged.

G4.93 Calculate the volume of a $0.156 \mathrm{M} \mathrm{CuSO}_{4}$ solution that would react with 7.89 g of zinc.
§ 4.94 Sodium carbonate $\left(\mathrm{Na}_{2} \mathrm{CO}_{3}\right)$ is available in very pure form and can be used to standardize acid solutions. What is the molarity of an HCl solution if 28.3 mL of the solution is required to react with 0.256 g of $\mathrm{Na}_{2} \mathrm{CO}_{3}$ ?
$\mathbb{Y} 4.95$ Identify each of the following compounds as a nonelectrolyte, a weak electrolyte, or a strong electrolyte: (a) ethanolamine $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{ONH}_{2}\right)$, (b) potassium fluoride (KF), (c) ammonium nitrate $\left(\mathrm{NH}_{4} \mathrm{NO}_{3}\right)$, (d) isopropanol $\left(\mathrm{C}_{3} \mathrm{H}_{7} \mathrm{OH}\right)$.
4.96 Identify each of the following compounds as a nonelectrolyte, a weak electrolyte, or a strong electrolyte: (a) lactose $\left(\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}\right)$,
(b) lactic acid $\left(\mathrm{HC}_{3} \mathrm{H}_{5} \mathrm{O}_{3}\right)$, (c) dimethylamine $\left[\left(\mathrm{CH}_{3}\right)_{2} \mathrm{NH}\right]$,
(d) barium hydroxide $\left[\mathrm{Ba}(\mathrm{OH})_{2}\right]$.
4.97 Determine the predominant species (there may be more than one) in an aqueous solution for each of the compounds in Problem 4.95.
4.98 Determine the predominant species (there may be more than one) in an aqueous solution for each of the compounds in Problem 4.96.

E4.99 A 3.664-g sample of a monoprotic acid was dissolved in water. It took 20.27 mL of a 0.1578 M NaOH solution to neutralize the acid. Calculate the molar mass of the acid.

Y4.100 Acetic acid $\left(\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right)$ is an important ingredient of vinegar. A sample of 50.0 mL of a commercial vinegar is titrated against a 1.00 M NaOH solution. What is the concentration (in $M$ ) of acetic acid present in the vinegar if 5.75 mL of the base is needed for the titration?

- 4.101 A $15.00-\mathrm{mL}$ solution of potassium nitrate $\left(\mathrm{KNO}_{3}\right)$ was diluted to 125.0 mL , and 25.00 mL of this solution was then diluted to 1.000 $\times 10^{3} \mathrm{~mL}$. The concentration of the final solution is 0.00383 M . Calculate the concentration of the original solution.
4.102 When 2.50 g of a zinc strip was placed in an $\mathrm{AgNO}_{3}$ solution, silver metal formed on the surface of the strip. After some time had passed, the strip was removed from the solution, dried, and weighed. If the mass of the strip was 3.37 g , calculate the mass of Ag and Zn metals present.
4.103 Calculate the mass of the precipitate formed when 2.27 L of $0.0820 M \mathrm{Ba}(\mathrm{OH})_{2}$ is mixed with 3.06 L of $0.0664 M \mathrm{Na}_{2} \mathrm{SO}_{4}$.

H4.104 Calculate the concentration of the acid (or base) remaining in solution when 10.7 mL of $0.211 \mathrm{M} \mathrm{HNO}_{3}$ is added to 16.3 mL of 0.258 M NaOH .
4.105 (a) Describe a preparation for magnesium hydroxide $\left[\mathrm{Mg}(\mathrm{OH})_{2}\right]$ and predict its solubility. (b) Milk of magnesia contains mostly $\mathrm{Mg}(\mathrm{OH})_{2}$ and is effective in treating acid (mostly hydrochloric acid) indigestion. Calculate the volume of a 0.035 M HCl solution (a typical acid concentration in an upset stomach) needed to react with two spoonfuls (approximately 10 mL ) of milk of magnesia [at $0.080 \mathrm{~g} \mathrm{Mg}(\mathrm{OH})_{2} / \mathrm{mL}$ ].
4.106 A quantitative definition of solubility is the number of grams of a solute that will dissolve in a given volume of water at a particular temperature. Describe an experiment that would enable you to determine the solubility of a soluble compound.

E4 4.107 A 60.0-mL $0.513 M$ glucose $\left(\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}\right)$ solution is mixed with 120.0 mL of a 2.33 M glucose solution. What is the concentration of the final solution? Assume the volumes are additive.
4.108 An ionic compound X is only slightly soluble in water. What test would you employ to show that the compound does indeed dissolve in water to a certain extent?
4.109 You are given a colorless liquid. Describe three chemical tests you would perform on the liquid to show that it is water.
4.110 Using the apparatus shown in Figure 4.1, a student found that a sulfuric acid solution caused the lightbulb to glow brightly. However, after the addition of a certain amount of a barium hydroxide $\left[\mathrm{Ba}(\mathrm{OH})_{2}\right]$ solution, the light began to dim even though $\mathrm{Ba}(\mathrm{OH})_{2}$ is also a strong electrolyte. Explain.
4.111 Which of the diagrams shown corresponds to the reaction between $\mathrm{AgOH}(s)$ and $\mathrm{HNO}_{3}(a q)$ ? Write a balanced equation for the reaction. (For simplicity, water molecules are not shown.)

(a)

(b)

(c)
4.112 Which of the diagrams shown corresponds to the reaction between $\mathrm{Ba}(\mathrm{OH})_{2}(\mathrm{aq})$ and $\mathrm{H}_{2} \mathrm{SO}_{4}(\mathrm{aq})$ ? Write a balanced equation for the reaction. (For simplicity, water molecules are not shown.)

(a)

(b)

(c)
4.113 You are given a soluble compound of an unknown molecular formula. (a) Describe three tests that would show that the compound is an acid. (b) Once you have established that the compound is an acid, describe how you would determine its molar mass using an NaOH solution of known concentration. (Assume the acid is monoprotic.) (c) How would you find out whether the acid is weak or strong? You are provided with a sample of NaCl and an apparatus like that shown in Figure 4.1 for comparison.
4.114 You are given two colorless solutions, one containing NaCl and the other sucrose $\left(\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}\right)$. Suggest a chemical and a physical test that would allow you to distinguish between these two solutions.

E4.115 The concentration of lead ions $\left(\mathrm{Pb}^{2+}\right)$ in a sample of polluted water that also contains nitrate ions $\left(\mathrm{NO}_{3}^{-}\right)$is determined by adding solid sodium sulfate $\left(\mathrm{Na}_{2} \mathrm{SO}_{4}\right)$ to exactly 500 mL of the water. (a) Write the molecular and net ionic equations for the reaction. (b) Calculate the molar concentration of $\mathrm{Pb}^{2+}$ if 0.00450 g of $\mathrm{Na}_{2} \mathrm{SO}_{4}$ was needed for the complete precipitation of $\mathrm{Pb}^{2+}$ ions as $\mathrm{PbSO}_{4}$.
4.116 Hydrochloric acid is not an oxidizing agent in the sense that sulfuric acid and nitric acid are. Explain why the chloride ion is not a strong oxidizing agent like $\mathrm{SO}_{4}^{2-}$ and $\mathrm{NO}_{3}^{-}$.
4.117 Explain how you would prepare potassium iodide (KI) by means of (a) an acid-base reaction and (b) a reaction between an acid and a carbonate compound.
4.118 Sodium reacts with water to yield hydrogen gas. Why is this reaction not used in the laboratory preparation of hydrogen?
4.119 Describe how you would prepare the following compounds: (a) $\mathrm{Mg}(\mathrm{OH})_{2}$, (b) AgI , (c) $\mathrm{Ba}_{3}\left(\mathrm{PO}_{4}\right)_{2}$.
4.120 Someone spilled concentrated sulfuric acid on the floor of a chemistry laboratory. To neutralize the acid, would it be preferable to pour concentrated sodium hydroxide solution or spray solid sodium bicarbonate over the acid? Explain your choice and the chemical basis for the action.
4.121 Describe in each case how you would separate the cations or anions in the following aqueous solutions: (a) $\mathrm{NaNO}_{3}$ and $\mathrm{Ba}\left(\mathrm{NO}_{3}\right)_{2}$, (b) $\mathrm{Mg}\left(\mathrm{NO}_{3}\right)_{2}$ and $\mathrm{KNO}_{3}$, (c) KBr and $\mathrm{KNO}_{3}$, (d) $\mathrm{K}_{3} \mathrm{PO}_{4}$ and $\mathrm{KNO}_{3}$, (e) $\mathrm{Na}_{2} \mathrm{CO}_{3}$ and $\mathrm{NaNO}_{3}$.
4.122 The following are common household compounds: salt ( NaCl ), sugar (sucrose), vinegar (contains acetic acid), baking soda $\left(\mathrm{NaHCO}_{3}\right)$, washing soda $\left(\mathrm{Na}_{2} \mathrm{CO}_{3} \cdot 10 \mathrm{H}_{2} \mathrm{O}\right)$, boric acid $\left(\mathrm{H}_{3} \mathrm{BO}_{3}\right.$, used in eyewash), Epsom salts $\left(\mathrm{MgSO}_{4} \cdot 7 \mathrm{H}_{2} \mathrm{O}\right)$, sodium hydroxide (used in drain openers), ammonia, milk of magnesia $\left[\mathrm{Mg}(\mathrm{OH})_{2}\right]$, and calcium carbonate. Based on what you have learned in this chapter, describe tests that would allow you to identify each of these compounds.
4.123 Sulfites (compounds containing the $\mathrm{SO}_{3}^{2-}$ ions) are used as preservatives in dried fruits and vegetables and in wine making. In an experiment to test the presence of sulfite in fruit, a student first soaked several dried apricots in water overnight and then filtered the solution to remove all solid particles. She then treated the solution with hydrogen peroxide $\left(\mathrm{H}_{2} \mathrm{O}_{2}\right)$ to oxidize the sulfite ions to sulfate ions. Finally, the sulfate ions were precipitated by treating the solution with a few drops of a barium chloride $\left(\mathrm{BaCl}_{2}\right)$ solution. Write a balanced equation for each of the preceding steps.
4.124 A $0.8870-\mathrm{g}$ sample of a mixture of NaCl and KCl is dissolved in water, and the solution is then treated with an excess of $\mathrm{AgNO}_{3}$ to yield 1.913 g of AgCl . Calculate the percent by mass of each compound in the mixture.

E4.125 Chlorine forms a number of oxides with the following oxidation numbers: $+1,+3,+4,+6$, and +7 . Write a formula for each of these compounds.
$\leftrightarrows 4.126$ A useful application of oxalic acid is the removal of rust $\left(\mathrm{Fe}_{2} \mathrm{O}_{3}\right)$ from, say, bathtub rings according to the reaction

$$
\mathrm{Fe}_{2} \mathrm{O}_{3}(s)+6 \mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}(a q) \longrightarrow 2 \mathrm{Fe}\left(\mathrm{C}_{2} \mathrm{O}_{4}\right)_{3}^{3-}(a q)+3 \mathrm{H}_{2} \mathrm{O}+6 \mathrm{H}^{+}(a q)
$$

Calculate the number of grams of rust that can be removed by $5.00 \times 10^{2} \mathrm{~mL}$ of a 0.100 M solution of oxalic acid.
4.127 Acetylsalicylic acid $\left(\mathrm{HC}_{9} \mathrm{H}_{7} \mathrm{O}_{4}\right)$ is a monoprotic acid commonly known as "aspirin." A typical aspirin tablet, however, contains only a small amount of the acid. In an experiment to determine its composition, an aspirin tablet was crushed and dissolved in water. It took 12.25 mL of 0.1466 M NaOH to neutralize the solution. Calculate the number of grains of aspirin in the tablet (one grain $=0.0648 \mathrm{~g})$.
4.128 A $0.9157-\mathrm{g}$ mixture of $\mathrm{CaBr}_{2}$ and NaBr is dissolved in water, and $\mathrm{AgNO}_{3}$ is added to the solution to form AgBr precipitate. If the mass of the precipitate is 1.6930 g , what is the percent by mass of NaBr in the original mixture?
4.129 Hydrogen halides ( $\mathrm{HF}, \mathrm{HCl}, \mathrm{HBr}, \mathrm{HI}$ ) are highly reactive compounds that have many industrial and laboratory uses. (a) In the laboratory, HF and HCl can be generated by combining $\mathrm{CaF}_{2}$ and NaCl with concentrated sulfuric acid. Write appropriate equations for the reactions. (Hint: These are not redox reactions.) (b) Why is it that HBr and HI cannot be prepared similarly, that is, by combining NaBr and NaI with concentrated sulfuric acid? (Hint: $\mathrm{H}_{2} \mathrm{SO}_{4}$ is a stronger oxidizing agent than both $\mathrm{Br}_{2}$ and $\mathrm{I}_{2}$.) (c) HBr can be prepared by reacting phosphorus tribromide $\left(\mathrm{PBr}_{3}\right)$ with water. Write an equation for this reaction.
$\leftrightarrows 4.130$ A $325-\mathrm{mL}$ sample of solution contains 25.3 g of $\mathrm{CaCl}_{2}$. (a) Calculate the molar concentration of $\mathrm{Cl}^{-}$in this solution. (b) How many grams of $\mathrm{Cl}^{-}$are in 0.100 L of this solution?
4.131 Phosphoric acid $\left(\mathrm{H}_{3} \mathrm{PO}_{4}\right)$ is an important industrial chemical used in fertilizers, detergents, and the food industry. It is produced by two different methods. In the electric furnace method elemental phosphorus $\left(\mathrm{P}_{4}\right)$ is burned in air to form $\mathrm{P}_{4} \mathrm{O}_{10}$, which is then combined with water to give $\mathrm{H}_{3} \mathrm{PO}_{4}$. In the wet process the mineral phosphate rock $\left[\mathrm{Ca}_{5}\left(\mathrm{PO}_{4}\right)_{3} \mathrm{~F}\right]$ is combined with sulfuric acid to give $\mathrm{H}_{3} \mathrm{PO}_{4}$ (and HF and $\mathrm{CaSO}_{4}$ ). Write equations for these processes, and classify each step as precipitation, acid-base, or redox reaction.

E4.132 Ammonium nitrate $\left(\mathrm{NH}_{4} \mathrm{NO}_{3}\right)$ is one of the most important nitrogen-containing fertilizers. Its purity can be analyzed by titrating a solution of $\mathrm{NH}_{4} \mathrm{NO}_{3}$ with a standard NaOH solution. In one experiment a $0.2041-\mathrm{g}$ sample of industrially prepared $\mathrm{NH}_{4} \mathrm{NO}_{3}$ required 24.42 mL of 0.1023 M NaOH for neutralization. (a) Write a net ionic equation for the reaction. (b) What is the percent purity of the sample?
4.133 Potassium superoxide $\left(\mathrm{KO}_{2}\right)$ is used in some self-containing breathing equipment by firefighters. It reacts with carbon dioxide in respired (exhaled) air to form potassium carbonate and oxygen gas. (a) Write an equation for the reaction. (b) What is the oxidation number of oxygen in the $\mathrm{O}_{2}^{-}$ion? (c) How many liters of respired air can react with 7.00 g of $\mathrm{KO}_{2}$ if each liter of respired air contains 0.063 g of $\mathrm{CO}_{2}$ ?
4.134 Barium sulfate $\left(\mathrm{BaSO}_{4}\right)$ has important medical uses. The dense salt absorbs X rays and acts as an opaque barrier. Thus, X-ray examination of a patient who has swallowed an aqueous suspension of $\mathrm{BaSO}_{4}$ particles allows the radiologist to diagnose an ailment of the patient's digestive tract. Given the following starting compounds, describe how you would prepare $\mathrm{BaSO}_{4}$ by neutralization and by precipitation: $\mathrm{Ba}(\mathrm{OH})_{2}, \mathrm{BaCl}_{2}, \mathrm{BaCO}_{3}$, $\mathrm{H}_{2} \mathrm{SO}_{4}$, and $\mathrm{K}_{2} \mathrm{SO}_{4}$.
4.135 Is the following reaction a redox reaction? Explain.

$$
3 \mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{O}_{3}(\mathrm{~g})
$$

4.136 What is the oxidation number of O in HFO ?
4.137 Draw molecular models to represent the following acid-base reactions:
(a) $\mathrm{OH}^{-}+\mathrm{H}_{3} \mathrm{O}^{+} \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}$
(b) $\mathrm{NH}_{4}^{+}+\mathrm{NH}_{2}^{-} \longrightarrow 2 \mathrm{NH}_{3}$

Identify the Brønsted acid and base in each case.
4.138 On standing, a concentrated nitric acid gradually turns yellow. Explain. (Hint: Nitric acid slowly decomposes. Nitrogen dioxide is a colored gas.)
4.139 When preparing a solution of known concentration, explain why one must first dissolve the solid completely before adding enough solvent to fill the volumetric flask to the mark.
4.140 Can the following decomposition reaction be characterized as an acid-base reaction? Explain.

$$
\mathrm{NH}_{4} \mathrm{Cl}(s) \longrightarrow \mathrm{NH}_{3}(g)+\mathrm{HCl}(g)
$$

4.141 Give a chemical explanation for each of the following: (a) When calcium metal is added to a sulfuric acid solution, hydrogen gas is generated. After a few minutes, the reaction slows down and eventually stops even though none of the reactants is used up. Explain. (b) In the activity series, aluminum is above hydrogen, yet the metal appears to be unreactive toward hydrochloric acid. Why? (Hint: Al forms an oxide, $\mathrm{Al}_{2} \mathrm{O}_{3}$, on the surface.) (c) Sodium and potassium lie above copper in the activity series. Explain why $\mathrm{Cu}^{2+}$ ions in a $\mathrm{CuSO}_{4}$ solution are not converted to metallic copper upon the addition of these metals. (d) A metal M reacts slowly with steam. There is no visible change when it is placed in a pale green iron(II) sulfate solution. Where should we place M in the activity series? (e) Before aluminum metal was obtained by electrolysis, it was produced by reducing its chloride $\left(\mathrm{AlCl}_{3}\right)$ with an active metal. What metals would you use to produce aluminum in that way?

E4.142 The recommended procedure for preparing a very dilute solution is not to weigh out a very small mass or measure a very small volume of a stock solution. Instead, it is done by a series of dilutions. A sample of 0.8214 g of $\mathrm{KMnO}_{4}$ was dissolved in water and made up to the volume in a $500-\mathrm{mL}$ volumetric flask. A $2.000-\mathrm{mL}$ sample of this solution was transferred to a $1000-\mathrm{mL}$ volumetric flask and diluted to the mark with water. Next, 10.00 mL of the diluted solution was transferred to a $250-\mathrm{mL}$ flask and diluted to the mark with water. (a) Calculate the concentration (in molarity) of the final solution. (b) Calculate the mass of $\mathrm{KMnO}_{4}$ needed to directly prepare the final solution.
4.143 The following "cycle of copper" experiment is performed in some general chemistry laboratories. The series of reactions starts with copper and ends with metallic copper. The steps are as follows: (1) A piece of copper wire of known mass is allowed to react with concentrated nitric acid [the products are copper(II) nitrate, nitrogen dioxide, and water]. (2) The copper(II) nitrate is treated with a sodium hydroxide solution to form copper(II) hydroxide precipitate. (3) On heating, copper(II) hydroxide decomposes to yield copper(II) oxide. (4) The copper(II) oxide is combined with concentrated sulfuric acid to yield copper(II) sulfate. (5) Copper(II) sulfate is treated with an excess of zinc metal to form metallic copper. (6) The remaining zinc metal is removed by treatment with hydrochloric acid, and metallic copper is filtered, dried, and weighed. (a) Write a balanced equation for each step and classify the reactions. (b) Assuming that a student started with 65.6 g of copper, calculate the theoretical yield at each step. (c) Considering the nature of the steps, comment on why it is possible to recover most of the copper used at the start.
4.144 Use the periodic table framework given here to show the names and positions of two metals that can (a) displace hydrogen from cold water and (b) displace hydrogen from acid. (c) Also show two metals that do not react with either water or acid.

4.145 A $22.02-\mathrm{mL}$ solution containing $1.615 \mathrm{~g} \mathrm{Mg}\left(\mathrm{NO}_{3}\right)_{2}$ is mixed with a $28.64-\mathrm{mL}$ solution containing 1.073 g NaOH . Calculate the concentrations of the ions remaining in solution after the reaction is complete. Assume volumes are additive.
4.146 Because the acid-base and precipitation reactions discussed in this chapter all involve ionic species, their progress can be monitored by measuring the electrical conductance of the solution. Match each of the following reactions with one of the diagrams shown here. The electrical conductance is shown in arbitrary units.
(1) A 1.0 M KOH solution is added to 1.0 L of $1.0 M \mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$.
(2) A 1.0 M NaOH solution is added to 1.0 L of 1.0 M HCl .
(3) A 1.0 M BaCl 2 solution is added to 1.0 L of $1.0 \mathrm{M}_{2} \mathrm{SO}_{4}$.
(4) A 1.0 M NaCl solution is added to 1.0 L of $1.0 \mathrm{M} \mathrm{AgNO}_{3}$.
(5) A $1.0 \mathrm{M} \mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$ solution is added to 1.0 L of $1.0 \mathrm{M} \mathrm{NH}_{3}$.

(a)

(b)

(d)
$\leftrightarrows$ 4.147 A volume of 35.2 mL of a $1.66 \mathrm{M} \mathrm{KMnO}_{4}$ solution is mixed with 16.7 mL of a $0.892 \mathrm{MMnO}_{4}$ solution. Calculate the concentration of the final solution.
4.148 A volume of 46.2 mL of a 0.568 M calcium nitrate $\left[\mathrm{Ca}\left(\mathrm{NO}_{3}\right)_{2}\right]$ solution is mixed with 80.5 mL of a 1.396 M calcium nitrate solution. Calculate the concentration of the final solution.
4.149 The general test for Type 2 diabetes is that the blood sugar (glucose, $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}$ ) level should be below 120 mg per deciliter. Convert this concentration to molarity.
4.150 The current maximum level of fluoride that the EPA allows in U.S. drinking water is $4 \mathrm{mg} / \mathrm{L}$. Convert this concentration to molarity.
4.151 The concentration of $\mathrm{Cu}^{2+}$ ions in the water (which also contains sulfate ions) discharged from a certain industrial plant is determined by adding excess sodium sulfide $\left(\mathrm{Na}_{2} \mathrm{~S}\right)$ solution to 0.800 L of the water. The molecular equation is

$$
\mathrm{Na}_{2} \mathrm{~S}(a q)+\mathrm{CuSO}_{4}(a q) \longrightarrow \mathrm{Na}_{2} \mathrm{SO}_{4}(a q)+\mathrm{CuS}(s)
$$

Write the net ionic equation and calculate the molar concentration of $\mathrm{Cu}^{2+}$ in the water sample if 0.0177 g of solid CuS is formed.

G4.152 Chemical tests of four metals A, B, C, and D show the following results.
(a) Only B and C react with 0.5 M HCl to give $\mathrm{H}_{2}$ gas.
(b) When B is added to a solution containing the ions of the other metals, metallic $\mathrm{A}, \mathrm{C}$, and D are formed.
(c) A reacts with $6 \mathrm{MNO}_{3}$ but D does not.

Arrange the metals in the increasing order as reducing agents. Suggest four metals that fit these descriptions.

## Pre-Professional Practice Exam Problems: Physical and Biological Sciences

One of the atmospheric pollutants that contributes to acid rain is nitrogen dioxide $\left(\mathrm{NO}_{2}\right)$. A major source of $\mathrm{NO}_{2}$ is automobile exhaust. When nitrogen in the air is burned in an internal combustion engine, it is converted to nitric oxide (NO):

$$
\mathrm{N}_{2}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{NO}(g)
$$

[Equation I]
The NO is then oxidized in the atmosphere to form $\mathrm{NO}_{2}$ :

$$
2 \mathrm{NO}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{NO}_{2}(g)
$$

[Equation II]
$\mathrm{NO}_{2}$ is a brown gas that is largely responsible for the orange-brown haze visible over some densely populated cities. It exists in equilibrium with its colorless dimeric form:

$$
2 \mathrm{NO}_{2}(g) \rightleftarrows \mathrm{N}_{2} \mathrm{O}_{4}(g)
$$

[Equation III]
Atmospheric $\mathrm{NO}_{2}$ reacts with water to form nitric and nitrous acids:

$$
2 \mathrm{NO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{HNO}_{3}(a q)+\mathrm{HNO}_{2}(a q) \quad \text { [Equation IV] }
$$

1. What is the reducing agent in Equation I?
a) $\mathrm{N}_{2}$
b) $\mathrm{O}_{2}$
c) NO
d) There is no reducing agent in Equation I.
2. According to Equation IV, if 5 g of $\mathrm{NO}_{2}$ reacts with 1355 mL of water, what will be the resulting concentration of $\mathrm{HNO}_{3}$ and the resulting concentration of $\mathrm{HNO}_{2}$, respectively? (Assume that the volume of the resulting solution is equal to the volume of water.)
a) 0.04 M and 0.01 M
b) 0.04 M and 0.04 M
c) 0.08 M and 0.02 M
d) 0.08 M and 0.08 M
3. What type of reaction does Equation IV represent?
a) Disproportionation
b) Decomposition
c) Combination
d) Combustion
4. What is the correct sequence of oxidation numbers for N in $\mathrm{N}_{2}, \mathrm{NO}_{2}$, $\mathrm{N}_{2} \mathrm{O}_{4}, \mathrm{HNO}_{3}$, and $\mathrm{HNO}_{2}$ ?
a) $+1,+4,+2,+6,+4$
b) $0,-2,+4,+5,+5$
c) $0,+4,+4,+5,+3$
d) $+1,+2,+4,+6,+4$

## Answers to In-Chapter Materials

## Answers to Practice Problems

4.1A weak electrolyte, strong electrolyte, strong electrolyte, and strong electrolyte. 4.1B $\mathrm{AD}_{2}<\mathrm{AB}_{2}<\mathrm{AC}_{2}$. 4.2A nonelectrolyte, weak electrolyte, and strong electrolyte. 4.2B weak electrolyte, nonelectrolyte, and strong electrolyte. 4.3A insoluble, soluble, and insoluble. 4.3B soluble, insoluble, and soluble. 4.4A $\mathrm{Sr}\left(\mathrm{NO}_{3}\right)_{2}(a q)+\mathrm{Li}_{2} \mathrm{SO}_{4}(a q) \longrightarrow$ $\mathrm{SrSO}_{4}(s)+2 \mathrm{LiNO}_{3}(a q), \mathrm{Sr}^{2+}(a q)+2 \mathrm{NO}_{3}^{-}(a q)+2 \mathrm{Li}^{+}(a q)+\mathrm{SO}_{4}^{2-}(a q)$

## Answers to Applying What You've Learned

a) $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}$ is a nonelectrolyte, $\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$ is a strong electrolyte, and $\mathrm{H}_{2} \mathrm{SO}_{4}$ is a strong electrolyte. $\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$ is a weak electrolyte, $\mathrm{Cr}_{2}\left(\mathrm{SO}_{4}\right)_{3}$ is a strong electrolyte, $\mathrm{K}_{2} \mathrm{SO}_{4}$ is a strong electrolyte, and $\mathrm{H}_{2} \mathrm{O}$ is a nonelectrolyte.
b) The ionic equation is
$3 \mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}(g)+4 \mathrm{~K}^{+}(a q)+2 \mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}(a q)+8 \mathrm{H}^{+}(a q)+8 \mathrm{HSO}_{4}^{-}(a q) \longrightarrow$

$$
3 \mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}(a q)+4 \mathrm{Cr}^{3+}(a q)+6 \mathrm{SO}_{4}^{2-}(a q)+4 \mathrm{~K}^{+}(a q)+2 \mathrm{SO}_{4}^{2-}(a q)+11 \mathrm{H}_{2} \mathrm{O}(l)
$$

The net ionic equation is
$3 \mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}(g)+2 \mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}(a q)+8 \mathrm{H}^{+}(a q)+8 \mathrm{HSO}_{4}^{-}(a q) \longrightarrow 3 \mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}(a q)+4 \mathrm{Cr}^{3+}(a q)+8 \mathrm{SO}_{4}^{2-}(a q)+11 \mathrm{H}_{2} \mathrm{O}(l)$
c) The oxidation state of each element in the overall equation is as follows:

d) The molar concentration of a 0.025 percent weight by volume solution of $\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$ is $8.5 \times 10^{-4} \mathrm{M}$. e) 15 mL of a 0.014 M stock solution of $\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$ would be required to prepare 250 mL of $8.5 \times 10^{-4} M \mathrm{~K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$.
f) $\left[\mathrm{K}^{+}\right]=1.7 \times 10^{-3} \mathrm{M}$; $\left[\mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}\right]=8.5 \times 10^{-4} \mathrm{M}$.

Doughnuts, although typically high in fat and Calories, are very popular. The energy content of food such as doughnuts is determined by burning a sample of the food in a calorimeter.

## How Thermochemistry Helped Uncover Deceptive Labeling of "Diet" Doughnuts

The Food and Drug Administration (FDA) and the U.S. Department of Agriculture (USDA) require "Nutrition Facts" labels on nearly all prepared foods. These labels indicate such things as serving size, grams of fat per serving, and Calories per serving. Health-conscious consumers typically are avid readers of food labels and use them to make informed dietary choices. Furthermore, because dieting to lose weight is something of a national obsession, many Americans are willing to pay premium prices for packaged foods that both taste good and are low in fat and Calories. For this reason, it is important that the labels on packaged foods contain accurate information.

In 1997, spurred by numerous complaints from consumers and health-care professionals, the FDA launched an investigation into the practices of a weight-loss product company with packaging facilities in Kentucky and Illinois. The company sold "low-fat, carob-coated" doughnuts that, according to package labeling, each contained just 3 g of fat and 135 Calories. According to an analysis by the FDA, the doughnuts were actually chocolate-coated and each contained 18 g of fat and 530 Calories! As the FDA investigation revealed, the company had simply purchased ordinary doughnuts from a Chicago bakery and repackaged them as "diet" doughnuts, marking up the price by as much as 200 percent. The investigation led to a criminal indictment.

Experimental determination of the caloric content of food is done using the techniques of thermochemistry. A weighed sample of the food is burned in a bomb calorimeter, and the heat generated by the combustion, which is equal to the energy content of the food, is determined by measuring the resulting temperature increase in the calorimeter.

Student Annotation: Carob is a chocolate substitute made from the seed pods of the Mediterranean Carob tree.

Student Annotation: Cell respiration is the complex, multistep process by which living things convert the food they eat into energy, carbon dioxide, and water. Combustion occurs in a single step but is the same overall process, with the same products, as cell respiration.

At the end of this chapter, you will be able to solve a series of problems related to the fat and calorie content of doughnuts [ H page 200].

## In This Chapter, You Will Learn:

About the energy changes associated with chemical reactions and physical processes. You will also learn how calorimetry is used to measure the energy released or absorbed during a process.

## Before you begin, you should review

- Tracking units [ It Section 1.6]
- Balancing chemical equations [/W4 Section 3.3]

### 5.1 Energy and Energy Changes

You have already learned that matter can undergo physical changes and chemical changes [ 14 Section 1.4]. The melting of ice, for example, is a physical change that can be represented by the following equation:

$$
\mathrm{H}_{2} \mathrm{O}(s) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)
$$

The formation of water from its constituent elements, represented by the following equation, is an example of a chemical change:

$$
2 \mathrm{H}_{2}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l)
$$

In each case, there is energy involved in the change. Energy (in the form of heat) must be supplied to melt ice, whereas energy (in the form of heat and light) is produced by the explosive combination of hydrogen and oxygen gases. In fact, every change that matter undergoes is accompanied by either the absorption or the release of energy. In this chapter, we will focus on the energy changes associated with physical and chemical processes.

## Forms of Energy

Energy is usually defined as the capacity to do work or transfer heat. All forms of energy are either kinetic or potential. Kinetic energy is the energy that results from motion. It is calculated with the equation

## Equation 5.1

$$
E_{\mathrm{k}}=\frac{1}{2} m u^{2}
$$

where $m$ is the mass of the object and $u$ is its velocity. One form of kinetic energy of particular interest to chemists is thermal energy, which is the energy associated with the random motion of atoms and molecules. We can monitor changes in thermal energy by measuring temperature changes.

Potential energy is the energy possessed by an object by virtue of its position. The two forms of potential energy of greatest interest to chemists are chemical energy and electrostatic energy. Chemical energy is energy stored within the structural units (molecules or polyatomic ions) of chemical substances. The amount of chemical energy in a sample of matter depends on the types and arrangements of atoms in the structural units that make up the sample.

Electrostatic energy is potential energy that results from the interaction of charged particles. Oppositely charged particles attract each other, whereas particles of like charges repel each other. The magnitude of the resulting electrostatic potential energy is proportional to the product of the two charges ( $Q_{1}$ and $Q_{2}$ ) divided by the distance ( $d$ ) between them.

Equation 5.2

$$
E_{\mathrm{el}} \propto \frac{Q_{1} Q_{2}}{d}
$$

If the charges $Q_{1}$ and $Q_{2}$ are opposite (i.e., one positive and one negative), the result is a negative value for $E_{\mathrm{e}}$, which indicates attraction. Like charges (i.e., both positive or both negative) result in a positive value for $E_{\text {el }}$, indicating repulsion.

Kinetic and potential energy are interconvertible-that is, one form can be converted to the other. For example, dropping an object and allowing it to fall converts potential energy to kinetic energy. Likewise, a chemical reaction that gives off heat converts chemical energy (potential) to thermal energy (kinetic). Although energy can assume many different forms that are interconvertible, the total amount of energy in the universe is constant. When energy of one form disappears, the same amount of energy must appear in another form or forms. This principle is known as the law of conservation of energy.

## Energy Changes in Chemical Reactions

To analyze energy changes associated with chemical reactions, we must first define the system, the specific part of the universe that is of interest to us. For chemists, systems usually include the substances involved in chemical and physical changes. In an acid-base neutralization experiment, for example, the system may be the contents of a beaker in which HCl and NaOH react with each other. The rest of the universe outside the system, including the beaker itself, constitutes the surroundings.

Many chemical reactions are carried out for the purpose of exploiting the associated energy change, rather than for the purpose of obtaining the products of the reactions. For example, combustion reactions involving fossil fuels are carried out for the thermal energy they produce, not for their products, which are carbon dioxide and water.

It is important to distinguish between thermal energy and heat. Heat is the transfer of thermal energy between two bodies that are at different temperatures. Although the term heat by itself implies the transfer of energy, we customarily talk of "heat flow," meaning "heat absorbed" or "heat released," when describing the energy changes that occur during a process. Thermochemistry is the study of heat (the transfer of thermal energy) in chemical reactions.

The combustion of hydrogen gas in oxygen is one of many chemical reactions that release considerable quantities of energy (Figure 5.1):

$$
2 \mathrm{H}_{2}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l)+\text { energy }
$$

In this case, we label the mixture of reactants and product (hydrogen, oxygen, and water molecules) the system. Because energy cannot be created or destroyed, any energy released by the system must be gained by the surroundings. Thus, the heat generated by the combustion process is transferred from the system to its surroundings. This reaction is an example of an exothermic process, which is any process that gives off heat-that is, transfers thermal energy from the system to the surroundings. Figure $5.2(\mathrm{a})$ shows the energy change for the combustion of hydrogen gas.

Next, consider the decomposition of mercury(II) oxide $(\mathrm{HgO})$ at high temperatures:

$$
\text { energy }+2 \mathrm{HgO}(s) \longrightarrow 2 \mathrm{Hg}(l)+\mathrm{O}_{2}(g)
$$

This reaction is an endothermic process because heat has to be supplied to the system (i.e., to HgO ) by the surroundings [Figure 5.2(b)] for the reaction to occur. Thus, thermal energy is transferred from the surroundings to the system in an endothermic process.

According to Figure 5.2, the energy of the products of an exothermic reaction is lower than the energy of the reactants. The difference in energy between the reactants $\mathrm{H}_{2}$ and $\mathrm{O}_{2}$ and the product $\mathrm{H}_{2} \mathrm{O}$ is the heat released by the system to the surroundings. In an endothermic reaction, on the other hand, the energy of the products is higher than the energy of the reactants. Here, the difference between the energy of the reactant HgO and the products Hg and $\mathrm{O}_{2}$ is the heat absorbed by the system from the surroundings.

## Units of Energy

The SI unit of energy is the joule (J), named for the physicist James Joule. ${ }^{1}$ The joule is a fairly small quantity of energy. It is the amount of kinetic energy possessed by a $2-\mathrm{kg}$ mass moving at a speed of $1 \mathrm{~m} / \mathrm{s}$.

$$
E_{\mathrm{k}}=\frac{1}{2} m u^{2}=\frac{1}{2}(2 \mathrm{~kg})(1 \mathrm{~m} / \mathrm{s})^{2}=1 \mathrm{~kg} \cdot \mathrm{~m}^{2} / \mathrm{s}^{2}=1 \mathrm{~J}
$$

Exothermic
(a)

Endothermic
(b)

[^7]

Figure 5.1 The Hindenburg, a German airship filled with hydrogen gas, was destroyed in a horrific fire as it landed at Lakehurst, New Jersey, in 1937.

Thermochemistry-heat flow in endothermic and exothermic reactions.

Student Annotation: In these examples, all the energy released or absorbed by the system is in the form of heat. In Section 5.2, we will consider examples in which some of the energy is in the form of work.

Figure 5.2 (a) An exothermic reaction. Heat is given off by the system. (b) An endothermic reaction. Heat is absorbed by the system.

Student Annotation: Remember that the base units of the joule are $\mathrm{kg} \cdot \mathrm{m}^{2} / \mathrm{s}^{2}$.

The joule can also be defined as the amount of energy exerted when a force of 1 newton (N) is applied over a distance of 1 meter.

$$
1 \mathrm{~J}=1 \mathrm{~N} \cdot \mathrm{~m}
$$

where

$$
1 \mathrm{~N}=1 \mathrm{~kg} \cdot \mathrm{~m} / \mathrm{s}^{2}
$$

Because the magnitude of a joule is so small, we very often express the energy changes in chemical reactions using the unit kilojoule (kJ).

$$
1 \mathrm{~kJ}=1000 \mathrm{~J}
$$

Sample Problem 5.1 shows how to calculate kinetic and potential energies.

## Sample Problem 5.1

(a) Calculate the kinetic energy of a helium atom moving at a speed of $125 \mathrm{~m} / \mathrm{s}$. (b) How much greater is the magnitude of electrostatic attraction between an electron and a nucleus containing three protons versus that between an electron and a nucleus containing one proton? (Assume that the distance between the nucleus and the electron is the same in each case.)

Strategy (a) Use Equation $5.1\left(E_{\mathrm{k}}=\frac{1}{2} m u^{2}\right)$ to calculate the kinetic energy of an atom. We will need to know the mass of the atom in kilograms.
(b) Use Equation $5.2\left(E_{\text {el }} \propto Q_{1} Q_{2} / d\right)$ to compare the electrostatic potential energy between the two charged particles in each case.

## Setup

(a) The mass of a helium atom is 4.003 amu . Its mass in kilograms is

$$
4.003 \mathrm{amu} \times \frac{1.661 \times 10^{-24} g}{1 \mathrm{gma}} \times \frac{1 \mathrm{~kg}}{1 \times 10^{3} g}=6.649 \times 10^{-27} \mathrm{~kg}
$$

(b) The charge on a nucleus with three protons is +3 ; the charge on a nucleus with one proton is +1 . In each case, the electron's charge is -1 . Although we are not given the distance between the opposite charges in either case, we are told that the distances in both cases are equal. We can write Equation 5.2 for each case and divide one by the other to determine the relative magnitudes of the results.

## Solution

(a) $E_{\mathrm{k}}=\frac{1}{2} m u^{2}$

$$
\begin{aligned}
& =\frac{1}{2}\left(6.649 \times 10^{-27} \mathrm{~kg}\right)(125 \mathrm{~m} / \mathrm{s})^{2} \\
& =5.19 \times 10^{-23} \mathrm{~kg} \cdot \mathrm{~m}^{2} / \mathrm{s}^{2}=5.19 \times 10^{-23} \mathrm{~J}
\end{aligned}
$$

(b) $E_{\mathrm{el}} \propto \frac{Q_{1} Q_{2}}{d}$

$$
\frac{E_{\mathrm{el}} \text { where } Z=+3}{E_{\mathrm{el}} \text { where } Z=-1}=\frac{E_{\mathrm{el}} \propto \frac{(+3)(-1)}{d}}{E_{\mathrm{el}} \propto \frac{(+1)(-1)}{d}}=3
$$

The electrostatic potential energy between charges of +3 and -1 is three times that between charges of +1 and -1 .

Practice Problem A (a) Calculate the energy in joules of a $5.25-\mathrm{g}$ object moving at a speed of $655 \mathrm{~m} / \mathrm{s}$, and (b) determine how much greater the electrostatic energy is between charges of +2 and -2 than it is between charges of +1 and -1 (assume that the distance between the charges is the same in each case).
$\oiint$ Practice Problem B (a) Calculate the velocity (in $\mathrm{m} / \mathrm{s}$ ) of a $0.340-\mathrm{g}$ object that has $E_{\mathrm{k}}=23.5 \mathrm{~J}$, and (b) determine which of the following pairs of charged particles has the greater electrostatic energy between them: charges of +1 and -2 separated by a distance of $d$ or charges of +2 and -2 separated by a distance of $2 d$.

Another unit used to express energy is the calorie (cal). Although the calorie is not an SI unit, its use is still quite common. The calorie is defined in terms of the joule:

$$
1 \mathrm{cal} \equiv 4.184 \mathrm{~J}
$$

Because this is a definition, the number 4.184 is an exact number, which does not limit the number of significant figures in a calculation [ 14 Section 1.5]. You may be familiar with the term calorie from nutrition labels. In fact, the "calories" listed on food packaging are really kilocalories. Often the distinction is made by capitalizing the "C" in "calorie" when it refers to the energy content of food:

$$
1 \mathrm{Cal} \equiv 1000 \mathrm{cal}
$$

and

$$
1 \mathrm{Cal} \equiv 4184 \mathrm{~J}
$$

## Checkpoint 5.1 Energy and Energy Changes

5.1.1 Calculate the kinetic energy of a $5.0-\mathrm{kg}$ mass moving at $26 \mathrm{~m} / \mathrm{s}$.
a) $1.7 \times 10^{3} \mathrm{~J}$
b) $3.4 \times 10^{3} \mathrm{~J}$
c) 130 J
d) 65 J
e) $13 \times 10^{3} \mathrm{~J}$
5.1.2 How much greater is the electrostatic potential energy between particles with charges +3 and -3 than between particles with charges +1 and -1 ? (Assume the same distance between particles.)
a) 3 times
b) 9 times
c) 6 times
d) 4 times
e) 30 times
5.1.3 Calculate the number of calories in 723.01 J .
a) 172.80 cal
b) 172.8 cal
c) 3025.1 cal
d) 3025 cal
e) 0.173 cal
5.1.4 The label on packaged food indicates that it contains 215 Cal per serving. Convert this amount of energy to joules.
a) 51.4 J
b) $5.14 \times 10^{4} \mathrm{~J}$
c) $5.14 \times 10^{-2} \mathrm{~J}$
d) $9.00 \times 10^{2} \mathrm{~J}$
e) $9.00 \times 10^{5} \mathrm{~J}$
5.1.5 Arrange the following pairs of charged particles in order of increasing electrostatic potential energy.
i
ii
iii
iv

a) i $<$ ii $<$ iii $<$ iv
b) iv $<$ iii $<$ ii $<$ i
c) i $=$ iii $<$ ii $<$ iv
d) ii $<$ i $=$ iii $<$ iv
e) iv $<$ i $=$ ii $<$ iii
5.1.6 Which of the following changes would double the magnitude of the electrostatic attraction between two oppositely charged particles? (Select all that apply.)
a) Doubling both charges
b) Doubling one of the charges
c) Doubling the distance between the charges
d) Reducing the distance between the charges by half
e) Doubling both charges and doubling the distance between the charges

Student Annotation: The triple equal sign is used to denote a definition. Recall that numbers with defined values are exact numbers [ 144 Section 1.5], which do not limit the number of significant figures in a calculation.

Student Annotation: The energy exchanged between open systems or closed systems and their surroundings is usually in the form of heat.

### 5.2 Introduction to Thermodynamics

Thermochemistry is part of a broader subject called thermodynamics, which is the scientific study of the interconversion of heat and other kinds of energy. The laws of thermodynamics provide useful guidelines for understanding the energetics and directions of processes. In this section we will introduce the first law of thermodynamics, which is particularly relevant to the study of thermochemistry. We will continue our discussion of thermodynamics in Chapter 18.

We have defined a system as the part of the universe we are studying. There are three types of systems. An open system can exchange mass and energy with its surroundings. For example, an open system may consist of a quantity of water in an open container, as shown in Figure 5.3(a). If we close the flask, as in Figure 5.3(b), so that no water vapor can escape from or condense into the container, we create a closed system, which allows the transfer of energy but not mass. By placing the water in an insulated container, as shown in Figure 5.3(c), we can construct an isolated system, which does not exchange either mass or energy with its surroundings.

## States and State Functions

In thermodynamics, we study changes in the state of a system, which is defined by the values of all relevant macroscopic properties, such as composition, energy, temperature, pressure, and volume. Energy, pressure, volume, and temperature are said to be state functions-properties that are determined by the state of the system, regardless of how that condition was achieved. In other words, when the state of a system changes, the magnitude of change in any state function depends only on the initial and final states of the system and not on how the change is accomplished.

Consider, for example, your position in a six-story building. Your elevation depends upon which floor you are on. If you change your elevation by taking the stairs from the ground floor up to the fourth floor, the change in your elevation depends only upon your initial state (the ground floor-the floor you started on) and your final state (the fourth floor-the floor you went to). It does not depend on whether you went directly to the fourth floor or up to the sixth and then down to the fourth floor. Your overall change in elevation is the same either way because it depends only on your initial and final elevations. Thus, change in elevation is a state function.

The amount of effort it takes to get from the ground floor to the fourth floor, on the other hand, depends on how you get there. More effort has to be exerted to go from the ground floor to the sixth floor and back down to the fourth floor than to go from the ground floor to the fourth floor directly. The effort required for this change in elevation is not a state function. Furthermore, if you subsequently return to the ground floor, your overall change in elevation will be zero, because your initial and final states are the same, but the amount of effort you exerted going from the ground floor to the fourth floor and back to the ground floor is not zero. Even though your initial and final states are the same, you do not get back the effort that went into climbing up and down the stairs.

Energy is a state function, too. Using potential energy as an example, your net increase in gravitational potential energy is always the same, regardless of how you get from the ground floor to the fourth floor of a building (Figure 5.4).

## The First Law of Thermodynamics

The first law of thermodynamics, which is based on the law of conservation of energy, states that energy can be converted from one form to another but cannot be created or destroyed. It would be impossible to demonstrate this by measuring the total amount of energy in the universe; in fact, just determining the total energy content of a small sample of matter would be extremely difficult. Fortunately, because energy is a state function, we can demonstrate the first law by measuring the change in the energy of a system between its initial state and its final state in a process. The change in internal energy, $\Delta U$, is given by

$$
\Delta U=U_{\mathrm{f}}-U_{\mathrm{i}}
$$

where $U_{\mathrm{i}}$ and $U_{\mathrm{f}}$ are the internal energies of the system in the initial and final states, respectively.
The internal energy of a system has two components: kinetic energy and potential energy. The kinetic energy component consists of various types of molecular motion and the movement of electrons within molecules. Potential energy is determined by the attractive interactions between electrons and nuclei and by repulsive interactions between electrons and between nuclei in individual molecules, as well as by interactions between molecules. It is impossible to measure all these contributions accurately, so we cannot calculate the total energy of a system with any certainty. Changes in energy, on the other hand, can be determined experimentally.

Consider the reaction between 1 mole of sulfur and 1 mole of oxygen gas to produce 1 mole of sulfur dioxide:

$$
\mathrm{S}(\mathrm{~s})+\mathrm{O}_{2}(\mathrm{~g}) \longrightarrow \mathrm{SO}_{2}(\mathrm{~g})
$$

In this case our system is composed of the reactant molecules and the product molecules. We do not know the internal energy content of either the reactants or the product, but we can accurately measure the change in energy content, $\Delta U$, given by

$$
\begin{aligned}
\Delta U & =U(\text { products })-U(\text { reactants }) \\
& =\text { energy content of } 1 \mathrm{~mol} \mathrm{SO}_{2}(g)-\text { energy content of } 1 \mathrm{~mol} \mathrm{~S}(s) \text { and } 1 \mathrm{~mol} \mathrm{O}_{2}(g)
\end{aligned}
$$

This reaction gives off heat. Therefore, the energy of the product is less than that of the reactants, and $\Delta U$ is negative.

The release of heat that accompanies this reaction indicates that some of the chemical energy contained in the system has been converted to thermal energy. Furthermore, the thermal energy released by the system is absorbed by the surroundings. The transfer of energy from the system to the surroundings does not change the total energy of the universe. That is, the sum of the energy changes is zero:

$$
\Delta U_{\text {sys }}+\Delta U_{\text {surr }}=0
$$

where the subscripts "sys" and "surr" denote system and surroundings, respectively. Thus, if a system undergoes an energy change $\Delta U_{\text {sys }}$, the rest of the universe, or the surroundings, must undergo a change in energy that is equal in magnitude but opposite in sign:

$$
\Delta U_{\mathrm{sys}}=-\Delta U_{\text {surr }}
$$

Figure 5.4 The change in elevation that occurs when a person goes from the ground floor to the fourth floor in a building does not depend on the path taken.

Student Annotation: The units for heat and work are the same as those for energy: joules, kilojoules, or calories.

Student Annotation: Interestingly, although neither $q$ nor $w$ is a state function (each depends on the path between the initial and final states of the system), their sum, $\Delta U$, is always the same because $U$ is a state function.

Figure 5.5 (a) When heat is released by the system (to the surroundings), $q$ is negative. When work is done by the system (on the surroundings), $w$ is negative. (b) When heat is absorbed by the system (from the surroundings), $q$ is positive. When work is done on the system (by the surroundings), $w$ is positive.

Energy released in one place must be gained somewhere else. Furthermore, because energy can be changed from one form to another, the energy lost by one system can be gained by another system in a different form. For example, the energy released by burning coal in a power plant may ultimately turn up in our homes as electric energy, heat, light, and so on.

## Work and Heat

Recall from Section 5.1 that energy is defined as the capacity to do work or transfer heat. When a system releases or absorbs heat, its internal energy changes. Likewise, when a system does work on its surroundings, or when the surroundings do work on the system, the system's internal energy also changes. The overall change in the system's internal energy is given by

## Equation 5.3

$$
\Delta U=q+w
$$

where $q$ is heat (released or absorbed by the system) and $w$ is work (done on the system or done by the system). Note that it is possible for the heat and work components to cancel each other out and for there to be no change in the system's internal energy.

In chemistry, we are normally interested in the energy changes associated with the system rather than the surroundings. Therefore, unless otherwise indicated, $\Delta U$ will refer specifically to $\Delta U_{\text {sys }}$. The sign conventions for $q$ and $w$ are as follows: $q$ is positive for an endothermic process and negative for an exothermic process, and $w$ is positive for work done on the system by the surroundings and negative for work done by the system on the surroundings. Table 5.1 summarizes the sign conventions for $q$ and $w$.

The drawings in Figure 5.5 illustrate the logic behind the sign conventions for $q$ and $w$. If a system releases heat to the surroundings or does work on the surroundings [Figure 5.5(a)], we would expect its internal energy to decrease because they are energy-depleting processes. For this reason, both $q$ and $w$ are negative. Conversely, if heat is added to the system or if work is done on the system [Figure $5.5(\mathrm{~b})$ ], then the internal energy of the system increases. In this case, both $q$ and $w$ are positive.

Sample Problem 5.2 shows how to determine the overall change in the internal energy of a system.

## TABLE 5.1 $\quad$ Sign Conventions for Heat $(q)$ and Work (w)

## Process

Heat absorbed by the system (endothermic process)
Heat released by the system (exothermic process)
Work done on the system by the surroundings (for example, a volume decrease)
Work done by the system on the surroundings $\quad w$ is negative (for example, a volume increase)

(a)
(b)

## Sample Problem 5.2

Calculate the overall change in internal energy, $\Delta U$, (in joules) for a system that absorbs 188 J of heat and does 141 J of work on its surroundings.

Strategy Combine the two contributions to internal energy using Equation 5.3 and the sign conventions for $q$ and $w$.

Setup The system absorbs heat, so $q$ is positive. The system does work on the surroundings, so $w$ is negative.

## Solution

$$
\Delta U=q+w=188 \mathrm{~J}+(-141 \mathrm{~J})=47 \mathrm{~J}
$$

Practice Problem A Calculate the change in total internal energy for a system that releases $1.34 \times 10^{4} \mathrm{~kJ}$ of heat and does $2.98 \times 10^{4} \mathrm{~kJ}$ of work on the surroundings.

HPactice Problem B Calculate the magnitude of $q$ for a system that does $7.05 \times 10^{5} \mathrm{~kJ}$ of work on its surroundings and for which the change in total internal energy is $-9.55 \times 10^{3} \mathrm{~kJ}$. Indicate whether heat is absorbed or released by the system.

## Checkpoint 5.2 Introduction to Thermodynamics

5.2.1 Calculate the overall change in internal energy for a system that releases 43 J in heat in a process in which no work is done.
a) 43 J
b) $-2.3 \times 10^{-2} \mathrm{~J}$
c) 0 J
d) $2.3 \times 10^{-2} \mathrm{~J}$
e) -43 J
5.2.2 Calculate $w$, and determine whether work is done by the system or on the system when 928 kJ of heat is released and $\Delta U=-1.47$ $\times 10^{3} \mathrm{~kJ}$.
a) $w=-1.36 \times 10^{6} \mathrm{~kJ}$, done by the system
b) $w=1.36 \times 10^{6} \mathrm{~kJ}$, done on the system
c) $w=-5.4 \times 10^{2} \mathrm{~kJ}$, done by the system
d) $w=2.4 \times 10^{3} \mathrm{~kJ}$, done on the system
e) $w=-2.4 \times 10^{3} \mathrm{~kJ}$, done by the system
5.2.3 Which of the following is a closed system? (Select all that apply.)
a) Pot of boiling water on a stove
b) Pot of cold water on a countertop
c) Helium-filled Mylar balloon
d) Styrofoam cup full of hot coffee (without lid)
e) Glass of iced tea
5.2.4 Which of the following could be described as a state function? (Select all that apply.)
a) Dieter's weight
b) Calories burned by a person walking to the health club
c) Distance traveled by a person walking to the health club
d) Distance between two points on a map
e) Energy required to heat a given amount of water from $25^{\circ} \mathrm{C}$ to the boiling point.

### 5.3 Enthalpy

To calculate $\Delta U$, we must know the values and signs of both $q$ and $w$. As we will see in Section 5.4 , we determine $q$ by measuring temperature changes. To determine $w$, we need to know whether the reaction occurs under constant-volume or constant-pressure conditions.

## Reactions Carried Out at Constant Volume or at Constant Pressure

Imagine carrying out the decomposition of sodium azide $\left(\mathrm{NaN}_{3}\right)$ in two different experiments. In the first experiment, the reactant is placed in a metal cylinder with a fixed volume. When detonated, the $\mathrm{NaN}_{3}$ reacts, generating a large quantity of $\mathrm{N}_{2}$ gas inside the closed, fixed-volume container.

Student Annotation: The explosive decomposition of $\mathrm{NaN}_{3}$ is the reaction that inflates air bags in cars.

$$
2 \mathrm{NaN}_{3}(s) \longrightarrow 2 \mathrm{Na}(s)+3 \mathrm{~N}_{2}(g)
$$

Student Annotation: The concept of pressure will be examined in detail in Chapter 11. However, if you have ever put air in the tire of an automobile or a bicycle, you are familiar with the concept.

Student Annotation: Pressure-volume work and electrical work are two important types of work done by chemical reactions. Electrical work will be discussed in detail in Chapter 19.

The effect of this reaction will be an increase in the pressure inside the container, similar to what happens if you shake a bottle of soda vigorously prior to opening it.

Now imagine carrying out the same reaction in a metal cylinder with a movable piston. As this explosive decomposition proceeds, the piston in the metal cylinder will move. The gas produced in the reaction pushes the cylinder upward, thereby increasing the volume of the container and preventing any increase in pressure. This is a simple example of mechanical work done by a chemical reaction. Specifically, this type of work is known as pressure-volume, or $P V$, work. The amount of work done by such a process is given by

## Equation 5.4

$$
w=-P \Delta V
$$

where $P$ is the external, opposing pressure and $\Delta V$ is the change in the volume of the container as the result of the piston being pushed upward. In keeping with the sign conventions in Table 5.1, an increase in volume results in a negative value for $w$, whereas a decrease in volume results in a positive value for $w$. Figure 5.6 illustrates this reaction (a) being carried out at a constant volume, and (b) at a constant pressure.

When a chemical reaction is carried out at constant volume, then no $P V$ work can be done because $\Delta V=0$ in Equation 5.4. From Equation 5.3 it follows that

Equation 5.5

$$
\Delta U=q-P \Delta V
$$

and, because $P \Delta V=0$ at constant volume,
Equation 5.6

$$
q_{V}=\Delta U
$$

We add the subscript " $V$ " to indicate that this is a constant-volume process. This equality may seem strange at first. We said earlier that $q$ is not a state function. However, for a process carried out under constant-volume conditions, $q$ can have only one specific value, which is equal to $\Delta U$. In other words, while $q$ is not a state function, $q_{V}$ is one.

Figure 5.6 (a) The explosive decomposition of $\mathrm{NaN}_{3}$ at constant volume results in an increase in pressure inside the vessel. (b) The decomposition at constant pressure, in a vessel with a movable piston, results in an increase in volume. The resulting change in volume, $\Delta V$, can be used to calculate the work done by the system.

Constant-volume conditions are often inconvenient and sometimes impossible to achieve. Most reactions occur in open containers, under conditions of constant pressure (usually at whatever the atmospheric pressure happens to be where the experiments are conducted). In general, for a constant-pressure process, we write

$$
\begin{aligned}
\Delta U & =q+w \\
& =q_{P}-P \Delta V
\end{aligned}
$$

or

$$
q_{P}=\Delta U+P \Delta V
$$

Equation 5.7
where the subscript " $P$ " denotes constant pressure.

## Enthalpy and Enthalpy Changes

There is a thermodynamic function of a system called enthalpy ( $H$ ), which is defined as

$$
\begin{equation*}
H=U+P V \tag{Equation 5.8}
\end{equation*}
$$

where $U$ is the internal energy of the system and $P$ and $V$ are the pressure and volume of the system, respectively. Because $U$ and $P V$ have energy units, enthalpy also has energy units. Furthermore, $U, P$, and $V$ are all state functions-that is, the changes in $(U+P V)$ depend only on the initial and final states. It follows, therefore, that the change in $H$, or $\Delta H$, also depends only on the initial and final states. Thus, $H$ is a state function.

For any process, the change in enthalpy is given by

$$
\Delta H=\Delta U+\Delta(P V)
$$

Equation 5.9
If the pressure is held constant, then

$$
\begin{equation*}
\Delta H=\Delta U+P \Delta V \tag{Equation 5.10}
\end{equation*}
$$

If we solve Equation 5.10 for $\Delta U$,

$$
\Delta U=\Delta H-P \Delta V
$$

Then, substituting the result for $\Delta U$ into Equation 5.7, we obtain

$$
q_{P}=(\Delta H-P \Delta V)+P \Delta V
$$

The $P \Delta V$ terms cancel, and for a constant-pressure process, the heat exchanged between the system and the surroundings is equal to the enthalpy change:

$$
\begin{equation*}
q_{P}=\Delta H \tag{Equation 5.11}
\end{equation*}
$$

Again, $q$ is not a state function, but $q_{P}$ is; that is, the heat change at constant pressure can have only one specific value and is equal to $\Delta H$.

We now have two quantities- $\Delta U$ and $\Delta H$-that can be associated with a reaction. If the reaction occurs under constant-volume conditions, then the heat change, $q_{V}$, is equal to $\Delta U$. If the reaction is carried out at constant pressure, on the other hand, the heat change, $q_{P}$, is equal to $\Delta H$.

Because most laboratory reactions are constant-pressure processes, the heat exchanged between the system and surroundings is equal to the change in enthalpy for the process. For any reaction, we define the change in enthalpy, called the enthalpy of reaction $(\Delta H)$, as the difference between the enthalpies of the products and the enthalpies of the reactants:

$$
\begin{equation*}
\Delta H=H(\text { products })-H(\text { reactants }) \tag{Equation 5.12}
\end{equation*}
$$

The enthalpy of reaction can be positive or negative, depending on the process. For an endothermic process (where heat is absorbed by the system from the surroundings), $\Delta H$ is positive (i.e., $\Delta H>0$ ). For an exothermic process (where heat is released by the system to the surroundings), $\Delta H$ is negative (i.e., $\Delta H<0$ ).

Student Annotation: The SI unit of pressure is the pascal ( Pa ), which in SI base units is $1 \mathrm{~kg} /\left(\mathrm{m} \cdot \mathrm{s}^{2}\right)$. Volume in SI base units is cubic meters $\left(m^{3}\right)$. Therefore, multiplying units of pressure by units of volume gives $\left(1 \mathrm{~kg} / \mathrm{m} \cdot \mathrm{s}^{2}\right)$ $\times \mathrm{m}^{3}=1 \mathrm{~kg} \cdot \mathrm{~m}^{2} / \mathrm{s}^{2}$, which is the definition of the joule (J). Thus, $P \Delta V$ has units of energy.

Student Annotation: The enthalpy of reaction is often symbolized by $\Delta H_{x x}$. The subscript can be changed to denote a specific type of reaction or physical process: $\Delta H_{\text {vap }}$ can be used for the enthalpy of vaporization, for example.

Student Annotation: Although, strictly speaking, it is unnecessary to include the sign of a positive number, we will include the sign of all positive $\Delta H$ values to emphasize the thermochemical sign convention.

Student Annotation: When you specify that a particular amount of heat is released, it is not necessary to include a negative sign.

Figure 5.7 (a) Melting 1 mole of ice at $0^{\circ} \mathrm{C}$, an endothermic process, results in an enthalpy increase of $6.01 \mathrm{~kJ}(\Delta H=+6.01 \mathrm{~kJ} / \mathrm{mol})$. (b) The burning of 1 mole of methane in oxygen gas, an exothermic process, results in an enthalpy decrease in the system of $890.4 \mathrm{~kJ}(\Delta H=-890.4 \mathrm{~kJ} / \mathrm{mol})$. The enthalpy diagrams of these two processes are not shown to the same scale.

We will now apply the idea of enthalpy changes to two common processes, the first involving a physical change and the second involving a chemical change.

## Thermochemical Equations

Under ordinary atmospheric conditions at sea level, ice melts to form liquid water when exposed to temperatures above $0^{\circ} \mathrm{C}$. Measurements show that for every mole of ice converted to liquid water under these conditions, 6.01 kJ of heat energy is absorbed by the system (the ice). Because the pressure is constant, the heat change is equal to the enthalpy change, $\Delta H$. This is an endothermic process $(\Delta H>0)$, because heat is absorbed by the ice from its surroundings (Figure 5.7a). The equation for this physical change is

$$
\mathrm{H}_{2} \mathrm{O}(s) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l) \quad \Delta H=+6.01 \mathrm{~kJ} / \mathrm{mol}
$$

The "per mole" in the unit for $\Delta H$ means that this is the enthalpy change per mole of the reaction (or process) as it is written - that is, when 1 mole of ice is converted to 1 mole of liquid water. Now consider the combustion of methane $\left(\mathrm{CH}_{4}\right)$, the principal component of natural gas:

$$
\mathrm{CH}_{4}(g)+2 \mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(l) \quad \Delta H=-890.4 \mathrm{~kJ} / \mathrm{mol}
$$

From experience we know that burning natural gas releases heat to the surroundings, so it is an exothermic process. Under constant-pressure conditions, this heat change is equal to the enthalpy change and $\Delta H$ must have a negative sign [Figure 5.7(b)]. Again, the "per mole" in the units for $\Delta H$ means that when 1 mole of $\mathrm{CH}_{4}$ reacts with 2 moles of $\mathrm{O}_{2}$ to yield 1 mole of $\mathrm{CO}_{2}$ and 2 moles of liquid $\mathrm{H}_{2} \mathrm{O}, 890.4 \mathrm{~kJ}$ of heat is released to the surroundings.

It is important to keep in mind that the $\Delta H$ value in $\mathrm{kJ} / \mathrm{mol}$ does not mean per mole of a particular reactant or product. It refers to all the species in a reaction in the molar amounts specified by the coefficients in the balanced equation. Thus, for the combustion of methane, the $\Delta H$ value of $-890.4 \mathrm{~kJ} / \mathrm{mol}$ can be expressed in any of the following ways:

$$
\frac{-890.4 \mathrm{~kJ}}{1 \mathrm{~mol} \mathrm{CH}_{4}} \quad \frac{-890.4 \mathrm{~kJ}}{2 \mathrm{~mol} \mathrm{O}_{2}} \quad \frac{-890.4 \mathrm{~kJ}}{1 \mathrm{~mol} \mathrm{CO}_{2}} \quad \frac{-890.4 \mathrm{~kJ}}{2 \mathrm{~mol} \mathrm{H}_{2} \mathrm{O}}
$$

Although the importance of expressing $\Delta H$ in units of $\mathrm{kJ} / \mathrm{mol}$ (rather than just kilojoules) will become apparent when we study thermodynamics in greater detail [ Chapter 18], you should learn and become comfortable with this convention now.

The equations for the melting of ice and the combustion of methane are examples of thermochemical equations, which are chemical equations that show the enthalpy changes as well as the mass relationships. It is essential to specify a balanced chemical equation when quoting the enthalpy change of a reaction. The following guidelines are helpful in interpreting, writing, and manipulating thermochemical equations:

1. When writing thermochemical equations, we must always specify the physical states of all reactants and products, because they help determine the actual enthalpy changes. In the

equation for the combustion of methane, for example, changing the liquid water product to water vapor changes the value of $\Delta H$ :

$$
\mathrm{CH}_{4}(g)+2 \mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(g) \quad \Delta H=-802.4 \mathrm{~kJ} / \mathrm{mol}
$$

The enthalpy change is -802.4 kJ rather than -890.4 kJ because 88.0 kJ is needed to convert 2 moles of liquid water to 2 moles of water vapor; that is,

$$
2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(\mathrm{~g}) \quad \Delta H=+88.0 \mathrm{~kJ} / \mathrm{mol}
$$

2. If we multiply both sides of a thermochemical equation by a factor $n$, then $\Delta H$ must also change by the same factor. Thus, for the melting of ice, if $n=2$, we have

$$
2 \mathrm{H}_{2} \mathrm{O}(s) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l) \quad \Delta H=2(6.01 \mathrm{~kJ} / \mathrm{mol})=+12.02 \mathrm{~kJ} / \mathrm{mol}
$$

3. When we reverse a chemical equation, we change the roles of reactants and products. Consequently, the magnitude of $\Delta H$ for the equation remains the same, but its sign changes. For example, if a reaction consumes thermal energy from its surroundings (i.e., if it is endothermic), then the reverse reaction must release thermal energy back to its surroundings (i.e., it must be exothermic) and the enthalpy change expression must also change its sign. Thus, reversing the melting of ice and the combustion of methane, the thermochemical equations become

$$
\begin{aligned}
\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}_{2} \mathrm{O}(s) & \Delta H & =-6.01 \mathrm{~kJ} / \mathrm{mol} \\
\mathrm{CO}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{CH}_{4}(g)+2 \mathrm{O}_{2}(\mathrm{~g}) & \Delta H & =+890.4 \mathrm{~kJ} / \mathrm{mol}
\end{aligned}
$$

What was an endothermic process becomes an exothermic process when reversed, and vice versa.

Sample Problem 5.3 illustrates the use of a thermochemical equation to relate the mass of a product to the energy consumed in the reaction.

## Sample Problem 5.3

Given the thermochemical equation for photosynthesis,

$$
6 \mathrm{H}_{2} \mathrm{O}(l)+6 \mathrm{CO}_{2}(\mathrm{~g}) \longrightarrow \mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}(s)+6 \mathrm{O}_{2}(\mathrm{~g}) \quad \Delta H=+2803 \mathrm{~kJ} / \mathrm{mol}
$$

calculate the solar energy required to produce 75.0 g of $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}$.
Strategy The thermochemical equation shows that for every mole of $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}$ produced, 2803 kJ is absorbed. We need to find out how much energy is absorbed for the production of 75.0 g of $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}$. We must first find out how many moles there are in 75.0 g of $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}$.

Setup The molar mass of $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}$ is $180.2 \mathrm{~g} / \mathrm{mol}$, so 75.0 g of $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}$ is

$$
75.0 \mathrm{~g} \times \frac{1 \mathrm{~mol} \mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}}{180.2 \mathrm{~g}}=0.416 \mathrm{~mol}
$$

We will multiply the thermochemical equation, including the enthalpy change, by 0.416 , in order to write the equation in terms of the appropriate amount of $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}$.

## Solution

$$
(0.416 \mathrm{~mol})\left[6 \mathrm{H}_{2} \mathrm{O}(l)+6 \mathrm{CO}_{2}(g) \longrightarrow \mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}(s)+6 \mathrm{O}_{2}(g)\right]
$$

and $(0.416 \mathrm{~mol})(\Delta H)=(0.416 \mathrm{~mol})(2803 \mathrm{~kJ} / \mathrm{mol})$ gives

$$
2.50 \mathrm{H}_{2} \mathrm{O}(l)+2.50 \mathrm{CO}_{2}(g) \longrightarrow 0.416 \mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}(s)+2.50 \mathrm{O}_{2}(g) \quad \Delta H=+1.17 \times 10^{3} \mathrm{~kJ}
$$

Therefore, $1.17 \times 10^{3} \mathrm{~kJ}$ of energy in the form of sunlight is consumed in the production of 75.0 g of $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}$. Note that the "per mole" units in $\Delta H$ are canceled when we multiply the thermochemical equation by the number of moles of $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}$.

Practice Problem A Calculate the solar energy required to produce 5255 g of $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}$.
HPractice Problem B Calculate the mass (in grams) of $\mathrm{O}_{2}$ that is produced by photosynthesis when $2.49 \times 10^{4} \mathrm{~kJ}$ of solar energy is consumed.

Student Annotation: Remember that the "per mole" in this context refers to per mole of reaction-not, in this case, per mole of water.

Student Annotation: Although heat capacity is typically given for an object rather than for a substance-the "object" may be a given quantity of a particular substance.

## Checkpoint 5.3 Enthalpy

5.3.1 Given the thermochemical equation: $\mathrm{H}_{2}(g)$ $+\mathrm{Br}_{2}(l) \longrightarrow 2 \mathrm{HBr}(g), \Delta H=-72.4 \mathrm{~kJ} /$ mol, calculate the amount of heat released when a kilogram of $\mathrm{Br}_{2}(l)$ is consumed in this reaction.
a) $7.24 \times 10^{4} \mathrm{~kJ}$
b) 453 kJ
c) 906 kJ
d) 227 kJ
e) 724 kJ
5.3.2 Given the thermochemical equation: $2 \mathrm{Cu}_{2} \mathrm{O}(s) \longrightarrow 4 \mathrm{Cu}(s)+\mathrm{O}_{2}(g), \Delta H=$ $+333.8 \mathrm{~kJ} / \mathrm{mol}$, calculate the mass of copper produced when $1.47 \times 10^{4} \mathrm{~kJ}$ is consumed in this reaction.
a) 11.2 kg
b) 176 kg
c) 44.0 kg
d) 334 kg
e) 782 kg

### 5.4 Calorimetry

In the study of thermochemistry, heat changes that accompany physical and chemical processes are measured with a calorimeter, a closed container designed specifically for this purpose. We begin our discussion of calorimetry, the measurement of heat changes, by defining two important terms: specific heat and heat capacity.

## Specific Heat and Heat Capacity

The specific heat $(s)$ of a substance is the amount of heat required to raise the temperature of 1 g of the substance by $1^{\circ} \mathrm{C}$. The heat capacity $(C)$ is the amount of heat required to raise the temperature of an object by $1^{\circ} \mathrm{C}$. We can use the specific heat of a substance to determine the heat capacity of a specified quantity of that substance. For example, we can use the specific heat of water, $4.184 \mathrm{~J} /\left(\mathrm{g} \cdot{ }^{\circ} \mathrm{C}\right)$, to determine the heat capacity of a kilogram of water:

$$
\text { heat capacity of } 1 \mathrm{~kg} \text { of water }=\frac{4.184 \mathrm{~J}}{1 \mathrm{~g} \cdot{ }^{\circ} \mathrm{C}} \times 1000 \mathrm{~g}=4184 \quad \text { or } 4.184 \times 10^{3} \mathrm{~J} /{ }^{\circ} \mathrm{C}
$$

Note that specific heat has the units $\mathrm{J} /\left(\mathrm{g} \cdot{ }^{\circ} \mathrm{C}\right)$ and heat capacity has the units $\mathrm{J} /{ }^{\circ} \mathrm{C}$. Table 5.2 shows the specific heat values of some common substances. If we know the specific heat and the amount of a substance, then the change in the sample's temperature $(\Delta T)$ will tell us the amount of heat $(q)$ that has been absorbed or released in a particular process. One equation for calculating the heat associated with a temperature change is given by

## Equation 5.13

$$
q=m s \Delta T
$$

where $m$ is the mass of the substance undergoing the temperature change, $s$ is the specific heat, and $\Delta T$ is the temperature change: $\Delta T=T_{\text {final }}-T_{\text {initial }}$. Another equation for calculating the heat associated with a temperature change is given by

## TABLE 5.2 Specific Heat Values of Some Common Substances

## Substance

2.46

$$
q=C \Delta T
$$

Equation 5.14
where $C$ is the heat capacity and $\Delta T$ is the temperature change. The sign convention for $q$ is the same as that for an enthalpy change: $q$ is positive for endothermic processes and negative for exothermic processes.

Sample Problem 5.4 shows how to use the specific heat of a substance to calculate the amount of heat needed to raise the temperature of the substance by a particular amount.

## Sample Problem 5.4

Calculate the amount of heat (in kJ ) required to heat 255 g of water from $25.2^{\circ} \mathrm{C}$ to $90.5^{\circ} \mathrm{C}$.
Strategy Use Equation $5.13(q=m s \Delta T)$ to calculate $q$.
Setup $m=255 \mathrm{~g}, s=4.184 \mathrm{~J} / \mathrm{g} \cdot{ }^{\circ} \mathrm{C}$, and $\Delta T=90.5^{\circ} \mathrm{C}-25.2^{\circ} \mathrm{C}=65.3^{\circ} \mathrm{C}$.

## Solution

$$
q=\frac{4.184 \mathrm{~J}}{\mathrm{~g} \cdot{ }^{\circ} \mathrm{C}} \times 255 \mathrm{~g} \times 65.3^{\circ} \mathrm{C}=6.97 \times 10^{4} \mathrm{~J} \quad \text { or } \quad 69.7 \mathrm{~kJ}
$$

Practice Problem A Calculate the amount of heat (in kJ ) required to heat 1.01 kg of water from $0.05^{\circ} \mathrm{C}$ to $35.81^{\circ} \mathrm{C}$.

GPractice Problem B What will be the final temperature of a $514-\mathrm{g}$ sample of water, initially at $10.0^{\circ} \mathrm{C}$, after 90.8 kJ have been added to it?

## Constant-Pressure Calorimetry

A crude constant-pressure calorimeter can be constructed from two Styrofoam coffee cups, as shown in Figure 5.8. This device, called a coffee-cup calorimeter, can be used to measure the heat exchanged between the system and surroundings for a variety of reactions, such as acid-base neutralization, heat of solution, and heat of dilution. Because the pressure is constant, the heat change for the process $(q)$ is equal to the enthalpy change $(\Delta H)$. In such experiments, we consider the reactants and products to be the system, and the water in the calorimeter to be the surroundings. We neglect the small heat capacity of the Styrofoam cups in our calculations. In the case of an exothermic reaction, the heat released by the system is absorbed by the water (surroundings), thereby increasing its temperature. Knowing the mass of the water in the calorimeter, the specific heat of water, and the change in temperature, we can calculate $q_{P}$ of the system using the equation

$$
q_{\mathrm{sys}}=-m s \Delta T
$$

Equation 5.15
Note that the minus sign makes $q_{\text {sys }}$ a negative number if $\Delta T$ is a positive number (i.e., if the temperature goes up). This is in keeping with the sign conventions listed in Table 5.1. A negative $\Delta H$ or a negative $q$ indicates an exothermic process, whereas a positive $\Delta H$ or a positive $q$ indicates an endothermic process. Table 5.3 lists some of the reactions that can be studied with a constant-pressure calorimeter. Figure 5.9 shows how constant-pressure calorimetry can be used to determine $\Delta H$ for a reaction.

## TABLE 5.3

Heats of Some Typical Reactions and Physical Processes Measured at Constant Pressure

| Type of Reaction | Example | $\Delta \boldsymbol{H}(\mathbf{k J} / \mathrm{mol})$ |
| :--- | :--- | :---: |
| Heat of neutralization | $\mathrm{HCl}(a q)+\mathrm{NaOH}(a q) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{NaCl}(a q)$ | -56.2 |
| Heat of ionization | $\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}^{+}(a q)+\mathrm{OH}^{-}(a q)$ | +56.2 |
| Heat of fusion | $\mathrm{H}_{2} \mathrm{O}(s) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)$ | +6.01 |
| Heat of vaporization | $\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}_{2} \mathrm{O}(g)$ | $+44.0^{*}$ |
| *Measured at $25^{\circ} \mathrm{C}$. At $100^{\circ} \mathrm{C}$, the value is $+40.79 \mathrm{kJ}$. |  |  |

Student Annotation: Note that $C=m s$. Although specific heat is a property of substances, and heat capacity is a property of objects, we can define a specified quantity of a substance as an "object" and determine its heat capacity using its mass and its specific heat.

Think About It Look carefully at the cancellation of units and make sure that the number of kilojoules is smaller than the number of joules. It is a common error to multiply by 1000 instead of dividing in conversions of this kind.

Figure 5.8 A constant-pressure coffee-cup calorimeter made of two Styrofoam cups. The nested cups help to insulate the reaction mixture from the surroundings. Two solutions of known volume containing the reactants at the same temperature are carefully mixed in the calorimeter. The heat produced or absorbed by the reaction can be determined by measuring the temperature change.

Figure 5.9

## Determination of $\Delta H_{r x n}^{\circ}$ by Constant-Pressure Calorimetry

One at a time, we pour the solutions into the calorimeter.

We start with 50.0 mL each of 1.00 M HCl and 1.00 M NaOH . Both solutions are at room temperature, which in this example is $25.0^{\circ} \mathrm{C}$. The net ionic equation that represents the reaction is

$$
\mathrm{H}^{+}(a q)+\mathrm{OH}^{-}(a q) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)
$$

We have $0.0500 \mathrm{~L} \times 1.00 \mathrm{M}=0.0500 \mathrm{~mol}$ of each reactant.

When both solutions have been added, we cap the calorimeter to prevent loss of energy to the environment and use the stirrer to ensure that the solutions are mixed thoroughly.

As the reaction proceeds, the temperature of the water increases as it absorbs the energy given off by the reaction. We record the maximum water temperature as $31.7^{\circ} \mathrm{C}$.

Assuming the density and specific heat of the solution to be the same as those of water $\left(1 \mathrm{~g} / \mathrm{mL}, 4.184 \mathrm{~J} / \mathrm{g} \cdot{ }^{\circ} \mathrm{C}\right)$, we calculate $q_{\text {soln }}$ as follows:

$$
\begin{aligned}
q_{\text {soln }} & =\text { specific heat of water } \times \text { mass of water } \times \text { temperature change } \\
& =\frac{4.184 \mathrm{~J}}{1 \mathrm{~g} \cdot{ }^{\circ} \mathrm{C}} \times 100.0 \mathrm{~g} \times(31.7-25.0)^{\circ} \mathrm{C}=2803 \mathrm{~J}
\end{aligned}
$$

Assuming that the heat capacity of the calorimeter is negligible, we know that $q_{\mathrm{soln}}=-q_{\mathrm{rxn}}$, and we can write

$$
q_{\mathrm{rxn}}=-2803 \mathrm{~J}
$$

This is the heat of reaction when $0.0500 \mathrm{~mol} \mathrm{H}^{+}$reacts with $0.0500 \mathrm{~mol} \mathrm{OH}^{-}$. To determine $\Delta H_{\mathrm{rxn}}$, we divide $q_{\mathrm{rxn}}$ by the number of moles. (These reactants are present in stoichiometric amounts. If there were a limiting reactant, we would divide by the number of moles of limiting reactant.)

$$
\Delta H_{\mathrm{rxn}}=\frac{-2803 \mathrm{~J}}{0.0500 \mathrm{~mol}}=-5.61 \times 10^{4} \mathrm{~J} / \mathrm{mol} \text { or }-56.1 \mathrm{~kJ} / \mathrm{mol}
$$

This result is very close to the number we get using Equation 5.12 and the data in Appendix 2.

## What's the point?

Constant-pressure calorimetry can be used to determine $\Delta H_{\mathrm{rxn}}$ — the heat of reaction for the reactant quantities specified by the balanced equation. However, when we carry out calorimetry experiments in the laboratory, we typically use much smaller quantities of reactants than those represented in a chemical equation. By measuring the temperature change of the surroundings (a known quantity of water in which the reactants are dissolved), we can determine $q_{\mathrm{rxn}}$ for the reactant quantities in the experiment. We can then divide $q_{\mathrm{rxn}}$ by the number of moles of reactant to determine $\Delta H_{\mathrm{rxn}}$.

Student Annotation: The temperature of the water stops changing when it and the temperature of the lead pellet are equal. Therefore, the final temperature of the pellet is also $23.17^{\circ} \mathrm{C}$.

Media Player/MPEG Animation: Figure 5.10, Determination of Specific Heat by ConstantPressure Calorimetry, pp. 190-191.

Think About It The units cancel properly to give appropriate units for heat capacity. Moreover, $\Delta T_{\text {pellet }}$ is a negative number because the temperature of the pellet decreases.

Constant-pressure calorimetry can also be used to determine the heat capacity of an object or the specific heat of a substance. Suppose, for example, that we have a lead pellet with a mass of 26.47 g originally at $89.98^{\circ} \mathrm{C}$. We drop the pellet into a constant-pressure calorimeter containing 100.0 g of water at $22.50^{\circ} \mathrm{C}$. The temperature of the water increases to $23.17^{\circ} \mathrm{C}$. In this case, we consider the pellet to be the system and the water to be the surroundings. Because it is the temperature of the surroundings that we measure and because $q_{\mathrm{sys}}=-q_{\mathrm{surr}}$, we can rewrite Equation 5.15 as

$$
q_{\mathrm{surr}}=m s \Delta T
$$

Thus, $q_{\text {water }}$ of the water is

$$
q_{\text {water }}=\frac{4.184 \mathrm{~J}}{\mathrm{~g} \cdot{ }^{\circ} \mathrm{C}} \times 100.0 \mathrm{~g} \times\left(23.17^{\circ} \mathrm{C}-22.50^{\circ} \mathrm{C}\right)=280 \mathrm{~J}
$$

and $q_{\text {pellet }}$ is -280 J . The negative sign indicates that heat is released by the pellet. Dividing $q_{\text {pellet }}$ by the temperature change $(\Delta T)$ gives us the heat capacity of the pellet ( $C_{\text {pellet }}$ ).

$$
C_{\text {pellet }}=\frac{-280 \mathrm{~J}}{23.17^{\circ} \mathrm{C}-89.95^{\circ} \mathrm{C}}=4.19 \mathrm{~J} /{ }^{\circ} \mathrm{C}
$$

Furthermore, because we know the mass of the pellet, we can determine the specific heat of lead $\left(s_{\text {lead }}\right)$ :

$$
s_{\mathrm{Pb}}=\frac{C_{\text {pellet }}}{m_{\text {pellet }}}=\frac{4.19 \mathrm{~J} /{ }^{\circ} \mathrm{C}}{26.47 \mathrm{~g}}=0.158 \mathrm{~J} / \mathrm{g} \cdot{ }^{\circ} \mathrm{C} \quad \text { or } \quad 0.16 \mathrm{~J} / \mathrm{g} \cdot{ }^{\circ} \mathrm{C}
$$

Sample Problem 5.5 shows how to use constant-pressure calorimetry to calculate the heat capacity ( $C$ ) of an object. Figure 5.10 (pp. 190-191) illustrates the process of determining the specific heat of a metal using constant-pressure calorimetry.

## Sample Problem 5.5

A metal pellet with a mass of 100.0 g , originally at $88.4^{\circ} \mathrm{C}$, is dropped into 125 g of water originally at $25.1^{\circ} \mathrm{C}$. The final temperature of both the pellet and the water is $31.3^{\circ} \mathrm{C}$. Calculate the heat capacity $C$ (in $\mathrm{J} /{ }^{\circ} \mathrm{C}$ ) of the pellet.

Strategy Use Equation $5.13(q=m s \Delta T)$ to determine the heat absorbed by the water; then use Equation $5.14(q=C \Delta T)$ to determine the heat capacity of the metal pellet.

Setup $m_{\text {water }}=125 \mathrm{~g}, s_{\text {water }}=4.184 \mathrm{~J} / \mathrm{g} \cdot{ }^{\circ} \mathrm{C}$, and $\Delta T_{\text {water }}=31.3^{\circ} \mathrm{C}-25.1^{\circ} \mathrm{C}=6.2^{\circ} \mathrm{C}$. The heat absorbed by the water must be released by the pellet: $q_{\text {water }}=-q_{\text {pellet }} \cdot m_{\text {pellet }}=100.0 \mathrm{~g}$ and $\Delta T_{\text {pellet }}=31.3^{\circ} \mathrm{C}-88.4^{\circ} \mathrm{C}=-57.1^{\circ} \mathrm{C}$.

Solution From Equation 5.13, we have

$$
q_{\text {water }}=\frac{4.184 \mathrm{~J}}{\mathrm{~g} \cdot{ }^{\circ} \mathrm{C}} \times 125 \mathrm{~g} \times 6.2^{\circ} \mathrm{C}=3242.6 \mathrm{~J}
$$

Thus,

$$
q_{\text {pellet }}=-3242.6 \mathrm{~J}
$$

From Equation 5.14, we have

$$
-3242.6 \mathrm{~J}=C_{\text {pellet }} \times\left(-57.1^{\circ} \mathrm{C}\right)
$$

Thus,

$$
C_{\text {pellet }}=57 \mathrm{~J} /{ }^{\circ} \mathrm{C}
$$

Practice Problem A What would the final temperature be if the pellet from Sample Problem 5.5, initially at $95^{\circ} \mathrm{C}$, were dropped into a $218-\mathrm{g}$ sample of water, initially at $23.8^{\circ} \mathrm{C}$ ?

HPractice Problem B What mass of water could be warmed from $23.8^{\circ} \mathrm{C}$ to $46.3^{\circ} \mathrm{C}$ by the pellet in Sample Problem 5.5 initially at $116^{\circ} \mathrm{C}$ ?

## Bringing Chemistry to Life

## Heat Capacity and Hypothermia

Like a warm metal pellet, the human body loses heat when it is immersed in cold water. Because we are warm-blooded animals, our body temperature is maintained at around $37^{\circ} \mathrm{C}$. The human body is about 70 percent water by mass and water has a very high specific heat, so fluctuations in body temperature normally are very small. An air temperature of $25^{\circ} \mathrm{C}$ (often described as "room temperature") feels warm to us because air has a small specific heat (about $1 \mathrm{~J} / \mathrm{g} \cdot{ }^{\circ} \mathrm{C}$ ) and a low density. Consequently, very little heat is lost from the body to the surrounding air. The situation is drastically different if the body is immersed in water at $25^{\circ} \mathrm{C}$. The heat lost by the human body when immersed in water can be thousands of times greater than that lost to air of the same temperature.

Hypothermia occurs when the body's mechanisms for producing and conserving heat are exceeded by loss of heat to the surroundings. Although hypothermia is dangerous and potentially deadly, there are certain circumstances under which it may actually be beneficial. A colder body temperature slows down all the normal biochemical processes, reducing the brain's need for oxygen, and prolonging the time period during which resuscitation efforts can be effective. Occasionally we hear about a seemingly miraculous recovery of a near-drowning victim who was submerged for a long period of time. These victims are usually small children who were submerged in icy water. The small size and, therefore, small heat capacity of a child allows for rapid cooling and may afford some protection from hypoxia-the lack of oxygen that causes death in drowning victims.

The lowest body temperature ever recorded for a human (who survived) was $13.7^{\circ} \mathrm{C}$. Anna Bagenholm, 29, spent over an hour submerged after falling headfirst through the ice on a frozen river. Although she was clinically dead when she was pulled from the river, she has made a full recovery. There's a saying among doctors who treat hypothermia patients: "No one is dead until they're warm and dead."

Student Annotation: Hypothermia routinely is induced in patients undergoing open heart surgery, drastically reducing the body's need for oxygen. Under these conditions, the heart can be stopped for the duration of the surgery.

Figure 5.10

## Determination of Specific Heat by Constant-Pressure Calorimetry

We add metal shot $\left(125.0 \mathrm{~g}\right.$ at $\left.100.0^{\circ} \mathrm{C}\right)$ to the water, and we cap the calorimeter to prevent loss of energy to the environment.

We place $100.0 \mathrm{~mL}(100.0 \mathrm{~g})$ of water in the calorimeter. The temperature of this water is $25.0^{\circ} \mathrm{C}$.

We place 125.0 g of metal shot in a test tube and immerse it in boiling water long enough to heat all of the metal to the boiling point of water $\left(100.0^{\circ} \mathrm{C}\right)$.

When the temperature of the metal shot and the water are equal, the temperature of the water has reached a maximum value. We record this temperature as $34.1^{\circ} \mathrm{C}$.

We know that $q_{\text {water }}=-q_{\text {metal }}$.
Substituting in the information given we write:
$q_{\text {water }}=$ specific heat of water $\times$ mass of water $\times$ temperature change

$$
=\frac{4.184 \mathrm{~J}}{1 \mathrm{~g} \cdot{ }^{\circ} \mathrm{C}} \times 100.0 \mathrm{~g} \times(34.1-25.0)^{\circ} \mathrm{C}=3807 \mathrm{~J}
$$

$q_{\text {metal }}=$ specific heat of metal $\times$ mass of metal $\times$ temperature change

$$
=x \times 125.0 \mathrm{~g} \times(34.1-100.0)^{\circ} \mathrm{C}=-8238 x \mathrm{~g} \cdot{ }^{\circ} \mathrm{C}
$$

and

$$
\begin{gathered}
3807 \mathrm{~J}=-(-8238 x) \mathrm{g} \cdot{ }^{\circ} \mathrm{C} \\
x=\frac{3807 \mathrm{~J}}{8238 \mathrm{~g} \cdot{ }^{\circ} \mathrm{C}}=0.46 \mathrm{~J} / \mathrm{g} \cdot{ }^{\circ} \mathrm{C}
\end{gathered}
$$

The specific heat of the metal is therefore $0.46 \mathrm{~J} / \mathrm{g} \cdot{ }^{\circ} \mathrm{C}$.

As energy is transferred from the metal shot to the water, the temperature of the water increases and the temperature of the metal shot decreases. We use the stirrer to ensure thorough mixing. The thermometer measures the temperature of the water.

## What's the point?

We can determine the specific heat of a metal by combining a known mass of the metal at a known temperature with a known mass of water at a known temperature. Assuming the calorimeter has a negligible heat capacity, the amount of energy lost by the hotter metal is equal to the amount of energy gained by the cooler water.

# What If the Heat Capacity of the Calorimeter Isn't Negligible? 

Although we usually assume that no heat is absorbed by the Styrofoam cups we use in the laboratory for constant-pressure calorimetry, in reality, the calorimeter generally does absorb a small portion of the heat produced by a chemical reaction. We can determine the heat capacity of a coffee-cup calorimeter by combining reactant solutions with precisely known concentrations and masses. Once we have determined the heat capacity, we can correct for the heat absorbed by the calorimeter when we carry out other experiments.

Consider an experiment in which we combine 50.0 mL of $0.250 \mathrm{MHCl}(\mathrm{aq})$ with 50.0 mL of 0.250 M NaOH . The calorimeter and both solutions are initially at $23.50^{\circ} \mathrm{C}$, and the density and specific heat of the combined solution are the same as that of water ( $1.000 \mathrm{~g} / \mathrm{mL}$ and $4.184 \mathrm{~J} / \mathrm{g} \cdot{ }^{\circ} \mathrm{C}$, respectively). We can determine the amount of heat the reaction will generate using moles of reactants and the heat of neutralization value from Table 5.3. We have $0.0500 \mathrm{~L} \times 0.250 \mathrm{M}=0.0125$ mole of each reactant. According to Table 5.3, the heat of neutralization is $-56.2 \mathrm{~kJ} / \mathrm{mol}$. Thus, we expect the enthalpy change of the system to be $0.0125 \mathrm{~mol} \times$ $(-56.2 \mathrm{~kJ} / \mathrm{mol})=-0.703 \mathrm{~kJ}$. Converting this to joules and using Equation 5.15, we calculate the temperature change we expect from the combination of these reactants.

$$
\begin{gathered}
q_{\mathrm{sys}}=-703 \mathrm{~J}=-100.0 \mathrm{~g} \times 4.184 \mathrm{~J} / \mathrm{g} \cdot{ }^{\circ} \mathrm{C} \times \Delta T \\
\Delta T=\frac{-703 \mathrm{~J}}{(-100.0 \mathrm{~g})\left(4.184 \mathrm{~J} / \mathrm{g} \cdot{ }^{\circ} \mathrm{C}\right)}=1.68^{\circ} \mathrm{C}
\end{gathered}
$$

Thus, we expect the temperature to increase by $1.68^{\circ} \mathrm{C}$. However, the measured final temperature is $25.09^{\circ} \mathrm{C}$, an increase of only $1.59^{\circ} \mathrm{C}$. The water temperature increased by less than expected because the calorimeter absorbed part of the heat produced by the neutralization reaction. We can determine how much heat the calorimeter absorbed by using Equation 5.15 again. This time, we use the measured temperature change to calculate the amount of heat absorbed by the water.

$$
q_{\text {surr }}=100.0 \mathrm{~g} \times 4.184 \mathrm{~J} / \mathrm{g} \cdot{ }^{\circ} \mathrm{C} \times 1.59^{\circ} \mathrm{C}=665 \mathrm{~J}
$$

We know that the reaction produced 703 J but the water absorbed only 665 J . The remaining energy, $703-665=38 \mathrm{~J}$, is $q_{\text {calorimeter }}$, the heat absorbed by the calorimeter itself. We use Equation 5.14 to calculate the heat capacity of the calorimeter.

$$
\begin{gathered}
38 \mathrm{~J}=C_{\text {calorimeter }} \times 1.59^{\circ} \mathrm{C} \\
C_{\text {calorimeter }}=23.9 \mathrm{~J} /{ }^{\circ} \mathrm{C}
\end{gathered}
$$

Sample Problem 5.6 shows how to take into account the heat capacity of a calorimeter.

## Sample Problem 5.6

A $12.1-\mathrm{g}$ piece of aluminum at $81.7^{\circ} \mathrm{C}$ is added to a sample of water at $23.4^{\circ} \mathrm{C}$ in a constantpressure calorimeter. If the final temperature of the water is $24.9^{\circ} \mathrm{C}$, and the heat capacity of the calorimeter is $19.8 \mathrm{~J} /{ }^{\circ} \mathrm{C}$, calculate the mass of the water in the calorimeter.

Strategy The first law of thermodynamics dictates that the energy given off by a system must be absorbed by the surroundings. In this case, the surroundings consist of the water and the calorimeter, both of which absorb the heat given off by the warm aluminum, which we will call the system. We should first calculate the amount of heat given off by the aluminum $\left(q_{\mathrm{Al}}\right)$ using Equation 5.13. Because $q_{\text {surr }}=-q_{\text {sys }}$, we know that the sum of $q_{\text {water }}$ and $q_{\text {calorimeter }}$ must equal $-q_{\mathrm{Al}}$.
Setup The specific heat of aluminum, from Table 5.2 , is $0.900 \mathrm{~J} / \mathrm{g} \cdot{ }^{\circ} \mathrm{C} . \Delta T_{\mathrm{Al}}$ is $24.9^{\circ} \mathrm{C}-81.7^{\circ} \mathrm{C}$ $=-56.8^{\circ} \mathrm{C} . \Delta T_{\text {water }}$ and $\Delta T_{\text {calorimeter }}$ are both $24.9^{\circ} \mathrm{C}-23.4^{\circ} \mathrm{C}=1.5^{\circ} \mathrm{C}$. The specific heat of water is $4.184 \mathrm{~J} / \mathrm{g} \cdot{ }^{\circ} \mathrm{C}$.

Solution

$$
\begin{gathered}
q_{\mathrm{Al}}=12.1 \mathrm{~g} \times\left(-56.8^{\circ} \mathrm{C}\right) \times 0.900 \mathrm{~J} / \mathrm{g} \cdot{ }^{\circ} \mathrm{C}=-618.6 \mathrm{~J} \\
q_{\text {water }}+q_{\text {calorimeter }}=618.6 \mathrm{~J}
\end{gathered}
$$

Let the mass of water be $x \mathrm{~g}$.

$$
\begin{gathered}
x \not q \times \frac{4.184 \mathrm{~J}}{q^{\circ} \ell} \times 1.5^{\circ} \ell+\frac{19.8 \mathrm{~J}}{{ }^{\circ} \ell} \times 1.5^{\circ} \ell=618.6 \mathrm{~J} \\
6.28 \mathrm{~J} x+29.7 \mathrm{~J}=618.6 \mathrm{~J} \\
6.28 \mathrm{~J} x=618.6 \mathrm{~J}-29.7 \mathrm{~J}=588.9 \mathrm{~J} \\
x=93.8
\end{gathered}
$$

The calorimeter contains 93.8 g of water.

Practice Problem A A 50.75-g sample of water at $75.6^{\circ} \mathrm{C}$ is added to a sample of water at $24.1^{\circ} \mathrm{C}$ in a constant-pressure calorimeter. If the final temperature of the combined water is $39.4^{\circ} \mathrm{C}$ and the heat capacity of the calorimeter is $26.3 \mathrm{~J} /{ }^{\circ} \mathrm{C}$, calculate the mass of the water originally in the calorimeter.

GPractice Problem B A 25.95-g sample of methanol at $35.6^{\circ} \mathrm{C}$ is added to a $38.65-\mathrm{g}$ sample of ethanol at $24.7^{\circ} \mathrm{C}$ in a constant-pressure calorimeter. If the final temperature of the combined liquids is $28.5^{\circ} \mathrm{C}$ and the heat capacity of the calorimeter is $19.3 \mathrm{~J} /{ }^{\circ} \mathrm{C}$, determine the specific heat of methanol.

Student Annotation: The calorimeter had the same initial temperature and the same final temperature as the solutions.

Think About It If we had neglected the heat capacity of the calorimeter, we would have concluded that there was a slightly larger mass of water in the calorimeter. In that case, the solution would have been

$$
\begin{gathered}
x \mathrm{~g} \times \frac{4.184 \mathrm{~J}}{\mathrm{~g} \cdot{ }^{\circ} \mathrm{C}} \times 1.5^{\circ} \mathrm{C}=618.6 \mathrm{~J} \\
\text { and } \quad x=98.5
\end{gathered}
$$

## Constant-Volume Calorimetry

The heat of combustion is usually measured using constant-volume calorimetry. Typically, a known mass of the compound to be analyzed is placed in a steel container called a constant-volume bomb, or simply a bomb, which is pressurized with oxygen. The closed bomb is then immersed in a known amount of water in an insulated container, as shown in Figure 5.11. (Together, the steel bomb and the water in which it is submerged constitute the calorimeter.) The sample is ignited electrically, and the heat released by the combustion of the sample is absorbed by the bomb and the water and can be determined by measuring the increase in temperature of the water. The special design of this type of calorimeter allows us to assume that no heat (or mass) is lost to the surroundings during the time it takes to carry out the reaction and measure the temperature change. Therefore, we can call the bomb and the water in which it is submerged an isolated system. Because no heat enters or leaves the system during the process, the heat change of the system overall $\left(q_{\text {system }}\right)$ is zero and we can write

$$
q_{\mathrm{cal}}=-q_{\mathrm{rxn}}
$$

where $q_{\mathrm{cal}}$ and $q_{\mathrm{rxn}}$ are the heat changes for the calorimeter and the reaction, respectively. Thus,

$$
q_{\mathrm{rxn}}=-q_{\mathrm{cal}}
$$

To calculate $q_{\text {cal }}$, we need to know the heat capacity of the calorimeter $\left(C_{\text {cal }}\right)$ and the change in temperature, that is,

$$
\begin{equation*}
q_{\mathrm{cal}}=C_{\mathrm{cal}} \Delta T \tag{Equation 5.16}
\end{equation*}
$$

And, because $q_{\mathrm{rxn}}=-q_{\mathrm{cal}}$,

$$
\begin{equation*}
q_{\mathrm{rxn}}=-C_{\mathrm{cal}} \Delta T \tag{Equation 5.17}
\end{equation*}
$$

The heat capacity of the calorimeter $\left(C_{\text {cal }}\right)$ is determined by burning a substance with an accurately known heat of combustion. For example, it is known that the combustion of a $1.000-\mathrm{g}$ sample of benzoic acid $\left(\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COOH}\right)$ releases 26.38 kJ of heat. If the measured temperature increase is $4.673^{\circ} \mathrm{C}$, then the heat capacity of the calorimeter is given by

$$
C_{\mathrm{cal}}=\frac{q_{\mathrm{cal}}}{\Delta T}=\frac{26.38 \mathrm{~kJ}}{4.673^{\circ} \mathrm{C}}=5.645 \mathrm{~kJ} /{ }^{\circ} \mathrm{C}
$$

Once $C_{\text {cal }}$ has been determined, the calorimeter can be used to measure the heat of combustion of other substances. Because a reaction in a bomb calorimeter occurs under constant-volume rather than constant-pressure conditions, the measured heat change corresponds to the internal energy change $(\Delta U)$ rather than to the enthalpy change $(\Delta H)$ (see Equations 5.6 and 5.11). It is possible to

Figure 5.11 A constant-volume bomb calorimeter. The calorimeter is filled with oxygen gas at high pressure before it is placed in the bucket. The sample is ignited electrically, and the heat produced by the reaction is determined by measuring the temperature increase in the known amount of water surrounding the bomb.
correct the measured heat changes so that they correspond to $\Delta H$ values, but the corrections usually are quite small, so we will not concern ourselves with the details here.

Sample Problem 5.7 shows how to use constant-volume calorimetry to determine the energy content per gram of a substance.

## Sample Problem 5.7

A Famous Amos bite-sized chocolate chip cookie weighing 7.25 g is burned in a bomb calorimeter to determine its energy content. The heat capacity of the calorimeter is $39.97 \mathrm{~kJ} /{ }^{\circ} \mathrm{C}$. During the combustion, the temperature of the water in the calorimeter increases by $3.90^{\circ} \mathrm{C}$. Calculate the energy content (in $\mathrm{kJ} / \mathrm{g}$ ) of the cookie.

Nutrition facts label on a box of Famous Amos chocolate chip cookies.

Strategy Use Equation $5.17\left(q_{\mathrm{rxn}}=-C_{\text {cal }} \Delta T\right)$ to calculate the heat released by the combustion of the cookie. Divide the heat released by the mass of the cookie to determine its energy content per gram.
Setup $C_{\text {cal }}=39.97 \mathrm{~kJ} /{ }^{\circ} \mathrm{C}$ and $\Delta T=3.90^{\circ} \mathrm{C}$.
Solution From Equation 5.17 we have

$$
q_{\mathrm{rxn}}=-C_{\mathrm{cal}} \Delta T=-\left(39.97 \mathrm{~kJ} /{ }^{\circ} \mathrm{C}\right)\left(3.90^{\circ} \mathrm{C}\right)=-1.559 \times 10^{2} \mathrm{~kJ}
$$

Because energy content is a positive quantity, we write

$$
\text { energy content per gram }=\frac{1.559 \times 10^{2} \mathrm{~kJ}}{7.25 \mathrm{~g}}=21.5 \mathrm{~kJ} / \mathrm{g}
$$

Practice Problem A A serving of Grape-Nuts cereal ( 5.80 g ) is burned in a bomb calorimeter with a heat capacity of $43.7 \mathrm{~kJ} /{ }^{\circ} \mathrm{C}$. During the combustion, the temperature of the water in the calorimeter increased by $1.92^{\circ} \mathrm{C}$. Calculate the energy content (in $\mathrm{kJ} / \mathrm{g}$ ) of Grape-Nuts.

GPractice Problem B The energy content of raisin bread is $13.1 \mathrm{~kJ} / \mathrm{g}$. Calculate the temperature increase when a slice of raisin bread ( 32.0 g ) is burned in the calorimeter in Sample Problem 5.7.

## Checkpoint 5.4 Calorimetry

5.4.1 A 1.000-g sample of benzoic acid is burned in a calorimeter to determine its heat capacity, $C_{\text {cal }}$. The reaction gives off 26.42 kJ of heat and the temperature of the water in the calorimeter increases from $23.40^{\circ} \mathrm{C}$ to $27.20^{\circ} \mathrm{C}$. What is the heat capacity of the calorimeter?
a) $3.80 \mathrm{~kJ} /{ }^{\circ} \mathrm{C}$
b) $6.95 \mathrm{~kJ} /{ }^{\circ} \mathrm{C}$
c) $100 \mathrm{~kJ} /{ }^{\circ} \mathrm{C}$
d) $0.144 \mathrm{~kJ} /{ }^{\circ} \mathrm{C}$
e) $7.81 \mathrm{~kJ} /{ }^{\circ} \mathrm{C}$
5.4.2 One-gram samples of $\mathrm{Al}, \mathrm{Fe}$, and Au are each heated from $40^{\circ} \mathrm{C}$ to $75^{\circ} \mathrm{C}$. Arrange the metals in order of increasing amount of heat absorbed in the process.
a) $\mathrm{Al}<\mathrm{Fe}<\mathrm{Au}$
b) $\mathrm{Al}<\mathrm{Au}<\mathrm{Fe}$
c) $\mathrm{Fe}<\mathrm{Au}<\mathrm{Al}$
d) $\mathrm{Au}<\mathrm{Fe}<\mathrm{Al}$
e) All the metals absorbed the same amount of heat.
5.4.3 A reaction, carried out in a bomb calorimeter with $C_{\text {cal }}=$ $5.01 \mathrm{~kJ} /{ }^{\circ} \mathrm{C}$, gives off 318 kJ of heat. The initial temperature of the water is $24.8^{\circ} \mathrm{C}$. What is the final temperature of the water in the calorimeter?
a) $88.3^{\circ} \mathrm{C}$
b) $63.5^{\circ} \mathrm{C}$
c) $29.8^{\circ} \mathrm{C}$
d) $162^{\circ} \mathrm{C}$
e) $76.7^{\circ} \mathrm{C}$
5.4.4 Quantities of 50.0 mL of 1.00 M HCl and 50.0 mL of 1.00 M NaOH are combined in a constant-pressure calorimeter. Both solutions are initially at $24.4^{\circ} \mathrm{C}$. Calculate the final temperature of the combined solutions. (Use the data from Table 5.3. Assume that the mass of the combined solutions is 100.0 g and that the solution's specific heat is the same as that for water, $4.184 \mathrm{~J} / \mathrm{g} \cdot{ }^{\circ} \mathrm{C}$.) The heat capacity of the calorimeter is negligibly small.
a) $31.1^{\circ} \mathrm{C}$
b) $29.0^{\circ} \mathrm{C}$
c) $44.2^{\circ} \mathrm{C}$
d) $91.8^{\circ} \mathrm{C}$
e) $35.7^{\circ} \mathrm{C}$

### 5.5 Hess's Law

Because enthalpy is a state function, the change in enthalpy that occurs when reactants are converted to products in a reaction is the same whether the reaction takes place in one step or in a series of steps. This observation is called Hess's law. ${ }^{2}$ An analogy for Hess's law can be made to the floors in a building. Suppose, for example, that you take the elevator from the first floor to the sixth floor of the building. The net gain in your gravitational potential energy (which is analogous to the enthalpy change for the overall process) is the same whether you go directly there or stop at each floor on your way up (breaking the trip into a series of steps).

Recall from Section 5.3 that the enthalpy change for the combustion of a mole of methane depends on whether the product water is liquid or gas. More heat is given off by the reaction that produces liquid water. We can use this example to illustrate Hess's law by envisioning the first of these reactions happening in two steps. In step 1, methane and oxygen are converted to carbon dioxide and liquid water, releasing heat.

$$
\mathrm{CH}_{4}(g)+2 \mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(l) \quad \Delta H=-890.4 \mathrm{~kJ} / \mathrm{mol}
$$

In step 2, the liquid water is vaporized, which requires an input of heat.

$$
2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(g) \quad \Delta H=+88.0 \mathrm{~kJ} / \mathrm{mol}
$$

We can add balanced chemical equations just as we can add algebraic equalities, canceling identical items on opposite sides of the equation arrow:

$$
\begin{array}{ll}
\mathrm{CH}_{4}(g)+2 \mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) & \Delta H=-890.4 \mathrm{~kJ} / \mathrm{mol} \\
+\quad 2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(\mathrm{~g}) & \Delta H=+88.0 \mathrm{~kJ} / \mathrm{mol} \\
\hline \mathrm{CH}_{4}(\mathrm{~g})+2 \mathrm{O}_{2}(\mathrm{~g}) \longrightarrow \mathrm{CO}_{2}(\mathrm{~g})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{~g}) & \Delta H=-802.4 \mathrm{~kJ} / \mathrm{mol}
\end{array}
$$

When we add thermochemical equations, we add the $\Delta H$ values as well. This gives us the overall enthalpy change for the net reaction. Using this method, we can deduce the enthalpy changes for many reactions, some of which may not be possible to carry out directly. In general, we apply Hess's law by arranging a series of chemical equations (corresponding to a series of steps) in

[^8]such a way that they sum to the desired overall equation. Often, in applying Hess's law, we must manipulate the equations involved, multiplying by appropriate coefficients, reversing equations, or both. It is important to follow the guidelines [/44 Section 5.3] for the manipulation of thermochemical equations and to make the corresponding change to the enthalpy change of each step.

Sample Problem 5.8 illustrates the use of this method for determining $\Delta H$.

## Sample Problem 5.8

Given the following thermochemical equations,

$$
\begin{aligned}
\mathrm{NO}(g)+\mathrm{O}_{3}(g) \longrightarrow \mathrm{NO}_{2}(g)+\mathrm{O}_{2}(g) & \Delta H & =-198.9 \mathrm{~kJ} / \mathrm{mol} \\
\mathrm{O}_{3}(g) \longrightarrow \frac{3}{2} \mathrm{O}_{2}(g) & \Delta H & =-142.3 \mathrm{~kJ} / \mathrm{mol} \\
\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{O}(g) & \Delta H & =+495 \mathrm{~kJ} / \mathrm{mol}
\end{aligned}
$$

determine the enthalpy change for the reaction

$$
\mathrm{NO}(g)+\mathrm{O}(g) \longrightarrow \mathrm{NO}_{2}(g)
$$

Strategy Arrange the given thermochemical equations so that they sum to the desired equation. Make the corresponding changes to the enthalpy changes, and add them to get the desired enthalpy change.

Setup The first equation has NO as a reactant with the correct coefficient, so we use it as is.

$$
\mathrm{NO}(g)+\mathrm{O}_{3}(g) \longrightarrow \mathrm{NO}_{2}(g)+\mathrm{O}_{2}(g) \quad \Delta H=-198.9 \mathrm{~kJ} / \mathrm{mol}
$$

The second equation must be reversed so that the $\mathrm{O}_{3}$ introduced by the first equation will cancel $\left(\mathrm{O}_{3}\right.$ is not part of the overall chemical equation). We also must change the sign on the corresponding $\Delta H$ value.

$$
\frac{3}{2} \mathrm{O}_{2}(g) \longrightarrow \mathrm{O}_{3}(g) \quad \Delta H=+142.3 \mathrm{~kJ} / \mathrm{mol}
$$

These two steps sum to give the following:

$$
\begin{aligned}
\mathrm{NO}(g)+\mathrm{O}_{3}(\mathrm{~g}) \longrightarrow \mathrm{NO}_{2}(g)+\mathrm{O}_{2}(\mathrm{~g}) & \Delta H=-198.9 \mathrm{~kJ} / \mathrm{mol} \\
+\frac{1}{2} \mathrm{O}_{2}(g) \frac{3}{2} \mathrm{O}_{2}(g) \longrightarrow \mathrm{O}_{3}(g) & \Delta H=+142.3 \mathrm{~kJ} / \mathrm{mol} \\
\hline \mathrm{NO}(g)+\frac{1}{2} \mathrm{O}_{2}(g) \longrightarrow \mathrm{NO}_{2}(g) & \Delta H=-56.6 \mathrm{~kJ} / \mathrm{mol}
\end{aligned}
$$

We then replace the $\frac{1}{2} \mathrm{O}_{2}$ on the left with O by incorporating the last equation. To do so, we divide the third equation by 2 and reverse its direction. As a result, we must also divide its $\Delta H$ value by 2 and change its sign.

$$
\mathrm{O}(g) \longrightarrow \frac{1}{2} \mathrm{O}_{2}(g) \quad \Delta H=-247.5 \mathrm{~kJ} / \mathrm{mol}
$$

Finally, we sum all the steps and add their enthalpy changes.

## Solution

$$
\begin{aligned}
\mathrm{NO}(g)+\mathrm{O}_{3}(\mathrm{~g}) \longrightarrow \mathrm{NO}_{2}(g)+\mathrm{O}_{2}(\mathrm{~g}) & \Delta H=-198.9 \mathrm{~kJ} / \mathrm{mol} \\
\frac{3}{2} \mathrm{O}_{2}(\mathrm{~g}) \longrightarrow \mathrm{O}_{5}(\mathrm{~g}) & \Delta H=+142.3 \mathrm{~kJ} / \mathrm{mol} \\
+\quad \mathrm{O}_{2}(\mathrm{~g}) \longrightarrow \frac{1}{2} \mathrm{O}_{2}(\mathrm{~g}) & \Delta H=-247.5 \mathrm{~kJ} / \mathrm{mol} \\
\hline \mathrm{NO}(g)+\mathrm{O}(\mathrm{~g}) \longrightarrow \mathrm{NO}_{2}(\mathrm{~g}) & \Delta H=-304 \mathrm{~kJ} / \mathrm{mol}
\end{aligned}
$$

Practice Problem A Use the thermochemical equations provided in Sample Problem 5.8 to determine the enthalpy change for the reaction $2 \mathrm{NO}(g)+4 \mathrm{O}(g) \longrightarrow 2 \mathrm{NO}_{2}(g)+\mathrm{O}_{2}(g)$.

GPractice Problem B Use the thermochemical equations provided in Sample Problem 5.8 to determine the enthalpy change for the reaction $2 \mathrm{NO}_{2}(g) \longrightarrow 2 \mathrm{NO}(g)+\mathrm{O}_{2}(g)$.

## Checkpoint 5.5 Hess's Law

5.5.1 Given the following information:

$$
\begin{aligned}
2 \mathrm{H}_{2}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) & \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(\mathrm{~g}) & \Delta H & =-483.6 \mathrm{~kJ} / \mathrm{mol} \\
3 \mathrm{O}_{2}(\mathrm{~g}) & 2 \mathrm{O}_{3}(\mathrm{~g}) & \Delta H & =+284.6 \mathrm{~kJ} / \mathrm{mol}
\end{aligned}
$$

what is $\Delta H$ for $3 \mathrm{H}_{2}(\mathrm{~g})+\mathrm{O}_{3}(\mathrm{~g}) \longrightarrow 3 \mathrm{H}_{2} \mathrm{O}(\mathrm{g})$ ?
a) $-199 \mathrm{~kJ} / \mathrm{mol}$
b) $-1010 \mathrm{~kJ} / \mathrm{mol}$
c) $-867.7 \mathrm{~kJ} / \mathrm{mol}$
d) $+768.2 \mathrm{~kJ} / \mathrm{mol}$
e) $-440.8 \mathrm{~kJ} / \mathrm{mol}$
5.5.2 Given the following information:

$$
\begin{array}{ll}
\mathrm{P}_{4}(s)+3 \mathrm{O}_{2}(g) \longrightarrow \mathrm{P}_{4} \mathrm{O}_{6}(s) \\
\mathrm{P}_{4}(s)+5 \mathrm{O}_{2}(g) \longrightarrow \mathrm{P}_{4} \mathrm{O}_{10}(s)
\end{array} \quad \begin{aligned}
& \Delta H=-1640.1 \mathrm{~kJ} / \mathrm{mol} \\
& \Delta H=-2940.1 \mathrm{~kJ} / \mathrm{mol}
\end{aligned}
$$

what is the value of $\Delta H_{\text {rxn }}$ for $\mathrm{P}_{4} \mathrm{O}_{6}(s)+2 \mathrm{O}_{2}(\mathrm{~g}) \longrightarrow \mathrm{P}_{4} \mathrm{O}_{10}(s)$ ?
a) $-1300.0 \mathrm{~kJ} / \mathrm{mol}$
b) $+4580.2 \mathrm{~kJ} / \mathrm{mol}$
c) $-4580.2 \mathrm{~kJ} / \mathrm{mol}$
d) $+982.6 \mathrm{~kJ} / \mathrm{mol}$
e) $-982.6 \mathrm{~kJ} / \mathrm{mol}$

### 5.6 Standard Enthalpies of Formation

So far we have learned that we can determine the enthalpy change that accompanies a reaction by measuring the heat absorbed or released (at constant pressure). According to Equation 5.11, $\Delta H$ can also be calculated if we know the enthalpies of all reactants and products. However, there is no way to measure the absolute value of the enthalpy of a substance. Only values relative to an arbitrary reference can be determined. This problem is similar to the one geographers face in expressing the elevations of specific mountains or valleys. Rather than trying to devise some type of "absolute" elevation scale (perhaps based on the distance from the center of Earth), by common agreement all geographical heights and depths are expressed relative to sea level, an arbitrary reference with a defined elevation of "zero" meters or feet. Similarly, chemists have agreed on an arbitrary reference point for enthalpy.

The "sea level" reference point for all enthalpy expressions is called the standard enthalpy of formation $\left(\Delta H_{\mathrm{f}}^{\circ}\right)$, which is defined as the heat change that results when 1 mole of a compound is formed from its constituent elements in their standard states. The superscripted degree sign denotes standard-state conditions, and the subscripted f stands for formation. The phrase "in their standard states" refers to the most stable form of an element under standard conditions, meaning at ordinary atmospheric pressure. The element oxygen, for example, can exist as atomic oxygen (O), diatomic oxygen $\left(\mathrm{O}_{2}\right)$, or ozone $\left(\mathrm{O}_{3}\right)$. By far the most stable form at ordinary atmospheric pressure, though, is diatomic oxygen. Thus, the standard state of oxygen is $\mathrm{O}_{2}(\mathrm{~g})$. Although the standard state does not specify a temperature, we will always use $\Delta H_{\mathrm{f}}^{\circ}$ values measured at $25^{\circ} \mathrm{C}$.

Appendix 2 lists the standard enthalpies of formation for a number of elements and compounds. By convention, the standard enthalpy of formation of any element in its most stable form is zero. Again, using the element oxygen as an example, we can write $\Delta H_{\mathrm{f}}^{\circ}\left(\mathrm{O}_{2}\right)=0$, but $\Delta H_{\mathrm{f}}^{\circ}\left(\mathrm{O}_{3}\right)$ $\neq 0$ and $\Delta H_{\mathrm{f}}^{\circ}(\mathrm{O}) \neq 0$. Similarly, graphite is a more stable allotropic form of carbon than diamond under standard conditions and $25^{\circ} \mathrm{C}$, so we have $\Delta H_{\mathrm{f}}^{\circ}($ graphite $)=0$ and $\Delta H_{\mathrm{f}}^{\circ}($ diamond $) \neq 0$.

The importance of the standard enthalpies of formation is that once we know their values, we can readily calculate the standard enthalpy of reaction $\left(\Delta H_{\mathrm{rxn}}^{\circ}\right)$, defined as the enthalpy of a reaction carried out under standard conditions. For example, consider the hypothetical reaction

$$
a \mathrm{~A}+b \mathrm{~B} \longrightarrow c \mathrm{C}+d \mathrm{D}
$$

where $a, b, c$, and $d$ are stoichiometric coefficients. For this reaction $\Delta H_{\mathrm{rxn}}^{\circ}$ is given by

$$
\Delta H_{\mathrm{rxn}}^{\circ}=\left[c \Delta H_{\mathrm{f}}^{\circ}(\mathrm{C})+d \Delta H_{\mathrm{f}}^{\circ}(\mathrm{D})\right]-\left[a \Delta H_{\mathrm{f}}^{\circ}(\mathrm{A})+b \Delta H_{\mathrm{f}}^{\circ}(\mathrm{B})\right] \quad \text { Equation } 5.18
$$

We can generalize Equation 5.18 as

$$
\Delta H_{\mathrm{rxn}}^{\circ}=\Sigma n \Delta H_{\mathrm{f}}^{\circ}(\text { products })-\Sigma m \Delta H_{\mathrm{f}}^{\circ}(\text { reactants }) \quad \text { Equation } 5.19
$$

where $m$ and $n$ are the stoichiometric coefficients for the reactants and products, respectively, and $\Sigma$ (sigma) means "the sum of." In these calculations the stoichiometric coefficients are treated as numbers without units. Thus, the result has units of $\mathrm{kJ} / \mathrm{mol}$, where again, "per mole" means per mole of reaction as written. To use Equation 5.19 to calculate $\Delta H_{\mathrm{rxn}}^{\circ}$, we must know the $\Delta H_{\mathrm{f}}^{\circ}$ values of the compounds that take part in the reaction. These values, tabulated in Appendix 2, are determined either by the direct method or the indirect method.

The direct method of measuring $\Delta H_{\mathrm{f}}^{\circ}$ works for compounds that can be synthesized from their elements easily and safely. Suppose we want to know the enthalpy of formation of carbon dioxide. We must measure the enthalpy of the reaction when carbon (graphite) and molecular oxygen in their standard states are converted to carbon dioxide in its standard state:

$$
\mathrm{C}(\text { graphite })+\mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g) \quad \Delta H_{\mathrm{rxn}}^{\circ}=-393.5 \mathrm{~kJ} / \mathrm{mol}
$$

We know from experience that this combustion goes to completion. Thus, from Equation 5.19 we can write

$$
\Delta H_{\mathrm{rxn}}^{\circ}=\Delta H_{\mathrm{f}}^{\circ}\left(\mathrm{CO}_{2}\right)-\left[\Delta H_{\mathrm{f}}^{\circ}(\text { graphite })+\Delta H_{\mathrm{f}}^{\circ}\left(\mathrm{O}_{2}\right)\right]=-393.5 \mathrm{~kJ} / \mathrm{mol}
$$

Because graphite and $\mathrm{O}_{2}$ are the most stable allotropic forms of their respective elements, $\Delta H_{\mathrm{f}}^{\circ}$ (graphite) and $\Delta H_{\mathrm{f}}^{\circ}\left(\mathrm{O}_{2}\right)$ are both zero. Therefore,

$$
\Delta H_{\mathrm{rxn}}^{\circ}=\Delta H_{\mathrm{f}}^{\circ}\left(\mathrm{CO}_{2}\right)=-393.5 \mathrm{~kJ} / \mathrm{mol}
$$

or

$$
\Delta H_{\mathrm{f}}^{\circ}\left(\mathrm{CO}_{2}\right)=-393.5 \mathrm{~kJ} / \mathrm{mol}
$$

Think About It Watch out for misplaced or missing minus signs. This is an easy place to lose track of them.

Arbitrarily assigning a value of zero to $\Delta H_{\mathrm{f}}^{\circ}$ for each element in its standard state does not affect the outcome of these calculations. Remember, in thermochemistry we are interested only in enthalpy changes because they can be determined experimentally, whereas the absolute enthalpy values cannot. The choice of a zero "reference level" for enthalpy is intended to simplify the calculations. Referring again to the terrestrial altitude analogy, we find that Mt. Everest (the highest peak in the world) is 8708 ft higher than Mt. Denali (the highest peak in North America). This difference in altitude would be the same whether we had chosen sea level or the center of Earth as our reference elevation.

Other compounds that can be studied by the direct method are $\mathrm{SF}_{6}, \mathrm{P}_{4} \mathrm{O}_{10}$, and $\mathrm{CS}_{2}$. The equations representing their syntheses are

$$
\begin{aligned}
\mathrm{S}(\text { rhombic })+3 \mathrm{~F}_{2}(g) & \longrightarrow \mathrm{SF}_{6}(g) \\
\mathrm{P}_{4}(\text { white })+5 \mathrm{O}_{2}(g) & \longrightarrow \mathrm{P}_{4} \mathrm{O}_{10}(s) \\
\mathrm{C} \text { (graphite) }+2 \mathrm{~S} \text { (rhombic) } & \longrightarrow \mathrm{CS}_{2}(l)
\end{aligned}
$$

S (rhombic) and P (white) are the most stable allotropes of sulfur and phosphorus, respectively, at 1 atm and $25^{\circ} \mathrm{C}$, so their $\Delta H_{\mathrm{f}}^{\circ}$ values are zero.

Sample Problem 5.9 shows how $\Delta H_{\mathrm{f}}^{\circ}$ values can be used to determine $\Delta H_{\mathrm{rxn}}^{\circ}$.

## Sample Problem 5.9

Using data from Appendix 2, calculate $\Delta H_{\mathrm{rxn}}^{\circ}$ for $\mathrm{Ag}^{+}(a q)+\mathrm{Cl}^{-}(a q) \longrightarrow \mathrm{AgCl}(s)$.
Strategy Use Equation $5.19\left[\Delta H_{\mathrm{rxn}}^{\circ}=\Sigma n \Delta H_{\mathrm{f}}^{\circ}\right.$ (products) $-\Sigma m \Delta H_{\mathrm{f}}^{\circ}($ reactants $\left.)\right]$ and $\Delta H_{\mathrm{f}}^{\circ}$ values from Appendix 2 to calculate $\Delta H_{\text {rxn }}^{\circ}$.

Setup The $\Delta H_{\mathrm{f}}^{\circ}$ values for $\mathrm{Ag}^{+}(a q), \mathrm{Cl}^{-}(a q)$, and $\mathrm{AgCl}(s)$ are $+105.9,-167.2$, and $-127.0 \mathrm{~kJ} / \mathrm{mol}$, respectively.

Solution Using Equation 5.19,

$$
\begin{aligned}
\Delta H_{\mathrm{rxn}}^{\circ} & =\Delta H_{\mathrm{f}}^{\circ}(\mathrm{AgCl})-\left[\Delta H_{\mathrm{f}}^{\circ}\left(\mathrm{Ag}^{+}\right)+\Delta H_{\mathrm{f}}^{\circ}\left(\mathrm{Cl}^{-}\right)\right] \\
& =-127.0 \mathrm{~kJ} / \mathrm{mol}-[(+105.9 \mathrm{~kJ} / \mathrm{mol})+(-167.2 \mathrm{~kJ} / \mathrm{mol})] \\
& =-127.0 \mathrm{~kJ} / \mathrm{mol}-(-61.3 \mathrm{~kJ} / \mathrm{mol})=-65.7 \mathrm{~kJ} / \mathrm{mol}
\end{aligned}
$$

Practice Problem A Using data from Appendix 2, calculate $\Delta H_{\mathrm{rxn}}^{\circ}$ for $\mathrm{CaCO}_{3}(s) \longrightarrow \mathrm{CaO}(s)+$ $\mathrm{CO}_{2}(g)$.
$\leftrightarrows$ Practice Problem B Using data from Appendix 2, calculate $\Delta H_{\mathrm{rxn}}^{\circ}$ for $2 \mathrm{SO}(g)+\frac{2}{3} \mathrm{O}_{3}(g) \longrightarrow$ $2 \mathrm{SO}_{2}(g)$.

Many compounds cannot be synthesized from their elements directly. In some cases, the reaction proceeds too slowly, or side reactions produce substances other than the desired compound. In these cases $\Delta H_{\mathrm{f}}^{\circ}$ can be determined by an indirect approach, using Hess's law. If we know a series of reactions for which $\Delta H_{\mathrm{rxn}}^{\circ}$ can be measured, and we can arrange them in such a way as to have them sum to the equation corresponding to the formation of the compound of interest, we can calculate $\Delta H_{\mathrm{f}}^{\circ}$ for the compound.

Sample Problem 5.10 shows how to use Hess's law to calculate the $\Delta H_{\mathrm{f}}^{\circ}$ value by the indirect method for a compound that cannot be produced easily from its constituent elements.

## Sample Problem 5.10

Given the following information, calculate the standard enthalpy of formation of acetylene $\left(\mathrm{C}_{2} \mathrm{H}_{2}\right)$ from its constituent elements:

$$
\begin{array}{cl}
\mathrm{C} \text { (graphite) }+\mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g) & \Delta H_{\mathrm{rxn}}^{\circ}=-393.5 \mathrm{~kJ} / \mathrm{mol} \\
\mathrm{H}_{2}(g)+\frac{1}{2} \mathrm{O}_{2}(g) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l) & \Delta H_{\mathrm{rxn}}^{\circ}=-285.8 \mathrm{~kJ} / \mathrm{mol} \\
2 \mathrm{C}_{2} \mathrm{H}_{2}(g)+5 \mathrm{O}_{2}(g) \longrightarrow 4 \mathrm{CO}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(l) & \Delta H_{\mathrm{rxn}}^{\circ}=-2598.8 \mathrm{~kJ} / \mathrm{mol} \tag{3}
\end{array}
$$

Strategy Arrange the equations that are provided so that they will sum to the desired equation. This may require reversing or multiplying one or more of the equations. For any such change, the corresponding change must also be made to the $\Delta H_{\mathrm{rxn}}^{\circ}$ value.

Setup The equation corresponding to the standard enthalpy of formation of acetylene is

$$
2 \mathrm{C} \text { (graphite) }+\mathrm{H}_{2}(g) \longrightarrow \mathrm{C}_{2} \mathrm{H}_{2}(g)
$$

We multiply Equation (1) and its $\Delta H_{\mathrm{rxn}}^{\circ}$ value by 2 :

$$
2 \mathrm{C}(\text { graphite })+2 \mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{CO}_{2}(g) \quad \Delta H_{\mathrm{rxn}}^{\circ}=-787.0 \mathrm{~kJ} / \mathrm{mol}
$$

We include Equation (2) and its $\Delta H_{\mathrm{rxn}}^{\circ}$ value as is:

$$
\mathrm{H}_{2}(g)+\frac{1}{2} \mathrm{O}_{2}(g) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l) \quad \Delta H_{\mathrm{rxn}}^{\circ}=-285.8 \mathrm{~kJ} / \mathrm{mol}
$$

We reverse Equation (3) and divide it by 2 (i.e., multiply through by $\frac{1}{2}$ ):

$$
2 \mathrm{CO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{C}_{2} \mathrm{H}_{2}(g)+\frac{5}{2} \mathrm{O}_{2}(g) \quad \Delta H_{\mathrm{rxn}}^{\circ}=+1299.4 \mathrm{~kJ} / \mathrm{mol}
$$

Solution Summing the resulting equations and the corresponding $\Delta H_{\mathrm{rxn}}^{\circ}$ values:

Student Annotation: The original $\Delta H^{\circ}{ }_{\text {rxn }}$ value of Equation (3) has its sign reversed and it is divided by 2 .

$$
\begin{array}{cl}
2 \mathrm{C}(\text { graphite })+2 \mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{CO}_{2}(g) & \Delta H_{\mathrm{rxn}}^{\circ}=-787.0 \mathrm{~kJ} / \mathrm{mol} \\
\mathrm{H}_{2}(g)+\frac{1}{2} \mathrm{O}_{2}(g) \longrightarrow \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) & \Delta H_{\mathrm{rxn}}^{\circ}=-285.8 \mathrm{~kJ} / \mathrm{mol} \\
+2 \mathrm{CO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow \mathrm{C}_{2} \mathrm{H}_{2}(g)+\frac{5}{2} \mathrm{O}_{2}(g) & \Delta H_{\mathrm{rxn}}^{\circ}=+1299.4 \mathrm{~kJ} / \mathrm{mol} \\
\hline 2 \mathrm{C}(\text { graphite })+\mathrm{H}_{2}(g) \longrightarrow \mathrm{C}_{2} \mathrm{H}_{2}(g) & \Delta H_{\mathrm{f}}^{\circ}=+226.6 \mathrm{~kJ} / \mathrm{mol}
\end{array}
$$

Practice Problem A Use the following data to calculate $\Delta H_{\mathrm{f}}^{\circ}$ for $\mathrm{CS}_{2}(l)$ :
Think About It Watch out for misplaced or missing minus signs. This is an easy place to lose track of them.

$$
\begin{aligned}
\mathrm{C}(\text { graphite })+\mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g) & \Delta H_{\mathrm{rxn}}^{\circ}=-393.5 \mathrm{~kJ} / \mathrm{mol} \\
\mathrm{~S}(\text { rhombic })+\mathrm{O}_{2}(g) \longrightarrow \mathrm{SO}_{2}(g) & \Delta H_{\mathrm{rxn}}^{\circ}=-296.4 \mathrm{~kJ} / \mathrm{mol} \\
\mathrm{CS}_{2}(l)+3 \mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g)+2 \mathrm{SO}_{2}(g) & \Delta H_{\mathrm{rxn}}^{\circ}=-1073.6 \mathrm{~kJ} / \mathrm{mol}
\end{aligned}
$$

EPPractice Problem B $\Delta H_{\mathrm{f}}^{\circ}$ of hydrogen chloride $[\mathrm{HCl}(g)]$ is $-92.3 \mathrm{~kJ} / \mathrm{mol}$. Given the following data, determine the identity of the two missing products and calculate $\Delta H_{\mathrm{rxn}}^{\circ}$ for Equation 3. [Hint: Start by writing the chemical equation that corresponds to $\Delta H_{\mathrm{f}}^{\circ}$ for $\mathrm{HCl}(g)$.]

$$
\begin{array}{ll}
\mathrm{N}_{2}(g)+4 \mathrm{H}_{2}(g)+\mathrm{Cl}_{2}(g) \longrightarrow 2 \mathrm{NH}_{4} \mathrm{Cl}(s) & \Delta H_{\mathrm{rxn}}^{\circ}=-630.78 \mathrm{~kJ} / \mathrm{mol} \\
\mathrm{~N}_{2}(g)+3 \mathrm{H}_{2}(g) \longrightarrow 2 \mathrm{NH}_{3}(g) & \Delta H_{\mathrm{rxn}}^{\circ}=-92.6 \mathrm{~kJ} / \mathrm{mol}
\end{array}
$$

$\mathrm{NH}_{4} \mathrm{Cl}(s) \longrightarrow$

## Checkpoint 5.6 Standard Enthalpies of Formation

5.6.1 Using data from Appendix 2, calculate $\Delta H_{\mathrm{rxn}}^{\circ}$ for $\mathrm{H}_{2}(\mathrm{~g})+\mathrm{F}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{HF}(\mathrm{g})$.
a) $-271.6 \mathrm{~kJ} / \mathrm{mol}$
b) $-543.2 \mathrm{~kJ} / \mathrm{mol}$
c) $+271.6 \mathrm{~kJ} / \mathrm{mol}$
d) $0 \mathrm{~kJ} / \mathrm{mol}$
e) $-135.8 \mathrm{~kJ} / \mathrm{mol}$
5.6.2 Using data from Appendix 2, calculate $\Delta H_{\mathrm{rxn}}^{\circ}$ for $2 \mathrm{NO}_{2}(g) \longrightarrow \mathrm{N}_{2} \mathrm{O}_{4}(g)$.
a) $-24.19 \mathrm{~kJ} / \mathrm{mol}$
b) $-33.85 \mathrm{~kJ} / \mathrm{mol}$
c) $+9.66 \mathrm{~kJ} / \mathrm{mol}$
d) $+67.7 \mathrm{~kJ} / \mathrm{mol}$
e) $-58.04 \mathrm{~kJ} / \mathrm{mol}$
5.6.3 Which of the following $\Delta H_{\mathrm{rxn}}^{\circ}$ values is a $\Delta H_{\mathrm{f}}^{\circ}$ value? (Select all that apply.)
a) $\mathrm{H}_{2}(g)+\mathrm{Br}_{2}(l) \longrightarrow 2 \mathrm{HBr}(g)$
b) $4 \mathrm{Al}(s)+3 \mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{Al}_{2} \mathrm{O}_{3}(s)$
c) $\mathrm{Ag}(s)+\frac{1}{2} \mathrm{Cl}_{2}(g) \longrightarrow \mathrm{AgCl}(s)$
d) $\mathrm{Cu}^{2+}(a q)+\mathrm{SO}_{4}^{2-}(a q) \longrightarrow \mathrm{CuSO}_{4}(s)$
e) $\frac{1}{2} \mathrm{H}_{2}(g)+\frac{1}{2} \mathrm{~N}_{2}(g)+\frac{3}{2} \mathrm{O}_{2}(g) \longrightarrow \mathrm{HNO}_{3}(l)$
5.6.4 Using the following data, calculate $\Delta H_{\mathrm{f}}^{\circ}$ for $\mathrm{CO}(g)$ :

$$
\begin{aligned}
\mathrm{C}(\text { graphite })+\mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g) & \Delta H_{\mathrm{rxn}}^{\circ}=-393.5 \mathrm{~kJ} / \mathrm{mol} \\
\mathrm{CO}(g)+\frac{1}{2} \mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g) & \Delta H_{\mathrm{rxn}}^{\circ}=-283.0 \mathrm{~kJ} / \mathrm{mol}
\end{aligned}
$$

a) $-393.5 \mathrm{~kJ} / \mathrm{mol}$
b) $-676.5 \mathrm{~kJ} / \mathrm{mol}$
c) $+676.5 \mathrm{~kJ} / \mathrm{mol}$
d) $+110.5 \mathrm{~kJ} / \mathrm{mol}$
e) $-110.5 \mathrm{~kJ} / \mathrm{mol}$

## Applying What You've Learned

One of the most popular approaches to dieting in recent years has been to reduce dietary fat. One reason many people want to avoid eating fat is its high Calorie content. Compared to carbohydrates and proteins, each of which contains an average of 4 Calories per gram ( $17 \mathrm{~kJ} / \mathrm{g}$ ), fat contains 9 Calories per gram ( $38 \mathrm{~kJ} / \mathrm{g}$ ). Tristearin, a typical fat, is metabolized (or combusted) according to the following equation:

$$
\mathrm{C}_{57} \mathrm{H}_{110} \mathrm{O}_{6}(s)+81.5 \mathrm{O}_{2}(g) \longrightarrow 57 \mathrm{CO}_{2}(g)+55 \mathrm{H}_{2} \mathrm{O}(l) \quad \Delta H^{\circ}=-37,760 \mathrm{~kJ} / \mathrm{mol}
$$

Although the food industry has succeeded in producing low-fat versions of nearly everything we eat, it has thus far failed to produce a palatable low-fat doughnut. The flavor, texture, and what the industry calls "mouth feel" of a doughnut depends largely on the process of deep-fat frying. Fortunately for people in the doughnut business, though, high fat content has not diminished the popularity of doughnuts.

Many popular foods are available in low-fat varieties.

Nutrition facts label for Krispy Kreme original glazed doughnuts.

## Problems:

According to information obtained from www.krispykreme.com, a Krispy Kreme original glazed doughnut weighs 52 g and contains 200 Cal and 12 g of fat.
a) Assuming that the fat in the doughnut is metabolized according to the given equation for tristearin, calculate the number of Calories in the reported 12 g of fat in each doughnut. [ 144 Sample Problem 5.3]
b) If all the energy contained in a Krispy Kreme doughnut (not just in the fat) were transferred to 6.00 kg of water originally at $25.5^{\circ} \mathrm{C}$, what would be the final temperature of the water? [ kA Sample Problem 5.4]
c) When a Krispy Kreme apple fritter weighing 101 g is burned in a bomb calorimeter with $C_{\text {cal }}=95.3 \mathrm{~kJ} /{ }^{\circ} \mathrm{C}$, the measured temperature increase is $16.7^{\circ} \mathrm{C}$. Calculate the number of Calories in a Krispy Kreme apple fritter. [ 14 Sample Problem 5.7]
d) What would the $\Delta H^{\circ}$ value be for the metabolism of 1 mole of the fat tristearin if the water produced by the reaction were gaseous instead of liquid? [ 144 Sample Problem 5.8] [Hint: Use data from Appendix 2 to determine the $\Delta H^{\circ}$ value for the reaction $\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow \mathrm{H}_{2} \mathrm{O}(\mathrm{g})$. [ 144 Sample Problem 5.9]]

## Chapter Summary

## Section 5.1

- Energy is the capacity to do work or transfer heat. Energy may be kinetic energy (the energy associated with motion) or potential energy (energy possessed by virtue of position). Thermal energy is a form of kinetic energy. Chemical energy and electrostatic energy are forms of potential energy.
- The law of conservation of energy states that energy can neither be created nor destroyed. The SI unit of energy is the joule (J).
- The system is the particular part of the universe that we are interested in studying-such as the reactants and products in a chemical reaction. The term surroundings refers to the rest of the universe. System + surroundings $=$ universe.
- Heat refers to the flow of thermal energy between two bodies at different temperatures. Thermochemistry is the study of the heat associated with chemical reactions and physical processes.
- In an exothermic process, heat is released to the surroundings, so the energy of the system decreases. In an endothermic process, heat is absorbed from the surroundings, so the energy of the system increases.

## Section 5.2

- Thermodynamics is the study of the conversions among different types of energy. Thermochemistry is a branch of thermodynamics.
- An open system is one that can exchange both matter and energy with its surroundings. A closed system is one that can exchange energy but not matter with its surroundings. An isolated system is one that cannot exchange either energy or matter with its surroundings.
- The state of a system is defined by the values of all relevant macroscopic properties, such as temperature, volume, and pressure. A state function is one whose value depends only on the state of the system and not on how that state was achieved. State functions include energy, pressure, volume, and temperature.
- The first law of thermodynamics states that energy cannot be created or destroyed, but it can be changed from one form to another. The first law of thermodynamics is based on the law of conservation of energy.

## Section 5.3

- Enthalpy is the heat exchanged between the system and surroundings at constant pressure. It is a state function. Enthalpy of reaction $\left(\Delta H_{\mathrm{rxn}}\right)$ is the heat exchanged at constant pressure for a specific reaction.
- A thermochemical equation is a balanced chemical equation for which the enthalpy change $\left(\Delta H_{\mathrm{rxn}}\right)$ is given.

## Section 5.4

- Calorimetry is the science of measuring temperature changes to determine heats associated with chemical reactions. Calorimetry may be carried out at constant pressure (in a coffee-cup calorimeter) or at constant volume (in a bomb calorimeter).
- The specific heat $(s)$ of a substance is the amount of heat required to increase the temperature of 1 g of the substance by $1^{\circ} \mathrm{C}$. The heat capacity of an object is the amount of heat required to increase the temperature of the object by $1^{\circ} \mathrm{C}$.

## Section 5.5

- Hess's law states that the enthalpy change for a reaction that occurs in a series of steps is equal to the sum of the enthalpy changes of the individual steps. Hess's law is valid because enthalpy is a state function.

## Section 5.6

- The standard enthalpy of formation $\left(\Delta H_{\mathrm{f}}^{\circ}\right)$ is the enthalpy change associated with the formation of 1 mole of a substance from its constituent elements, each in their standard states. The standard enthalpy of reaction $\left(\Delta H_{\mathrm{rxn}}^{\circ}\right)$ can be calculated for any reaction using tabulated standard enthalpies of formation $\left(\Delta H_{\mathrm{f}}^{\circ}\right)$ of the products and reactants.

## Questions and Problems

## Section 5.1: Energy and Energy Changes

## Review Questions

5.1 Define these terms: system, surroundings, thermal energy, chemical energy, potential energy, kinetic energy, law of conservation of energy.
5.2 What is heat? How does heat differ from thermal energy? Under what condition is heat transferred from one system to another?
5.3 What are the units for energy commonly employed in chemistry?
5.4 A truck initially traveling at $60 \mathrm{~km} / \mathrm{h}$ is brought to a complete stop at a traffic light. Does this change violate the law of conservation of energy? Explain.
5.5 These are various forms of energy: chemical, heat, light, mechanical, and electrical. Suggest several ways of converting one form of energy to another.
5.6 Describe the interconversions of forms of energy occurring in these processes: (a) You throw a softball up into the air and catch it. (b) You switch on a flashlight. (c) You ride the ski lift to the top of the hill and then ski down. (d) You strike a match and let it burn completely.
5.7 Define these terms: thermochemistry, exothermic process, endothermic process.
5.8 Stoichiometry is based on the law of conservation of mass. On what law is thermochemistry based?
5.9 Describe two exothermic processes and two endothermic processes.
5.10 Decomposition reactions are usually endothermic, whereas combination reactions are usually exothermic. Give a qualitative explanation for these trends.

## Section 5.2: Introduction to Thermodynamics

## Review Questions

5.11 On what law is the first law of thermodynamics based? Explain the sign conventions in the equation

$$
\Delta U=q+w
$$

5.12 Explain what is meant by a state function. Give two examples of quantities that are state functions and two that are not state functions.

## Problems

5.13 The work done to compress a gas is 74 J . As a result, 26 J of heat is given off to the surroundings. Calculate the change in energy of the gas.

E 5.14 In a gas expansion, 87 J of heat is absorbed from the surroundings and the energy of the system decreases by 128 J . Calculate the work done.
5.15 Calculate $w$, and determine whether work is done by the system or on the system when 67 J of heat is released and $\Delta U=510 \mathrm{~J}$.

E5 5.16 Calculate $q$, and determine whether heat is absorbed or released when a system does work on the surroundings equal to 64 J and $\Delta U=-213 \mathrm{~J}$.

## Section 5.3: Enthalpy

## Review Questions

§ 5.17 Consider these changes.
(a) $\mathrm{Hg}(l) \longrightarrow \mathrm{Hg}(g)$
(b) $3 \mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{O}_{3}(\mathrm{~g})$
(c) $\mathrm{CuSO}_{4} \cdot 5 \mathrm{H}_{2} \mathrm{O}(s) \longrightarrow \mathrm{CuSO}_{4}(s)+5 \mathrm{H}_{2} \mathrm{O}(g)$
(d) $\mathrm{H}_{2}(g)+\mathrm{F}_{2}(g) \longrightarrow 2 \mathrm{HF}(g)$

At constant pressure, in which of the reactions is work done by the system on the surroundings? By the surroundings on the system? In which of them is no work done?
5.18 Define these terms: enthalpy and enthalpy of reaction. Under what condition is the heat of a reaction equal to the enthalpy change of the same reaction?
5.19 In writing thermochemical equations, why is it important to indicate the physical state (that is, gaseous, liquid, solid, or aqueous) of each substance?
5.20 Explain the meaning of this thermochemical equation:
$4 \mathrm{NH}_{3}(g)+5 \mathrm{O}_{2}(g) \longrightarrow 4 \mathrm{NO}(g)+6 \mathrm{H}_{2} \mathrm{O}(g)$
$\Delta H=-904 \mathrm{~kJ} / \mathrm{mol}$
5.21 Consider this reaction:

$$
\begin{aligned}
& 2 \mathrm{CH}_{3} \mathrm{OH}(l)+3 \mathrm{O}_{2}(g) \longrightarrow 4 \mathrm{H}_{2} \mathrm{O}(l)+2 \mathrm{CO}_{2}(g) \\
& \Delta H=-1452.8 \mathrm{~kJ} / \mathrm{mol}
\end{aligned}
$$

What is the value of $\Delta H$ if (a) the equation is multiplied throughout by 2 ; (b) the direction of the reaction is reversed so that the products become the reactants, and vice versa; (c) water vapor instead of liquid water is formed as the product?

## Problems

- 5.22 A sample of nitrogen gas expands in volume from 1.6 to 5.4 L at constant temperature. Calculate the work done in joules if the gas expands (a) against a vacuum, (b) against a constant pressure of 0.80 atm , and (c) against a constant pressure of 3.7 atm . (See Equation 5.4. $1 \mathrm{~L} \cdot \mathrm{~atm}=101.3 \mathrm{~J}$. )

H5.23 A gas expands in volume from 26.7 to 89.3 mL at constant temperature. Calculate the work done (in joules) if the gas expands (a) against a vacuum, (b) against a constant pressure of 1.5 atm , and (c) against a constant pressure of 2.8 atm . $(1 \mathrm{~L} \cdot \mathrm{~atm}=101.3 \mathrm{~J}$.
$\$ 5.24$ A gas expands and does $P V$ work on the surroundings equal to 325 J . At the same time, it absorbs 127 J of heat from the surroundings. Calculate the change in energy of the gas.

E5.25 The first step in the industrial recovery of zinc from the zinc sulfide ore is roasting, that is, the conversion of ZnS to ZnO by heating:

$$
2 \mathrm{ZnS}(s)+3 \mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{ZnO}(s)+2 \mathrm{SO}_{2}(g) \quad \Delta H=-879 \mathrm{~kJ} / \mathrm{mol}
$$

Calculate the heat evolved (in kJ ) per gram of ZnS roasted.
\$5.26 Determine the amount of heat (in kJ) given off when $1.26 \times 10^{4} \mathrm{~g}$ of $\mathrm{NO}_{2}$ are produced according to the equation

$$
2 \mathrm{NO}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{NO}_{2}(g) \quad \Delta H=-114.6 \mathrm{~kJ} / \mathrm{mol}
$$

5.27 Consider the reaction

$$
2 \mathrm{H}_{2} \mathrm{O}(\mathrm{~g}) \longrightarrow 2 \mathrm{H}_{2}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) \quad \Delta H=+483.6 \mathrm{~kJ} / \mathrm{mol}
$$

at a certain temperature. If the increase in volume is 32.7 L against an external pressure of 1.00 atm , calculate $\Delta U$ for this reaction. $(1 \mathrm{~L} \cdot \mathrm{~atm}=101.3 \mathrm{~J}$.
5.28 Consider the reaction

$$
\mathrm{H}_{2}(\mathrm{~g})+\mathrm{Cl}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{HCl}(\mathrm{~g}) \quad \Delta H=-184.6 \mathrm{~kJ} / \mathrm{mol}
$$

If 3 moles of $\mathrm{H}_{2}$ react with 3 moles of $\mathrm{Cl}_{2}$ to form HCl , calculate the work done (in joules) against a pressure of 1.0 atm . What is $\Delta U$ for this reaction? Assume the reaction goes to completion and that $\Delta V=0 .(1 \mathrm{~L} \cdot \mathrm{~atm}=101.3 \mathrm{~J}$.
5.29 For most biological processes, the changes in internal energy are approximately equal to the changes in enthalpy. Explain.

## Section 5.4: Calorimetry

## 104

## Visualizing Chemistry

## Figure 5.9 and Figure 5.10

VC 5.1 Referring to Figure 5.9, which of the following would result in the calculated value of $\Delta H_{\mathrm{rxn}}$ being too high?
a) Spilling some of one of the reactant solutions before adding it to the calorimeter.
b) Reading the final temperature before it reached its maximum value.
c) Misreading the thermometer at the beginning of the experiment and recording too low an initial temperature.

VC 5.2 How would the $\Delta H_{\text {rxn }}$ calculated in Figure 5.9 be affected if the concentration of one of the reactant solutions were twice as high as it was supposed to be?
a) The calculated $\Delta H_{\mathrm{rxn}}$ would not be affected.
b) The calculated $\Delta H_{\mathrm{rxn}}$ would be too low.
c) The calculated $\Delta H_{\mathrm{rxn}}$ would be too high.

VC 5.3 For an exothermic reaction like the one depicted in Figure 5.9, if the heat capacity of the calorimeter is not negligibly small, the heat absorbed by the water will be $\qquad$ the heat given off by the reaction.
a) greater than
b) less than
c) equal to

VC 5.4 Referring to Figure 5.9, how would the results of the experiment have been different if the reaction had been endothermic?
a) The results would have been the same.
b) There would have been a smaller temperature increase.
c) There would have been a temperature decrease.

VC 5.5 What would happen to the specific heat calculated in Figure 5.10 if some of the warm metal shot were lost during the transfer to the calorimeter?
a) It would not affect the calculated value of specific heat.
b) It would cause the calculated value of specific heat to be too high.
c) It would cause the calculated value of specific heat to be too low.

VC 5.6 What would happen to the specific heat calculated in Figure 5.10 if the test tube containing the metal shot were left in the boiling water for longer than the recommended time?
a) It would not affect the calculated value of specific heat.
b) It would cause the calculated value of specific heat to be too high.
c) It would cause the calculated value of specific heat to be too low.
VC 5.7 What would happen to the specific heat calculated in Figure 5.10 if some of the water were spilled prior to being added to the calorimeter?
a) It would not affect the calculated value of specific heat.
b) It would cause the calculated value of specific heat to be too high.
c) It would cause the calculated value of specific heat to be too low.
VC 5.8 Referring to the process depicted in Figure 5.10, which of the following must be known precisely for the calculated specific heat to be accurate.
a) The mass of the boiling water.
b) The temperature of the metal shot before it is immersed in the boiling water.
c) The mass of the water that is added to the calorimeter.

## Review Questions

5.30 What is the difference between specific heat and heat capacity? What are the units for these two quantities? Which is the intensive property and which is the extensive property?
5.31 Consider two metals A and B, each having a mass of 100 g and an initial temperature of $20^{\circ} \mathrm{C}$. The specific heat of A is larger than that of B. Under the same heating conditions, which metal would take longer to reach a temperature of $21^{\circ} \mathrm{C}$ ?
5.32 Define calorimetry and describe two commonly used calorimeters. In a calorimetric measurement, why is it important that we know the heat capacity of the calorimeter? How is this value determined?
5.33 Consider the following data:

| Metal | Al | $\mathbf{C u}$ |
| :--- | :---: | :---: |
| Mass $(\mathrm{g})$ | 10 | 30 |
| Specific heat $\left(\mathrm{J} / \mathrm{g} \cdot{ }^{\circ} \mathrm{C}\right)$ | 0.900 | 0.385 |
| Temperature $\left({ }^{\circ} \mathrm{C}\right)$ | 40 | 60 |

When these two metals are placed in contact, which of the following will take place?
(a) Heat will flow from Al to Cu because Al has a larger specific heat.
(b) Heat will flow from Cu to Al because Cu has a larger mass.
(c) Heat will flow from Cu to Al because Cu has a larger heat capacity.
(d) Heat will flow from Cu to Al because Cu is at a higher temperature.
(e) No heat will flow in either direction.

## Problems

55.34 A piece of silver with a mass of 362 g has a heat capacity of $85.7 \mathrm{~J} /{ }^{\circ} \mathrm{C}$. What is the specific heat of silver?

E 5.35 A $6.22-\mathrm{kg}$ piece of copper metal is heated from $20.5^{\circ} \mathrm{C}$ to $324.3^{\circ} \mathrm{C}$. Calculate the heat absorbed (in kJ ) by the metal.

E55.36 Calculate the amount of heat liberated (in kJ ) from 366 g of mercury when it cools from $77.0^{\circ} \mathrm{C}$ to $12.0^{\circ} \mathrm{C}$.
$\boldsymbol{Y}$ 5.37 A sheet of gold weighing 10.0 g and at a temperature of $18.0^{\circ} \mathrm{C}$ is placed flat on a sheet of iron weighing 20.0 g and at a temperature of $55.6^{\circ} \mathrm{C}$. What is the final temperature of the combined metals? Assume that no heat is lost to the surroundings. (Hint: The heat gained by the gold must be equal to the heat lost by the iron. The specific heats of the metals are given in Table 5.2.)

- 5.38 A $0.1375-\mathrm{g}$ sample of solid magnesium is burned in a constantvolume bomb calorimeter that has a heat capacity of $3024 \mathrm{~J} /{ }^{\circ} \mathrm{C}$. The temperature increases by $1.126^{\circ} \mathrm{C}$. Calculate the heat given off by the burning Mg , in $\mathrm{kJ} / \mathrm{g}$ and in $\mathrm{kJ} / \mathrm{mol}$.

E5.39 A quantity of $2.00 \times 10^{2} \mathrm{~mL}$ of 0.862 M HCl is mixed with $2.00 \times$ $10^{2} \mathrm{~mL}$ of $0.431 \mathrm{M} \mathrm{Ba}(\mathrm{OH})_{2}$ in a constant-pressure calorimeter of negligible heat capacity. The initial temperature of the HCl and $\mathrm{Ba}(\mathrm{OH})_{2}$ solutions is the same at $20.48^{\circ} \mathrm{C}$. For the process

$$
\mathrm{H}^{+}(a q)+\mathrm{OH}^{-}(a q) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)
$$

the heat of neutralization is $-56.2 \mathrm{~kJ} / \mathrm{mol}$. What is the final temperature of the mixed solution? Assume the specific heat of the solution is the same as that for pure water.
5.40 The fuel value of hamburger is approximately $3.6 \mathrm{kcal} / \mathrm{g}$. If a man eats 1 pound of hamburger for lunch and if none of the energy is stored in his body, estimate the amount of water that would have to be lost in perspiration to keep his body temperature constant. The heat of vaporization of water may be taken as $2.41 \mathrm{~kJ} / \mathrm{g}$ $(1 \mathrm{lb}=453.6 \mathrm{~g})$.
5.41 Metabolic activity in the human body releases approximately $1.0 \times 10^{4} \mathrm{~kJ}$ of heat per day. Assuming the body contains 50 kg of water, how fast would the body temperature rise if it were an isolated system? How much water must the body eliminate as perspiration to maintain the normal body temperature $\left(98.6^{\circ} \mathrm{F}\right)$ ? The heat of vaporization of water may be taken as $2.41 \mathrm{~kJ} / \mathrm{g}$. Comment on your results.

E5.42 A hemoglobin molecule (molar mass $=65,000 \mathrm{~g}$ ) can bind up to four oxygen molecules. In a certain experiment a $0.085-\mathrm{L}$ solution containing 6.0 g of deoxyhemoglobin (hemoglobin without oxygen molecules bound to it) was combined with an excess of oxygen in a constant-pressure calorimeter of negligible heat capacity. Calculate the enthalpy of reaction per mole of oxygen bound if the temperature rose by $0.044^{\circ} \mathrm{C}$. Assume the solution is dilute so that the specific heat of the solution is equal to that of water.

## Section 5.5: Hess's Law

## Review Questions

5.43 State Hess's law. Explain, with one example, the usefulness of Hess's law in thermochemistry.
5.44 Describe how chemists use Hess's law to determine the $\Delta H_{\mathrm{f}}^{\circ}$ of a compound by measuring its heat (enthalpy) of combustion.

## Problems

E5.45 From these data,

$$
\begin{aligned}
& \mathrm{S}(\text { rhombic })+\mathrm{O}_{2}(g) \longrightarrow \mathrm{SO}_{2}(g) \begin{array}{l}
\Delta H_{\mathrm{rxn}}^{\circ}=-296.06 \mathrm{~kJ} / \mathrm{mol} \\
\mathrm{~S}(\text { monoclinic })+\mathrm{O}_{2}(g) \longrightarrow \mathrm{SO}_{2}(g)
\end{array} \\
& \Delta H_{\mathrm{rxn}}^{\circ}=-296.36 \mathrm{~kJ} / \mathrm{mol}
\end{aligned}
$$

calculate the enthalpy change for the transformation

$$
\mathrm{S}(\text { rhombic }) \longrightarrow \mathrm{S}(\text { monoclinic })
$$

(Monoclinic and rhombic are different allotropic forms of elemental sulfur.)

E5.46 From the following data,

$$
\begin{aligned}
& \mathrm{C} \text { (graphite) }+\mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g) \quad \Delta H_{\mathrm{rxn}}^{\circ}=-393.5 \mathrm{~kJ} / \mathrm{mol} \\
& \mathrm{H}_{2}(g)+\frac{1}{2} \mathrm{O}_{2}(g) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l) \quad \Delta H_{\mathrm{rxn}}^{\circ}=-285.8 \mathrm{~kJ} / \mathrm{mol} \\
& 2 \mathrm{C}_{2} \mathrm{H}_{6}(g)+7 \mathrm{O}_{2}(g) \longrightarrow 4 \mathrm{CO}_{2}(g)+6 \mathrm{H}_{2} \mathrm{O}(l) \\
& \Delta H_{\mathrm{rxn}}^{\circ}=-3119.6 \mathrm{~kJ} / \mathrm{mol}
\end{aligned}
$$

calculate the enthalpy change for the reaction

$$
2 \mathrm{C}(\text { graphite })+3 \mathrm{H}_{2}(g) \longrightarrow \mathrm{C}_{2} \mathrm{H}_{6}(g)
$$

E5.47 From the following heats of combustion,

$$
\begin{aligned}
& \mathrm{CH}_{3} \mathrm{OH}(l)+\frac{3}{2} \mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(l) \\
& \Delta H_{\mathrm{rxn}}^{\circ}=-726.4 \mathrm{~kJ} / \mathrm{mol} \\
& \mathrm{C} \text { (graphite) }+\mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g) \quad \Delta H_{\mathrm{rxn}}^{\circ}=-393.5 \mathrm{~kJ} / \mathrm{mol} \\
& \mathrm{H}_{2}(g)+\frac{1}{2} \mathrm{O}_{2}(g) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l) \quad \Delta H_{\mathrm{rxn}}^{\circ}=-285.8 \mathrm{~kJ} / \mathrm{mol}
\end{aligned}
$$

calculate the enthalpy of formation of methanol $\left(\mathrm{CH}_{3} \mathrm{OH}\right)$ from its elements:

$$
\mathrm{C}(\text { graphite })+2 \mathrm{H}_{2}(g)+\frac{1}{2} \mathrm{O}_{2}(g) \longrightarrow \mathrm{CH}_{3} \mathrm{OH}(l)
$$

E 5.48 Calculate the standard enthalpy change for the reaction

$$
2 \mathrm{Al}(s)+\mathrm{Fe}_{2} \mathrm{O}_{3}(s) \longrightarrow 2 \mathrm{Fe}(s)+\mathrm{Al}_{2} \mathrm{O}_{3}(s)
$$

given that

$$
\begin{array}{ll}
2 \mathrm{Al}(s)+\frac{3}{2} \mathrm{O}_{2}(g) \longrightarrow \mathrm{Al}_{2} \mathrm{O}_{3}(s) & \Delta H_{\mathrm{rxn}}^{\circ}=-1669.8 \mathrm{~kJ} / \mathrm{mol} \\
2 \mathrm{Fe}(s)+\frac{3}{2} \mathrm{O}_{2}(g) \longrightarrow \mathrm{Fe}_{2} \mathrm{O}_{3}(s) & \Delta H_{\mathrm{rxn}}^{\circ}=-822.2 \mathrm{~kJ} / \mathrm{mol}
\end{array}
$$

## Section 5.6: Standard Enthalpies of Formation

## Review Questions

5.49 What is meant by the standard-state condition?
5.50 How are the standard enthalpies of an element and of a compound determined?
5.51 What is meant by the standard enthalpy of a reaction?
5.52 Write the equation for calculating the enthalpy of a reaction. Define all the terms.

## Problems

5.53 Which of the following standard enthalpy of formation values is not zero at $25^{\circ} \mathrm{C}: \mathrm{Na}$ (monoclinic), $\mathrm{Ne}(g), \mathrm{CH}_{4}(g), \mathrm{S}_{8}$ (monoclinic), $\mathrm{Hg}(l), \mathrm{H}(\mathrm{g})$ ?
5.54 The $\Delta H_{\mathrm{f}}^{\circ}$ values of the two allotropes of oxygen, $\mathrm{O}_{2}$ and $\mathrm{O}_{3}$, are 0 and $142.2 \mathrm{~kJ} / \mathrm{mol}$, respectively, at $25^{\circ} \mathrm{C}$. Which is the more stable form at this temperature?
5.55 Which is the more negative quantity at $25^{\circ} \mathrm{C}: \Delta H_{\mathrm{f}}^{\circ}$ for $\mathrm{H}_{2} \mathrm{O}(l)$ or $\Delta H_{\mathrm{f}}^{\circ}$ for $\mathrm{H}_{2} \mathrm{O}(g)$ ?

H5.56 Predict the value of $\Delta H_{\mathrm{f}}^{\circ}$ (greater than, less than, or equal to zero) for these elements at $25^{\circ} \mathrm{C}$ : (a) $\mathrm{Br}_{2}(g), \mathrm{Br}_{2}(l)$; (b) $\mathrm{I}_{2}(g), \mathrm{I}_{2}(s)$.
5.57 In general, compounds with negative $\Delta H_{\mathrm{f}}^{\circ}$ values are more stable than those with positive $\Delta H_{\mathrm{f}}^{\circ}$ values. $\mathrm{H}_{2} \mathrm{O}_{2}(l)$ has a negative $\Delta H_{\mathrm{f}}^{\circ}$ (see Appendix 2). Why, then, does $\mathrm{H}_{2} \mathrm{O}_{2}(l)$ have a tendency to decompose to $\mathrm{H}_{2} \mathrm{O}(l)$ and $\mathrm{O}_{2}(g)$ ?
5.58 Suggest ways (with appropriate equations) that would allow you to measure the $\Delta H_{\mathrm{f}}^{\circ}$ values of $\mathrm{Ag}_{2} \mathrm{O}(s)$ and $\mathrm{CaCl}_{2}(s)$ from their elements. No calculations are necessary.

E5 5.59 Calculate the heat of decomposition for this process at constant pressure and $25^{\circ} \mathrm{C}$ :

$$
\mathrm{CaCO}_{3}(s) \longrightarrow \mathrm{CaO}(s)+\mathrm{CO}_{2}(g)
$$

(Look up the standard enthalpy of formation of the reactant and products in Appendix 2.)
5.60 The standard enthalpies of formation of ions in aqueous solutions are obtained by arbitrarily assigning a value of zero to $\mathrm{H}^{+}$ions; that is, $\Delta H_{\mathrm{f}}^{\circ}\left[\mathrm{H}^{+}(a q)\right]=0$. (a) For the following reaction

$$
\mathrm{HCl}(g) \xrightarrow{\mathrm{H}_{2} \mathrm{O}} \mathrm{H}^{+}(a q)+\mathrm{Cl}^{-}(a q) \quad \Delta H^{\circ}=-74.9 \mathrm{~kJ} / \mathrm{mol}
$$

calculate $\Delta H_{\mathrm{f}}^{\circ}$ for the $\mathrm{Cl}^{-}$ions. (b) Given that $\Delta H_{\mathrm{f}}^{\circ}$ for $\mathrm{OH}^{-}$ions is $-229.6 \mathrm{~kJ} / \mathrm{mol}$, calculate the enthalpy of neutralization when 1 mole of a strong monoprotic acid (such as HCl ) is titrated by 1 mole of a strong base (such as KOH ) at $25^{\circ} \mathrm{C}$.

Ey 5.61 Calculate the heats of combustion for the following reactions from the standard enthalpies of formation listed in Appendix 2:
(a) $2 \mathrm{H}_{2}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l)$
(b) $2 \mathrm{C}_{2} \mathrm{H}_{2}(g)+5 \mathrm{O}_{2}(g) \longrightarrow 4 \mathrm{CO}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(l)$

E 5.62 Calculate the heats of combustion for the following reactions from the standard enthalpies of formation listed in Appendix 2:
(a) $\mathrm{C}_{2} \mathrm{H}_{4}(g)+3 \mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{CO}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(l)$
(b) $2 \mathrm{H}_{2} \mathrm{~S}(g)+3 \mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l)+2 \mathrm{SO}_{2}(g)$

E 5.63 Methanol, ethanol, and $n$-propanol are three common alcohols. When 1.00 g of each of these alcohols is burned in air, heat is liberated as follows: (a) methanol $\left(\mathrm{CH}_{3} \mathrm{OH}\right),-22.6 \mathrm{~kJ}$; (b) ethanol $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right),-29.7 \mathrm{~kJ}$; (c) n-propanol $\left(\mathrm{C}_{3} \mathrm{H}_{7} \mathrm{OH}\right),-33.4 \mathrm{~kJ}$. Calculate the heats of combustion of these alcohols in $\mathrm{kJ} / \mathrm{mol}$.

G5.64 The standard enthalpy change for the following reaction is $436.4 \mathrm{~kJ} / \mathrm{mol}$ :

$$
\mathrm{H}_{2}(\mathrm{~g}) \longrightarrow \mathrm{H}(\mathrm{~g})+\mathrm{H}(\mathrm{~g})
$$

Calculate the standard enthalpy of formation of atomic hydrogen $(\mathrm{H})$.
5.65 From the standard enthalpies of formation, calculate $\Delta H_{\mathrm{rxn}}^{\circ}$ for the reaction

$$
\mathrm{C}_{6} \mathrm{H}_{12}(l)+9 \mathrm{O}_{2}(g) \longrightarrow 6 \mathrm{CO}_{2}(g)+6 \mathrm{H}_{2} \mathrm{O}(l)
$$

For $\mathrm{C}_{6} \mathrm{H}_{12}(l), \Delta H_{\mathrm{f}}^{\circ}=-151.9 \mathrm{~kJ} / \mathrm{mol}$.

EI 5.66 Pentaborane-9 $\left(\mathrm{B}_{5} \mathrm{H}_{9}\right)$ is a colorless, highly reactive liquid that will burst into flames when exposed to oxygen. The reaction is

$$
2 \mathrm{~B}_{5} \mathrm{H}_{9}(l)+12 \mathrm{O}_{2}(g) \longrightarrow 5 \mathrm{~B}_{2} \mathrm{O}_{3}(s)+9 \mathrm{H}_{2} \mathrm{O}(l)
$$

Calculate the kilojoules of heat released per gram of the compound reacted with oxygen. The standard enthalpy of formation of $\mathrm{B}_{5} \mathrm{H}_{9}$ is $73.2 \mathrm{~kJ} / \mathrm{mol}$.
5.67 Determine the amount of heat (in kJ ) given off when $1.26 \times 10^{4} \mathrm{~g}$ of ammonia is produced according to the equation

$$
\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \longrightarrow 2 \mathrm{NH}_{3}(g) \quad \Delta H_{\mathrm{rxn}}^{\circ}=-92.6 \mathrm{~kJ} / \mathrm{mol}
$$

Assume that the reaction takes place under standard-state conditions at $25^{\circ} \mathrm{C}$.

EJ 5.68 Using the data in Appendix 2, calculate the enthalpy change for the gaseous reaction shown here. (Hint: First determine the limiting reactant.)

## Additional Problems

5.69 The convention of arbitrarily assigning a zero enthalpy value for the most stable form of each element in the standard state at $25^{\circ} \mathrm{C}$ is a convenient way of dealing with enthalpies of reactions. Explain why this convention cannot be applied to nuclear reactions.
5.70 Consider the following two reactions:

$\Delta H_{\mathrm{rxn}}^{\circ}=H_{1}$
$\Delta H_{\mathrm{rxn}}^{\circ}=H_{2}$
Determine the enthalpy change for the process

$$
2 \mathrm{~B} \longrightarrow \mathrm{C}
$$

E5.71 The standard enthalpy change $\Delta H^{\circ}$ for the thermal decomposition of silver nitrate according to the following equation is +78.67 kJ :

$$
\mathrm{AgNO}_{3}(s) \longrightarrow \mathrm{AgNO}_{2}(s)+\frac{1}{2} \mathrm{O}_{2}(g)
$$

The standard enthalpy of formation of $\mathrm{AgNO}_{3}(s)$ is $-123.02 \mathrm{~kJ} /$ mol. Calculate the standard enthalpy of formation of $\mathrm{AgNO}_{2}(s)$.
5.72 Hydrazine $\left(\mathrm{N}_{2} \mathrm{H}_{4}\right)$ decomposes according to the following reaction:

$$
3 \mathrm{~N}_{2} \mathrm{H}_{4}(l) \longrightarrow 4 \mathrm{NH}_{3}(g)+\mathrm{N}_{2}(g)
$$

(a) Given that the standard enthalpy of formation of hydrazine is $50.42 \mathrm{~kJ} / \mathrm{mol}$, calculate $\Delta H^{\circ}$ for its decomposition. (b) Both hydrazine and ammonia burn in oxygen to produce $\mathrm{H}_{2} \mathrm{O}(l)$ and $\mathrm{N}_{2}(g)$. Write balanced equations for each of these processes, and calculate $\Delta H^{\circ}$ for each of them. On a mass basis (per kg), which would be the better fuel: hydrazine or ammonia?

E 5.73 Consider the reaction

$$
\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \longrightarrow 2 \mathrm{NH}_{3}(g) \quad \Delta H=-92.6 \mathrm{~kJ} / \mathrm{mol}
$$

When 2 moles of $\mathrm{N}_{2}$ react with 6 moles of $\mathrm{H}_{2}$ to form 4 moles of $\mathrm{NH}_{3}$ at 1 atm and a certain temperature, there is a decrease in volume equal to 98 L . Calculate $\Delta U$ for this reaction. (The conversion factor is $1 \mathrm{~L} \cdot \mathrm{~atm}=101.3 \mathrm{~J}$.)

EI 5.74 Calculate the heat released when $2.00 \mathrm{~L}^{\text {of }} \mathrm{Cl}_{2}(g)$ with a density of $1.88 \mathrm{~g} / \mathrm{L}$ reacts with an excess of sodium metal at $25^{\circ} \mathrm{C}$ and 1 atm to form sodium chloride.
5.75 Photosynthesis produces glucose $\left(\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}\right)$ and oxygen from carbon dioxide and water:

$$
6 \mathrm{CO}_{2}(g)+6 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}(s)+6 \mathrm{O}_{2}(g)
$$

(a) How would you determine experimentally the $\Delta H_{\mathrm{rxn}}^{\circ}$ value for this reaction? (b) Solar radiation produces about $7.0 \times 10^{14} \mathrm{~kg}$ of glucose a year on Earth. What is the corresponding $\Delta H^{\circ}$ change?

E 5.76 Consider the reaction

$$
2 \mathrm{Na}(s)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{NaOH}(a q)+\mathrm{H}_{2}(g)
$$

When 2 moles of Na react with water at $25^{\circ} \mathrm{C}$ and 1 atm , the volume of $\mathrm{H}_{2}$ formed is 24.5 L . Calculate the work done in joules when 0.34 g of Na reacts with water under the same conditions. (The conversion factor is $1 \mathrm{~L} \cdot \mathrm{~atm}=101.3 \mathrm{~J}$.)
$\$$ 5.77 You are given the following data:

$$
\begin{aligned}
\mathrm{H}_{2}(g) & \Delta H^{\circ}=436.4 \mathrm{~kJ} / \mathrm{mol} \\
\mathrm{Br}_{2}(g) \longrightarrow 2 \mathrm{Br}(g) & \Delta H^{\circ}=192.5 \mathrm{~kJ} / \mathrm{mol} \\
\mathrm{H}_{2}(g)+\mathrm{Br}_{2}(g) \longrightarrow 2 \mathrm{HBr}(g) & \Delta H^{\circ}=-72.4 \mathrm{~kJ} / \mathrm{mol}
\end{aligned}
$$

Calculate $\Delta H^{\circ}$ for the reaction

$$
\mathrm{H}(g)+\mathrm{Br}(g) \longrightarrow \mathrm{HBr}(g)
$$

5.78 Methanol $\left(\mathrm{CH}_{3} \mathrm{OH}\right)$ is an organic solvent and is also used as a fuel in some automobile engines. From the following data, calculate the standard enthalpy of formation of methanol:

$$
\begin{array}{r}
2 \mathrm{CH}_{3} \mathrm{OH}(l)+3 \mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{CO}_{2}(g)+4 \mathrm{H}_{2} \mathrm{O}(l) \\
\Delta H_{\mathrm{rxn}}^{\circ}=-1452.8 \mathrm{~kJ} / \mathrm{mol}
\end{array}
$$

$\boldsymbol{H} 5.79$ A 44.0-g sample of an unknown metal at $99.0^{\circ} \mathrm{C}$ was placed in a constant-pressure calorimeter containing 80.0 g of water at $24.0^{\circ} \mathrm{C}$. The final temperature of the system was found to be $28.4^{\circ} \mathrm{C}$. Calculate the specific heat of the metal. (The heat capacity of the calorimeter is $12.4 \mathrm{~J} /{ }^{\circ} \mathrm{C}$.)

E5.80 A student mixes 88.6 g of water at $74.3^{\circ} \mathrm{C}$ with 57.9 g of water at $24.8^{\circ} \mathrm{C}$ in an insulated flask. What is the final temperature of the combined water?
5.81 Producer gas (carbon monoxide) is prepared by passing air over red-hot coke:

$$
\mathrm{C}(\mathrm{~s})+\frac{1}{2} \mathrm{O}_{2}(\mathrm{~g}) \longrightarrow \mathrm{CO}(\mathrm{~g})
$$

Water gas (a mixture of carbon monoxide and hydrogen) is prepared by passing steam over red-hot coke:

$$
\mathrm{C}(s)+\mathrm{H}_{2} \mathrm{O}(g) \longrightarrow \mathrm{CO}(g)+\mathrm{H}_{2}(g)
$$

For many years, both producer gas and water gas were used as fuels in industry and for domestic cooking. The large-scale preparation of these gases was carried out alternately, that is, first producer gas, then water gas, and so on. Using thermochemical reasoning, explain why this procedure was chosen.

E5.82 Compare the heat produced by the complete combustion of 1 mole of methane $\left(\mathrm{CH}_{4}\right)$ with a mole of water gas $\left(0.50\right.$ mole $\mathrm{H}_{2}$ and 0.50 mole CO ) under the same conditions. On the basis of your answer, would you prefer methane over water gas as a fuel? Can you suggest two other reasons why methane is preferable to water gas as a fuel?

H5.83 The so-called hydrogen economy is based on hydrogen produced from water using solar energy. The gas is then burned as a fuel:

$$
2 \mathrm{H}_{2}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l)
$$

A primary advantage of hydrogen as a fuel is that it is nonpolluting. A major disadvantage is that it is a gas and therefore is harder to store than liquids or solids. Calculate the number of moles of $\mathrm{H}_{2}$ required to produce an amount of energy equivalent
to that produced by the combustion of a gallon of octane $\left(\mathrm{C}_{8} \mathrm{H}_{18}\right)$. The density of octane is $2.66 \mathrm{~kg} / \mathrm{gal}$, and its standard enthalpy of formation is $-249.9 \mathrm{~kJ} / \mathrm{mol}$.

Ef 5.84 Ethanol $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right)$ and gasoline (assumed to be all octane, $\mathrm{C}_{8} \mathrm{H}_{18}$ ) are both used as automobile fuel. If gasoline is selling for $\$ 2.20$ / gal, what would the price of ethanol have to be in order to provide the same amount of heat per dollar? The density and $\Delta H_{\mathrm{f}}^{\circ}$ of octane are $0.7025 \mathrm{~g} / \mathrm{mL}$ and $-249.9 \mathrm{~kJ} / \mathrm{mol}$, respectively, and of ethanol are $0.7894 \mathrm{~g} / \mathrm{mL}$ and $-277.0 \mathrm{~kJ} / \mathrm{mol}$, respectively ( 1 gal $=3.785 \mathrm{~L}$ ).

E5.85 The combustion of how many moles of ethane $\left(\mathrm{C}_{2} \mathrm{H}_{6}\right)$ would be required to heat 855 g of water from $25.0^{\circ} \mathrm{C}$ to $98.0^{\circ} \mathrm{C}$ ?
5.86 If energy is conserved, how can there be an energy crisis?

E5.87 The heat of vaporization of a liquid $\left(\Delta H_{\text {vap }}\right)$ is the energy required to vaporize 1.00 g of the liquid at its boiling point. In one experiment, 60.0 g of liquid nitrogen (boiling point $=-196^{\circ} \mathrm{C}$ ) is poured into a Styrofoam cup containing $2.00 \times 10^{2} \mathrm{~g}$ of water at $55.3^{\circ} \mathrm{C}$. Calculate the molar heat of vaporization of liquid nitrogen if the final temperature of the water is $41.0^{\circ} \mathrm{C}$.
5.88 Explain the cooling effect experienced when ethanol is rubbed on your skin, given that

$$
\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(l) \longrightarrow \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(g) \quad \Delta H^{\circ}=42.2 \mathrm{~kJ} / \mathrm{mol}
$$

5.89 For which of the following reactions does $\Delta H_{\mathrm{rxn}}^{\circ}=\Delta H_{\mathrm{f}}^{\circ}$ ?
(a) $\mathrm{H}_{2}(g)+\mathrm{S}$ (rhombic) $\longrightarrow \mathrm{H}_{2} \mathrm{~S}(g)$
(b) C (diamond) $+\mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g)$
(c) $\mathrm{H}_{2}(g)+\mathrm{CuO}(s) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{Cu}(s)$
(d) $\mathrm{O}(g)+\mathrm{O}_{2}(g) \longrightarrow \mathrm{O}_{3}(g)$
5.90 Calculate the work done (in joules) when 1.0 mole of water is frozen at $0^{\circ} \mathrm{C}$ and 1.0 atm . The volumes of 1 mole of water and ice at $0^{\circ} \mathrm{C}$ are 0.0180 and 0.0196 L , respectively. (The conversion factor is $1 \mathrm{~L} \cdot \mathrm{~atm}=101.3 \mathrm{~J}$.)

EI5.91 A certain gas initially at 0.050 L undergoes expansion until its volume is 0.50 L . Calculate the work done (in joules) by the gas if it expands (a) against a vacuum and (b) against a constant pressure of 0.20 atm . (The conversion factor is $1 \mathrm{~L} \cdot \mathrm{~atm}=101.3 \mathrm{~J}$.)

E5.92 Calculate the standard enthalpy of formation for diamond, given that

$$
\begin{aligned}
\mathrm{C} \text { (graphite) }+\mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g) & \Delta H^{\circ}=-393.5 \mathrm{~kJ} / \mathrm{mol} \\
\mathrm{C} \text { (diamond) }+\mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g) & \Delta H^{\circ}=-395.4 \mathrm{~kJ} / \mathrm{mol}
\end{aligned}
$$

5.93 (a) For most efficient use, refrigerator freezer compartments should be fully packed with food. What is the thermochemical basis for this recommendation? (b) Starting at the same temperature, tea and coffee remain hot longer in a thermal flask than chicken noodle soup. Explain.
5.94 Calculate the standard enthalpy change for the fermentation process, in which glucose $\left(\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}\right)$ is converted to ethanol $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right)$ and carbon dioxide.

E5.95 Portable hot packs are available for skiers and people engaged in other outdoor activities in a cold climate. The air-permeable paper packet contains a mixture of powdered iron, sodium chloride, and other components, all moistened by a little water. The exothermic reaction that produces the heat is a very common one-the rusting of iron:

$$
4 \mathrm{Fe}(s)+3 \mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{Fe}_{2} \mathrm{O}_{3}(s)
$$

When the outside plastic envelope is removed, $\mathrm{O}_{2}$ molecules penetrate the paper, causing the reaction to begin. A typical
packet contains 250 g of iron to warm your hands or feet for up to 4 hours. How much heat (in kJ ) is produced by this reaction? (Hint: See Appendix 2 for $\Delta H_{\mathrm{f}}^{\circ}$ values.)
5.96 A man ate 0.50 pound of cheese (an energy intake of $4 \times 10^{3} \mathrm{~kJ}$ ). Suppose that none of the energy was stored in his body. What mass (in grams) of water would he need to perspire in order to maintain his original temperature? (It takes 44.0 kJ to vaporize 1 mole of water.)
5.97 The total volume of the Pacific Ocean is estimated to be $7.2 \times$ $10^{8} \mathrm{~km}^{3}$. A medium-sized atomic bomb produces $1.0 \times 10^{15} \mathrm{~J}$ of energy upon explosion. Calculate the number of atomic bombs needed to release enough energy to raise the temperature of the water in the Pacific Ocean by $1^{\circ} \mathrm{C}$.

GI5.98 A woman expends 95 kJ of energy walking a kilometer. The energy is supplied by the metabolic breakdown of food, which has an efficiency of 35 percent. How much energy does she save by walking the kilometer instead of driving a car that gets 8.2 km per liter of gasoline (approximately $20 \mathrm{mi} / \mathrm{gal}$ )? The density of gasoline is $0.71 \mathrm{~g} / \mathrm{mL}$, and its enthalpy of combustion is $-49 \mathrm{~kJ} / \mathrm{g}$.
5.99 The carbon dioxide exhaled by sailors in a submarine is often removed by reaction with an aqueous lithium hydroxide solution. (a) Write a balanced equation for this process. (Hint: The products are water and a soluble salt.) (b) If every sailor consumes $1.2 \times$ $10^{4} \mathrm{~kJ}$ of energy every day and assuming that this energy is totally supplied by the metabolism of glucose $\left(\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}\right)$, calculate the amounts of $\mathrm{CO}_{2}$ produced and LiOH required to purify the air.
5.100 The enthalpy of combustion of benzoic acid $\left(\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COOH}\right)$ is commonly used as the standard for calibrating constant-volume bomb calorimeters; its value has been accurately determined to be $-3226.7 \mathrm{~kJ} / \mathrm{mol}$. When 1.9862 g of benzoic acid are burned in a calorimeter, the temperature rises from $21.84^{\circ} \mathrm{C}$ to $25.67^{\circ} \mathrm{C}$. What is the heat capacity of the bomb? (Assume that the quantity of water surrounding the bomb is exactly 2000 g .)

E5.101 Calcium oxide $(\mathrm{CaO})$ is used to remove sulfur dioxide generated by coal-burning power stations:

$$
2 \mathrm{CaO}(s)+2 \mathrm{SO}_{2}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{CaSO}_{4}(s)
$$

Calculate the enthalpy change if $6.6 \times 10^{5} \mathrm{~g}$ of $\mathrm{SO}_{2}$ is removed by this process.

H5.102 Glauber's salt, sodium sulfate decahydrate $\left(\mathrm{Na}_{2} \mathrm{SO}_{4} \cdot 10 \mathrm{H}_{2} \mathrm{O}\right)$, undergoes a phase transition (that is, melting or freezing) at a convenient temperature of about $32^{\circ} \mathrm{C}$ :
$\mathrm{Na}_{2} \mathrm{SO}_{4} \cdot 10 \mathrm{H}_{2} \mathrm{O}(s) \longrightarrow \mathrm{Na}_{2} \mathrm{SO}_{4} \cdot 10 \mathrm{H}_{2} \mathrm{O}(l)$

$$
\Delta H^{\circ}=74.4 \mathrm{~kJ} / \mathrm{mol}
$$

As a result, this compound is used to regulate the temperature in homes. It is placed in plastic bags in the ceiling of a room. During the day, the endothermic melting process absorbs heat from the surroundings, cooling the room. At night, it gives off heat as it freezes. Calculate the mass of Glauber's salt in kilograms needed to lower the temperature of air in a room by $8.2^{\circ} \mathrm{C}$. The mass of air in the room is 605.4 kg ; the specific heat of air is $1.2 \mathrm{~J} / \mathrm{g} \cdot{ }^{\circ} \mathrm{C}$.
5.103 An excess of zinc metal is added to 50.0 mL of a $0.100{\mathrm{M} \mathrm{AgNO}_{3}}^{2}$ solution in a constant-pressure calorimeter like the one pictured in Figure 5.8. As a result of the reaction

$$
\mathrm{Zn}(s)+2 \mathrm{Ag}^{+}(a q) \longrightarrow \mathrm{Zn}^{2+}(a q)+2 \mathrm{Ag}(s)
$$

the temperature rises from $19.25^{\circ} \mathrm{C}$ to $22.17^{\circ} \mathrm{C}$. If the heat capacity of the calorimeter is $98.6 \mathrm{~J} /{ }^{\circ} \mathrm{C}$, calculate the enthalpy change for the given reaction on a molar basis. Assume that the density and specific heat of the solution are the same as those for water, and ignore the specific heats of the metals.

H5.104 (a) A person drinks four glasses of cold water $\left(3.0^{\circ} \mathrm{C}\right)$ every day. The volume of each glass is $2.5 \times 10^{2} \mathrm{~mL}$. How much heat (in kJ ) does the body have to supply to raise the temperature of the water to $37^{\circ} \mathrm{C}$, the body temperature? (b) How much heat would your body lose if you were to ingest $8.0 \times 10^{2} \mathrm{~g}$ of snow at $0^{\circ} \mathrm{C}$ to quench your thirst? (The amount of heat necessary to melt snow is $6.01 \mathrm{~kJ} / \mathrm{mol}$.)
5.105 A driver's manual states that the stopping distance quadruples as the speed doubles; that is, if it takes 30 ft to stop a car moving at 25 mph , then it would take 120 ft to stop a car moving at 50 mph . Justify this statement by using mechanics and the first law of thermodynamics. [Assume that when a car is stopped, its kinetic energy $\left(\frac{1}{2} m u^{2}\right)$ is totally converted to heat.]
55.106 At $25^{\circ} \mathrm{C}$ the standard enthalpy of formation of $\mathrm{HF}(\mathrm{aq})$ is $-320.1 \mathrm{~kJ} / \mathrm{mol}$; of $\mathrm{OH}^{-}(a q)$, it is $-229.6 \mathrm{~kJ} / \mathrm{mol}$; of $\mathrm{F}^{-}(a q)$, it is $-329.1 \mathrm{~kJ} / \mathrm{mol}$; and of $\mathrm{H}_{2} \mathrm{O}(l)$, it is $-285.8 \mathrm{~kJ} / \mathrm{mol}$.
(a) Calculate the standard enthalpy of neutralization of $\operatorname{HF}(a q)$ :

$$
\mathrm{HF}(a q)+\mathrm{OH}^{-}(a q) \longrightarrow \mathrm{F}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l)
$$

(b) Using the value of -56.2 kJ as the standard enthalpy change for the reaction

$$
\mathrm{H}^{+}(a q)+\mathrm{OH}^{-}(a q) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)
$$

calculate the standard enthalpy change for the reaction

$$
\mathrm{HF}(a q) \longrightarrow \mathrm{H}^{+}(a q)+\mathrm{F}^{-}(a q)
$$

5.107 Why are cold, damp air and hot, humid air more uncomfortable than dry air at the same temperatures? [The specific heats of water vapor and air are approximately $1.9 \mathrm{~J} /\left(\mathrm{g} \cdot{ }^{\circ} \mathrm{C}\right)$ and $1.0 \mathrm{~J} /\left(\mathrm{g} \cdot{ }^{\circ} \mathrm{C}\right)$, respectively.]
5.108 From the enthalpy of formation for $\mathrm{CO}_{2}$ and the following information, calculate the standard enthalpy of formation for carbon monoxide (CO).

$$
\mathrm{CO}(g)+\frac{1}{2} \mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g) \quad \Delta H^{\circ}=-283.0 \mathrm{~kJ} / \mathrm{mol}
$$

Why can't we obtain the standard enthalpy of formation directly by measuring the enthalpy of the following reaction?

$$
\mathrm{C} \text { (graphite) }+\frac{1}{2} \mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}(g)
$$

H5.109 A 46-kg person drinks 500 g of milk, which has a "caloric" value of approximately $3.0 \mathrm{~kJ} / \mathrm{g}$. If only 17 percent of the energy in milk is converted to mechanical work, how high (in meters) can the person climb based on this energy intake? [Hint: The work done in ascending is given by $m g h$, where $m$ is the mass (in kg ), $g$ is the gravitational acceleration $\left(9.8 \mathrm{~m} / \mathrm{s}^{2}\right)$, and $h$ is the height (in meters).]
5.110 The height of Niagara Falls on the American side is 51 m . (a) Calculate the potential energy of 1.0 g of water at the top of the falls relative to the ground level. (b) What is the speed of the falling water if all the potential energy is converted to kinetic energy? (c) What would be the increase in temperature of the water if all the kinetic energy were converted to heat? (See Problem 5.109 for information.)
5.111 In the nineteenth century two scientists named Dulong and Petit noticed that for a solid element, the product of its molar mass and its specific heat is approximately $25 \mathrm{~J} /{ }^{\circ} \mathrm{C}$. This observation, now called Dulong and Petit's law, was used to estimate the specific heat of metals. Verify the law for the metals listed in Table 5.2. The law does not apply to one of the metals. Which one is it? Why?
5.112 Determine the standard enthalpy of formation of ethanol $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right)$ from its standard enthalpy of combustion $(-1367.4 \mathrm{~kJ} / \mathrm{mol})$.

I5.113 Acetylene $\left(\mathrm{C}_{2} \mathrm{H}_{2}\right)$ and benzene $\left(\mathrm{C}_{6} \mathrm{H}_{6}\right)$ have the same empirical formula. In fact, benzene can be made from acetylene as follows:

$$
3 \mathrm{C}_{2} \mathrm{H}_{2}(g) \longrightarrow \mathrm{C}_{6} \mathrm{H}_{6}(l)
$$

The enthalpies of combustion for $\mathrm{C}_{2} \mathrm{H}_{2}$ and $\mathrm{C}_{6} \mathrm{H}_{6}$ are -1299.4 and $-3267.4 \mathrm{~kJ} / \mathrm{mol}$, respectively. Calculate the standard enthalpies of formation of $\mathrm{C}_{2} \mathrm{H}_{2}$ and $\mathrm{C}_{6} \mathrm{H}_{6}$ and hence the enthalpy change for the formation of $\mathrm{C}_{6} \mathrm{H}_{6}$ from $\mathrm{C}_{2} \mathrm{H}_{2}$.

E 5.114 Ice at $0^{\circ} \mathrm{C}$ is placed in a Styrofoam cup containing 361 g of a soft drink at $23^{\circ} \mathrm{C}$. The specific heat of the drink is about the same as that of water. Some ice remains after the ice and soft drink reach an equilibrium temperature of $0^{\circ} \mathrm{C}$. Determine the mass of ice that has melted. Ignore the heat capacity of the cup. (Hint: It takes 334 J to melt 1 g of ice at $0^{\circ} \mathrm{C}$.)
5.115 A gas company in Massachusetts charges 27 cents for a mole of natural gas $\left(\mathrm{CH}_{4}\right)$. Calculate the cost of heating 200 mL of water (enough to make a cup of coffee or tea) from $20^{\circ} \mathrm{C}$ to $100^{\circ} \mathrm{C}$. Assume that only 50 percent of the heat generated by the combustion is used to heat the water; the rest of the heat is lost to the surroundings.
5.116 How much metabolic energy must a 5.2-g hummingbird expend to fly to a height of 12 m ? (See the hint in Problem 5.109.)
5.117 Acetylene $\left(\mathrm{C}_{2} \mathrm{H}_{2}\right)$ can be made by combining calcium carbide $\left(\mathrm{CaC}_{2}\right)$ with water. (a) Write an equation for the reaction. (b) What is the maximum amount of heat (in joules) that can be obtained from the combustion of acetylene, starting with 74.6 g of $\mathrm{CaC}_{2}$ ?
5.118 The average temperature in deserts is high during the day but quite cool at night, whereas that in regions along the coastline is more moderate. Explain.
5.119 Both glucose and fructose are simple sugars with the same molecular formula of $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}$. Sucrose $\left(\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}\right)$, or table sugar, consists of a glucose molecule bonded to a fructose molecule (a water molecule is eliminated in the formation of sucrose). (a) Calculate the energy released when a $2.0-\mathrm{g}$ glucose tablet is burned in air. (b) To what height can a $65-\mathrm{kg}$ person climb after ingesting such a tablet, assuming only 30 percent of the energy released is available for work. (See the hint for Problem 5.109.) Repeat the calculations for a $2.0-\mathrm{g}$ sucrose tablet.
5.120 About $6.0 \times 10^{13} \mathrm{~kg}$ of $\mathrm{CO}_{2}$ is fixed (converted to more complex organic molecules) by photosynthesis every year. (a) Assuming all the $\mathrm{CO}_{2}$ ends up as glucose $\left(\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}\right)$, calculate the energy (in kJ ) stored by photosynthesis per year. (b) A typical coal-burning electric power station generates about $2.0 \times 10^{6} \mathrm{~W}$ per year. How many such stations are needed to generate the same amount of energy as that captured by photosynthesis $(1 \mathrm{~W}=1 \mathrm{~J} / \mathrm{s})$ ?
5.121 When 1.034 g of naphthalene $\left(\mathrm{C}_{10} \mathrm{H}_{8}\right)$ is burned in a constantvolume bomb calorimeter at $298 \mathrm{~K}, 41.56 \mathrm{~kJ}$ of heat is evolved. Calculate $\Delta U$ and $w$ for the reaction on a molar basis.
5.122 From a thermochemical point of view, explain why a carbon dioxide fire extinguisher or water should not be used on a magnesium fire.
5.123 Consider the reaction

$$
2 \mathrm{H}_{2}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l)
$$

Under atmospheric conditions (1.00 atm) it was found that the formation of water resulted in a decrease in volume equal to 73.4 L . Calculate $\Delta U$ for the process. $\Delta H=-571.6 \mathrm{~kJ} / \mathrm{mol}$. (The conversion factor is $1 \mathrm{~L} \cdot \mathrm{~atm}=101.3 \mathrm{~J}$.)
5.124 Lime is a term that includes calcium oxide ( CaO , also called quicklime) and calcium hydroxide $\left[\mathrm{Ca}(\mathrm{OH})_{2}\right.$, also called slaked lime]. It is used in the steel industry to remove acidic impurities, in air-pollution control to remove acidic oxides such as $\mathrm{SO}_{2}$, and in water treatment. Quicklime is made industrially by heating limestone $\left(\mathrm{CaCO}_{3}\right)$ above $2000^{\circ} \mathrm{C}$ :

$$
\mathrm{CaCO}_{3}(s) \longrightarrow \mathrm{CaO}(s)+\mathrm{CO}_{2}(g) \quad \Delta H^{\circ}=177.8 \mathrm{~kJ} / \mathrm{mol}
$$

Slaked lime is produced by treating quicklime with water:

$$
\mathrm{CaO}(s)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{Ca}(\mathrm{OH})_{2}(s) \quad \Delta H^{\circ}=-65.2 \mathrm{~kJ} / \mathrm{mol}
$$

The exothermic reaction of quicklime with water and the rather small specific heats of both quicklime $\left[0.946 \mathrm{~J} /\left(\mathrm{g} \cdot{ }^{\circ} \mathrm{C}\right)\right]$ and slaked lime $\left[1.20 \mathrm{~J} /\left(\mathrm{g} \cdot{ }^{\circ} \mathrm{C}\right)\right]$ make it hazardous to store and transport lime in vessels made of wood. Wooden sailing ships carrying lime would occasionally catch fire when water leaked into the hold. (a) If a $500.0-\mathrm{g}$ sample of water reacts with an equimolar amount of CaO (both at an initial temperature of $25^{\circ} \mathrm{C}$ ), what is the final temperature of the product, $\mathrm{Ca}(\mathrm{OH})_{2}$ ? Assume that the product absorbs all the heat released in the reaction. (b) Given that the standard enthalpies of formation of CaO and $\mathrm{H}_{2} \mathrm{O}$ are -635.6 and $-285.8 \mathrm{~kJ} / \mathrm{mol}$, respectively, calculate the standard enthalpy of formation of $\mathrm{Ca}(\mathrm{OH})_{2}$.
5.125 A 4.117-g impure sample of glucose $\left(\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}\right)$ was burned in a constant-volume calorimeter having a heat capacity of $19.65 \mathrm{~kJ} /{ }^{\circ} \mathrm{C}$. If the rise in temperature is $3.134^{\circ} \mathrm{C}$, calculate the percent by mass of the glucose in the sample. Assume that the impurities are unaffected by the combustion process and that $\Delta U=\Delta H$. See Appendix 2 for thermodynamic data.
5.126 The combustion of 0.4196 g of a hydrocarbon releases 17.55 kJ of heat. The masses of the products are $\mathrm{CO}_{2}=1.419 \mathrm{~g}$ and $\mathrm{H}_{2} \mathrm{O}=0.290 \mathrm{~g}$. (a) What is the empirical formula of the compound? (b) If the approximate molar mass of the compound is $76 \mathrm{~g} / \mathrm{mol}$, calculate its standard enthalpy of formation.
§5.127 In a constant-pressure calorimetry experiment, a reaction gives off 21.8 kJ of heat. The calorimeter contains 150 g of water, initially at $23.4^{\circ} \mathrm{C}$. What is the final temperature of the water? The heat capacity of the calorimeter is negligibly small.
$\leftrightarrows 5.128$ At $850^{\circ} \mathrm{C}, \mathrm{CaCO}_{3}$ undergoes substantial decomposition to yield CaO and $\mathrm{CO}_{2}$. Assuming that the $\Delta H_{\mathrm{f}}^{\circ}$ values of the reactant and products are the same at $850^{\circ} \mathrm{C}$ as they are at $25^{\circ} \mathrm{C}$, calculate the enthalpy change (in kJ ) if 66.8 g of $\mathrm{CO}_{2}$ is produced in one reaction.
5.129 For reactions in condensed phases (liquids and solids), the difference between $\Delta H$ and $\Delta U$ is usually quite small. This statement holds for reactions carried out under atmospheric conditions. For certain geochemical processes, however, the external pressure may be so great that $\Delta H$ and $\Delta U$ can differ by a significant amount. A well-known example is the slow conversion of graphite to diamond under Earth's surface. Calculate $\Delta H-\Delta U$ for the conversion of 1 mole of graphite to 1 mole of diamond at a pressure of $50,000 \mathrm{~atm}$. The densities of graphite and diamond are $2.25 \mathrm{~g} / \mathrm{cm}^{3}$ and $3.52 \mathrm{~g} / \mathrm{cm}^{3}$, respectively.
5.130 Which of the constant-pressure processes given here has the smallest difference between $\Delta H$ and $\Delta U:($ a) water $\longrightarrow$ water vapor, (b) water $\longrightarrow$ ice, (c) ice $\longrightarrow$ water vapor? Explain.
5.131 Construct a table with the headings $q, w, \Delta U$, and $\Delta H$. For each of the following processes, deduce whether each of the quantities listed is positive $(+)$, negative $(-)$, or zero (0): (a) freezing of benzene, (b) reaction of sodium with water, (c) boiling of liquid ammonia, (d) melting of ice, (e) expansion of a gas at constant temperature.
5.132 Give an example for each of the following situations: (a) adding heat to a system raises its temperature, (b) adding heat to a system does not change its temperature, and (c) a system's temperature changes despite no heat being added to it or removed from it.
5.133 Metabolic activity in the human body releases approximately $1.0 \times 10^{4} \mathrm{~kJ}$ of heat per day. Assume that a $55-\mathrm{kg}$ body has the same specific heat as water; how much would the body temperature rise if it were an isolated system? How much water must the body eliminate as perspiration to maintain the normal body temperature $\left(98.6^{\circ} \mathrm{F}\right)$ ? Comment on your results. (The heat of vaporization of water is $2.41 \mathrm{~kJ} / \mathrm{g}$.)
5.134 A 3.52-g sample of ammonium nitrate $\left(\mathrm{NH}_{4} \mathrm{NO}_{3}\right)$ was added to 80.0 mL of water in a constant-pressure calorimeter of negligible heat capacity. As a result, the temperature of the solution decreased from $21.6^{\circ} \mathrm{C}$ to $18.1^{\circ} \mathrm{C}$. Calculate the heat of solution ( $\Delta H_{\text {soln }}$ ) in $\mathrm{kJ} / \mathrm{mol}$ :

$$
\mathrm{NH}_{4} \mathrm{NO}_{3}(s) \longrightarrow \mathrm{NH}_{4}^{+}(a q)+\mathrm{NO}_{3}^{-}(a q)
$$

Assume the specific heat of the solution is the same as that of water.
5.135 A quantity of 50.0 mL of $0.200 \mathrm{MBa}(\mathrm{OH})_{2}$ is mixed with 50.0 mL of $0.400 \mathrm{M} \mathrm{HNO}_{3}$ in a constant-pressure calorimeter having a heat capacity of $496 \mathrm{~J} /{ }^{\circ} \mathrm{C}$. The initial temperature of both solutions is the same at $22.4^{\circ} \mathrm{C}$. What is the final temperature of the mixed solution? Assume that the specific heat of the solutions is the same as that of water and the molar heat of neutralization is $-56.2 \mathrm{~kJ} / \mathrm{mol}$.
5.136 A quantity of 85.0 mL of 0.600 M HCl is mixed with 85.0 mL of 0.600 M KOH in a constant-pressure calorimeter. The initial temperature of both solutions is the same at $17.35^{\circ} \mathrm{C}$, and the final temperature of the mixed solution is $19.02^{\circ} \mathrm{C}$. What is the heat capacity of the calorimeter? Assume that the specific heat of the solutions is the same as that of water and the molar heat of neutralization is $-56.2 \mathrm{~kJ} / \mathrm{mol}$.

## Pre-Professional Practice Exam Problems: Physical and Biological Sciences

A bomb calorimeter was calibrated by burning 1.013 g of benzoic acid $\left(\mathrm{C}_{7} \mathrm{H}_{6} \mathrm{O}_{2}\right)\left(\Delta U_{\text {comb }}=3.221 \times 10^{3} \mathrm{~kJ} / \mathrm{mol}\right)$. The temperature change in the calorimeter during the calibration combustion was $5.19^{\circ} \mathrm{C}$. A nutritional chemist then used the calibrated calorimeter to determine the energy content of food. The chemist carefully dried a sample of food and placed 0.8996 g of the sample in the calorimeter with sufficient oxygen for the combustion to go to completion. Combustion of the food sample caused the temperature of the calorimeter to increase by $4.42^{\circ} \mathrm{C}$.

1. Approximately how many moles of $\mathrm{O}_{2}$ gas were consumed in the calibration combustion?
a) 0.008
b) 0.1
c) 0.2
d) 0.06
2. What is the heat capacity $\left(C_{V}\right)$ of the calorimeter?
a) $5.15 \mathrm{~kJ} /{ }^{\circ} \mathrm{C}$
b) $5.08 \mathrm{~kJ} /{ }^{\circ} \mathrm{C}$
c) $5.12 \mathrm{~kJ} /{ }^{\circ} \mathrm{C}$
d) $4.97 \mathrm{~kJ} /{ }^{\circ} \mathrm{C}$
3. What is the energy content of the food?
a) $22.8 \mathrm{~kJ} / \mathrm{g}$
b) $4.97 \mathrm{~kJ} / \mathrm{g}$
c) $25.3 \mathrm{~kJ} / \mathrm{g}$
d) $0.201 \mathrm{~kJ} / \mathrm{g}$
4. What would be the effect on the result if the food sample were not completely dried prior to being placed in the calorimeter?
a) The combustion of the sample would be incomplete.
b) The calculated energy content per gram would be too low.
c) The calculated energy content per gram would be too high.
d) There would be no effect on the result.

## How Our Understanding of Electronic Structure Has Advanced Medicine

Over the past two decades, the use of lasers has revolutionized many medical procedures, including the excision of malignant tumors, the treatment of the symptoms associated with an enlarged prostate, and a wide variety of cosmetic procedures. The benefits of laser surgery typically include smaller incisions, less bleeding, less pain, and shorter recovery times than with traditional surgical methods. Among the most popular laser procedures is LASIK surgery to improve eyesight. In LASIK, a nearly circular incision is made in the cornea, creating a hinged flap on the surface of the eyeball. The flap is then lifted, and a laser is used to reshape the cornea by selective ablation or vaporization of the underlying corneal tissue. The flap is then replaced, conforming to the reshaped cornea. Many patients report an immediate improvement in vision, and typical recovery times are very short.
The light emitted by a laser is the result of electronic transitions and is powerful enough to vaporize biological tissue. Although the nuclear model that Rutherford proposed based on his gold-foil experiment specified the location of the protons and the neutrons in an atom, it failed to describe the location or behavior of the electrons. Early in the twentieth century, the application of a radical new theory in physics called quantum theory, and the ingenious interpretation of experimental evidence by Max Planck, Albert Einstein, and others, led to our current understanding of the electronic structure of atoms. This understanding of electronic structure is what makes such things as lasers possible.

Student Annotation: LASIK is an acronym for LASer-assisted In situ Keratomileusis.

At the end of this chapter, you will be able to answer a variety of questions about the nature of light and the electronic structure of the atom. [M page 247]

## In This Chapter, You Will Learn:

About some of the properties of electromagnetic radiation or light and how these properties have been used to study and elucidate the electronic structure of atoms. You will also learn how to determine the arrangement of electrons in a particular atom.

Before you begin, you should review

- Tracking units [ If Section 1.6]
- The nuclear model of the atom [ 144 Section 2.2]

Student Annotation: The speed of light is defined to be $2.99792458 \times 10^{8} \mathrm{~m} / \mathrm{s}$. It is, therefore, an exact number and usually does not limit the number of significant figures in a calculated result. In most calculations, however, the speed of light is rounded to three significant figures: $c=3.00 \times 10^{8} \mathrm{~m} / \mathrm{s}$.

## Student Annotation: Frequency is

 expressed as cycles per second, or simply reciprocal seconds $\left(\mathrm{s}^{-1}\right)$, which is also known as hertz (Hz).
### 6.1 The Nature of Light

When we say "light," we generally mean visible light, which is the light we can detect with our eyes. Visible light, however, is only a small part of the continuum of radiation that comprises the electromagnetic spectrum. In addition to visible light, the electromagnetic spectrum includes radio waves, microwave radiation, infrared and ultraviolet radiation, X rays, and gamma rays, as shown in Figure 6.1. Some of these terms may be familiar to you. For instance, the danger of exposure to ultraviolet radiation is why you need to use sunscreen. You may have used microwave radiation from a microwave oven to reheat food or to pop popcorn; you may have had X rays during a routine dental checkup or after breaking a bone; and you may recall from Chapter 2 that gamma rays are emitted from some radioactive materials. Although these phenomena may seem very different from each other and from visible light, they all are the transmission of energy in the form of waves.

## Properties of Waves

The fundamental properties of waves are illustrated in Figure 6.2. Waves are characterized by their wavelength, frequency, and amplitude. Wavelength $\lambda$ (lambda) is the distance between identical points on successive waves (e.g., successive peaks or successive troughs). The frequency $\nu$ (nu) is the number of waves that pass through a particular point in 1 second. Amplitude is the vertical distance from the midline of a wave to the top of the peak or the bottom of the trough.

The speed of a wave depends on the type of wave and the nature of the medium through which the wave is traveling (e.g., air, water, or a vacuum). The speed of light through a vacuum, $c$, is $2.99792458 \times 10^{8} \mathrm{~m} / \mathrm{s}$. The speed, wavelength, and frequency of a wave are related by the equation

## Equation 6.1

$$
c=\lambda v
$$

where $\lambda$ and $v$ are expressed in meters (m) and reciprocal seconds $\left(\mathrm{s}^{-1}\right)$, respectively. While wavelength in meters is convenient for this equation, the units customarily used to express the wavelength of electromagnetic radiation depend on the type of radiation and the magnitude of the corresponding wavelength. The wavelength of visible light, for instance, is on the order of nanometers ( nm , or $10^{-9} \mathrm{~m}$ ), and that of microwave radiation is on the order of centimeters ( cm , or $10^{-2} \mathrm{~m}$ ).

Figure 6.1 Electromagnetic spectrum. Each type of radiation is spread over a specific range of wavelengths (and frequencies). Visible light ranges from 400 nm (violet) to 700 nm (red).

## The Electromagnetic Spectrum

In 1873 James Clerk Maxwell proposed that visible light consisted of electromagnetic waves. According to Maxwell's theory, an electromagnetic wave has an electric field component and a magnetic field component. These two components have the same wavelength and frequency, and hence the same speed, but they travel in mutually perpendicular planes (Figure 6.3). The significance of Maxwell's theory is that it provides a mathematical description of the general behavior of light. In particular, his model accurately describes how energy in the form of radiation can be propagated through space as oscillating electric and magnetic fields.

## The Double-Slit Experiment

A simple yet convincing demonstration of the wave nature of light is the phenomenon of interference. When a light source passes through a narrow opening, called a slit, a bright line is generated in the path of the light through the slit. When the same light source passes through two closely spaced slits, however, as shown in Figure 6.4, the result is not two bright lines, one in the path of each slit, but rather a series of light and dark lines known as an interference pattern. When the light sources recombine after passing through the slits, they do so constructively where the two waves are in phase (giving rise to the light lines) and destructively where the waves are out of phase (giving rise to the dark lines). Constructive interference and destructive interference are properties of waves.

The various types of electromagnetic radiation in Figure 6.1 differ from one another in wavelength and frequency. Radio waves, which have long wavelengths and low frequencies, are

Figure 6.2 Characteristics of waves: wavelength, amplitude, and frequency.

Figure 6.3 Electric field and magnetic field components of an electromagnetic wave. These two components have the same wavelength, frequency, and amplitude, but they vibrate in two mutually perpendicular planes.

Figure 6.4 Double-slit experiment. (a) Red lines correspond to the maximum intensity resulting from constructive interference. Dashed blue lines correspond to the minimum intensity resulting from destructive interference. (b) Interference pattern with alternating bright and dark lines.
emitted by large antennas, such as those used by broadcasting stations. The shorter, visible light waves are produced by the motions of electrons within atoms and molecules. The shortest waves, which also have the highest frequency, are $\gamma$ (gamma) rays, which result from nuclear processes [ 14 Section 2.2]. As we will see shortly, the higher the frequency, the more energetic the radiation. Thus, ultraviolet radiation, X rays, and $\gamma$ rays are high-energy radiation, whereas infrared radiation, microwave radiation, and radio waves are low-energy radiation.

Sample Problem 6.1 illustrates the conversion between wavelength and frequency.

## Sample Problem 6.1

One type of laser used in the treatment of vascular skin lesions is a neodymium-doped yttrium aluminum garnet or Nd:YAG laser. The wavelength commonly used in these treatments is 532 nm . What is the frequency of this radiation?

Strategy Wavelength and frequency are related by Equation $6.1(c=\lambda \nu)$, so we must rearrange Equation 6.1 to solve for frequency. Because we are given the wavelength of the electromagnetic radiation in nanometers, we must convert this wavelength to meters and use $c=3.00 \times 10^{8} \mathrm{~m} / \mathrm{s}$.

Setup Solving for frequency gives $v=c / \lambda$. Next we convert the wavelength to meters:

$$
\lambda(\text { in meters })=532 \mathrm{~nm} \times \frac{1 \times 10^{-9} \mathrm{~m}}{1 \mathrm{~nm}}=5.32 \times 10^{-7} \mathrm{~m}
$$

## Solution

$$
v=\frac{3.00 \times 10^{8} \mathrm{~m} / \mathrm{s}}{5.32 \times 10^{-7} \mathrm{~m}}=5.64 \times 10^{14} \mathrm{~s}^{-1}
$$

Practice Problem A What is the wavelength (in meters) of an electromagnetic wave whose frequency is $1.61 \times 10^{12} \mathrm{~s}^{-1}$ ?

GPractice Problem B What is the frequency (in reciprocal seconds) of electromagnetic radiation with a wavelength of 1.03 cm ?

## Checkpoint 6.1 The Nature of Light

6.1.1 Calculate the wavelength of light with frequency $3.45 \times 10^{14} \mathrm{~s}^{-1}$.
a) $1.15 \times 10^{-6} \mathrm{~nm}$
b) $1.04 \times 10^{23} \mathrm{~nm}$
c) $8.70 \times 10^{2} \mathrm{~nm}$
d) 115 nm
e) $9.66 \times 10^{-24} \mathrm{~nm}$
6.1.2 Calculate the frequency of light with wavelength 126 nm .
a) $2.38 \times 10^{15} \mathrm{~s}^{-1}$
b) $4.20 \times 10^{-16} \mathrm{~s}^{-1}$
c) $37.8 \mathrm{~s}^{-1}$
d) $2.65 \times 10^{-2} \mathrm{~s}^{-1}$
e) $3.51 \times 10^{19} \mathrm{~s}^{-1}$
6.1.3 When traveling through a translucent medium, such as glass, light travels more slowly than it travels through a vacuum. Red light with a wavelength of 684 nm travels through Pyrex glass with a frequency of $2.92 \times 10^{14} \mathrm{~s}^{-1}$. Calculate the speed of this light.
a) $3.00 \times 10^{8} \mathrm{~m} / \mathrm{s}$
b) $2.00 \times 10^{8} \mathrm{~m} / \mathrm{s}$
c) $2.92 \times 10^{6} \mathrm{~m} / \mathrm{s}$
d) $4.23 \times 10^{7} \mathrm{~m} / \mathrm{s}$
e) $2.23 \times 10^{8} \mathrm{~m} / \mathrm{s}$
6.1.4 Of the waves pictured, $\qquad$ has the greatest frequency, $\ldots$ has the greatest wavelength, and $\qquad$ has the greatest amplitude.

a) i, ii, iii
b) i, iii, ii
c) $\mathrm{ii}, \mathrm{i}, \mathrm{ii}$
d) ii, i, iii
e) ii, iii, ii

### 6.2 Quantum Theory

Early attempts by nineteenth-century physicists to figure out the structure of the atom met with only limited success. This was largely because they were attempting to understand the behavior of subatomic particles using the laws of classical physics that govern the behavior of macroscopic objects. It took a long time to realize-and an even longer time to accept-that the properties of atoms are not governed by the same physical laws as larger objects.

## Quantization of Energy

When a solid is heated, it emits electromagnetic radiation, known as blackbody radiation, over a wide range of wavelengths. The red glow of the element of an electric stove and the bright white light of a tungsten lightbulb are examples of blackbody radiation. Measurements taken in the latter part of the nineteenth century showed that the amount of energy given off by an object at a certain temperature depends on the wavelength of the emitted radiation. Attempts to account for this dependence in terms of established wave theory and thermodynamic laws were only partially successful. One theory was able to explain short-wavelength dependence but failed to account for the longer wavelengths. Another theory accounted for the longer wavelengths but failed for short wavelengths. With no one theory that could explain both observations, it seemed that something fundamental was missing from the laws of classical physics.

In 1900, Max Planck ${ }^{1}$ provided the solution and launched a new era in physics with an idea that departed drastically from accepted concepts. Classical physics assumed that radiant energy was continuous; that is, it could be emitted or absorbed in any amount. Based on data from blackbody radiation experiments, Planck proposed that radiant energy could only be emitted or absorbed in discrete quantities, like small packages or bundles. Planck gave the name quantum to the smallest quantity of energy that can be emitted (or absorbed) in the form of electromagnetic radiation. The energy $E$ of a single quantum of energy is given by

[^9]Student Annotation: The National Institute of Standards and Technology (NIST) gives a value of $6.6260693 \times 10^{-34} \mathrm{~J} \cdot \mathrm{~s}$ for Planck's constant. Typically, three significant figures are sufficient for solving problems.

Student Annotation: Although the $1064-\mathrm{nm}$ laser beam is less energetic than the $532-\mathrm{nm}$ beam, it poses a greater danger to the eye because it is not visible and does not evoke the blink response that visible wavelengths do. Despite not being visible, a 1064 -nm beam passes through the anterior structures of the eye and damages the retina. Because the beam is not visible, the damage is not immediately apparent, but it is permanent.

## Equation 6.2 <br> $$
E=h v
$$

where $h$ is called Planck's constant and $v$ is the frequency of the radiation. The value of Planck's constant is $6.63 \times 10^{-34} \mathrm{~J} \cdot \mathrm{~s}$.

According to quantum theory, energy is always emitted in whole-number multiples of $h v$. At the time Planck presented his theory, he could not explain why energies should be fixed or quantized in this manner. Starting with this hypothesis, however, he had no difficulty correlating the experimental data for the emission by solids over the entire range of wavelengths; the experimental data supported his new quantum theory.

The idea that energy is quantized rather than continuous may seem strange, but the concept of quantization has many everyday analogies. For example, vending machines dispense cans or bottles of soft drinks only in whole numbers (you can't buy part of a can or bottle from a machine). Each can or bottle is a quantum of its soft drink. Even processes in living systems involve quantized phenomena. The eggs laid by hens are quanta (hens lay only whole eggs). Similarly, when a dog or cat gives birth to a litter, the number of offspring is always an integer. Each puppy or kitten is a quantum of that animal. Planck's quantum theory revolutionized physics. Indeed, the flurry of research that ensued altered our concept of nature forever.

## Bringing Chemistry to Life

## Laser Pointers

The laser pointers that have become so common typically emit radiation in the red region of the visible spectrum with output wavelengths ranging from 630 to 680 nm . Low prices and availability have made the devices popular not only with instructors and other speakers, but with teenagers and even children-raising some significant safety concerns. Although the human blink reflex generally is sufficient to protect against serious or permanent injury to the eye by one of these devices, intentional prolonged exposure of the eye to the beam from a laser pointer can be dangerous. Of particular concern are the new green laser pointers that emit a wavelength of 532 nm . The lasers in these devices also produce radiation in the infrared region of the electromagnetic spectrum (1064 nm), but they are equipped with filters to prevent the emission of infrared radiation. However, some of the inexpensive imported lasers do not bear adequate safety labeling and the filters are easily removed-potentially resulting in the emission of dangerous radiation.

## Sample Problem 6.2

How much more energy per photon is there in green light of wavelength 532 nm than in red light of wavelength 635 nm ?

Strategy Convert each wavelength to frequency using Equation 6.1, and then calculate the energy per photon using Equation 6.2.

Setup Convert the wavelengths to meters:

$$
\begin{aligned}
& 532 \mathrm{nMA} \times \frac{1 \times 10^{-9} \mathrm{~m}}{1 \mathrm{~nm}}=5.32 \times 10^{-7} \mathrm{~m} \\
& 634 \mathrm{nMr} \times \frac{1 \times 10^{-9} \mathrm{~m}}{1 \mathrm{nM}}=6.35 \times 10^{-7} \mathrm{~m}
\end{aligned}
$$

Planck's constant, $h$, is $6.63 \times 10^{-34} \mathrm{~J} \cdot \mathrm{~s}$.
Solution For 532 nm ,

$$
v=\frac{c}{\lambda}=\frac{3.00 \times 10^{8} \mathrm{~m} / \mathrm{s}}{5.32 \times 10^{-7} \mathrm{~m}}=5.64 \times 10^{14} \mathrm{~s}^{-1}
$$

and

$$
E=h v=\left(6.63 \times 10^{-34} \mathrm{~J} \cdot \mathrm{~s}\right)\left(5.64 \times 10^{14} \mathrm{~s}^{-1}\right)=3.74 \times 10^{-19} \mathrm{~J}
$$

The energy of a single photon with wavelength 532 nm is $3.74 \times 10^{-19} \mathrm{~J}$.
Following the same procedure, the energy of a photon of wavelength 635 nm is $3.13 \times 10^{-19} \mathrm{~J}$. The difference between them is $\left(3.74 \times 10^{-19} \mathrm{~J}\right)-\left(3.13 \times 10^{-19} \mathrm{~J}\right)=6.1 \times 10^{-20} \mathrm{~J}$. Therefore,
a photon of green light $(\lambda=532 \mathrm{~nm})$ has $6.1 \times 10^{-20} \mathrm{~J}$ more energy than a photon of red light ( $\lambda=635 \mathrm{~nm}$ ).

Practice Problem A Calculate the difference in energy (in joules) between a photon with $\lambda=680 \mathrm{~nm}$ (red) and a photon with $\lambda=442 \mathrm{~nm}$ (blue).

HPractice Problem B In what region of the electromagnetic spectrum is a photon found that possesses twice as much energy as one in the blue region $(\lambda=442 \mathrm{~nm})$ of the visible spectrum?

## Photons and the Photoelectric Effect

In 1905, only 5 years after Planck presented his quantum theory, Albert Einstein ${ }^{2}$ used the theory to explain another mysterious physical phenomenon, the photoelectric effect, in which electrons are ejected from the surface of a metal exposed to light of at least a certain minimum frequency, called the threshold frequency (Figure 6.5). The number of electrons ejected was proportional to the intensity (or brightness) of the light, but the energies of the ejected electrons were not. Below the threshold frequency no electrons were ejected no matter how intense the light.

The photoelectric effect could not be explained by the wave theory of light, which associated the energy of light with its intensity. Einstein, however, made an extraordinary assumption. He suggested that a beam of light is really a stream of particles. These particles of light are now called photons. Using Planck's quantum theory of radiation as a starting point, Einstein deduced that each photon must possess energy $E$ given by the equation

$$
E_{\text {photon }}=h v
$$

where $h$ is Planck's constant and $v$ is the frequency of the light. Electrons are held in a metal by attractive forces, and so removing them from the metal requires light of a sufficiently high frequency (which corresponds to a sufficiently high energy) to break them free. Shining a beam of light onto a metal surface can be thought of as shooting a beam of particles-photons-at the metal atoms. If the frequency of the photons is such that $h v$ exactly equals the energy that binds the electrons in the metal, then the light will have just enough energy to knock the electrons loose. If we use light of a higher frequency, then not only will the electrons be knocked loose, but they will also acquire some kinetic energy. This situation is summarized by the equation

$$
\text { Equation } 6.3 \quad h v=\mathrm{KE}+W
$$

where KE is the kinetic energy of the ejected electron and $W$ is the binding energy of the electron in the metal. [Binding energies are typically given in units of electron volts (eV), where $1 \mathrm{eV}=$ $1.602 \times 10^{-19} \mathrm{~J}$.] Rewriting Equation 6.3 as

$$
\mathrm{KE}=h v-W
$$

shows that the more energetic the photon (i.e., the higher its frequency), the greater the kinetic energy of the ejected electron. If the frequency of light is below the threshold frequency, the photon will simply bounce off the surface and no electrons will be ejected. If the frequency is equal to the threshold frequency, it will dislodge the most loosely held electron. Above the threshold frequency, it will not only dislodge the electron, but also impart some kinetic energy to the ejected electron.

Now consider two beams of light having the same frequency (greater than the threshold frequency) but different intensities. The more intense beam of light consists of a larger number of photons, so it ejects more electrons from the metal's surface than the weaker beam of light. Thus, the more intense the light, the greater the number of electrons emitted by the target metal; the higher the frequency of the light, the greater the kinetic energy of the ejected electrons.

[^10]Think About It As wavelength decreases, frequency increases. Energy, being directly proportional to frequency, also increases.

Figure 6.5 Apparatus for studying the photoelectric effect. Light of a certain frequency falls on a clean metal surface. Ejected electrons are attracted toward the positive electrode. The flow of electrons is registered by a detecting meter.

## FA@ You May Be Wondering...

## Where Have I Encountered the Photoelectric Effect?

Chances are good that you encounter the photoelectric effect regularly. Some everyday applications include the type of device that prevents a garage door from closing when something is in the door's path and motion-detection systems used in museums and other high-security environments. These sorts of devices work simply by responding to an interruption in a beam of light. In each case, a beam of light normally shines on a photocathode, a surface that emits photoelectrons, and the photoelectrons, accelerated toward an anode by high voltage, constitute a current. When the beam of light is interrupted, the flow of photoelectrons stops and the current is cut off. In the case of the garage-door safety device, when the current stops, the movement of the door stops. In the case of the motion-detection systems, when the current stops, an alarm may sound or a light may turn on.

One of the more exotic uses of the photoelectric effect is in night-vision goggles. Although you may never have looked through night-vision goggles, you have probably seen nightvision images on the news or in a suspense-filled movie such as Silence of the Lambs. Typically, the night-vision images we see are from what are known as third-generation night-vision devices. These devices use a photocathode material (gallium arsenide) that emits photoelectrons when struck by photons in the infrared region of the electromagnetic spectrum. (First- and second-generation devices used different photocathode materials and relied more on the amplification of low-level visible light.) The photoelectrons emitted by the photocathode enter a microchannel plate (MCP), an array of tiny parallel tubes, where each strikes the internal surface of a tube causing many more electrons to be ejected-a process called secondary emission. This effectively amplifies the current generated by each photoelectron. The amplified current is then accelerated by high voltage toward a phosphorus screen, where incident electrons cause the emission of visible light, generating the familiar green glow of night vision.

(a) Night-vision goggles schematic. 1. Photocathode (gallium arsenide). 2. Microchannel plate (MCP). 3. High-voltage source. 4. Phosphorus screen. (b) The green glow of night vision.

Sample Problem 6.3 shows how to determine the energy of a single photon of light of a given wavelength and how to determine the maximum kinetic energy of an electron ejected via the photoelectric effect.

Einstein's theory of light posed a dilemma for scientists. On the one hand, it explains the photoelectric effect. On the other hand, the particle theory of light is inconsistent with the known wavelike properties of light. The only way to resolve the dilemma is to accept the idea that light possesses properties characteristic of both particles and waves. Depending on the experiment, light behaves either as a wave or as a stream of particles. This concept was totally alien to the way physicists had thought about matter and radiation, and it took a long time for them to accept it. We will see in Section 6.4 that possessing properties of both particles and waves is not unique to light but ultimately is characteristic of all matter, including electrons.

## Sample Problem 6.3

Calculate the energy (in joules) of (a) a photon with a wavelength of $5.00 \times 10^{4} \mathrm{~nm}$ (infrared region) and (b) a photon with a wavelength of 52 nm (ultraviolet region). (c) Calculate the kinetic energy of an electron ejected by the photon in part (b) from a metal with a binding energy of 3.7 eV .

Strategy In parts (a) and (b), we are given the wavelength of light. Use Equation 6.1 to convert wavelength to frequency; then use Equation 6.2 to determine the energy of the photon for each wavelength. In part (c), we are asked to determine the kinetic energy of an ejected electron. For this we use Equation 6.3. The binding energy, given in electron volts, must be converted to joules for units to cancel.

Setup The wavelengths must be converted from nanometers to meters:
(a) $5.00 \times 10^{4} \mathrm{nmI} \times \frac{1 \times 10^{-9} \mathrm{~m}}{1 \mathrm{~nm}}=5.00 \times 10^{-5} \mathrm{~m}$
(b) $52 \mathrm{~nm} \times \frac{1 \times 10^{-9} \mathrm{~m}}{1 \mathrm{~nm}}=5.2 \times 10^{-8} \mathrm{~m}$

Planck's constant, $h$, is $6.63 \times 10^{-34} \mathrm{~J} \cdot \mathrm{~s}$.
(c) $W=3.7 \mathrm{eV} \times \frac{1.602 \times 10^{-19} \mathrm{~J}}{1 \mathrm{eV}}=5.9 \times 10^{-19} \mathrm{~J}$

Solution (a) $v=\frac{c}{\lambda}=\frac{3.00 \times 10^{8} \mathrm{~m} / \mathrm{s}}{5.00 \times 10^{-5} \mathrm{~m}}=6.00 \times 10^{12} \mathrm{~s}^{-1}$
and
$E=h \nu=\left(6.63 \times 10^{-34} \mathrm{~J} \cdot \mathrm{~s}\right)\left(6.00 \times 10^{12} \mathrm{~s}^{-1}\right)=3.98 \times 10^{-21} \mathrm{~J}$
This is the energy of a single photon with wavelength $5.00 \times 10^{4} \mathrm{~nm}$.
(b) Following the same procedure as in part (a), the energy of a photon of wavelength 52 nm is $3.8 \times 10^{-18} \mathrm{~J}$.
(c) $\mathrm{KE}=h v-W=3.8 \times 10^{-18} \mathrm{~J}-5.9 \times 10^{-19} \mathrm{~J}=3.2 \times 10^{-18} \mathrm{~J}$.

Practice Problem A Calculate the energy (in joules) of (a) a photon with wavelength $2.11 \times 10^{2} \mathrm{~nm}$, and (b) a photon with frequency $1.78 \times 10^{8} \mathrm{~s}^{-1}$. (c) Calculate the kinetic energy of an electron ejected by the photon in part (a) from a metal with a binding energy of 4.66 eV .

EPractice Problem $\mathbf{B}$ (a) Calculate the wavelength (in nm) of light with energy $1.89 \times 10^{-20} \mathrm{~J}$ per photon. (b) For light of wavelength 410 nm , calculate the number of photons per joule. (c) Determine the binding energy (in eV ) of a metal if the kinetic energy possessed by an ejected electron [using one of the photons in part (b)] is $2.93 \times 10^{-19} \mathrm{~J}$.

## Checkpoint 6.2 Quantum Theory

6.2.1 Calculate the energy per photon of light with wavelength 650 nm .
a) $1.29 \times 10^{-31} \mathrm{~J}$
b) $4.31 \times 10^{-40} \mathrm{~J}$
c) $1.02 \times 10^{-27} \mathrm{~J}$
d) $1.44 \times 10^{-48} \mathrm{~J}$
e) $3.06 \times 10^{-19} \mathrm{~J}$
6.2.2 Calculate the wavelength of light that has energy $1.32 \times 10^{-23} \mathrm{~J} /$ photon.
a) $5.02 \times 10^{-9} \mathrm{~cm}$
b) $6.64 \times 10^{3} \mathrm{~cm}$
c) $2.92 \times 10^{-63} \mathrm{~cm}$
d) 1.51 cm
e) 66.4 cm

Think About It Remember that frequency and wavelength are inversely proportional (Equation 6.1). Thus, as wavelength decreases, frequency and energy increase. Note that the binding energy becomes less significant as the energy of the incident photon increases.

Student Annotation: If you have ever seen a rainbow, you are familiar with this phenomenon. The rainbow is the visible portion of the sun's emission spectrum.

## Checkpoint 6.2 Quantum Theory (continued)

6.2.3 Which of the following is characteristic of high-energy radiation?
a) High wavelength
b) High velocity
c) High frequency
d) High amplitude
e) All of the above
6.2.4 A clean metal surface is irradiated with light of three different wavelengths: $\lambda_{1}, \lambda_{2}$, and $\lambda_{3}$. The kinetic energies of the ejected electrons are as follows: $\lambda_{1}: 2.9 \times 10^{-20} \mathrm{~J}$; $\lambda_{2}$ : approximately zero; $\lambda_{3}: 4.2 \times 10^{-19} \mathrm{~J}$. Arrange the light in order of increasing wavelength.
a) $\lambda_{1}<\lambda_{2}<\lambda_{3}$
b) $\lambda_{2}<\lambda_{1}<\lambda_{3}$
c) $\lambda_{3}<\lambda_{2}<\lambda_{1}$
d) $\lambda_{3}<\lambda_{1}<\lambda_{2}$
e) $\lambda_{2}<\lambda_{3}<\lambda_{1}$

### 6.3 Bohr's Theory of the Hydrogen Atom

In addition to explaining the photoelectric effect, Planck's quantum theory and Einstein's ideas made it possible for scientists to unravel another nineteenth-century mystery in physics: atomic line spectra.

In the seventeenth century, Newton had shown that sunlight is composed of various color components that can be recombined to produce white light. Since that time, chemists and physicists have studied the characteristics of such emission spectra. The emission spectrum of a substance can be seen by energizing a sample of material with either thermal energy or some other form of energy (such as a high-voltage electrical discharge if the substance is a gas). A "red-hot" or "white-hot" iron bar freshly removed from a fire produces a characteristic glow. The glow is the visible portion of its emission spectrum. The heat given off by the same iron bar is another portion of its emission spectrum - the infrared region. A feature common to the emission spectrum of the sun and that of a heated solid is that both are continuous; that is, all wavelengths of visible light are present in each spectrum (Figure 6.6).

## Atomic Line Spectra

Unlike those of the sun or a white-hot iron bar, the emission spectra of atoms in the gas phase do not show a continuous spread of wavelengths from red to violet; rather, the atoms produce bright lines in distinct parts of the visible spectrum. These line spectra are the emission of light only at

Figure 6.6 The visible white light emitted by (a) the sun and (b) a white-hot iron bar. In each case, the white light is the combination of all visible wavelengths (see Figure 6.1).

specific wavelengths. Figure 6.7 is a schematic diagram of a discharge tube that is used to study emission spectra.

Every element has a unique emission spectrum, so the characteristic lines in atomic spectra can be used in chemical analysis to identify elements, much as fingerprints are used to identify people. When the lines of the emission spectrum of a known element exactly match the lines of the emission spectrum of an unknown sample, the identity of the element in the sample is established. Although the procedure of identifying elements by their line spectra had been used for many years in chemical analysis, the origin of the spectral lines was not understood until early in the twentieth century. Figure 6.8 shows the emission spectra of several elements.

In 1885, Johann Balmer ${ }^{3}$ developed a remarkably simple equation that could be used to calculate the wavelengths of the four visible lines in the emission spectrum of hydrogen. Johannes Rydberg ${ }^{4}$ developed Balmer's equation further, yielding an equation that could calculate not only the visible wavelengths, but those of all hydrogen's spectral lines:

$$
\frac{1}{\lambda}=R_{\infty}\left(\frac{1}{n_{1}^{2}}-\frac{1}{n_{2}^{2}}\right)
$$

Equation 6.4

In Equation 6.4, now known as the Rydberg equation, $\lambda$ is the wavelength of a line in the spectrum; $R_{\infty}$ is the Rydberg constant ( $1.09737316 \times 10^{7} \mathrm{~m}^{-1}$ ); and $n_{1}$ and $n_{2}$ are positive integers, where $n_{2}>n_{1}$.

## The Line Spectrum of Hydrogen

In 1913, not long after Planck's and Einstein's discoveries, a theoretical explanation of the emission spectrum of the hydrogen atom was presented by the Danish physicist Niels Bohr. ${ }^{5}$ Bohr's treatment is very complex and is no longer considered to be correct in all its details. We will concentrate only on his important assumptions and final results, which account for the observed spectral lines and provide an important step toward the understanding of quantum theory.

[^11]Figure 6.7 (a) Experimental arrangement for studying the emission spectra of atoms and molecules. The gas being studied is in a discharge tube containing two electrodes. As electrons flow from the negative electrode to the positive electrode, they collide with the gas particles. The collisions lead to the emission of light by the atoms (or molecules). The emitted light is separated into its components by a prism. (b) Line emission spectrum of hydrogen.

Student Annotation: The Rydberg equation is a mathematical relationship that was derived from experimental data. Although it predates quantum theory by decades, it agrees remarkably well with it for one-electron systems such as the hydrogen atom.

Figure 6.8 Emission spectra of several elements.

Media Player/MPEG Animation: Figure 6.10, Emission Spectrum of Hydrogen, pp. 224-225.

When Bohr first approached this problem, physicists already knew that the atom contains electrons and protons. They thought of an atom as an entity in which electrons whirled around the nucleus in circular orbits at high velocities. This was an appealing description because it resembled the familiar model of planetary motion around the sun. However, according to the laws of classical physics, an electron moving in an orbit of a hydrogen atom would experience an acceleration toward the nucleus by radiating away energy in the form of electromagnetic waves. Thus, such an electron would quickly spiral into the nucleus and annihilate itself with the proton. To explain why this does not happen, Bohr postulated that the electron is allowed to occupy only certain orbits of specific energies. In other words, the energies of the electron are quantized. An electron in any of the allowed orbits will not radiate energy and therefore will not spiral into the nucleus.

Bohr attributed the emission of radiation by an energized hydrogen atom to the electron dropping from a higher-energy orbit to a lower one and giving up a quantum of energy (a photon) in the form of light (Figure 6.10, pp. 224-225). Using arguments based on electrostatic interaction and Newton's laws of motion, Bohr showed that the energies that the electron in the hydrogen atom can possess are given by

Equation 6.5

$$
E_{n}=-2.18 \times 10^{-18} \mathrm{~J}\left(\frac{1}{n^{2}}\right)
$$

where $n$ is an integer with values $n=1,2,3$, and so on. The negative sign in Equation 6.5 is an arbitrary convention, signifying that the energy of the electron in the atom is lower than the energy of a free electron, which is an electron that is infinitely far from the nucleus. The energy of a free electron is arbitrarily assigned a value of zero. Mathematically, this corresponds to setting $n$ equal to infinity in Equation 6.5:

$$
E_{\infty}=-2.18 \times 10^{-18} \mathrm{~J}\left(\frac{1}{\infty^{2}}\right)=0
$$

As the electron gets closer to the nucleus (as $n$ decreases), $E_{n}$ becomes larger in absolute value, but also more negative. The most negative value, then, is reached when $n=1$, which corresponds to the most stable energy state. We call this the ground state, the lowest energy state of an atom. The stability of the electron diminishes as $n$ increases. Each energy state in which $n>1$ is called an excited state. Each excited state is higher in energy than the ground state. In the hydrogen atom, an electron for which $n$ is greater than 1 is said to be in an excited state.

The radius of each circular orbit in Bohr's model depends on $n^{2}$. Thus, as $n$ increases from 1 to 2 to 3 , the orbit radius increases very rapidly. The higher the excited state, the farther away the electron is from the nucleus (and the less tightly held it is by the nucleus).

Bohr's theory enables us to explain the line spectrum of the hydrogen atom. Radiant energy absorbed by the atom causes the electron to move from the ground state ( $n=1$ ) to an excited state ( $n>1$ ). Conversely, radiant energy (in the form of a photon) is emitted when the electron moves from a higher-energy excited state to a lower-energy excited state or the ground state.

The quantized movement of the electron from one energy state to another is analogous to the movement of a tennis ball either up or down a set of stairs (Figure 6.9). The ball can be on any of several steps but never between steps. The journey from a lower step to a higher one is an energy-requiring process, whereas movement from a higher step to a lower step is an energyreleasing process. The quantity of energy involved in either type of change is determined by the distance between the beginning and ending steps. Similarly, the amount of energy needed to move an electron in the Bohr atom depends on the difference in energy levels between the initial and final states.

To apply Equation 6.5 to the emission process in a hydrogen atom, let us suppose that the electron is initially in an excited state characterized by $n_{i}$. During emission, the electron drops to a lower-energy state characterized by $n_{\mathrm{f}}$ (the subscripts i and f denote the initial and final states, respectively). This lower-energy state may be the ground state, but it can be any state lower than the initial excited state. The difference between the energies of the initial and final states is

$$
\Delta E=E_{\mathrm{f}}-E_{\mathrm{i}}
$$

From Equation 6.5,

$$
E_{\mathrm{f}}=-2.18 \times 10^{-18} \mathrm{~J}\left(\frac{1}{n_{\mathrm{f}}^{2}}\right)
$$

and

$$
E_{\mathrm{i}}=-2.18 \times 10^{-18} \mathrm{~J}\left(\frac{1}{n_{\mathrm{i}}^{2}}\right)
$$

Therefore,

$$
\begin{aligned}
\Delta E & =\left(\frac{-2.18 \times 10^{-18} \mathrm{~J}}{n_{\mathrm{f}}^{2}}\right)-\left(\frac{-2.18 \times 10^{-18} \mathrm{~J}}{n_{\mathrm{i}}^{2}}\right) \\
& =-2.18 \times 10^{-18} \mathrm{~J}\left(\frac{1}{n_{\mathrm{f}}^{2}}-\frac{1}{n_{\mathrm{i}}^{2}}\right)
\end{aligned}
$$

Because this transition results in the emission of a photon of frequency $\nu$ and energy $h \nu$, we can write

$$
\Delta E=h \nu=-2.18 \times 10^{-18} \mathrm{~J}\left(\frac{1}{n_{\mathrm{f}}^{2}}-\frac{1}{n_{\mathrm{i}}^{2}}\right)
$$

Equation 6.6

A photon is emitted when $n_{\mathrm{i}}>n_{\mathrm{f}}$. Consequently, the term in parentheses is positive, making $\Delta E$ negative (energy is lost to the surroundings). A photon is absorbed when $n_{\mathrm{f}}>n_{\mathrm{i}}$, making the term in parentheses negative, so $\Delta E$ is positive. Each spectral line in the emission spectrum of hydrogen corresponds to a particular transition in a hydrogen atom. When we study a large number of hydrogen atoms, we observe all possible transitions and hence the corresponding spectral lines. The brightness of a spectral line depends on how many photons of the same wavelength are emitted.

To calculate the wavelength of an emission line, we substitute $c / \lambda$ for $v$ and then divide both sides of Equation 6.6 by $h c$. In addition, because wavelength (and frequency) can only have positive values, we take the absolute value of the right side of the equation. (In this case, we do so simply by eliminating the negative sign.)

$$
\begin{equation*}
\frac{1}{\lambda}=\frac{2.18 \times 10^{-18} \mathrm{~J}}{h c}\left(\frac{1}{n_{\mathrm{f}}^{2}}-\frac{1}{n_{\mathrm{i}}^{2}}\right) \tag{Equation 6.7}
\end{equation*}
$$

The emission spectrum of hydrogen includes a wide range of wavelengths from the infrared to the ultraviolet. Table 6.1 (p.226) lists the series of transitions in the hydrogen spectrum, each with a different value of $n_{\mathrm{f}}$. The series are named after their discoverers (Lyman, Balmer, Paschen, and Brackett). The Balmer series was the first to be studied because some of its lines occur in the visible region.

Figure 6.9 Mechanical analogy for the emission processes. The ball can rest on any step but not between steps.

Student Annotation: When $n_{i}>n_{f}, \Delta E$ is negative, indicating energy is emitted. When $n_{f}>n_{i}, \Delta E$ is positive, indicating energy is absorbed.

Figure 6.10

## Emission Spectrum of Hydrogen

Hydrogen atoms in the ground state are excited by the addition of energy. Electrons that have been promoted to higher energy levels ( $n>1$ ) return to lower energy levels and emit the excess energy as electromagnetic radiation.

$$
n=1
$$

## What's the point?

Each line in the visible emission spectrum of hydrogen is the result of an electronic transition from a higher excited state $(n=3,4,5$, or 6 ) to a lower excited state $(n=2)$. The energy gap between the initial and final states determines the wavelength of the light emitted.

## TABLE 6.1 <br> Emission Series in the Hydrogen Spectrum

| Series | $\boldsymbol{n}_{\mathrm{f}}$ | $\boldsymbol{n}_{\mathbf{i}}$ | Spectrum Region |
| :--- | :---: | :---: | :--- |
| Lyman | 1 | $2,3,4, \ldots$ | Ultraviolet |
| Balmer | 2 | $3,4,5, \ldots$ | Visible and ultraviolet |
| Paschen | 3 | $4,5,6, \ldots$ | Infrared |
| Brackett | 4 | $5,6,7, \ldots$ | Infrared |

Figure 6.11 Energy levels in the hydrogen atom and the various emission series. Each series terminates at a different value of $n$.

Figure 6.11 shows transitions associated with spectral lines in each of the emission series. Each horizontal line represents one of the allowed energy levels for the electron in a hydrogen atom. The energy levels are labeled with their $n$ values.

Sample Problem 6.4 illustrates the use of Equation 6.7.

## Sample Problem 6.4

Calculate the wavelength (in nm ) of the photon emitted when an electron transitions from the $n=4$ state to the $n=2$ state in a hydrogen atom.

Strategy Use Equation 6.7 to calculate $\lambda$.
Setup According to the problem, the transition is from $n=4$ to $n=2$, so $n_{\mathrm{i}}=4$ and $n_{\mathrm{f}}=2$. The required constants are $h=6.63 \times 10^{-34} \mathrm{~J} \cdot \mathrm{~s}$ and $c=3.00 \times 10^{8} \mathrm{~m} / \mathrm{s}$.

## Solution

$$
\begin{aligned}
\frac{1}{\lambda} & =\frac{2.18 \times 10^{-18} \mathrm{~J}}{h c}\left(\frac{1}{n_{\mathrm{f}}^{2}}-\frac{1}{n_{\mathrm{i}}^{2}}\right) \\
& =\frac{2.18 \times 10^{-18} \mathrm{~J}}{\left(6.63 \times 10^{-34} \mathrm{~J} \cdot \mathrm{~s}\right)\left(3.00 \times 10^{8} \mathrm{~m} / \mathrm{s}\right)}\left(\frac{1}{2^{2}}-\frac{1}{4^{2}}\right) \\
& =2.055 \times 10^{6} \mathrm{~m}^{-1}
\end{aligned}
$$

Therefore,

$$
\lambda=4.87 \times 10^{-7} \mathrm{~m}=487 \mathrm{~nm}
$$

Practice Problem A What is the wavelength (in nm) of a photon emitted during a transition from the $n=3$ state to the $n=1$ state in the H atom?

EPractice Problem B What is the value of $n_{i}$ for an electron that emits a photon of wavelength 93.14 nm when it returns to the ground state in the H atom?

## Bringing Chemistry to Life

## Lasers

The word laser is an acronym for light amplification by stimulated emission of radiation. It is a special type of emission that may involve electronic transitions in atoms or molecules. The first laser, developed in 1960, was a ruby laser. Ruby is a deep-red mineral consisting of corundum $\left(\mathrm{Al}_{2} \mathrm{O}_{3}\right)$, in which some of the $\mathrm{Al}^{3+}$ ions have been replaced by $\mathrm{Cr}^{3+}$ ions. A cylindrical ruby crystal is positioned between two perfectly parallel mirrors, one of which is only partially reflective. A light source called a flashlamp is used to excite the chromium atoms to a higher energy level. The excited atoms are unstable, so at a given instant some of them return to the ground state by emitting a photon in the red region of the spectrum $(\lambda=694.3 \mathrm{~nm})$. Spontaneous emission of photons occurs in all directions, but photons emitted directly at either mirror will be reflected back. As the reflected photons pass back through the ruby crystal, they stimulate the emission of more photons in the same direction. These photons, in turn, are reflected back through the crystal, stimulating still more emissions, and so on. Because the light waves are in phase-that is, their maxima coincide and their minima coincide-the photons enhance one another, increasing their power with each passage between the mirrors. When the light reaches a certain intensity, it emerges from the partially reflective mirror as a laser beam. Laser light is characterized by three properties: It is intense, it has a precisely known wavelength and therefore energy, and it is coherent.

The applications of lasers are quite numerous. In addition to their use in surgery, their high intensity and ease of focus make them suitable for drilling holes in metals, welding, and carrying out nuclear fusion. The fact that they are highly directional and have precisely known wavelengths makes them very useful for telecommunications. Lasers are also used in isotope separation, in chemical analysis, in holography (three-dimensional photography), in compact disc players, and in supermarket scanners.

Think About It Look again at the line spectrum of hydrogen in Figure 6.7 and make sure that your result matches one of them. Note that for an emission, $n_{\mathrm{i}}$ is always greater than $n_{\mathrm{f}}$, and Equation 6.7 gives a positive result.

Student Annotation: Coherent means that the light waves are all in phase.

## Checkpoint 6.3 Bohr's Theory of the Hydrogen Atom

6.3.1 Calculate the energy of an electron in the $n=3$ state in a hydrogen atom.
a) $2.42 \times 10^{-19} \mathrm{~J}$
b) $-2.42 \times 10^{-19} \mathrm{~J}$
c) $7.27 \times 10^{-19} \mathrm{~J}$
d) $-7.27 \times 10^{-19} \mathrm{~J}$
e) $-6.54 \times 10^{-18} \mathrm{~J}$
6.3.2 Calculate $\Delta E$ of an electron that goes from $n=1$ to $n=5$.
a) $8.72 \times 10^{-20} \mathrm{~J}$
b) $-8.72 \times 10^{-20} \mathrm{~J}$
c) $5.45 \times 10^{-17} \mathrm{~J}$
d) $2.09 \times 10^{-18} \mathrm{~J}$
e) $-2.09 \times 10^{-18} \mathrm{~J}$
6.3.3 What is the wavelength of light emitted when an electron in a hydrogen atom goes from $n=5$ to $n=3$ ?
a) $4.87 \times 10^{-7} \mathrm{~m}$
b) $6.84 \times 10^{-7} \mathrm{~m}$
c) $1.28 \times 10^{-6} \mathrm{~m}$
d) $3.65 \times 10^{-7} \mathrm{~m}$
e) $1.02 \times 10^{-7} \mathrm{~m}$
6.3.4 Which wavelength corresponds to the transition of an electron in a hydrogen atom from $n=2$ to $n=1$ ?
a) 182 nm
b) 91.2 nm
c) 724 nm
d) 812 nm
e) 122 nm

### 6.4 Wave Properties of Matter

Bohr's theory was both fascinating and puzzling. It fit the experimental data for hydrogen, but physicists did not understand the underlying principle. Why, for example, was an electron restricted to orbiting the nucleus at certain fixed distances? For a decade no one, not even Bohr himself, could offer a logical explanation. In 1924 Louis de Broglie ${ }^{6}$ provided a solution to this puzzle. De Broglie reasoned that if energy (light) can, under certain circumstances, behave like a stream of particles (photons), then perhaps particles such as electrons can, under certain circumstances, exhibit wavelike properties.

## The de Broglie Hypothesis

In developing his revolutionary theory, de Broglie incorporated his observations of macroscopic phenomena that exhibited quantized behavior. For example, a guitar string has certain discrete frequencies of vibration, like those shown in Figure 6.12(a). The waves generated by plucking a guitar string are standing or stationary waves because they do not travel along the string. Some points on the string, called nodes, do not move at all; that is, the amplitude of the wave at these points is zero. There is a node at each end, and there may be one or more nodes between the ends. The greater the frequency of vibration, the shorter the wavelength of the standing wave and the greater the number of nodes. According to de Broglie, an electron in an atom behaves like a standing wave. However, as Figure 6.12 shows, only certain wavelengths are possible or allowed.

De Broglie argued that if an electron does behave like a standing wave in the hydrogen atom, the wavelength must fit the circumference of the orbit exactly; that is, the circumference of the orbit must be an integral multiple of the wavelength, as shown in Figure 6.12(b). Otherwise, the wave would partially cancel itself by destructive interference on each successive orbit, quickly reducing its amplitude to zero.

The relationship between the circumference of an allowed orbit ( $2 \pi r$ ) and the wavelength $(\lambda)$ of the electron is given by

$$
\text { Equation } 6.8
$$

$$
2 \pi r=n \lambda
$$

[^12]
where $r$ is the radius of the orbit, $\lambda$ is the wavelength of the electron wave, and $n$ is a positive integer ( $1,2,3, \ldots$ ). Because $n$ is an integer, $r$ can have only certain values (integral multiples of $\lambda$ ) as $n$ increases from 1 to 2 to 3 and so on. And, because the energy of the electron depends on the size of the orbit (or the value of $r$ ), the energy can have only certain values, too. Thus, the energy of the electron in a hydrogen atom, if it behaves like a standing wave, must be quantized.

De Broglie's reasoning led to the conclusion that waves can behave like particles and particles can exhibit wavelike properties. De Broglie deduced that the particle and wave properties are related by the following expression:

$$
\lambda=\frac{h}{m u} \quad \text { Equation } 6.9
$$

where $\lambda, m$, and $u$ are the wavelength associated with a moving particle, its mass, and its velocity, respectively. Equation 6.9 implies that a particle in motion can be treated as a wave, and a wave can exhibit the properties of a particle. To help you remember this important point, notice that the left side of Equation 6.9 involves the wavelike property of wavelength, whereas the right side involves mass, a property of particles. A wavelength calculated using Equation 6.9 is usually referred to specifically as a de Broglie wavelength. Likewise, we will refer to a mass calculated using Equation 6.9 as a de Broglie mass.

Sample Problem 6.5 illustrates how de Broglie's theory and Equation 6.9 can be applied.

## Sample Problem 6.5

Calculate the de Broglie wavelength of the "particle" in the following two cases: (a) a $25-\mathrm{g}$ bullet traveling at $612 \mathrm{~m} / \mathrm{s}$, and (b) an electron ( $m=9.109 \times 10^{-31} \mathrm{~kg}$ ) moving at $63.0 \mathrm{~m} / \mathrm{s}$.

Strategy Use Equation 6.9 to calculate the de Broglie wavelengths. Remember that the mass in Equation 6.9 must be expressed in kilograms for the units to cancel properly.

Setup Planck's constant, $h$, is $6.63 \times 10^{-34} \mathrm{~J} \cdot \mathrm{~s}$ or, for the purpose of making the unit cancellation obvious, $6.63 \times 10^{-34} \mathrm{~kg} \cdot \mathrm{~m}^{2} / \mathrm{s}$.

Figure 6.12 Standing waves of a vibrating guitar string. The length of the string must be equal to a whole number times one-half the wavelength ( $\lambda / 2$ ). (b) In a circular orbit, only whole number multiples of wavelengths are allowed. Any fractional number of wavelengths would result in cancellation of the wave due to destructive interference.

Student Annotation: Mass ( $m$ ) must be expressed in kilograms for units to cancel properly in Equation 6.9.

Think About It While you are new at solving these problems, always write out the units of Planck's constant (J $\cdot \mathrm{s}$ ) as $\mathrm{kg} \cdot \mathrm{m}^{2} / \mathrm{s}$. This will enable you to check your unit cancellations and detect common errors such as expressing mass in grams rather than kilograms. Note that the calculated wavelength of a macroscopic object, even one as small as a bullet, is extremely small. An object must be at least as small as a subatomic particle for its wavelength to be large enough for us to observe.

Student Annotation: Momentum has units of $\mathrm{kg} \cdot \mathrm{m} / \mathrm{s}$ or $\mathrm{N} \cdot \mathrm{s}$, where N is the newton, the SI unit of force. The newton is a derived SI unit: $1 \mathrm{~N}=1 \mathrm{~kg} \cdot \mathrm{~m} / \mathrm{s}^{2}$.

(a)

(b)

Figure 6.13 (a) X-ray diffraction pattern of aluminum foil. (b) Electron diffraction of aluminum foil. The similarity of these two patterns shows that electrons can behave like X rays and display wave properties.

## Solution

(a) $25 \mathrm{~g} \times \frac{1 \mathrm{~kg}}{1000 \mathrm{~g}}=0.025 \mathrm{~kg}$

$$
\lambda=\frac{h}{m u}=\frac{6.63 \times 10^{-34} \mathrm{~kg} \cdot \mathrm{~m}^{2} / \mathrm{s}}{(0.025 \mathrm{~kg})(612 \mathrm{~m} / \mathrm{s})}=4.3 \times 10^{-35} \mathrm{~m}
$$

(b) $\lambda=\frac{h}{m u}=\frac{6.63 \times 10^{-34} \mathrm{~kg} \cdot \mathrm{~m}^{2} / \mathrm{s}}{\left(9.109 \times 10^{-31} \mathrm{~kg}\right)(63.0 \mathrm{~m} / \mathrm{s})}=1.16 \times 10^{-5} \mathrm{~m}$

Practice Problem A Calculate the de Broglie wavelength (in nm ) of a hydrogen atom ( $m=1.674 \times$ $10^{-27} \mathrm{~kg}$ ) moving at $1500 \mathrm{~cm} / \mathrm{s}$.

HPractice Problem B Use Equation 6.9 to calculate the momentum, $p$ (defined as mass times velocity, $m \times u)$ associated with a photon of radiation of wavelength 810 nm . The velocity of a photon is the speed of light, $c$.

## Diffraction of Electrons

Shortly after de Broglie introduced his equation and predicted that electrons should exhibit wave properties, successful electron diffraction experiments were carried out by Clinton Davisson ${ }^{7}$ and Lester Germer ${ }^{8}$ in the United States and G. P. Thomson ${ }^{9}$ in England. These experiments demonstrated that electrons do indeed possess wavelike properties. By directing a beam of electrons (which are most definitely particles) through a thin piece of gold foil, Thomson obtained a set of concentric rings on a screen, similar to the diffraction pattern observed when $X$ rays (which are most definitely waves) were used. Figure 6.13 shows X-ray and electron diffraction patterns for aluminum.

## Checkpoint 6.4 Wave Properties of Matter

6.4.1 Calculate the de Broglie wavelength associated with a helium-4 atom $(4.00 \mathrm{amu})$ moving at $3.0 \times 10^{6} \mathrm{~m} / \mathrm{s}$.
a) $2.0 \times 10^{-20} \mathrm{~m}$
b) $3.3 \times 10^{-11} \mathrm{~m}$
c) $3.3 \times 10^{-14} \mathrm{~m}$
d) $1.8 \times 10^{-19} \mathrm{~m}$
e) $6.6 \times 10^{-27} \mathrm{~m}$
6.4.2 What is the momentum of a photon of light with $\lambda=122 \mathrm{~nm}$ ? (The velocity of a photon is the speed of light, $c$.)
a) $5.43 \times 10^{-27} \mathrm{~kg} \cdot \mathrm{~m} / \mathrm{s}$
b) $6.63 \times 10^{-34} \mathrm{~kg} \cdot \mathrm{~m} / \mathrm{s}$
c) $6.00 \times 10^{-17} \mathrm{~kg} \cdot \mathrm{~m} / \mathrm{s}$
d) $8.64 \times 10^{-11} \mathrm{~kg} \cdot \mathrm{~m} / \mathrm{s}$
e) $2.71 \times 10^{-27} \mathrm{~kg} \cdot \mathrm{~m} / \mathrm{s}$

### 6.5 Quantum Mechanics

The discovery that waves could have matterlike properties and that matter could have wavelike properties was revolutionary. Although scientists had long believed that energy and matter were distinct entities, the distinction between them, at least at the atomic level, was no longer clear. Bohr's theory was tremendously successful in explaining the line spectrum of hydrogen, but it failed to explain the spectra of atoms with more than one electron. The electron appeared to behave as a particle in some circumstances and as a wave in others. Neither description could completely explain the behavior of electrons in atoms. This left scientists frustrated in their quest to understand exactly where the electrons in an atom are.

[^13]
## The Uncertainty Principle

To describe the problem of trying to locate a subatomic particle that behaves like a wave, Werner Heisenberg ${ }^{10}$ formulated what is now known as the Heisenberg uncertainty principle: It is impossible to know simultaneously both the momentum $p$ and the position $x$ of a particle with certainty. Stated mathematically,

$$
\Delta x \cdot \Delta p \geq \frac{h}{4 \pi}
$$

Equation 6.10
For a particle of mass $m$,

$$
\Delta x \cdot m \Delta u \geq \frac{h}{4 \pi}
$$

Equation 6.11
where $\Delta x$ and $\Delta u$ are the uncertainties in measuring the position and velocity of the particle, respectively. The $\geq$ signs have the following meaning. If the measured uncertainties of position and velocity are large (say, in a crude experiment), their product can be substantially greater than $h / 4 \pi$ (hence the $>$ sign). The significance of Equation 6.11 is that even in the most favorable conditions for measuring position and velocity, the product of the uncertainties can never be less than $h / 4 \pi$ (hence the $=$ sign). Thus, making measurement of the velocity of a particle more precise (i.e., making $\Delta u$ a small quantity) means that the position must become correspondingly less precise (i.e., $\Delta x$ will become larger). Similarly, if the position of the particle is known more precisely, its velocity measurement must become less precise.

If the Heisenberg uncertainty principle is applied to the hydrogen atom, we find that the electron cannot orbit the nucleus in a well-defined path, as Bohr thought. If it did, we could determine precisely both the position of the electron (from the radius of the orbit) and its speed (from its kinetic energy) at the same time. This would violate the uncertainty principle.

Sample Problem 6.6 shows how the Heisenberg uncertainty principle can be applied.

## Sample Problem 6.6

An electron in a hydrogen atom is known to have a velocity of $5 \times 10^{6} \mathrm{~m} / \mathrm{s} \pm 1$ percent. Using the uncertainty principle, calculate the minimum uncertainty in the position of the electron and, given that the diameter of the hydrogen atom is less than 1 angstrom $(\AA)$, comment on the magnitude of this uncertainty compared to the size of the atom.

Strategy The uncertainty in the velocity, 1 percent of $5 \times 10^{6} \mathrm{~m} / \mathrm{s}$, is $\Delta u$. Using Equation 6.11, calculate $\Delta x$ and compare it with the diameter of the hydrogen atom. Recall that $1 \AA$ is equal to $1 \times 1^{-10} \mathrm{~m}$. [14Section 2.2]

Setup The mass of an electron (from Table 2.1, rounded to three significant figures and converted to kilograms) is $9.11 \times 10^{-31} \mathrm{~kg}$. Planck's constant, $h$, is $6.63 \times 10^{-34} \mathrm{~kg} \cdot \mathrm{~m}^{2} / \mathrm{s}$.
Solution

$$
\begin{gathered}
\Delta u=0.01 \times 5 \times 10^{6} \mathrm{~m} / \mathrm{s}=5 \times 10^{4} \mathrm{~m} / \mathrm{s} \\
\Delta x=\frac{h}{4 \pi \cdot m \Delta u}
\end{gathered}
$$

Therefore,

$$
\Delta x=\frac{6.63 \times 10^{-34} \mathrm{~kg} \cdot \mathrm{~m}^{2} / \mathrm{s}}{4 \pi\left(9.11 \times 10^{-31} \mathrm{~kg}\right)\left(5 \times 10^{4} \mathrm{~m} / \mathrm{s}\right)} \geq 1 \times 10^{-9} \mathrm{~m}
$$

The minimum uncertainty in the position $x$ is $1 \times 10^{-9} \mathrm{~m}=10 \AA$. The uncertainty in the electron's position is 10 times larger than the atom!

Practice Problem A Calculate the minimum uncertainty in the position of the $25-\mathrm{g}$ bullet from Sample Problem 6.5 if the uncertainty in its velocity is (a) $\pm 1$ percent and (b) $\pm 0.01$ percent.
\&Practice Problem B (a) Calculate the minimum uncertainty in the momentum of an object for which the uncertainty in position is $3 \AA$. To what minimum uncertainty in velocity does this correspond if the particle is $(b)$ a neutron (mass $=1.0087 \mathrm{amu})$ and $(\mathrm{c})$ an electron $\left(\right.$ mass $\left.=5.486 \times 10^{-4} \mathrm{amu}\right)$ ?

[^14]Student Annotation: Like the de Broglie wavelength equation, Equation 6.11 requires that mass be expressed in kilograms. Unit cancellation will be more obvious if you express Planck's constant in $\mathrm{kg} \cdot \mathrm{m}^{2} / \mathrm{s}$ rather than $\mathrm{J} \cdot \mathrm{s}$.

Think About It A common error is expressing the mass of the particle in grams instead of kilograms, but you should discover this inconsistency if you check your unit cancellation carefully. Remember that if one uncertainty is small, the other must be large. The uncertainty principle applies in a practical way only to submicroscopic particles. In the case of a macroscopic object, where the mass is much larger than that of an electron, small uncertainties, relative to the size of the object, are possible for both position and velocity.

Figure 6.14 Representation of the electron density distribution surrounding the nucleus in the hydrogen atom. It shows a higher probability of finding the electron closer to the nucleus.

## The Schrödinger Equation

Bohr made a significant contribution to our understanding of atoms, and his suggestion that the energy of an electron in an atom is quantized remains unchallenged, but his theory did not provide a complete description of the behavior of electrons in atoms. In 1926 the Austrian physicist Erwin Schrödinger, ${ }^{11}$ using a complex mathematical technique, formulated an equation that describes the behavior and energies of submicroscopic particles in general, an equation analogous to Newton's laws of motion for macroscopic objects. The Schrödinger equation requires advanced calculus to solve, and we will not discuss it here. The equation, however, incorporates both particle behavior, in terms of mass $m$, and wave behavior, in terms of a wave function $\psi$ ( psi ), which depends on the location in space of the system (such as an electron in an atom).

The wave function itself has no direct physical meaning. However, the probability of finding the electron in a certain region in space is proportional to the square of the wave function, $\psi^{2}$. The idea of relating $\psi^{2}$ to probability stemmed from a wave theory analogy. According to wave theory, the intensity of light is proportional to the square of the amplitude of the wave, or $\psi^{2}$. The most likely place to find a photon is where the intensity is greatest-that is, where the value of $\psi^{2}$ is greatest. A similar argument associates $\psi^{2}$ with the likelihood of finding an electron in regions surrounding the nucleus.

Schrödinger's equation launched an entirely new field, called quantum mechanics (or wave mechanics), and began a new era in physics and chemistry. We now refer to the developments in quantum theory from 1913-when Bohr presented his model of the hydrogen atom-to 1926 as "old quantum theory."

## The Quantum Mechanical Description of the Hydrogen Atom

The Schrödinger equation specifies the possible energy states the electron can occupy in a hydrogen atom and identifies the corresponding wave functions $(\psi)$. These energy states and wave functions are characterized by a set of quantum numbers (to be discussed shortly), with which we can construct a comprehensive model of the hydrogen atom.

Although quantum mechanics does not allow us to specify the exact location of an electron in an atom, it does define the region where the electron is most likely to be at a given time. The concept of electron density gives the probability that an electron will be found in a particular region of an atom. The square of the wave function, $\psi^{2}$, defines the distribution of electron density in three-dimensional space around the nucleus. Regions of high electron density represent a high probability of locating the electron (Figure 6.14).

To distinguish the quantum mechanical description of an atom from Bohr's model, we speak of an atomic orbital, rather than an orbit. An atomic orbital can be thought of as the wave function of an electron in an atom. When we say that an electron is in a certain orbital, we mean that the distribution of the electron density or the probability of locating the electron in space is described by the square of the wave function associated with that orbital. An atomic orbital, therefore, has a characteristic energy, as well as a characteristic distribution of electron density.

## Checkpoint 6.5 Quantum Mechanics

6.5.1 What is the minimum uncertainty in the position of an electron moving at a speed of $4 \times 10^{6} \mathrm{~m} / \mathrm{s} \pm 1$ percent? (The mass of an electron is $9.11 \times 10^{-31} \mathrm{~kg}$.)
a) $2 \times 10^{-8} \mathrm{~m}$
b) $1 \times 10^{-9} \mathrm{~m}$
c) $6 \times 10^{-9} \mathrm{~m}$
d) $7 \times 10^{-8} \mathrm{~m}$
e) $1 \times 10^{-12} \mathrm{~m}$
6.5.2 What is the minimum uncertainty in the position of a proton moving at a speed of $4 \times 10^{6} \mathrm{~m} / \mathrm{s} \pm 1$ percent? (The mass of a proton is $1.67 \times 10^{-27} \mathrm{~kg}$.)
a) $1 \times 10^{-13} \mathrm{~m}$
b) $8 \times 10^{-10} \mathrm{~m}$
c) $4 \times 10^{-11} \mathrm{~m}$
d) $3 \times 10^{-12} \mathrm{~m}$
e) $8 \times 10^{-13} \mathrm{~m}$

[^15]
### 6.6 Quantum Numbers

In Bohr's model of the hydrogen atom, only one number, $n$, was necessary to describe the location of the electron. In quantum mechanics, three quantum numbers are required to describe the distribution of electron density in an atom. These numbers are derived from the mathematical solution of Schrödinger's equation for the hydrogen atom. They are called the principal quantum number, the angular momentum quantum number, and the magnetic quantum number. Each atomic orbital in an atom is characterized by a unique set of these three quantum numbers.

## Principal Quantum Number ( $n$ )

The principal quantum number ( $\boldsymbol{n}$ ) designates the size of the orbital. The larger $n$ is, the greater the average distance of an electron in the orbital from the nucleus and therefore the larger the orbital. The principal quantum number can have integral values of $1,2,3$, and so forth, and it corresponds to the quantum number in Bohr's model of the hydrogen atom. Recall from Equation 6.5 that in a hydrogen atom, the value of $n$ alone determines the energy of an orbital. (As we will see shortly, this is not the case for an atom that contains more than one electron.)

## Angular Momentum Quantum Number ( $\ell$ )

The angular momentum quantum number ( $\ell$ ) describes the shape of the atomic orbital (see Section 6.7). The values of $\ell$ are integers that depend on the value of the principal quantum number, $n$. For a given value of $n$, the possible values of $\ell$ range from 0 to $n-1$. If $n=1$, there is only one possible value of $\ell$; that is, $0(n-1$ where $n=1)$. If $n=2$, there are two values of $\ell: 0$ and 1 . If $n=3$, there are three values of $\ell: 0,1$, and 2 . The value of $\ell$ is designated by the letters $s, p, d$, and $f$ as follows: ${ }^{12}$

| $\ell$ | 0 | 1 | 2 | 3 |
| :---: | :---: | :---: | :---: | :---: |
| Orbital designation | $s$ | $p$ | $d$ | $f$ |

Thus, if $\ell=0$, we have an $s$ orbital; if $\ell=1$, we have a $p$ orbital; and so on.
A collection of orbitals with the same value of $n$ is frequently called a shell. One or more orbitals with the same $n$ and $\ell$ values are referred to as a subshell. For example, the shell designated by $n=2$ is composed of two subshells: $\ell=0$ and $\ell=1$ (the allowed values of $\ell$ for $n=2$ ). These subshells are called the $2 s$ and $2 p$ subshells where 2 denotes the value of $n$, and $s$ and $p$ denote the values of $\ell$.

## Magnetic Quantum Number ( $\boldsymbol{m}_{\ell}$ )

The magnetic quantum number ( $\boldsymbol{m}_{\ell}$ ) describes the orientation of the orbital in space (see Section 6.7). Within a subshell, the value of $m_{\ell}$ depends on the value of $\ell$. For a certain value of $\ell$, there are $(2 \ell+1)$ integral values of $m_{\ell}$ as follows:

$$
-\ell, \ldots 0, \ldots,+\ell
$$

If $\ell=0$, there is only one possible value of $m_{\ell}: 0$. If $\ell=1$, then there are three values of $m_{\ell}:-1$, 0 , and +1 . If $\ell=2$, there are five values of $m_{\ell}$, namely, $-2,-1,0,+1$, and +2 , and so on. The number of $m_{\ell}$ values indicates the number of orbitals in a subshell with a particular $\ell$ value; that is, each $m_{\ell}$ value refers to a different orbital.

Table 6.2 summarizes the allowed values of the three quantum numbers, $n, \ell$, and $m_{\ell}$, and Figure 6.15 illustrates schematically how the allowed values of quantum numbers give rise to the number of subshells and orbitals in each shell of an atom.

Sample Problem 6.7 gives you some practice with the allowed values of quantum numbers.

[^16]Student Annotation: The three quantum numbers $n, \ell$, and $m_{\ell}$ specify the size, shape, and orientation of an orbital, respectively.

Student Annotation: The number of subshells in a shell is equal to $n$. The number of orbitals in a shell is equal to $n^{2}$. The number of orbitals in a subshell is equal to $2 \ell+1$.

## TABLE 6.2 Allowed Values of the Quantum Numbers $n, \ell$, and $m_{\ell}$

Figure 6.15 Illustration of how quantum numbers designate shells, subshells, and orbitals.

## Sample Problem 6.7

What are the possible values for the magnetic quantum number $\left(m_{\ell}\right)$ when the principal quantum number $(n)$ is 3 and the angular momentum quantum number $(\ell)$ is 1 ?

Strategy Use the rules governing the allowed values of $m_{\ell}$. Recall that the possible values of $m_{\ell}$ depend on the value of $\ell$, not on the value of $n$.

Setup The possible values of $m_{\ell}$ are $-\ell, \ldots, 0, \ldots,+\ell$.
Solution The possible values of $m_{\ell}$ are $-1,0$, and +1 .

Practice Problem A (a) What are the possible values for $m_{\ell}$ when the principal quantum number ( $n$ ) is 2 and the angular momentum quantum number $(\ell)$ is 0 ? (b) What are the possible values for $m_{\ell}$ when the principal quantum number $(n)$ is 3 and the angular momentum quantum number $(\ell)$ is 2 ?

- Practice Problem B (a) What is the lowest possible value of the principal quantum number ( $n$ ) when the angular momentum quantum number $(\ell)$ is 1 ? (b) What are the possible values of the angular momentum quantum number $(\ell)$ when the magnetic quantum number $\left(m_{\ell}\right)$ is 0 ?

## Electron Spin Quantum Number ( $m_{s}$ )

Whereas three quantum numbers are sufficient to describe an atomic orbital, an additional quantum number becomes necessary to describe an electron that occupies the orbital.

Experiments on the emission spectra of hydrogen and sodium atoms indicated that each line in the emission spectra could be split into two lines by the application of an external magnetic field. The only way physicists could explain these results was to assume that electrons act like tiny magnets. If electrons are thought of as spinning on their own axes, as Earth does, their
magnetic properties can be accounted for. According to electromagnetic theory, a spinning charge generates a magnetic field, and it is this motion that causes an electron to behave like a magnet. Figure 6.16 shows the two possible spinning motions of an electron, one clockwise and the other counterclockwise. To specify the electron's spin, we use the electron spin quantum number $\left(\boldsymbol{m}_{s}\right)$. Because there are two possible directions of spin, opposite each other, $m_{s}$ has two possible values: $+\frac{1}{2}$ and $-\frac{1}{2}$.

Conclusive proof of electron spin was established by Otto Stern ${ }^{13}$ and Walther Gerlach ${ }^{14}$ in 1924. Figure 6.17 shows the basic experimental arrangement. A beam of gaseous atoms generated in a hot furnace passes through a nonuniform magnetic field. The interaction between an electron and the magnetic field causes the atom to be deflected from its straight-line path. Because the direction of spin is random, the electrons in half of the atoms will be spinning in one direction. Those atoms will be deflected in one way. The electrons in the other half of the atoms will be spinning in the opposite direction. Those atoms will be deflected in the other direction. Thus, two spots of equal intensity are observed on the detecting screen.

To summarize, we can designate an orbital in an atom with a set of three quantum numbers. These three quantum numbers indicate the size $(n)$, shape $(\ell)$, and orientation $\left(m_{\ell}\right)$ of the orbital. A fourth quantum number $\left(m_{s}\right)$ is necessary to designate the spin of an electron in the orbital.

## Checkpoint 6.6 Quantum Numbers

6.6.1 Which of the following is a legitimate set of three quantum numbers: $n, \ell$, and $m_{\ell}$ ? (Select all that apply.)
a) $1,0,0$
b) $2,0,0$
c) $1,0,+1$
d) $2,1,+1$
e) $2,2,-1$
6.6.2 How many orbitals are there in a subshell designated by the quantum numbers $n=3$, $\ell=2$ ?
a) 2
b) 3
c) 5
d) 7
e) 10

Student Annotation: Two electrons in the same orbital with opposite spins are referred to as "paired."

Figure 6.16 (a) Clockwise and (b) counterclockwise spins of an electron. The magnetic fields generated by these two spinning motions are analogous to those from the two magnets. The upward and downward arrows are used to denote the direction of spin.

Figure 6.17 Experimental arrangement for demonstrating electron spin. A beam of atoms is directed through a magnetic field. When a hydrogen atom, with a single electron, passes through the field, it is deflected in one direction or the other, depending on the direction of the electron's spin. In a stream consisting of many atoms, there will be equal distributions of the two kinds of spins, so two spots of equal intensity are detected on the screen.

[^17]Student Annotation: The radial probability distribution can be thought of as a map of "where an electron spends most of its time."

### 6.7 Atomic Orbitals

Strictly speaking, an atomic orbital does not have a well-defined shape because the wave function characterizing the orbital extends from the nucleus to infinity. In that sense, it is difficult to say what an orbital looks like. On the other hand, it is certainly useful to think of orbitals as having specific shapes. Being able to visualize atomic orbitals is essential to understanding the formation of chemical bonds and molecular geometry, which are discussed in Chapters 8 and 9. In this section, we will look at each type of orbital separately.

## $s$ Orbitals

For any value of the principal quantum number $(n)$, the value 0 is possible for the angular momentum quantum number $(\ell)$, corresponding to an $s$ subshell. Furthermore, when $\ell=0$, the magnetic quantum number ( $m_{\ell}$ ) has only one possible value, 0 , corresponding to an $s$ orbital. Therefore, there is an $s$ subshell in every shell, and each $s$ subshell contains just one orbital, an $s$ orbital.

Figure 6.18 illustrates three ways to represent the distribution of electrons: the probability density, the spherical distribution of electron density, and the radial probability distribution (the density, the spherical distribution of electron density, and the radial probability distribution (the

Figure 6.18 From top to bottom, the probability density and corresponding relief map, the distribution of electron density represented spherically with shading corresponding to the relief map above, and the radial probability distribution for (a) the $1 s$, (b) the $2 s$, and (c) the $3 s$ orbitals of hydrogen.
probability of finding the electron as a function of distance from the nucleus) for the $1 s, 2 s$, and $3 s$ orbitals of hydrogen. The boundary surface (the outermost surface of the spherical representation) is a common way to represent atomic orbitals, incorporating the volume in which there is about a 90 percent probability of finding the electron at any given time.

All $s$ orbitals are spherical in shape but differ in size, which increases as the principal quantum number increases. The radial probability distribution for the $1 s$ orbital exhibits a maximum at $52.9 \mathrm{pm}(0.529 \AA)$ from the nucleus. The radial probability distribution plots for the $2 s$ and $3 s$ orbitals exhibit two and three maxima, respectively, with the greatest probability occurring at a greater distance from the nucleus as $n$ increases. Between the two maxima for the $2 s$ orbital there is a point on the plot where the probability drops to zero. This corresponds to a node in the electron density, where the standing wave has zero amplitude. There are two such nodes in the radial probability distribution plot of the $3 s$ orbital.

Although the boundary surface diagram of an $s$ orbital does not show the number of nodes, the most important features of atomic orbitals, for our purposes, are their overall shapes and relative sizes. These features are adequately represented by boundary surface diagrams.

## p Orbitals

When the principal quantum number $(n)$ is 2 or greater, the value 1 is possible for the angular momentum quantum number $(\ell)$, corresponding to a $p$ subshell. And, when $\ell=1$, the magnetic quantum number $\left(m_{\ell}\right)$ has three possible values: $-1,0$, and +1 , each corresponding to a different $\boldsymbol{p}$ orbital. Therefore, there is a $p$ subshell in every shell for which $n \geq 2$, and each $p$ subshell contains three $p$ orbitals. These three $p$ orbitals are labeled $2 p_{x}, 2 p_{y}$, and $2 p_{z}$ (Figure 6.19), with the subscripted letters indicating the axis along which each orbital is oriented. These three $p$ orbitals are identical in size, shape, and energy; they differ from one another only in orientation. Note, however, that there is no simple relation between the values of $m_{\ell}$ and the $x, y$, and $z$ directions. For our purpose, you need only remember that because there are three possible values of $m_{\ell}$, there are three $p$ orbitals with different orientations.

The boundary surface diagrams of $p$ orbitals in Figure 6.19 show that each $p$ orbital can be thought of as two lobes on opposite sides of the nucleus. Like $s$ orbitals, $p$ orbitals increase in size from $2 p$ to $3 p$ to $4 p$ orbital and so on.

## d Orbitals and Other Higher-Energy Orbitals

When the principal quantum number $(n)$ is 3 or greater, the value 2 is possible for the angular momentum quantum number $(\ell)$, corresponding to a $d$ subshell. When $\ell=2$, the magnetic quantum number $\left(m_{\ell}\right)$ has five possible values, $-2,-1,0,+1$, and +2 , each corresponding to a different $\boldsymbol{d}$ orbital. Again there is no direct correspondence between a given orientation and a particular $m_{\ell}$ value. All the $3 d$ orbitals in an atom are identical in energy and are labeled with subscripts denoting their orientation with respect to the $x, y$, and $z$ axes and to the planes defined by them. The $d$ orbitals that have higher principal quantum numbers ( $4 d, 5 d$, etc.) have shapes similar to those shown for the $3 d$ orbitals in Figure 6.20.

Student Annotation: Interestingly, this distance is equal to the radius of the $n=1$ orbit in the Bohr model of the hydrogen atom and is defined as the Bohr radius.

Figure 6.19 (a) Electron distribution in a $p$ orbital. (b) Boundary surfaces for the $p_{x}, p_{y}$, and $p_{z}$ orbitals.

Figure 6.20 Boundary surfaces for the $d$ orbitals.

Think About It Consult Figure 6.15 to verify your answers.

Student Annotation: Recall that Bohr, whose model only had one quantum number, was able to calculate the energies of electrons in the hydrogen atom accurately.

Figure 6.21 Orbital energy levels in the hydrogen atom. Each box represents one orbital. Orbitals with the same principal quantum number ( $n$ ) all have the same energy.

The $f$ orbitals are important when accounting for the behavior of elements with atomic numbers greater than 57 , but their shapes are difficult to represent. In general chemistry we will not concern ourselves with the shapes of orbitals having $\ell$ values greater than 2 .

Sample Problem 6.8 shows how to label orbitals with quantum numbers.

## Sample Problem 6.8

List the values of $n, \ell$, and $m_{\ell}$ for each of the orbitals in a $4 d$ subshell.
Strategy Consider the significance of the number and the letter in the $4 d$ designation and determine the values of $n$ and $\ell$. There are multiple possible values for $m_{\ell}$, which will have to be deduced from the value of $\ell$.

Setup The integer at the beginning of an orbital designation is the principal quantum number ( $n$ ). The letter in an orbital designation gives the value of the angular momentum quantum number $(\ell)$. The magnetic quantum number $\left(m_{s}\right)$ can have integral values of $-\ell, \ldots, 0, \ldots,+\ell$.

Solution The values of $n$ and $\ell$ are 4 and 2 , respectively, so the possible values of $m_{\ell}$ are $-2,-1,0$, +1 , and +2 .

Practice Problem A Give the values of $n, \ell$, and $m_{\ell}$ for the orbitals in a $3 d$ subshell.
§Practice Problem B Using quantum numbers, explain why there is no $2 d$ subshell.

## Energies of Orbitals

The energies of orbitals in the hydrogen atom, or any one-electron ion, depend only on the value of the principal quantum number ( $n$ ), and energy increases as $n$ increases. For this reason, orbitals in the same shell have the same energy regardless of their subshell (Figure 6.21).

$$
1 s<2 s=2 p<3 s=3 p=3 d<4 s=4 p=4 d=4 f
$$

Thus, all four orbitals (one $2 s$ and three $2 p$ ) in the second shell have the same energy; all nine orbitals (one $3 s$, three $3 p$, and five $3 d$ ) in the third shell have the same energy; and all sixteen orbitals (one $4 s$, three $4 p$, five $4 d$, and seven $4 f$ ) in the fourth shell have the same energy. The energy picture is more complex for many-electron atoms than it is for hydrogen, as is discussed in Section 6.8.

## Checkpoint 6.7 Atomic Orbitals

6.7.1 How many orbitals are there in the $5 f$ subshell?
a) 5
b) 7
c) 14
d) 16
e) 28
6.7.2 The energy of an orbital in the hydrogen atom depends on $\qquad$ -.
a) $n, \ell$, and $m_{\ell}$
b) $n$ and $\ell$
c) $n$ only
d) $\ell$ only
e) $m_{\ell}$ only
6.7.3 In a hydrogen atom, which orbitals are higher in energy than a $3 s$ orbital? (Select all that apply.)
a) $3 p$
b) $4 s$
c) $2 p$
d) $3 d$
e) $4 p$
6.7.4 Which of the following sets of quantum numbers, $n, \ell$, and $m_{\ell}$, corresponds to a $3 p$ orbital?
a) $3,0,0$
b) $3,1,0$
c) $3,2,-1$
d) $1,1,-2$
e) $1,3,1$

### 6.8 Electron Configuration

The hydrogen atom is a particularly simple system because it contains only one electron. The electron may reside in the $1 s$ orbital (the ground state), or it may be found in some higher-energy orbital (an excited state). With many-electron systems, we need to know the ground-state electron configuration-that is, how the electrons are distributed in the various atomic orbitals. To do this, we need to know the relative energies of atomic orbitals in a many-electron system, which differ from those in a one-electron system such as hydrogen.

## Energies of Atomic Orbitals in Many-Electron Systems

Consider the two emission spectra shown in Figure 6.22. The spectrum of helium contains more lines than that of hydrogen. This indicates that there are more possible transitions, corresponding to emission in the visible range, in a helium atom than in a hydrogen atom. This is due to the splitting of energy levels caused by electrostatic interactions between helium's two electrons.

Figure 6.23 shows the general order of orbital energies in a many-electron atom. In contrast to the hydrogen atom, in which the energy of an orbital depends only on the value of $n$ (Figure 6.21), the energy of an orbital in a many-electron system depends on both the value of $n$ and the value of $\ell$. For example, $3 p$ orbitals all have the same energy, but they are higher in energy than the $3 s$ orbital and lower in energy than the $3 d$ orbitals. In a many-electron atom, for a given value of $n$, the energy of an orbital increases with increasing value of $\ell$. One important consequence of the splitting of energy levels is the relative energies of $d$ orbitals in one shell and the $s$ orbital in the next higher shell. As Figure 6.23 shows, the $4 s$ orbital is lower in energy than the $3 d$ orbitals. Likewise, the $5 s$ orbital is lower in energy than the $4 d$ orbital, and so on. This fact becomes important when we determine how the electrons in an atom populate the atomic orbitals.

Student Annotation: "Splitting" of energy levels refers to the splitting of a shell into subshells of different energies, as shown in Figure 6.23.

Figure 6.22 Comparison of the emission spectra of H and He .

Figure 6.23 Orbital energy levels in many-electron atoms. For a given value of $n$, orbital energy increases with the value of $\ell$.

Student Annotation: Two electrons in the same orbital with opposite spins are said to have paired spins.

Student Annotation: $1 s^{1}$ is read as "one $s$ one."

Student Annotation: The ground state for a many-electron atom is the one in which all the electrons occupy orbitals of the lowest possible energy.

## The Pauli Exclusion Principle

According to the Pauli ${ }^{15}$ exclusion principle, no two electrons in the same atom can have the same four quantum numbers. If two electrons in an atom have the same $n, \ell$, and $m_{\ell}$ values (meaning that they occupy the same orbital), then they must have different values of $m_{s}$; that is, one must have $m_{s}=+\frac{1}{2}$ and the other must have $m_{s}=-\frac{1}{2}$. Because there are only two possible values for $m_{s}$, and no two electrons in the same orbital may have the same value for $m_{s}$, a maximum of two electrons may occupy an atomic orbital, and these two electrons must have opposite spins.

We can indicate the arrangement of electrons in atomic orbitals with labels that identify each orbital (or subshell) and the number of electrons in it. Thus, we could describe a hydrogen atom in the ground state using $1 s^{1}$.

We can also represent the arrangement of electrons in an atom using orbital diagrams, in which each orbital is represented by a labeled box. The orbital diagram for a hydrogen atom in the ground state is

The upward arrow denotes one of the two possible spins (one of the two possible $m_{s}$ values) of the electron in the hydrogen atom (the other possible spin is indicated with a downward arrow). Under certain circumstances, as we will see shortly, it is useful to indicate the explicit locations of electrons.

The orbital diagram for a helium atom in the ground state is

[^18]The label $1 s^{2}$ indicates there are two electrons in the $1 s$ orbital. Note also that the arrows in the box point in opposite directions, representing opposite electron spins. Generally when an orbital diagram includes an orbital with a single electron, we represent it with an upward arrow-although we could represent it equally well with a downward arrow. The choice is arbitrary and has no effect on the energy of the electron.

## The Aufbau Principle

We can continue the process of writing electron configurations for elements based on the order of orbital energies and the Pauli exclusion principle. This process is based on the Aufbau principle, which makes it possible to "build" the periodic table of the elements and determine their electron configurations by steps. Each step involves adding one proton to the nucleus and one electron to the appropriate atomic orbital. Through this process we gain a detailed knowledge of the electron configurations of the elements. As we will see in later chapters, knowledge of electron configurations helps us understand and predict the properties of the elements. It also explains why the elements fit into the periodic table the way they do.

After helium, the next element in the periodic table is lithium, which has three electrons. Because of the restrictions imposed by the Pauli exclusion principle, an orbital can accommodate no more than two electrons. Thus, the third electron cannot reside in the $1 s$ orbital. Instead, it must reside in the next available orbital with the lowest possible energy. According to Figure 6.23, this is the $2 s$ orbital. Therefore, the electron configuration of lithium is $1 s^{2} 2 s^{1}$, and the orbital diagram is

Similarly, we can write the electron configuration of beryllium as $1 s^{2} 2 s^{2}$ and represent it with the orbital diagram

With both the $1 s$ and the $2 s$ orbitals filled to capacity, the next electron, which is needed for the electron configuration of boron, must reside in the $2 p$ subshell. Because all three $2 p$ orbitals are of equal energy, or degenerate, the electron can occupy any one of them. By convention, we usually show the first electron to occupy the $p$ subshell in the first empty box in the orbital diagram.

## Hund's Rule

Will the sixth electron, which is needed to represent the electron configuration of carbon, reside in the $2 p$ orbital that is already half occupied, or will it reside in one of the other, empty $2 p$ orbitals? According to Hund's ${ }^{16}$ rule, the most stable arrangement of electrons in orbitals of equal energy is the one in which the number of electrons with the same spin is maximized. As we have seen, no two electrons in any orbital may have the same spin, so maximizing the number of electrons with the same spin requires putting the electrons in separate orbitals. Accordingly, in any subshell, an electron will occupy an empty orbital rather than one that already contains an electron.

The electron configuration of carbon is, therefore, $1 s^{2} 2 s^{2} 2 p^{2}$, and its orbital diagram is

Similarly, the electron configuration of nitrogen is $1 s^{2} 2 s^{2} 2 p^{3}$, and its orbital diagram is

[^19]Student Annotation: $1 s^{2}$ is read as "one $s$ two," not as "one s squared."

Student Annotation: Electrons with the same spin are said to have parallel spins.

Student Annotation: Because electrons are negatively charged, they repel one another. Maximizing parallel spins in separate orbitals minimizes the electron-electron repulsions in a subshell.

Figure 6.24 A simple way to remember the order in which orbitals fill with electrons.

Student Annotation: Remember that in this context, degenerate means "of equal energy." Orbitals in the same subshell are degenerate.

Multimedia
Atomic Structure-electron configurations.

## Think About It Look at

 Figure 6.23 again to make sure you have filled the orbitals in the right order and that the sum of electrons is 20 . Remember that the $4 s$ orbital fills before the $3 d$ orbitals.Once all the $2 p$ orbitals are singly occupied, additional electrons will have to pair with those already in the orbitals. Thus, the electron configurations and orbital diagrams for O, F, and Ne are as follows:

## General Rules for Writing Electron Configurations

Based on the preceding examples we can formulate the following general rules for determining the electron configuration of an element in the ground state:

1. Electrons will reside in the available orbitals of the lowest possible energy.
2. Each orbital can accommodate a maximum of two electrons.
3. Electrons will not pair in degenerate orbitals if an empty orbital is available.
4. Orbitals will fill in the order indicated in Figure 6.23. Figure 6.24 provides a simple way for you to remember the proper order.

Sample Problem 6.9 illustrates the procedure for determining the ground-state electron configuration of an atom.

## Sample Problem 6.9

Write the electron configuration and give the orbital diagram of a calcium $(\mathrm{Ca})$ atom $(Z=20)$.
Strategy Use the general rules given and the Aufbau principle to "build" the electron configuration of a calcium atom and represent it with an orbital diagram.

Setup Because $Z=20$, we know that a Ca atom has 20 electrons. They will fill orbitals in the order designated in Figure 6.23, obeying the Pauli exclusion principle and Hund's rule. Orbitals will fill in the following order: $1 s, 2 s, 2 p, 3 s, 3 p, 4 s$. Each $s$ subshell can contain a maximum of two electrons, whereas each $p$ subshell can contain a maximum of six electrons.

## Solution

Practice Problem A Write the electron configuration and give the orbital diagram of a rubidium $(\mathrm{Rb})$ atom $(Z=37)$.

HPractice Problem B Write the electron configuration and give the orbital diagram of a bromine ( Br ) atom $(Z=35)$.

### 6.9 Electron Configurations and the Periodic Table

The electron configurations of all elements except hydrogen and helium can be represented using a noble gas core, which shows in brackets the electron configuration of the noble gas element that most recently precedes the element in question, followed by the electron configuration in the outermost occupied subshells. Figure 6.25 gives the outermost ground-state electron configurations of elements from $\mathrm{H}(Z=1)$ through $\operatorname{Rg}(Z=111)$. Notice the similar pattern of electron configurations in the elements lithium $(Z=3)$ through neon $(Z=10)$ and those of sodium $(Z=11)$ through argon $(Z=18)$. Both Li and Na , for example, have the configuration $n s^{1}$ in their outermost occupied subshells. For $\mathrm{Li}, n=2$; for $\mathrm{Na}, n=3$. Both F and Cl have electron configuration $n s^{2} n p^{5}$, where $n=2$ for F and $n=3$ for Cl , and so on.

As mentioned in Section 6.8, the $4 s$ subshell is filled before the $3 d$ subshell in a manyelectron atom (see Figure 6.23). Thus, the electron configuration of potassium $(Z=19)$ is $1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2} 3 p^{6} 4 s^{1}$. Because $1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2} 3 p^{6}$ is the electron configuration of argon, we can simplify the electron configuration of potassium by writing [ Ar$] 4 s^{1}$, where [ Ar ] denotes the "argon core."

$$
\mathrm{K} \quad \underbrace{1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2} 3 p^{6}}_{[\mathrm{Ar}]} 4 s^{1} \longrightarrow[\mathrm{Ar}] 4 s^{1}
$$

The placement of the outermost electron in the $4 s$ orbital (rather than in the $3 d$ orbital) of potassium is strongly supported by experimental evidence. The physical and chemical properties of potassium are very similar to those of lithium and sodium, the first two alkali metals. In both lithium and sodium, the outermost electron is in an $s$ orbital (there is no doubt that their outermost electrons occupy $s$ orbitals because there is no $1 d$ or $2 d$ subshell). Based on its similarities to the other alkali metals, we expect potassium to have an analogous electron configuration; that is, we expect the last electron in potassium to occupy the $4 s$ rather than the $3 d$ orbital.

The elements from Group 3B through Group 1B are transition metals [ 14 Section 2.4]. Transition metals either have incompletely filled $d$ subshells or readily give rise to cations that have incompletely filled $d$ subshells. In the first transition metal series, from scandium $(Z=21)$ through copper $(Z=29)$, additional electrons are placed in the $3 d$ orbitals according to Hund's rule. However, there are two anomalies. The electron configuration of chromium $(Z=24)$ is $[\mathrm{Ar}] 4 s^{1} 3 d^{5}$ and not $[\mathrm{Ar}] 4 s^{2} 3 d^{4}$, as we might expect. A similar break in the pattern is observed for

Figure 6.25 Outermost ground-state electron configurations for the known elements.

Student Annotation: Electron configurations such as these may also be written with the $d$ subshell first. For example, $[\operatorname{Ar}] 4 s^{1} 3 d^{10}$ can also be written as $[\operatorname{Ar}] 3 d^{10} 4 s^{1}$. Either way is acceptable.
copper, whose electron configuration is $[\mathrm{Ar}] 4 s^{1} 3 d^{10}$ rather than $[\mathrm{Ar}] 4 s^{2} 3 d^{9}$. The reason for these anomalies is that a slightly greater stability is associated with the half-filled ( $3 d^{5}$ ) and completely filled ( $3 d^{10}$ ) subshells.

$$
\begin{aligned}
& \mathrm{Cr} \quad[\mathrm{Ar}] \begin{array}{|c}
1 \\
4 s
\end{array} \\
& \begin{array}{|l|l|l|l|l|}
\hline 1 & 1 & 1 & 1 & 1 \\
\hline 3 d & 3 d & 3 d & 3 d & 3 d
\end{array} \\
& \mathrm{Cu} \quad[\mathrm{Ar}] \frac{1}{4 s}
\end{aligned}
$$

For elements $\mathrm{Zn}(Z=30)$ through $\mathrm{Kr}(Z=36)$, the $3 d, 4 s$, and $4 p$ subshells fill in a straightforward manner. With rubidium $(Z=37)$, electrons begin to enter the $n=5$ energy level.

Some of the electron configurations in the second transition metal series [yttrium ( $Z=39$ ) through silver $(Z=47)]$ are also irregular, but the details of many of these irregularities are beyond the scope of this text and we will not be concerned with them.

The sixth period of the periodic table begins with cesium $(Z=55)$ and barium $(Z=56)$, whose electron configurations are $[\mathrm{Xe}] 6 s^{1}$ and $[\mathrm{Xe}] 6 s^{2}$, respectively. Following barium, there is a gap in the periodic table where the lanthanide (rare earth) series belongs. The lanthanides are a series of 14 elements that have incompletely filled $4 f$ subshells or that readily give rise to cations
that have incompletely filled $4 f$ subshells. The lanthanides (and the actinides, to be discussed next) are shown at the bottom of the periodic table to keep the table from being too wide.

| Lanthanides 6 | La | Ce | Pr | Nd | Pm | Sm | Eu | Gd | Tb | Dy | Ho | Er | Tm | Yb | 6 |
| ---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Actinides 7 | Ac | Th | Pa | U | Np | Pu | Am | Cm | Bk | Cf | Es | Fm | Md | No | 7 |

In theory, the lanthanides arise from the filling of the seven degenerate $4 f$ orbitals. In reality, however, the energies of the $5 d$ and $4 f$ orbitals are very close and the electron configurations of these elements sometimes involve $5 d$ electrons. For example, in lanthanum itself $(Z=57)$ the $4 f$ orbital is slightly higher in energy than the $5 d$ orbital. Thus, lanthanum's electron configuration is $[\mathrm{Xe}] 6 s^{2} 5 d^{1}$ rather than [Xe] $6 s^{2} 4 f^{1}$.

After the $4 f$ subshell is completely filled, the next electron enters the $5 d$ subshell of lutetium $(Z=71)$. This series of elements, including lutetium and hafnium $(Z=72)$ and extending through mercury $(Z=80)$, is characterized by the filling of the $5 d$ subshell. The $6 p$ subshells are filled next, which takes us to radon $(Z=86)$.

The last row of elements begins with francium $\left(Z=87\right.$; electron configuration $\left.[\mathrm{Rn}] 7 s^{1}\right)$ and radium $\left(Z=88\right.$; electron configuration $\left.[\mathrm{Rn}] 7 s^{2}\right)$, and then continues with the actinide series, which starts at actinium $(Z=89)$ and ends with nobelium $(Z=102)$. The actinide series has partially filled $5 f$ and/or $6 d$ subshells. The elements lawrencium $(Z=103)$ through darmstadtium $(Z=110)$ have a filled $5 f$ subshell and are characterized by the filling of the $6 d$ subshell.

With few exceptions, you should be able to write the electron configuration of any element, using Figure 6.23 (or Figure 6.24 ) as a guide. Elements that require particular care are the transition metals, the lanthanides, and the actinides. You may notice from looking at the electron configurations of gadolinium $(Z=64)$ and curium $(Z=96)$ that half-filled $f$ subshells also appear to exhibit slightly enhanced stability. As we noted earlier, at larger values of the principal quantum number $n$, the order of subshell filling may be irregular due to the closeness of the energy levels.

Figure 6.26 groups the elements according to the type of subshell in which the outermost electrons are placed. Elements whose outermost electrons are in an $s$ subshell are referred to as $s$-block elements, those whose outermost electrons are in a $p$ subshell are referred to as $p$-block elements, and so on.

Sample Problem 6.10 shows how to write electron configurations.

Student Annotation: When $n=4, \ell$ can equal 3 , corresponding to an $f$ subshell. There are seven possible values for $m_{\ell}$ when $\ell=3$ : $-3,-2,-1,0,+1,+2$, and +3 . Therefore, there are seven $f$ orbitals.

Student Annotation: Most of these elements are not found in nature but have been synthesized in nuclear reactions, which are the subject of Chapter 20.

| $1 s$ |  |  |  | $1 s$ |
| :---: | :---: | :---: | :---: | :---: |
| $2 s$ |  |  | $2 p$ |  |

Figure 6.26 Classification of groups of elements in the periodic table according to the type of subshell being filled with electrons.

Think About It Arsenic is a p-block element; therefore, we should expect its outermost electrons to reside in a $p$ subshell.

## Sample Problem 6.10

Without referring to Figure 6.25, write the electron configuration for an arsenic atom $(Z=33)$ in the ground state.

Strategy Use Figure 6.23 or Figure 6.24 to determine the order in which the subshells will fill, and then assign electrons to the appropriate subshells.

Setup The noble gas core for As is [Ar], where $Z=18$ for Ar. The order of filling beyond the noble gas core is $4 s, 3 d$, and $4 p$. Fifteen electrons must go into these subshells because there are $33-18=15$ electrons in As beyond its noble gas core.

Solution $[\mathrm{Ar}] 4 s^{2} 3 d^{10} 4 p^{3}$

Practice Problem A Without referring to Figure 6.25, write the electron configuration for a radium atom $(Z=88)$ in the ground state.

EPractice Problem B Without referring to Figure 6.25, determine the identity of the element with the following electron configuration:

$$
[\mathrm{Xe}] 6 s^{2} 4 f^{14} 5 d^{10} 6 p^{5}
$$

## Checkpoint 6.9 Electron Configurations and the Periodic Table

6.9.1 Which of the following electron configurations correctly represents the Ag atom?
a) $[\mathrm{Kr}] 5 s^{2} 4 d^{9}$
b) $[\mathrm{Kr}] 5 s^{2} 4 d^{10}$
c) $[\mathrm{Kr}] 5 s^{1} 4 d^{10}$
d) $[\mathrm{Xe}] 5 s^{2} 4 d^{9}$
e) $[\mathrm{Xe}] 5 s^{1} 4 d^{10}$
6.9.2 What element is represented by the following electron configuration: $[\mathrm{Kr}] 5 s^{2} 4 d^{10} 5 p^{5}$ ?
a) Tc
b) Br
c) I
d) Xe
e) Te
6.9.3 Which of the following is a $d$-block element? (Select all that apply.)
a) Sb
b) Au
c) Ca
d) Zn
e) $U$
6.9.4 Which of the following is a $p$-block element? (Select all that apply.)
a) Pb
b) C
c) Sr
d) Xe
e) Na

## Applying What You've Learned

Two of the most commonly used lasers in medicine are the $\mathrm{CO}_{2}$ laser, which emits a beam at $10,600 \mathrm{~nm}$, and the Ar ion laser, which emits beams at 488 nm and 514 nm . The $\mathrm{CO}_{2}$ laser is used to remove benign skin lesions such as warts and moles; to remove tumors from especially sensitive areas such as the brain and spinal cord; to resurface scars, skin irregularities, and wrinkles for cosmetic purposes; and as a "laser scalpel" in situations where there may be a risk of excessive bleeding. Ar laser light is strongly absorbed by melanin, the pigment found in human skin, making it useful in the removal of dark-colored skin anomalies. Ar lasers are also used in some surgeries on the retina and the inner ear.

## Problems:

a) Calculate the frequency and the energy per photon of the light emitted by a $\mathrm{CO}_{2}$ laser. [144 Sample Problems 6.1 and 6.2]
b) Calculate the difference in energy per photon in the two wavelengths emitted by the Ar laser. Which of the wavelengths is more energetic?
[ 14 Sample Problem 6.3]
c) Calculate the de Broglie wavelength of an argon atom moving at $1000 \mathrm{~m} / \mathrm{s}$. [ 14 Sample Problem 6.5]
d) Give the values of $n$, $\ell$, and $m_{\ell}$ for the $3 p$ orbitals in an Ar atom. [ 14 Sample Problem 6.8]
e) Write the electron configuration of Ar. [144 Sample Problems 6.9 and 6.10]

## Chapter Summary

## Section 6.1

- What we commonly refer to as "light" is actually the visible portion of the electromagnetic spectrum. All light has certain common characteristics including wavelength, frequency, and amplitude.
- Wavelength $(\lambda)$ is the distance between two crests or two troughs of a wave. Frequency $(v)$ is the number of waves that pass a point per unit time. Amplitude is the distance between the midpoint and crest or trough of a wave.
- Electromagnetic waves have both electric and magnetic components that are both mutually perpendicular and in phase.

## Section 6.2

- Blackbody radiation is the electromagnetic radiation given off by a solid when it is heated.
- Max Planck proposed that energy, like matter, was composed of tiny, indivisible "packages" called quanta. Quanta is the plural of quantum.
- Albert Einstein used Planck's revolutionary quantum theory to explain the photoelectric effect, in which electrons are emitted when light of a certain minimum frequency shines on a metal surface.
- A quantum of light is referred to as a photon.

## Section 6.3

- An emission spectrum is the light given off by an object when it is excited thermally. Emission spectra may be continuous, including all the wavelengths within a particular range, or they may be line spectra, consisting only of certain discrete wavelengths.
- The ground state is the lowest possible energy state for an atom. An excited state is any energy level higher than the ground state.

## Section 6.4

- A node is a point at which a standing wave has zero amplitude.
- Having observed that light could exhibit particle-like behavior, de Broglie proposed that matter might also exhibit wavelike behavior. The de Broglie wavelength is the wavelength associated with a particle of very small mass. Soon after de Broglie's proposal, experiments showed that electrons could exhibit diffraction-a property of waves.

## Section 6.5

- According to the Heisenberg uncertainty principle, the product of the uncertainty of the location and the uncertainty of the momentum of a very small particle must have a certain minimum value. It is thus impossible to know simultaneously both the location and momentum of an electron.
- The electron density gives the probability of finding an electron in a particular region in an atom. An atomic orbital is the region of threedimensional space, defined by $\psi^{2}$ (the square of the wave function, $\psi$ ), where the probability of finding an electron is high. An atomic orbital can accommodate a maximum of two electrons.

## Section 6.6

- An atomic orbital is defined by three quantum numbers: the principal quantum number ( $n$ ), the angular momentum quantum number $(\ell)$, and the magnetic quantum number ( $\boldsymbol{m}_{\ell}$ ).
- The principal quantum number $(n)$ indicates distance from the nucleus. Possible values of $n$ are $(1,2,3, \ldots)$ The angular momentum quantum number $(\ell)$ indicates the shape of the orbital. Possible values of $\ell$ are $(0,1, \ldots, n-1)$. The magnetic quantum number $\left(m_{\ell}\right)$ indicates the orbital's orientation in space. Possible values of $m_{\ell}$ are $(-\ell, \ldots, 0, \ldots$, $+\ell$ ).
- Two electrons that occupy the same atomic orbital in the ground state must have different electron spin quantum numbers ( $\boldsymbol{m}_{s}$ ), either $+\frac{1}{2}$ or $-\frac{1}{2}$.

## Section 6.7

- The value of the angular momentum quantum number $(\ell)$ determines the type of the atomic orbital: $\ell=0$ corresponds to an $\boldsymbol{s}$ orbital, $\ell=1$ corresponds to a $\boldsymbol{p}$ orbital, $\ell=2$ corresponds to a $\boldsymbol{d}$ orbital, and $\ell=3$ corresponds to an $f$ orbital.

## Section 6.8

- The electron configuration specifies the arrangement of electrons in the atomic orbitals of an atom.
- According to the Pauli exclusion principle, no two electrons in an atom in the ground state can have the same four quantum numbers, $n$, $\ell, m_{\ell}$, and $m_{s}$.
- The Aufbau principle describes the theoretical, sequential building up of the elements in the periodic table by the stepwise addition of protons and electrons.
- Atomic orbitals that have the same energy are called degenerate. According to Hund's rule, degenerate orbitals must all contain one electron before any can contain two electrons.

## Section 6.9

- The noble gas core makes it possible to abbreviate the writing of electron configurations.
- The lanthanide (rare earth) series and actinide series appear at the bottom of the periodic table. They represent the filling of $f$ orbitals.

## Key Words

Actinide series, 245
Amplitude, 212
Angular momentum quantum number ( $\ell$ ), 233
Atomic orbital, 232
Aufbau principle, 241

Blackbody radiation, 215
$d$ orbital, 237
de Broglie wavelength, 229
Degenerate, 241
Electromagnetic spectrum, 212
Electromagnetic wave, 213

Electron configuration, 239
Electron density, 232
Electron spin quantum number $\left(m_{s}\right), 235$
Emission spectra, 220
Excited state, 222
forbital, 238
Frequency ( $\nu$ ), 212
Ground state, 222
Heisenberg uncertainty
principle, 231
Hund's rule, 241

Noble gas core, 243
Node, 228
p orbital, 237
Pauli exclusion principle, 240

Photoelectric effect, 217
Photons, 218
Principal quantum number ( $n$ ), 233
Quantum, 215

Quantum numbers, 233
s orbital, 236
Wavelength ( $\lambda$ ), 212

## Key Equations

$$
\begin{array}{ll}
6.1 & c=\lambda v \\
6.2 & E=h v \\
6.3 & h v=\mathrm{KE}+W \\
6.4 & \frac{1}{\lambda}=R_{\infty}\left(\frac{1}{n_{1}^{2}}-\frac{1}{n_{2}^{2}}\right) \\
6.5 & E_{n}=-2.18 \times 10^{-18} \mathrm{~J}\left(\frac{1}{n^{2}}\right) \\
6.6 & \Delta E=h v=-2.18 \times 10^{-18} \mathrm{~J}\left(\frac{1}{n_{\mathrm{f}}^{2}}-\frac{1}{n_{\mathrm{i}}^{2}}\right) \\
6.7 & \frac{1}{\lambda}=\frac{-2.18 \times 10^{-18} \mathrm{~J}}{h c}\left(\frac{1}{n_{\mathrm{f}}^{2}}-\frac{1}{n_{\mathrm{i}}^{2}}\right) \\
6.8 & 2 \pi r=n \lambda \\
6.9 & \lambda=\frac{h}{m u} \\
6.10 & \Delta x \cdot \Delta p \geq \frac{h}{4 \pi} \\
6.11 & \Delta x \cdot m \Delta u \geq \frac{h}{4 \pi}
\end{array}
$$

## Questions and Problems

## Section 6.1: The Nature of Light

## Review Questions

6.1 What is a wave? Using a diagram, define the following terms associated with waves: wavelength, frequency, amplitude.
6.2 What are the units for wavelength and frequency of electromagnetic waves? What is the speed of light in meters per second and miles per hour?
6.3 List the types of electromagnetic radiation, starting with the radiation having the longest wavelength and ending with the radiation having the shortest wavelength.
6.4 Give the high and low wavelength values that define the visible region of the electromagnetic spectrum.

## Problems

E 6.5 (a) What is the wavelength (in nm ) of light having a frequency of $8.6 \times 10^{13} \mathrm{~Hz}$ ? (b) What is the frequency (in Hz ) of light having a wavelength of 566 nm ?

E 6.6 (a) What is the frequency of light having a wavelength of 456 nm ? (b) What is the wavelength (in nm ) of radiation having a frequency of $2.45 \times 10^{9} \mathrm{~Hz}$ ? (This is the type of radiation used in microwave ovens.)

E 6.7 The average distance between Mars and Earth is about $1.3 \times$ $10^{8}$ miles. How long would it take video images transmitted from the Mars Spirit rover on Mars' surface to reach Earth (1 mile = $1.61 \mathrm{~km})$ ?
6.8 How many minutes would it take a radio wave to travel from the planet Venus to Earth? (The average distance from Venus to Earth $=28$ million miles.)
6.9 The SI unit of time is the second, which is defined as $9,192,631,770$ cycles of radiation associated with a certain emission process in the cesium atom. Calculate the wavelength of this radiation (to three significant figures). In which region of the electromagnetic spectrum is this wavelength found?
6.10 The SI unit of length is the meter, which is defined as the length equal to $1,650,763.73$ wavelengths of the light emitted by a particular energy transition in krypton atoms. Calculate the frequency of the light to three significant figures.

## Section 6.2: Quantum Theory

## Review Questions

6.11 Briefly explain Planck's quantum theory and explain what a quantum is. What are the units for Planck's constant?
6.12 Give two everyday examples that illustrate the concept of quantization.
6.13 Explain what is meant by the photoelectric effect.
6.14 What are photons? What role did Einstein's explanation of the photoelectric effect play in the development of the particle-wave interpretation of the nature of electromagnetic radiation?

## Problems

\& 6.15 A photon has a wavelength of 705 nm . Calculate the energy of the photon in joules.
\$ 6.16 The blue color of the sky results from the scattering of sunlight by molecules in the air. The blue light has a frequency of about $7.5 \times 10^{14} \mathrm{~Hz}$. (a) Calculate the wavelength (in nm ) associated with this radiation, and (b) calculate the energy (in joules) of a single photon associated with this frequency.
\& 6.17 A photon has a frequency of $6.5 \times 10^{9} \mathrm{~Hz}$. (a) Convert this frequency into wavelength ( nm ). Does this frequency fall in the visible region? (b) Calculate the energy (in joules) of this photon. (c) Calculate the energy (in joules) of 1 mole of photons all with this frequency.
\& 6.18 What is the wavelength (in nm ) of radiation that has an energy content of $2.13 \times 10^{3} \mathrm{~kJ} / \mathrm{mol}$ ? In which region of the electromagnetic spectrum is this radiation found?
6.19 When copper is bombarded with high-energy electrons, X rays are emitted. Calculate the energy (in joules) associated with the photons if the wavelength of the X rays is 0.154 nm .

E6.20 A particular form of electromagnetic radiation has a frequency of $9.87 \times 10^{15} \mathrm{~Hz}$. (a) What is its wavelength in nanometers? In meters? (b) To what region of the electromagnetic spectrum would you assign it? (c) What is the energy (in joules) of one quantum of this radiation?
6.21 Photosynthesis makes use of visible light to bring about chemical changes. Explain why heat energy in the form of infrared radiation is ineffective for photosynthesis.

G6.22 The retina of a human eye can detect light when radiant energy incident on it is at least $4.0 \times 10^{-17}$ J. For light of $585-\mathrm{nm}$ wavelength, how many photons does this energy correspond to?
G/ 6.23 The radioactive ${ }^{60}$ Co isotope is used in nuclear medicine to treat certain types of cancer. Calculate the wavelength and frequency of an emitted gamma particle having the energy of $1.29 \times 10^{11} \mathrm{~J} / \mathrm{mol}$.

## Section 6.3: Bohr's Theory of the Hydrogen Atom

## Visualizing Chemistry

Figure 6.10
VC 6.1 Which of the following best explains why we see only four lines in the emission spectrum of hydrogen?
a) Hydrogen has only four different electronic transitions.
b) Only four of hydrogen's electronic transitions correspond to visible wavelengths.
c) The other lines in hydrogen's emission spectrum can't be seen easily against the black background.
VC 6.2 One way to see the emission spectrum of hydrogen is to view the hydrogen in an electric discharge tube through a spectroscope, a device that separates the wavelengths. Why
can we not view the emission spectrum simply by pointing the spectroscope at a sample of hydrogen confined in a glass tube or flask?
a) Without the electrons being in excited states, there would be no emission of light.
b) The glass would make it impossible to see the emission spectrum.
c) Hydrogen alone does not exhibit an emission spectrumit must be combined with oxygen.
VC 6.3 How many lines would we see in the emission spectrum of hydrogen if the downward transitions from excited states all ended at $n=1$ and no transitions ended at $n=2$ ?
a) We would still see four lines.
b) We would see five lines.
c) We would not see any lines.

VC 6.4 For a hydrogen atom in which the electron has been excited to $n=4$, how many different transitions can occur as the electron eventually returns to the ground state?
a) 1 .
b) 2 .
c) 3 .

## Review Questions

6.24 What are emission spectra? How do line spectra differ from continuous spectra?
6.25 What is an energy level? Explain the difference between ground state and excited state.
6.26 Briefly describe Bohr's theory of the hydrogen atom and how it explains the appearance of an emission spectrum. How does Bohr's theory differ from concepts of classical physics?
6.27 Explain the meaning of the negative sign in Equation 6.5.

## Problems

6.28 Explain why elements produce their own characteristic colors when they emit photons.
6.29 Some copper compounds emit green light when they are heated in a flame. How would you determine whether the light is of one wavelength or a mixture of two or more wavelengths?
6.30 Is it possible for a fluorescent material to emit radiation in the ultraviolet region after absorbing visible light? Explain your answer.
6.31 Explain how astronomers are able to tell which elements are present in distant stars by analyzing the electromagnetic radiation emitted by the stars.

H 6.32 Consider the following energy levels of a hypothetical atom:
$E_{4}:-1.0 \times 10^{-19} \mathrm{~J}$
$E_{3}:-5.0 \times 10^{-19} \mathrm{~J}$
$E_{2}:-10 \times 10^{-19} \mathrm{~J}$
$E_{1}:-15 \times 10^{-19} \mathrm{~J}$
(a) What is the wavelength of the photon needed to excite an electron from $E_{1}$ to $E_{4}$ ? (b) What is the energy (in joules) a photon must have to excite an electron from $E_{2}$ to $E_{3}$ ? (c) When an electron drops from the $E_{3}$ level to the $E_{1}$ level, the atom is said to undergo emission. Calculate the wavelength of the photon emitted in this process.
6.33 The first line of the Balmer series occurs at a wavelength of 656.3 nm . What is the energy difference between the two energy levels involved in the emission that results in this spectral line?

EI 6.34 Calculate the wavelength (in nm ) of a photon emitted by a hydrogen atom when its electron drops from the $n=7$ state to the $n=2$ state .

G6.35 Calculate the frequency $(\mathrm{Hz})$ and wavelength $(\mathrm{nm})$ of the emitted photon when an electron drops from the $n=4$ to the $n=3$ level in a hydrogen atom.

E6.36 Careful spectral analysis shows that the familiar yellow light of sodium lamps (such as street lamps) is made up of photons of two wavelengths, 589.0 nm and 589.6 nm . What is the difference in energy (in joules) between photons with these wavelengths?

E6.37 An electron in the hydrogen atom makes a transition from an energy state of principal quantum number $n_{i}$ to the $n=1$ state. If the photon emitted has a wavelength of 94.9 nm , what is the value of $n_{i}$ ?

## Section 6.4: Wave Properties of Matter

## Review Questions

6.38 How does de Broglie's hypothesis account for the fact that the energies of the electron in a hydrogen atom are quantized?
6.39 Why is Equation 6.9 meaningful only for submicroscopic particles, such as electrons and atoms, and not for macroscopic objects?
6.40 Does a baseball in flight possess wave properties? If so, why can we not determine its wave properties?

## Problems

E 6.41 Thermal neutrons are neutrons that move at speeds comparable to those of air molecules at room temperature. These neutrons are most effective in initiating a nuclear chain reaction among ${ }^{235} \mathrm{U}$ isotopes. Calculate the wavelength (in nm ) associated with a beam of neutrons moving at $7.00 \times 10^{2} \mathrm{~m} / \mathrm{s}$ (mass of a neutron $=$ $1.675 \times 10^{-27} \mathrm{~kg}$ ).
© 6.42 Protons can be accelerated to speeds near that of light in particle accelerators. Estimate the wavelength (in nm) of such a proton moving at $2.90 \times 10^{8} \mathrm{~m} / \mathrm{s}$ (mass of a proton $=1.673 \times 10^{-27} \mathrm{~kg}$ ).
E.43 What is the de Broglie wavelength (in cm ) of a $12.4-\mathrm{g}$ hummingbird flying at $1.20 \times 10^{2} \mathrm{mph}(1$ mile $=1.61 \mathrm{~km})$ ?

El 6.44 What is the de Broglie wavelength (in nm ) associated with a $2.5-\mathrm{g}$ Ping-Pong ball traveling at 15 mph ?

## Section 6.5: Quantum Mechanics

## Review Questions

6.45 What are the inadequacies of Bohr's theory?
6.46 What is the Heisenberg uncertainty principle? What is the Schrödinger equation?
6.47 What is the physical significance of the wave function?
6.48 How is the concept of electron density used to describe the position of an electron in the quantum mechanical treatment of an atom?
6.49 What is an atomic orbital? How does an atomic orbital differ from an orbit?

## Problems

E6.50 Alveoli are tiny sacs of air in the lungs. Their average diameter is $5.0 \times 10^{-5} \mathrm{~m}$. Calculate the uncertainty in the velocity of an oxygen molecule $\left(5.3 \times 10^{-26} \mathrm{~kg}\right)$ trapped within a sac. (Hint: The maximum uncertainty in the position of the molecule is given by the diameter of the sac.)
6.51 Suppose that photons of blue light ( 430 nm ) are used to locate the position of a $2.80-\mathrm{g}$ Ping-Pong ball in flight and that the uncertainty in the position is equal to one wavelength. What is the minimum uncertainty in the speed of the Ping-Pong ball? Comment on the magnitude of your result.

## Section 6.6: Quantum Numbers

## Review Questions

6.52 Describe the four quantum numbers used to characterize an electron in an atom.
6.53 Which quantum number defines a shell? Which quantum numbers define a subshell?
6.54 Which of the four quantum numbers $\left(n, \ell, m_{\ell}, m_{s}\right)$ determine (a) the energy of an electron in a hydrogen atom and in a manyelectron atom, (b) the size of an orbital, (c) the shape of an orbital, (d) the orientation of an orbital in space?

## Problems

6.55 An electron in a certain atom is in the $n=2$ quantum level. List the possible values of $\ell$ and $m_{\ell}$ that it can have.

E6.56 An electron in an atom is in the $n=3$ quantum level. List the possible values of $\ell$ and $m_{\ell}$ that it can have.
6.57 List all the possible subshells and orbitals associated with the principal quantum number $n$, if $n=4$.

E6.58 List all the possible subshells and orbitals associated with the principal quantum number $n$, if $n=5$.

## Section 6.7: Atomic Orbitals

## Review Questions

6.59 Describe the shapes of $s, p$, and $d$ orbitals. How are these orbitals related to the quantum numbers $n, \ell$, and $m_{\ell}$ ?
6.60 List the hydrogen orbitals in increasing order of energy.
6.61 Describe the characteristics of an $s$ orbital, $p$ orbital, and $d$ orbital. Which of the following orbitals do not exist: $1 p, 2 s, 2 d, 3 p, 3 d$, $3 f, 4 g$ ?
6.62 Why is a boundary surface diagram useful in representing an atomic orbital?

## Problems

EI 6.63 Give the values of the quantum numbers associated with the following orbitals: (a) $2 p$, (b) $3 s$, (c) $5 d$.

E6.64 Give the values of the four quantum numbers of an electron in the following orbitals: (a) $3 s$, (b) $4 p$, (c) $3 d$.
6.65 Discuss the similarities and differences between a $1 s$ and a $2 s$ orbital.
6.66 What is the difference between a $2 p_{x}$ and a $2 p_{y}$ orbital?
6.67 Why do the $3 s, 3 p$, and $3 d$ orbitals have the same energy in a hydrogen atom but different energies in a many-electron atom?
6.68 Make a chart of all allowable orbitals in the first four principal energy levels of the hydrogen atom. Designate each by type (for example, $s, p$ ), and indicate how many orbitals of each type there are.

EI 6.69 For each of the following pairs of hydrogen orbitals, indicate which is higher in energy: (a) $1 s, 2 s$; (b) $2 p, 3 p$; (c) $3 d_{x y}, 3 d_{y z}$; (d) $3 s, 3 d$; (e) $4 f, 5 s$.
$\$ 6.70$ Which orbital in each of the following pairs is lower in energy in a many-electron atom: (a) $2 s, 2 p$; (b) $3 p, 3 d$; (c) $3 s, 4 s$; (d) $4 d, 5 f$ ?

## Section 6.8: Electron Configuration

## Review Questions

6.71 What is electron configuration? Describe the roles that the Pauli exclusion principle and Hund's rule play in writing the electron configuration of elements.
6.72 Explain the meaning of the symbol $4 d^{6}$.
6.73 State the Aufbau principle, and explain the role it plays in classifying the elements in the periodic table.

## Problems

G6.74 Calculate the total number of electrons that can occupy (a) one $s$ orbital, (b) three $p$ orbitals, (c) five $d$ orbitals, (d) seven $f$ orbitals.
6.75 What is the total number of electrons that can be held in all orbitals having the same principal quantum number $n$ ?

E6.76 Determine the maximum number of electrons that can be found in each of the following subshells: $3 s, 3 d, 4 p, 4 f, 5 f$.
6.77 Indicate the total number of (a) $p$ electrons in $\mathrm{N}(Z=7)$, (b) $s$ electrons in $\mathrm{Si}(Z=14)$, and (c) $3 d$ electrons in $\mathrm{S}(Z=16)$.

E 6.78 Indicate which of the following sets of quantum numbers in an atom are unacceptable and explain why: (a) ( $1,1,+\frac{1}{2},-\frac{1}{2}$ ), (b) (3, $\left.0,-1,+\frac{1}{2}\right)$, (c) $\left(2,0,+1,+\frac{1}{2}\right)$, (d) $\left(4,3,-2,+\frac{1}{2}\right)$, (e) $(3,2,+1,1)$.
6.79 The ground-state electron configurations listed here are incorrect. Explain what mistakes have been made in each and write the correct electron configurations.
$\mathrm{Al}: 1 s^{2} 2 s^{2} 2 p^{4} 3 s^{2} 3 p^{3}$
B: $1 s^{2} 2 s^{2} 2 p^{5}$
F: $1 s^{2} 2 s^{2} 2 p^{6}$
E 6.80 Indicate the number of unpaired electrons present in each of the following atoms: $\mathrm{B}, \mathrm{Ne}, \mathrm{P}, \mathrm{Sc}, \mathrm{Mn}, \mathrm{Se}, \mathrm{Kr}, \mathrm{Fe}, \mathrm{Cd}, \mathrm{I}, \mathrm{Pb}$.
EI 6.81 The electron configuration of a neutral atom is $1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2}$. Write a complete set of quantum numbers for each of the electrons. Name the element.
$\leftrightarrows 6.82$ Which of the following species has the greatest number of unpaired electrons: $\mathrm{S}^{+}, \mathrm{S}$, or $\mathrm{S}^{-}$? Explain how you arrive at your answer.

## Section 6.9: Electron Configurations and the Periodic Table

## Review Questions

6.83 Describe the characteristics of transition metals.
6.84 What is the noble gas core? How does it simplify the writing of electron configurations?
6.85 What are the group and period of the element osmium?
6.86 Define the following terms and give an example of each: lanthanides, actinides.
6.87 Explain why the ground-state electron configurations of Cr and Cu are different from what we might expect.
6.88 Write the electron configuration of a xenon core.
6.89 Comment on the correctness of the following statement: The probability of finding two electrons with the same four quantum numbers in an atom is zero.

## Problems

$\$ 6.90$ Use the Aufbau principle to obtain the ground-state electron configuration of selenium.
6.91 Use the Aufbau principle to obtain the ground-state electron configuration of technetium.
E 6.92 Write the ground-state electron configurations for the following elements: B, V, C, As, I, Au.
6.93 Write the ground-state electron configurations for the following elements: $\mathrm{Ge}, \mathrm{Fe}, \mathrm{Zn}, \mathrm{Ni}, \mathrm{W}, \mathrm{Tl}$.

## Additional Problems

6.94 When a compound containing cesium ion is heated in a Bunsen burner flame, photons with an energy of $4.30 \times 10^{-19} \mathrm{~J}$ are emitted. What color is the cesium flame?
6.95 Discuss the current view of the correctness of the following statements. (a) The electron in the hydrogen atom is in an orbit that never brings it closer than 100 pm to the nucleus. (b) Atomic absorption spectra result from transitions of electrons from lower to higher energy levels. (c) A many-electron atom behaves somewhat like a solar system that has a number of planets.
6.96 Distinguish carefully between the following terms: (a) wavelength and frequency, (b) wave properties and particle properties, (c) quantization of energy and continuous variation in energy.

E 6.97 What is the maximum number of electrons in an atom that can have the following quantum numbers? Specify the orbitals in which the electrons would be found. (a) $n=2, m_{s}=+\frac{1}{2}$; (b) $n=4, m_{\ell}=+1$; (c) $n=3, \ell=2$; (d) $n=2, \ell=0, m_{s}=-\frac{1}{2}$; (e) $n=4, \ell=3, m_{\ell}=-2$.
6.98 Identify the following individuals and their contributions to the development of quantum theory: Bohr, de Broglie, Einstein, Planck, Heisenberg, Schrödinger.
Y6.99 In a photoelectric experiment a student uses a light source whose frequency is greater than that needed to eject electrons from a certain metal. However, after continuously shining the light on the same area of the metal for a long period of time the student notices that the maximum kinetic energy of ejected electrons begins to decrease, even though the frequency of the light is held constant. How would you account for this behavior?
§6.100 A baseball pitcher's fastballs have been clocked at about 100 mph . (a) Calculate the wavelength of a $0.141-\mathrm{kg}$ baseball (in nm ) at this speed. (b) What is the wavelength of a hydrogen atom at the same speed $(1 \mathrm{mile}=1609 \mathrm{~m})$ ?
G6.101 A ruby laser produces radiation of wavelength 633 nm in pulses whose duration is $1.00 \times 10^{-9} \mathrm{~s}$. (a) If the laser produces 0.376 J of energy per pulse, how many photons are produced in each pulse? (b) Calculate the power (in watts) delivered by the laser per pulse ( $1 \mathrm{~W}=1 \mathrm{~J} / \mathrm{s}$ ).

Ef 6.102 A 368-g sample of water absorbs infrared radiation at $1.06 \times 10^{4} \mathrm{~nm}$ from a carbon dioxide laser. Suppose all the absorbed radiation is converted to heat. Calculate the number of photons at this wavelength required to raise the temperature of the water by $5.00^{\circ} \mathrm{C}$.
6.103 Photodissociation of water

$$
\mathrm{H}_{2} \mathrm{O}(l)+h v \longrightarrow \mathrm{H}_{2}(g)+\frac{1}{2} \mathrm{O}_{2}(g)
$$

has been suggested as a source of hydrogen. The $\Delta H_{\mathrm{rxn}}^{\circ}$ for the reaction, calculated from thermochemical data, is 285.8 kJ per mole of water decomposed. Calculate the maximum wavelength (in nm ) that would provide the necessary energy. In principle, is it feasible to use sunlight as a source of energy for this process?
6.104 Spectral lines of the Lyman and Balmer series do not overlap. Verify this statement by calculating the longest wavelength associated with the Lyman series and the shortest wavelength associated with the Balmer series (in nm ).

G16.105 Only a fraction of the electric energy supplied to a tungsten lightbulb is converted to visible light. The rest of the energy shows up as infrared radiation (that is, heat). A 75-W lightbulb converts 15.0 percent of the energy supplied to it into visible light (assume the wavelength to be 550 nm ). How many photons are emitted by the lightbulb per second ( $1 \mathrm{~W}=1 \mathrm{~J} / \mathrm{s}$ )?
$\$ 6.106$ Certain sunglasses have small crystals of silver chloride $(\mathrm{AgCl})$ incorporated in the lenses. When the lenses are exposed to light of the appropriate wavelength, the following reaction occurs:

$$
\mathrm{AgCl} \longrightarrow \mathrm{Ag}+\mathrm{Cl}
$$

The Ag atoms formed produce a uniform gray color that reduces the glare. If $\Delta H$ for the preceding reaction is $248 \mathrm{~kJ} / \mathrm{mol}$, calculate the maximum wavelength of light that can induce this process.

E6.107 The He ion contains only one electron and is therefore a hydrogenlike ion. Calculate the wavelengths, in increasing order, of the first four transitions in the Balmer series of the $\mathrm{He}^{+}$ion. Compare these wavelengths with the same transitions in an H atom. Comment on the differences. (The Rydberg constant for He is $4.39 \times 10^{7} \mathrm{~m}^{-1}$.)

E 6.108 The retina of a human eye can detect light when radiant energy incident on it is at least $4.0 \times 10^{-17} \mathrm{~J}$. For light of $575-\mathrm{nm}$ wavelength, how many photons does this correspond to?
6.109 An electron in an excited state in a hydrogen atom can return to the ground state in two different ways: (a) via a direct transition in which a photon of wavelength $\lambda_{1}$ is emitted and (b) via an intermediate excited state reached by the emission of a photon of wavelength $\lambda_{2}$. This intermediate excited state then decays to the ground state by emitting another photon of wavelength $\lambda_{3}$. Derive an equation that relates $\lambda_{1}$ to $\lambda_{2}$ and $\lambda_{3}$.
6.110 A photoelectric experiment was performed by separately shining a laser at 450 nm (blue light) and a laser at 560 nm (yellow light) on a clean metal surface and measuring the number and kinetic energy of the ejected electrons. Which light would generate more electrons? Which light would eject electrons with greater kinetic energy? Assume that the same amount of energy is delivered to the metal surface by each laser and that the frequencies of the laser lights exceed the threshold frequency.

E6.111 The electron configurations described in this chapter all refer to gaseous atoms in their ground states. An atom may absorb a quantum of energy and promote one of its electrons to a higherenergy orbital. When this happens, we say that the atom is in an excited state. The electron configurations of some excited atoms are given. Identify these atoms and write their ground-state configurations:
(a) $1 s^{1} 2 s^{1}$
(b) $1 s^{2} 2 s^{2} 2 p^{2} 3 d^{1}$
(c) $1 s^{2} 2 s^{2} 2 p^{6} 4 s^{1}$
(d) $[\mathrm{Ar}] 4 s^{1} 3 d^{10} 4 p^{4}$
(e) $[\mathrm{Ne}] 3 s^{2} 3 p^{4} 3 d^{1}$
6.112 Draw the shapes (boundary surfaces) of the following orbitals: (a) $2 p_{y}$, (b) $3 d_{z^{2}}$, (c) $3 d_{x^{2}-y^{2}}$. (Show coordinate axes in your sketches.)

Ef6.113 Draw orbital diagrams for atoms with the following electron configurations:
(a) $1 s^{2} 2 s^{2} 2 p^{5}$
(b) $1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2} 3 p^{3}$
(c) $1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2} 3 p^{6} 4 s^{2} 3 d^{7}$
6.114 If Rutherford and his coworkers had used electrons instead of alpha particles to probe the structure of the nucleus (see Chapter 2), how would the result have changed?

G6.115 Scientists have found interstellar hydrogen atoms with quantum number $n$ in the hundreds. Calculate the wavelength of light emitted when a hydrogen atom undergoes a transition from $n=236$ to $n=235$. In what region of the electromagnetic spectrum does this wavelength fall?
6.116 Ionization energy is the minimum energy required to remove an electron from an atom. It is usually expressed in units of $\mathrm{kJ} / \mathrm{mol}$, that is, the energy in kilojoules required to remove one mole of electrons from one mole of atoms. (a) Calculate the ionization energy for the hydrogen atom. (b) Repeat the calculation, assuming in this second case that the electrons are removed from the $n=2$ state, instead of from the ground state.
6.117 An electron in a hydrogen atom is excited from the ground state to the $n=4$ state. Comment on the correctness of the following statements (true or false).
(a) $n=4$ is the first excited state.
(b) It takes more energy to ionize (remove) the electron from $n=4$ than from the ground state.
(c) The electron is farther from the nucleus (on average) in $n=4$ than in the ground state.
(d) The wavelength of light emitted when the electron drops from $n=4$ to $n=1$ is longer than that from $n=4$ to $n=2$.
(e) The wavelength the atom absorbs in going from $n=1$ to $n=4$ is the same as that emitted as it goes from $n=4$ to $n=1$.

G6.118 The ionization energy of a certain element is $412 \mathrm{~kJ} / \mathrm{mol}$ (see Problem 6.116). However, when the atoms of this element are in the first excited state, the ionization energy is only $126 \mathrm{~kJ} / \mathrm{mol}$. Based on this information, calculate the wavelength of light emitted in a transition from the first excited state to the ground state.
6.119 How many photons at 586 nm must be absorbed to melt $5.0 \times$ $10^{2} \mathrm{~g}$ of ice? On average, how many $\mathrm{H}_{2} \mathrm{O}$ molecules does one photon convert from ice to water? (Hint: It takes 334 J to melt 1 g of ice at $0^{\circ} \mathrm{C}$.)
E.120 Portions of orbital diagrams representing the ground-state electron configurations of certain elements are shown here. Which of them violate the Pauli exclusion principle? Which violate Hund's rule?

G 6.121 The UV light that is responsible for tanning the skin falls in the 320- to 400-nm region. Calculate the total energy (in joules) absorbed by a person exposed to this radiation for 2.5 h , given that
there are $2.0 \times 10^{16}$ photons hitting Earth's surface per square centimeter per second over a $80-\mathrm{nm}(320$ to 400 nm ) range and that the exposed body area is $0.45 \mathrm{~m}^{2}$. Assume that only half of the radiation is absorbed and the other half is reflected by the body. (Hint: Use an average wavelength of 360 nm in calculating the energy of a photon.)
6.122 The sun is surrounded by a white circle of gaseous material called the corona, which becomes visible during a total eclipse of the sun. The temperature of the corona is in the millions of degrees Celsius, which is high enough to break up molecules and remove some or all of the electrons from atoms. One way astronomers have been able to estimate the temperature of the corona is by studying the emission lines of ions of certain elements. For example, the emission spectrum of $\mathrm{Fe}^{14+}$ ions has been recorded and analyzed. Knowing that it takes $3.5 \times 10^{4} \mathrm{~kJ} / \mathrm{mol}$ to convert $\mathrm{Fe}^{13+}$ to $\mathrm{Fe}^{14+}$, estimate the temperature of the sun's corona. (Hint: The average kinetic energy of one mole of a gas is $\frac{3}{2} R T$.)
6.123 When an electron makes a transition between energy levels of a hydrogen atom, there are no restrictions on the initial and final values of the principal quantum number $n$. However, there is a quantum mechanical rule that restricts the initial and final values of the orbital angular momentum $\ell$. This is the selection rule, which states that $\Delta \ell= \pm 1$; that is, in a transition, the value of $\ell$ can only increase or decrease by 1 . According to this rule, which of the following transitions are allowed: (a) $1 s \longrightarrow 2 s$,
(b) $2 p \longrightarrow 1 s$, (c) $1 s \longrightarrow 3 d$, (d) $3 d \longrightarrow 4 f$,
(e) $4 d \longrightarrow 3 s$ ? In view of this selection rule, explain why it is possible to observe the various emission series shown in Figure 6.11.
6.124 In 1996 physicists created an anti-atom of hydrogen. In such an atom, which is the antimatter equivalent of an ordinary atom, the electric charges of all the component particles are reversed. Thus the nucleus of an anti-atom is made of an antiproton, which has the same mass as a proton but bears a negative charge, while the electron is replaced by an anti-electron (also called a positron) with the same mass as an electron, but bearing a positive charge. Would you expect the energy levels, emission spectra, and atomic orbitals of an antihydrogen atom to be different from those of a hydrogen atom? What would happen if an anti-atom of hydrogen collided with a hydrogen atom?
f6.125 In an electron microscope, electrons are accelerated by passing them through a voltage difference. The kinetic energy thus acquired by the electrons is equal to the voltage times the charge on the electron. Thus a voltage difference of 1 volt imparts a kinetic energy of $1.602 \times 10^{-19}$ volt-coulomb or $1.602 \times 10^{-19} \mathrm{~J}$. Calculate the wavelength associated with electrons accelerated by $5.00 \times 10^{3}$ volts.
$\$ 6.126$ A microwave oven operating at $1.22 \times 10^{8} \mathrm{~nm}$ is used to heat 150 mL of water (roughly the volume of a tea cup) from $20^{\circ} \mathrm{C}$ to $100^{\circ} \mathrm{C}$. Calculate the number of photons needed if 92.0 percent of microwave energy is converted to the thermal energy of water.
6.127 Calculate the wavelength and frequency of an emitted gamma particle having the energy of $3.14 \times 10^{11} \mathrm{~J} / \mathrm{mol}$.

E 6.128 (a) An electron in the ground state of the hydrogen atom moves at an average speed of $5 \times 10^{6} \mathrm{~m} / \mathrm{s}$. If the speed is known to an uncertainty of 20 percent, what is the minimum uncertainty in its position? Given that the radius of the hydrogen atom in the ground state is $5.29 \times 10^{-11} \mathrm{~m}$, comment on your result. The mass of an electron is $9.1094 \times 10^{-31} \mathrm{~kg}$. (b) A $0.15-\mathrm{kg}$ baseball thrown at 100 mph has a momentum of $6.7 \mathrm{~kg} \cdot \mathrm{~m} / \mathrm{s}$. If the uncertainty in measuring the momentum is $1.0 \times 10^{-7}$ of the momentum, calculate the uncertainty in the baseball's position.
6.129 Calculate the energies needed to remove an electron from the $n=1$ state and the $n=5$ state in the $\mathrm{Li}^{2+}$ ion. What is the wavelength (in nm ) of the emitted photon in a transition from $n=5$ to $n=1$ ? Solving Equation 6.4 for energy gives $\Delta E=R_{\infty} h c\left(\frac{1}{n_{1}^{2}}-\frac{1}{n_{2}^{2}}\right)$,
where the Rydberg constant $R_{\infty}$ for hydrogen-like atoms is $1.097 \times 10^{7} \mathrm{~m}^{-1} \cdot Z^{2}$, and $Z$ is the atomic number.
6.130 According to Einstein's special theory of relativity, the mass of a moving particle, $m_{\text {moving }}$, is related to its mass at $m_{\text {rest }}$, by the following equation

$$
m_{\mathrm{moving}}=\frac{m_{\mathrm{rest}}}{\sqrt{1-(u / c)^{2}}}
$$

where $u$ and $c$ are the speeds of the particle and light, respectively. (a) In particle accelerators, protons, electrons, and other charged particles are often accelerated to speeds close to the speed of light. Calculate the wavelength (in nm ) of a proton moving at 50.0 percent the speed of light. The mass of a proton is $1.67 \times$ $10^{-27} \mathrm{~kg}$. (b) Calculate the mass of a $6.0 \times 10^{-2} \mathrm{~kg}$ tennis ball moving at $63 \mathrm{~m} / \mathrm{s}$. Comment on your results.
6.131 The mathematical equation for studying the photoelectric effect is

$$
h v=W+\frac{1}{2} m_{e} u^{2}
$$

where $v$ is the frequency of light shining on the metal; $W$ is the energy needed to remove an electron from the metal; and $m_{e}$ and $u$ are the mass and speed of the ejected electron, respectively. In an experiment, a student found that a maximum wavelength of 351 nm is needed to just dislodge electrons from a zinc metal surface. Calculate the velocity (in $\mathrm{m} / \mathrm{s}$ ) of an ejected electron when the student employed light with a wavelength of 313 nm .
6.132 In the beginning of the twentieth century, some scientists thought that a nucleus may contain both electrons and protons. Use the Heisenberg uncertainty principle to show that an electron cannot be confined within a nucleus. Repeat the calculation for a proton. Comment on your results. Assume the radius of a nucleus to be $1.0 \times 10^{-15} \mathrm{~m}$. The masses of an electron and a proton are $9.109 \times 10^{-31} \mathrm{~kg}$ and $1.673 \times 10^{-27} \mathrm{~kg}$, respectively. (Hint: Treat the radius of the nucleus as the uncertainty in position.)
6.133 Blackbody radiation is the term used to describe the dependence of the radiation energy emitted by an object on wavelength at a certain temperature. Planck proposed the quantum theory to account for the dependence. Shown in the figure is a plot of the radiation energy emitted by our sun versus wavelength. This curve is characteristic of objects at about 6000 K , which is the temperature at the surface of the sun. At a higher temperature, the curve has a similar shape but the maximum will shift to a shorter wavelength. (a) What does this curve reveal about two

consequences of great biological significance on Earth? (b) How are astronomers able to determine the temperature at the surface of stars in general?
6.134 All molecules undergo vibrational motions. Quantum mechanical treatment shows that the vibrational energy $E_{\text {vib }}$ of a diatomic molecule such as HCl is given by

$$
E_{\mathrm{vib}}=\left(n+\frac{1}{2}\right) h v
$$

where $n$ is a quantum number $(n=0,1,2,3, \ldots)$ and $v$ is the fundamental frequency of vibration. (a) Sketch the first three vibrational energy levels for HCl . (b) Calculate the energy required to excite an HCl molecule from the ground level to the first excited level. The fundamental frequency of vibration for

HCl is $8.66 \times 10^{13} \mathrm{~s}^{-1}$. (c) The fact that the lowest vibrational energy in the ground level is not zero but equal to $1 / 2 h v$ means that molecules will vibrate at all temperatures, including absolute zero. Use the Heisenberg uncertainty principle to justify this prediction. (Hint: Consider a molecule that is not vibrating and start by predicting the uncertainty in its momentum.)

E 6.135 The wave function for the $2 s$ orbital in the hydrogen atom is

$$
\Psi_{2 s}=\frac{1}{\sqrt{2 a_{0}^{3}}}\left(1-\frac{\rho}{2}\right) e^{-\rho / 2}
$$

where $a_{0}$ is the value of the radius of the first Bohr orbit, equal to $0.529 \mathrm{~nm} ; \rho$ is $Z\left(r / a_{0}\right)$; and $r$ is the distance from the nucleus in meters. Calculate the distance from the nucleus (in nm ) of the node of the $2 s$ wave function.

## Pre-Professional Practice Exam Problems: Physical and Biological Sciences

According to Wien's law, the wavelength of maximum intensity in blackbody radiation, $\lambda_{\max }$, is inversely proportional to the temperature of the radiating body. Mathematically,

$$
\lambda_{\max }=\frac{b}{T}
$$

where $b$ is Wien's displacement constant $\left(2.898 \times 10^{6} \mathrm{~nm} \cdot \mathrm{~K}\right)$ and $T$ is the temperature of the radiating body in kelvins. The sun, composed primarily of hydrogen, emits a continuous spectrum from the region known as the photosphere, with the most intense emission occurring at approximately 500 nm .

1. What is the approximate surface temperature of the sun?
a) $60,000 \mathrm{~K}$
b) 6000 K
c) 1500 K
d) 500 K
2. What is the frequency of the sun's $\lambda_{\max }$ ?
a) $6.0 \times 10^{14} \mathrm{~s}^{-1}$
b) $5.0 \times 10^{14} \mathrm{~s}^{-1}$
c) $2.5 \times 10^{2} \mathrm{~s}^{-1}$
d) $5.9 \times 10^{-14} \mathrm{~s}^{-1}$
3. What is the energy of a photon with wavelength $\lambda_{\max }$ for a blackbody at 5200 K ?
a) $5.4 \times 10^{-14} \mathrm{~J}$
b) $5.4 \times 10^{14} \mathrm{~J}$
c) $3.6 \times 10^{-19} \mathrm{~J}$
d) $5.6 \times 10^{-7} \mathrm{~J}$
4. The visible region of the electromagnetic spectrum includes wavelengths from about 400 nm to about 700 nm . What is the minimum approximate temperature that would be required for the maximum intensity wavelength emitted by a blackbody to occur in the ultraviolet region of the spectrum?
a) $71,000 \mathrm{~K}$
b) 9100 K
c) 7300 K
d) $64,000 \mathrm{~K}$

## What an Element's Position in the Periodic Table Can Tell Us

Elements in the same group of the periodic table tend to exhibit similar physical and chemical properties. The alkali metals, for example, Li, Na, and K, all form chloride salts that have similar properties. Because of their similarities to sodium chloride $(\mathrm{NaCl})$, lithium chloride $(\mathrm{LiCl})$ and potassium chloride $(\mathrm{KCl})$ have both been used as salt substitutes for people on low-sodium diets. Despite their similarities, only one of these salt substitutes proved to be safe. In the 1940s, a group of cardiac patients on low-sodium diets were given lithium chloride to use in place of sodium chloride. Lithium chloride looks just like sodium chloride and has a very similar taste. The resulting unregulated intake of lithium had disastrous results. Many of the patients developed symptoms of severe lithium toxicity and several of them died. Today, salt substitutes such as Morton Salt Substitute and Nu-Salt contain potassium chloride, which also looks and tastes like sodium chloride. The similarities in appearance and flavor of these compounds are largely due to the chemical similarity of the Group 1A elements they contain.

Although some of their biochemical properties vary, the physical and chemical properties of the alkali metals are quite similar. This is why they were placed in the same group in the periodic table in the first place. It turns out they belong in the same group because they have the same valence electron configuration.

NET WT. $31 / 8$ 02. (88.6g)

At the end of this chapter, you will be able to answer a series of questions about the alkali metals and the ions that they form [ $\|$ Page 288].

## In This Chapter, You Will Learn:

Some of the chemical and physical properties of the elements and how these properties are related to each element's position in the periodic table.

## Before you begin, you should review

- Atomic ions [I4 Section 2.7]
- Electron configurations and the periodic table [I4 Section 6.9]

### 7.1 Development of the Periodic Table

In the nineteenth century, chemists had only a vague idea of atoms and molecules and did not yet know about electrons and protons. Nevertheless, they devised the periodic table using their knowledge of atomic masses. Accurate measurements of the atomic masses of many elements had already been made. Arranging elements according to their atomic masses in a periodic table seemed logical to those chemists, who believed that chemical behavior should somehow be related to atomic mass.

In 1864 the English chemist John Newlands ${ }^{1}$ noticed that when the elements were arranged in order of atomic mass, every eighth element had similar properties. Newlands referred to this peculiar relationship as the law of octaves. However, this "law" turned out to be inadequate for elements beyond calcium, and Newlands's work was not accepted by the scientific community.

In 1869 the Russian chemist Dmitri Mendeleev ${ }^{2}$ and the German chemist Lothar Meyer ${ }^{3}$ independently proposed a much more extensive tabulation of the elements based on the regular, periodic recurrence of properties-a phenomenon known as periodicity.

Mendeleev's classification system was a great improvement over Newlands's for two reasons. First, it grouped the elements together more accurately, according to their properties. Second, and equally important, it made it possible to predict the properties of several elements that had not yet been discovered. For example, Mendeleev proposed the existence of an unknown element that he called eka-aluminum and predicted a number of its properties. (Eka is a Sanskrit word meaning "first"; thus, eka-aluminum would be the first element under aluminum in the same group.) When gallium was discovered 4 years later, its properties matched the predicted properties of eka-aluminum remarkably well:

|  | Eka-Aluminum (Ea) | Gallium (Ga) |
| :--- | :--- | :--- |
| Atomic mass | 68 amu | 69.9 amu |
| Melting point | Low | $30.15^{\circ} \mathrm{C}$ |
| Density | $5.9 \mathrm{~g} / \mathrm{cm}^{3}$ | $5.94 \mathrm{~g} / \mathrm{cm}^{3}$ |
| Formula of oxide | $\mathrm{Ea}_{2} \mathrm{O}_{3}$ | $\mathrm{Ga}_{2} \mathrm{O}_{3}$ |

Mendeleev's periodic table included 66 known elements. By 1900, some 30 more had been added to the list, filling in some of the empty spaces. Figure 7.1 gives the time period during which each element was discovered.

Although this periodic table was remarkably successful, the early versions had some inconsistencies that were impossible to overlook. For example, the atomic mass of argon ( 39.95 amu ) is greater than that of potassium ( 39.10 amu ), but argon comes before potassium in the periodic table. If elements were arranged solely according to increasing atomic mass, argon would appear in the position occupied by potassium in our modern periodic table (see the inside front cover). No chemist would place argon, a gas with no tendency to react, in the same group as lithium and sodium, two highly reactive metals! This and other discrepancies suggested that some fundamental property other than atomic mass must be the basis of periodicity. The fundamental property turned out to be the number of protons in an atom's nucleus, something that could not have been known by Mendeleev and his contemporaries.

In 1913 a young English physicist, Henry Moseley, ${ }^{4}$ discovered a correlation between what he called atomic number and the frequency of X rays generated by bombarding an element with high-energy electrons. Moseley noticed that, in general, the frequencies of X rays emitted from the elements increased with increasing atomic mass. Among the few exceptions he found were argon and potassium. Although argon has a greater atomic mass than potassium, the X-ray emission from potassium indicated that it has the greater atomic number. Ordering the periodic table using atomic

[^20]

| La | Ce | Pr | Nd | Pm | Sm | Eu | Gd | Tb | Dy | Ho | Er | Tm | Yb |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Ac | Th | Pa | U | Np | Pu | Am | Cm | Bk | Cf | Es | Fm | Md | No |

number enabled scientists to make sense out of the discrepancies that had puzzled them earlier. Moseley concluded that the atomic number was equal to the number of protons in the nucleus and to the number of electrons in an atom.

Entries in modern periodic tables usually include an element's atomic number along with its symbol. Electron configurations of elements help to explain the periodic recurrence of physical and chemical properties. The importance and usefulness of the periodic table lie in the fact that we can use our understanding of the general properties and trends within a group or a period to predict with considerable accuracy the properties of any element, even though that element may be unfamiliar to us.

Sample Problem 7.1 shows how the periodic table can be used to predict similarities and differences in the properties of elements.

## Sample Problem 7.1

What elements would you expect to exhibit properties most similar to those of chlorine?
Strategy Because elements in the same group tend to have similar properties, you should identify elements in the same group as chlorine.

Setup Chlorine is a member of Group 7A.
Solution Fluorine, bromine, and iodine, the other nonmetals in Group 7A, should have properties most similar to those of chlorine.

Practice Problem A What element(s) would you expect to exhibit properties most similar to those of silicon (Si)?

EPractice Problem B Arrange the following Group 5A elements in order of increasing similarity of properties to N : $\mathrm{As}, \mathrm{Bi}$, and P .

Figure 7.1 Periodic table of elements classified by dates of discovery.

Think About It Astatine (At) is also in Group 7A. Astatine, though, is classified as a metalloid, and we have to be careful comparing nonmetals to metalloids (or to metals). As a metalloid, the properties of astatine should be less similar to those of chlorine than the other members of Group 7A.

Student Annotation: Actually, astatine is radioactive and very little is known about its properties.

## Bringing Chemistry to Life

## The Chemical Elements of Life

Of the 117 elements currently known, relatively few are essential to living systems. Actually, only six nonmetallic elements form the building blocks of cells: $\mathrm{C}, \mathrm{H}, \mathrm{O}, \mathrm{N}, \mathrm{P}$, and S . They are the constituent elements of proteins, nucleic acids, and carbohydrates. Although the natural abundance of carbon is quite low (about 0.1 percent by mass of Earth's crust), it is present in nearly all biological
molecules. Carbon is perhaps the most versatile element because it has the ability to form various types of chemical bonds. Carbon atoms can form bonds to each other, linking up to form an enormous variety of chains and ring structures.

The metals play several different roles in living systems. As cations $\left(\mathrm{Na}^{+}, \mathrm{K}^{+}, \mathrm{Ca}^{2+}\right.$, and $\mathrm{Mg}^{2+}$ ), they serve to maintain the balance between intracellular and extracellular fluids, nerve transmissions, and other activities. They are also needed for protein functions. For example, the $\mathrm{Fe}^{2+}$ ion binds oxygen in hemoglobin molecules and $\mathrm{Cu}^{2+}, \mathrm{Zn}^{2+}$, and $\mathrm{Mg}^{2+}$ ions are essential for enzyme activity. In addition, calcium in the form of $\mathrm{Ca}_{5}\left(\mathrm{PO}_{4}\right)_{3}(\mathrm{OH})$ and $\mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}$ is an essential component of teeth and bones.

Bulk elements
Trace elements
The periodic table shown highlights the essential elements in the human body. Of special interest are the trace elements, such as iron (Fe), copper ( Cu ), zinc $(\mathrm{Zn})$, iodine ( I$)$, cobalt ( Co ), selenium ( Se ), and fluorine ( F ), which together make up about 0.1 percent of the body's mass. Although the trace elements are present in very small amounts, they are crucial for our health. In many cases, however, their exact biological role is still not fully understood.

These elements are necessary for biological functions such as growth, the transport of oxygen for metabolism, and defense against disease. There is a delicate balance in the amounts of these elements in our bodies. Too much or too little over an extended period of time can lead to serious illness, retardation, or even death.

## Checkpoint 7.1 Development of the Periodic Table

7.1.1 Which of the following elements would you expect to have chemical properties most similar to those of S ?
a) P
b) Cl
c) Se
d) Na
e) Sr
7.1.2 Which of the following elements would you expect to have properties similar to those of Ba ?
a) Sr
b) Rb
c) Na
d) K
e) $B$
7.1.3 Element 117 is not known to exist. However, based on its position in the periodic table, which of the following properties would you expect it to exhibit?
(i) gaseous at room temperature
(ii) unreactive
(iii) properties similar to At
(iv) properties similar to Ra
a) i and iv
b) i, ii, and iv
c) iii only
d) iv only
e) i and iii

### 7.2 The Modern Periodic Table

Figure 7.2 shows the modern periodic table together with the outermost ground-state electron configurations of the elements. (The electron configurations of the elements are also given in Figure 6.25.) Starting with hydrogen, the electronic subshells are filled in the order shown in Figure 6.23 [14 Section 6.8].

## Classification of Elements

Based on the type of subshell containing the outermost electrons, the elements can be divided into categories - the main group elements, the noble gases, the transition elements (or transition metals), the lanthanides, and the actinides. The main group elements (also called the representative elements) are the elements in Groups 1A through 7A. With the exception of helium, each of the noble gases (the Group 8A elements) has a completely filled $p$ subshell. The electron configurations are $1 s^{2}$ for helium and $n s^{2} n p^{6}$ for the other noble gases, where $n$ is the principal quantum number for the outermost shell.

The transition metals are the elements in Groups 1B and 3B through 8B. Transition metals either have incompletely filled $d$ subshells or readily produce cations with incompletely filled $d$ subshells. According to this definition, the elements of Group 2B are not transition metals. They are $d$-block elements, though, so they generally are included in the discussion of transition metals.

Student Annotation: In this context, outermost electrons refers to those that are placed in orbitals last using the Aufbau principle [ 14 Section 6.8].

Student Annotation: The metals of Group 2B typically form +2 ions, although they can also form +1 ions. In either case, the electron configuration includes a completed $d$ subshell [ $M$ Section 7.6]. Thus, strictly speaking, Zn, Cd , and Hg are not transition metals.

Figure 7.2 Valence electron configurations of the elements. For simplicity, the filled $f$-subshells are not shown in elements 72 through 86 ,
104 through 116, and 118.

# Why Are There Two Different Sets of Numbers at the Top of the Periodic Table? 

The numbering of the transition metal groups 3B through 7B indicates the similarity between the outer electron configurations of these elements and those of the corresponding main group elements. For example, scandium (Sc; Group 3B) and gallium (Ga; Group 3A) each have three outer electrons. However, because their outer electrons reside in different types of atomic orbitals ( $s$ and $d$ orbitals in the case of Sc; $s$ and $p$ orbitals in the case of $\mathrm{Ga})$, they belong in different groups. The elements of Groups 1B and 2B have filled $d$ subshells [ 14 Section 6.9]. Unlike the elements of Group 2B, elements of Group 1B form cations with incompletely filled $d$ subshells. Their group numbers correspond to the one and two electrons, respectively, that they have in $s$ orbitals-just like the main group elements in Groups 1A and 2 A . The elements iron ( Fe ), cobalt ( Co ), and nickel ( Ni ), and the
elements that appear beneath them in the periodic table, cannot be classified in this way and are all placed in Group 8B.

The designation of A and B groups is not universal. In Europe, the practice is to use B for main group elements and A for transition or $d$-block elements, which is just the opposite of the American convention. The International Union of Pure and Applied Chemistry (IUPAC) has recommended eliminating ambiguity by numbering the columns sequentially with Arabic numerals 1 through 18 (see Figure 7.2). The proposal has not been accepted universally, and many modern periodic tables retain the traditional group designations. Periodic tables in this text display both the IUPAC-recommended Arabic numerals and the traditional American numbering system. Discussions in the text will refer to the traditional American group numbers.

Figure 7.3 Periodic table with color-coding of main group elements, noble gases, transition metals, group 2B metals, lanthanides, and actinides.

The lanthanides and actinides are sometimes called $f$-block transition elements because they have incompletely filled $f$ subshells. Figure 7.3 distinguishes the groups of elements discussed here.

There is a distinct pattern to the electron configurations of the elements in a particular group. See, for example, the electron configurations of Groups 1A and 2A in Table 7.1. Each member of Group 1A has a noble gas core plus one additional electron, giving each alkali metal the general electron configuration of [noble gas]ns ${ }^{1}$. Similarly, the Group 2A alkaline earth metals have a noble gas core and an outer electron configuration of $n s^{2}$.

The outermost electrons of an atom are called valence electrons, which are the ones involved in the formation of chemical bonds between atoms. The similarity of the valence electron configurations (i.e., they have the same number and type of valence electrons) is what makes the elements in the same group resemble one another chemically. This observation holds true for the other main group elements as well. For instance, the halogens (Group 7A) all have outer electron configurations of $n s^{2} n p^{5}$, and they have similar properties.

## TABLE 7.1

## Electron Configurations of Group 1A and Group 2A Elements

## Group 1A

| Li | $[\mathrm{He}] 2 s^{1}$ |
| :--- | :--- |
| Na | $[\mathrm{Ne}] 3 s^{1}$ |
| K | $[\mathrm{Ar}] 4 s^{1}$ |
| Rb | $[\mathrm{Kr}] 5 s^{1}$ |
| Cs | $[\mathrm{Xe}] 6 s^{1}$ |
| Fr | $[\mathrm{Rn}] 7 s^{1}$ |

## Group 2A

| Be | $[\mathrm{He}] 2 s^{2}$ |
| :--- | :--- |
| Mg | $[\mathrm{Ne}] 3 s^{2}$ |
| Ca | $[\mathrm{Ar}] 4 s^{2}$ |
| Sr | $[\mathrm{Kr}] 5 s^{2}$ |
| Ba | $[\mathrm{Xe}] 6 s^{2}$ |
| Ra | $[\mathrm{Rn}] 7 s^{2}$ |

In predicting properties for Groups 3A through 7A, we must take into account that each of these groups contains elements on both sides of the line that divides metals and nonmetals. For example, the elements in Group 4A all have the same outer electron configuration, $n s^{2} n p^{2}$, but there is considerable variation in chemical properties among these elements because carbon is a nonmetal, silicon and germanium are metalloids, and tin and lead are metals.

As a group, the noble gases behave very similarly. The noble gases are chemically inert because they all have completely filled outer $n s$ and $n p$ subshells, a condition that imparts unusual stability. With the exception of krypton and xenon, they do not undergo chemical reactions.

Although the outer electron configuration of the transition metals is not always the same within a group and there is often no regular pattern in the way the electron configuration changes from one metal to the next in the same period, all transition metals share many characteristics (multiple oxidation states, richly colored compounds, magnetic properties, and so on) that set them apart from other elements. These properties are similar because all these metals have incompletely filled $d$ subshells. Likewise, the lanthanide and actinide elements resemble one another because they have incompletely filled $f$ subshells.

Sample Problem 7.2 shows how to determine the electron configuration from the number of electrons in an atom.

## Sample Problem 7.2

Without using a periodic table, give the ground-state electron configuration and block designation ( $s$-, $p-, d$-, or $f$-block) of an atom with (a) 17 electrons, (b) 37 electrons, and (c) 22 electrons. Classify each atom as a main group element or transition metal.

Strategy Use the Aufbau principle discussed in Section 6.8. Start writing each electron configuration with principal quantum number $n=1$, and then continue to assign electrons to orbitals in the order presented in Figure 6.23 until all the electrons have been accounted for.

Setup According to Figure 6.23, orbitals fill in the following order: $1 s, 2 s, 2 p, 3 s, 3 p, 4 s, 3 d, 4 p$, $5 s, 4 d, 5 p, 6 s$, and so on. Recall that an $s$ subshell contains one orbital, a $p$ subshell contains three orbitals, and a $d$ subshell contains five orbitals. Remember, too, that each orbital can accommodate a maximum of two electrons. The block designation of an element corresponds to the type of subshell occupied by the last electrons added to the configuration according to the Aufbau principle.

## Solution

(a) $1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2} 3 p^{5}, p$-block, main group
(b) $1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2} 3 p^{6} 4 s^{2} 3 d^{10} 4 p^{6} 5 s^{1}, s$-block, main group
(c) $1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2} 3 p^{6} 4 s^{2} 3 d^{2}, d$-block, transition metal

Practice Problem A Without using a periodic table, give the ground-state electron configuration and block designation ( $s$-, $p-, d$-, or $f$-block) of an atom with (a) 15 electrons, (b) 20 electrons, and (c) 35 electrons.
$\leftrightarrow \nmid$ Practice Problem B Identify the elements represented by (a) $1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2} 3 p^{1}$, (b) $1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2} 3 p^{6} 4 s^{2}$ $3 d^{10}$, and (c) $1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2} 3 p^{6} 4 s^{2} 3 d^{10} 4 p^{6} 5 s^{2}$.

Student Annotation: Although hydrogen's electron configuration is $1 s^{1}$ [ kA Section 6.9, Figure 6.25], it is a nonmetal and is not really a member of Group 1A.

Think About It Consult
Figure 6.25 on page 244 to confirm your answers.

Student Annotation: Recall that allotropes are different forms of the same element [14 Section 2.6].

## Representing Free Elements in Chemical Equations

Having classified the elements according to their ground-state electron configurations, we can now learn how chemists represent elements in chemical equations.
Metals Because metals do not exist in discrete molecular units but rather in complex, threedimensional networks of atoms, we always use their empirical formulas in chemical equations. The empirical formulas are the same as the symbols that represent the elements. For example, the empirical formula for iron is Fe , the same as the symbol for the element.

Nonmetals There is no single rule regarding the representation of nonmetals in chemical equations. Carbon, for example, exists in several allotropic forms. Regardless of the allotrope, we use its empirical formula C to represent elemental carbon in chemical equations. Often the symbol C will be followed by the specific allotrope in parentheses as in the equation representing the conversion of graphite to diamond, two of carbon's allotropic forms:

$$
\mathrm{C} \text { (graphite) } \longrightarrow \mathrm{C} \text { (diamond) }
$$

For nonmetals that exist as polyatomic molecules, we generally use the molecular formula in equations: $\mathrm{H}_{2}, \mathrm{~N}_{2}, \mathrm{O}_{2}, \mathrm{~F}_{2}, \mathrm{Cl}_{2}, \mathrm{Br}_{2}, \mathrm{I}_{2}$, and $\mathrm{P}_{4}$, for example. In the case of sulfur, however, we usually use the empirical formula $S$ rather than the molecular formula $S_{8}$. Thus, instead of writing the equation for the combustion of sulfur as

$$
\mathrm{S}_{8}(s)+8 \mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 8 \mathrm{SO}_{2}(\mathrm{~g})
$$

we usually write

$$
\mathrm{S}(\mathrm{~s})+\mathrm{O}_{2}(\mathrm{~g}) \longrightarrow \mathrm{SO}_{2}(g)
$$

although, technically, both ways are correct.
Noble Gases All the noble gases exist as isolated atoms, so we use their symbols: $\mathrm{He}, \mathrm{Ne}, \mathrm{Ar}$, $\mathrm{Kr}, \mathrm{Xe}$, and Rn .

Metalloids The metalloids, like the metals, all have complex three-dimensional networks, so we also represent them with their empirical formulas-that is, their symbols: $\mathrm{B}, \mathrm{Si}, \mathrm{Ge}$, and so on.

## Checkpoint 7.2 The Modern Periodic Table

7.2.1 Which electron configuration is correct for a germanium $(\mathrm{Ge})$ atom in the ground state?
a) $1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2} 3 p^{6} 4 s^{2} 4 p^{2}$
b) $1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2} 3 p^{6} 4 s^{2} 3 d^{10} 4 p^{2}$
c) $1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2} 3 p^{2}$
d) $1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2} 3 p^{6} 4 s^{2} 4 p^{2} 4 d^{10}$
e) $1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2} 3 p^{2} 3 d^{10}$
7.2.2 Which of the following equations correctly represent the chemical reaction in which graphite combines with sulfur to form carbon disulfide gas $\left[\mathrm{CS}_{2}(g)\right]$ ? (Select all that apply.)
a) C (graphite) $+2 \mathrm{~S}(s) \longrightarrow \mathrm{CS}_{2}(g)$
b) C (graphite) $+\mathrm{S}_{2}(s) \longrightarrow \mathrm{CS}_{2}(g)$
c) C (graphite) $+\mathrm{S}_{8}(s) \longrightarrow \mathrm{CS}_{8}(g)$
d) C (graphite) $+\frac{1}{4} \mathrm{~S}_{8}(s) \longrightarrow \mathrm{CS}_{2}(g)$
e) 4 C (graphite) $+\mathrm{S}_{8}(s) \longrightarrow 4 \mathrm{CS}_{2}(g)$

### 7.3 Effective Nuclear Charge

As we have seen, the electron configurations of the elements show a periodic variation with increasing atomic number. In this and the next few sections, we will examine how electron configuration explains the periodic variation of physical and chemical properties of the elements. We begin by introducing the concept of effective nuclear charge.

Nuclear charge $(Z)$ is simply the number of protons in the nucleus of an atom. Effective nuclear charge ( $Z_{\text {eff }}$ ) is the actual magnitude of positive charge that is "experienced" by an electron in the atom. The only atom in which the nuclear charge and effective nuclear charge are the same is hydrogen, which has only one electron. In all other atoms, the electrons are simultaneously attracted to the nucleus and repelled by one another. This results in a phenomenon known as shielding. An electron in a many-electron atom is partially shielded from the positive charge of the nucleus by the other electrons in the atom.

Student Annotation: Shielding is also known as screening.

One way to illustrate how electrons in an atom shield one another is to consider the amounts of energy required to remove the two electrons from a helium atom, shown in Figure 7.4. Experiments show that it takes $3.94 \times 10^{-18} \mathrm{~J}$ to remove the first electron but $8.72 \times 10^{-18} \mathrm{~J}$ to remove the second one. There is no shielding once the first electron is removed, so the second electron feels the full effect of the +2 nuclear charge and is more difficult to remove.

Although all the electrons in an atom shield one another to some extent, those that are most effective at shielding are the core electrons. As a result, the value of $Z_{\text {eff }}$ increases steadily from left to right across a period of the periodic table because the number of core electrons remains the same (only the number of protons, $Z$, and the number of valence electrons increases).

As we move to the right across period 2 , the nuclear charge increases by 1 with each new element, but the effective nuclear charge increases only by an average of 0.64 . (If the valence electrons did not shield one another, the effective nuclear charge would also increase by 1 each time a proton was added to the nucleus.)

|  | $\mathbf{L i}$ | $\mathbf{B e}$ | $\mathbf{B}$ | $\mathbf{C}$ | $\mathbf{N}$ | $\mathbf{O}$ | $\mathbf{F}$ |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 3 | 4 | 5 | 6 | 7 | 8 | 9 |
| $Z_{\text {eff }}$ (felt by valence electrons) | 1.28 | 1.91 | 2.42 | 3.14 | 3.83 | 4.45 | 5.10 |

In general, the effective nuclear charge is given by

$$
Z_{\mathrm{eff}}=Z-\sigma
$$

Equation 7.1
where $\sigma$ is the shielding constant. The shielding constant is greater than zero but smaller than $Z$.
The change in $Z_{\text {eff }}$ as we move from the top of a group to the bottom is generally less significant than the change as we move across a period. Although each step down a group represents a large increase in the nuclear charge, there is also an additional shell of core electrons to shield the valence electrons from the nucleus. Consequently, the effective nuclear charge changes less than the nuclear charge as we move down a column of the periodic table.

### 7.4 Periodic Trends in Properties of Elements

Several physical and chemical properties of the elements depend on effective nuclear charge. To understand the trends in these properties, it is helpful to visualize the electrons of an atom in shells. Recall that the value of the principal quantum number ( $n$ ) increases as the distance from the nucleus increases [ 144 Section 6.7]. If we take this statement literally, and picture all the electrons in a shell at the same distance from the nucleus, the result is a sphere of uniformly distributed negative charge, with its distance from the nucleus depending on the value of $n$. With this as a starting point, we will examine the periodic trends in atomic radius, ionization energy, and electron affinity.

## Atomic Radius

Intuitively, we think of the atomic radius as the distance between the nucleus of an atom and its valence shell (i.e., the outermost shell that is occupied by one or more electrons), because we usually envision atoms as spheres with discrete boundaries. According to the quantum mechanical model of the atom, though, there is no specific distance from the nucleus beyond which an electron may not be found [ 14 Section 6.7]. Therefore, the atomic radius requires a specific definition.

There are two ways in which the atomic radius is commonly defined. One is the metallic radius, which is half the distance between the nuclei of two adjacent, identical metal atoms [Figure 7.5(a)]. The other is the covalent radius, which is half the distance between adjacent, identical nuclei in a molecule [Figure 7.5(b)].

Figure 7.4 Removal of the first electron in He requires less energy than removal of the second electron because of shielding.

Figure 7.5 (a) Atomic radius in metals is defined as half the distance between adjacent metal atoms. (b) Atomic radius in nonmetals is defined as half the distance between bonded identical atoms in a molecule.

Student Annotation: Although the overall trend in atomic size for transition elements is also to decrease from left to right and increase from top to bottom, the observed radii do not vary in as regular a way as do the main group elements.

Figure 7.6 Atomic radii of the elements (in picometers).

Figure 7.7 Atomic radius decreases from left to right across a period because of the increased electrostatic attraction between the effective nuclear charge and the charge on the valence shell. The white circle shows the atomic size in each case. The comparison of attractive forces between the nuclei and valence shells is done using Coulomb's law [ $M$ Page 272].

Figure 7.6 shows the atomic radii of the main group elements according to their positions in the periodic table. There are two distinct trends. The atomic radius decreases as we move from left to right across a period and increases from top to bottom as we move down within a group. The increase down a group is fairly easily explained. As we step down a column, the outermost occupied shell has an ever-increasing value of $n$, so it lies farther from the nucleus, making the radius bigger.

Now let's try to understand the decrease in radius from left to right across a period. Although this trend may at first seem counterintuitive, given that the number of valence electrons is increasing with each new element, consider the shell model in which all the electrons in a shell form a uniform sphere of negative charge around the nucleus at a distance specified by the value of $n$. As we move from left to right across a period, the effective nuclear charge increases and each step to the right adds another electron to the valence shell. Coulomb's law dictates that there will be a more powerful attraction between the nucleus and the valence shell when the magnitudes of both charges increase. The result is that as we step across a period the valence shell is drawn closer to the nucleus, making the atomic radius smaller. Figure 7.7 shows how the effective nuclear charge, charge on the valence shell, and atomic radius vary across period 2 . We can picture the valence shells in all the atoms as

being initially at the same distance (determined by $n$ ) from the nuclei, but being pulled closer by a larger attractive force resulting from increases in both $Z_{\text {eff }}$ and the number of valence electrons.

Sample Problem 7.3 shows how to use these trends to compare the atomic radii of different elements.

## Sample Problem 7.3

Referring only to a periodic table, arrange the elements $\mathrm{P}, \mathrm{S}$, and O in order of increasing atomic radius.

Strategy Use the left-to-right (decreasing) and top-to-bottom (increasing) trends to compare the atomic radii of two of the three elements at a time.

Setup Sulfur is to the right of phosphorus in the third row, so sulfur should be smaller than phosphorus. Oxygen is above sulfur in Group 6A, so oxygen should be smaller than sulfur.

Solution: $\mathrm{O}<\mathrm{S}<\mathrm{P}$.

Practice Problem A Referring only to a periodic table, arrange the elements $\mathrm{Ge}, \mathrm{Se}$, and F in order of increasing atomic radius.

HPractice Problem B For which of the following pairs of elements can the atomic radii not be compared using the periodic table alone: P and $\mathrm{Se}, \mathrm{Se}$ and Cl , or P and O ?

## Ionization Energy

Ionization energy ( $\boldsymbol{I} \boldsymbol{E}$ ) is the minimum energy required to remove an electron from an atom in the gas phase. Typically, we express ionization energy in $\mathrm{kJ} / \mathrm{mol}$, the number of kilojoules required to remove a mole of electrons from a mole of gaseous atoms. Sodium, for example, has an ionization energy of $495.8 \mathrm{~kJ} / \mathrm{mol}$, meaning that the energy input required to drive the process

$$
\mathrm{Na}(g) \longrightarrow \mathrm{Na}^{+}(g)+e^{-}
$$

is $495.8 \mathrm{~kJ} / \mathrm{mol}$. Specifically, this is the first ionization energy of sodium, $I E_{1}(\mathrm{Na})$, which corresponds to the removal of the most loosely held electron. Figure 7.8(a) shows the first ionization energies of the main group elements according to their positions in the periodic table. Figure 7.8 (b) shows a graph of $I E_{1}$ as a function of atomic number.

Think About It Consult Figure 7.6 to confirm the order. Note that there are circumstances under which the trends alone will be insufficient to compare the radii of two elements. Using only a periodic table, for example, it would not be possible to determine that chlorine ( $r=99 \mathrm{pm}$ ) has a larger radius than oxygen ( $r=73 \mathrm{pm}$ ).

Student Annotation: As with atomic radius, ionization energy changes in a similar but somewhat less regular way among the transition elements.

Figure 7.8 (a) First ionization energies (in $\mathrm{kJ} / \mathrm{mol}$ ) of the main group elements. (b) First ionization energy as a function of atomic number.

In general, as effective nuclear charge increases, ionization energy also increases. Thus, $I E_{1}$ increases from left to right across a period. Despite this trend, the graph in Figure 7.8(b) shows that $I E_{1}$ for a Group 3A element is smaller than that for the corresponding Group 2A element. Likewise, $I E_{1}$ for a Group 6A element is smaller than that for the corresponding Group 5A element. Both of these interruptions of the upward trend in $I E_{1}$ can be explained by using electron configuration.

Recall that the energy of an electron in a many-electron system depends not only on the principal quantum number ( $n$ ), but also on the angular momentum quantum number ( $\ell$ ) [ 14 Section 6.8, Figure 6.23]. Within a given shell, electrons with the higher value of $\ell$ have a higher energy (are less tightly held by the nucleus) and are therefore easier to remove. Figure 7.9(a) shows the relative energies of an $s$ subshell $(\ell=0)$ and a $p$ subshell $(\ell=1)$. Ionization of an element in Group 2A requires the removal of an electron from an $s$ orbital, whereas ionization of an element in Group 3A requires the removal of an electron from a $p$ orbital; therefore, the element in Group 3A has a lower ionization energy than the element in Group 2A.

As for the decrease in ionization energy in elements of Group 6A compared to those in Group 5A, both ionizations involve the removal of a $p$ electron, but the ionization of an atom in Group 6A involves the removal of a paired electron. The repulsive force between two electrons in the same orbital makes it easier to remove one of them, making the ionization energy for the Group 6A element actually lower than that for the Group 5A element. [See Figure 7.9(b).]

The first ionization energy $I E_{1}$ decreases as we move from top to bottom within a group due to the increasing atomic radius. Although the effective nuclear charge does not change significantly as we step down a group, the atomic radius increases because the value of $n$ for the valence shell increases. According to Coulomb's law, the attractive force between a valence electron and the effective nuclear charge gets weaker as the distance between them increases. This makes it easier to remove an electron, and so $I E_{1}$ decreases.

It is possible to remove additional electrons in subsequent ionizations, giving $I E_{2}, I E_{3}$, and so on. The second and third ionizations of sodium, for example, can be represented, respectively, as

$$
\mathrm{Na}^{+}(g) \longrightarrow \mathrm{Na}^{2+}(g)+e^{-} \quad \text { and } \quad \mathrm{Na}^{2+}(g) \longrightarrow \mathrm{Na}^{3+}(g)+e^{-}
$$

However, the removal of successive electrons requires ever-increasing amounts of energy because it is harder to remove an electron from a cation than from an atom (and it gets even harder as the charge on the cation increases). Table 7.2 lists the ionization energies of the elements in period

Figure 7.9 (a) It is harder to remove an electron from an $s$ orbital than it is to remove an electron from a $p$ orbital with the same principal quantum number. (b) Within a $p$ subshell, it is easier to remove an electron from a doubly occupied orbital than from a singly occupied orbital.

TABLE 7.2 Ionization Energies (in $\mathrm{kJ} / \mathrm{mol}$ ) for Elements 3 through 11*

|  | Z | $I E_{1}$ | $I E_{2}$ | $I E_{3}$ | $I E_{4}$ | $I E_{5}$ | $I E_{6}$ | $I E_{7}$ | $I E_{8}$ | $I E_{9}$ | $I E_{10}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Li | 3 | 520 | 7,298 | 11,815 |  |  |  |  |  |  |  |
| Be | 4 | 899 | 1,757 | 14,848 | 21,007 |  |  |  |  |  |  |
| B | 5 | 800 | 2,427 | 3,660 | 25,026 | 32,827 |  |  |  |  |  |
| C | 6 | 1,086 | 2,353 | 4,621 | 6,223 | 37,831 | 47,277 |  |  |  |  |
| N | 7 | 1,402 | 2,856 | 4,578 | 7,475 | 9,445 | 53,267 | 64,360 |  |  |  |
| O | 8 | 1,314 | 3,388 | 5,301 | 7,469 | 10,990 | 13,327 | 71,330 | 84,078 |  |  |
| F | 9 | 1,681 | 3,374 | 6,050 | 8,408 | 11,023 | 15,164 | 17,868 | 92,038 | 106,434 |  |
| Ne | 10 | 2,080 | 3,952 | 6,122 | 9,371 | 12,177 | 15,238 | 19,999 | 23,069 | 115,380 | 131,432 |
| Na | 11 | 496 | 4,562 | 6,910 | 9,543 | 13,354 | 16,613 | 20,117 | 25,496 | 28,932 | 141,362 |

[^21]2 and of sodium. These data show that it takes much more energy to remove core electrons than to remove valence electrons. There are two reasons for this. First, core electrons are closer to the nucleus, and second, core electrons experience a greater effective nuclear charge because there are fewer filled shells shielding them from the nucleus. Both of these factors contribute to a greater attractive force between the electrons and the nucleus, which must be overcome to remove the electrons.

Sample Problem 7.4 shows how to use these trends to compare first ionization energies, and subsequent ionization energies, of specific atoms.

## Sample Problem 7.4

Would you expect Na or Mg to have the greater first ionization energy $\left(I E_{1}\right)$ ? Which should have the greater second ionization energy $\left(I E_{2}\right)$ ?

Strategy Consider effective nuclear charge and electron configuration to compare the ionization energies. Effective nuclear charge increases from left to right in a period (thus increasing $I E$ ), and it is more difficult to remove a paired core electron than an unpaired valence electron.

Setup Na is in Group 1A, and Mg is beside it in Group 2A. Na has one valence electron, and Mg has two valence electrons.

Solution $I E_{1}(\mathrm{Mg})>I E_{1}(\mathrm{Na})$ because Mg is to the right of Na in the periodic table (i.e., Mg has the greater effective nuclear charge, so it is more difficult to remove its electron). $I E_{2}(\mathrm{Na})>I E_{2}(\mathrm{Mg})$ because the second ionization of Mg removes a valence electron, whereas the second ionization of Na removes a core electron.

Practice Problem A Which element, Mg or Al , will have the higher first ionization energy and which will have the higher third ionization energy?
$\Psi$ Practice Problem B Explain why Rb has a lower $I E_{1}$ than Sr , but Sr has a lower $I E_{2}$ than Rb .

## Electron Affinity

Electron affinity (EA) is the energy released (the negative of the enthalpy change $\Delta H$ ) when an atom in the gas phase accepts an electron. Consider the process in which a gaseous chlorine atom accepts an electron:

$$
\mathrm{Cl}(g)+e^{-} \longrightarrow \mathrm{Cl}^{-}(g) \quad \Delta H=-349.0 \mathrm{~kJ} / \mathrm{mol}
$$

A negative value of $\Delta H$ indicates an exothermic process [ $/ 44$ Section 5.3], so $349.0 \mathrm{~kJ} / \mathrm{mol}$ of energy is released (the definition of electron affinity) when a mole of gaseous chlorine atoms accepts a mole of electrons. A positive electron affinity indicates a process that is energetically favorable. In general, the larger and more positive the $E A$ value, the more favorable the process and the more apt it is to occur. Figure 7.10 shows electron affinities for the main group elements.

Like ionization energy, electron affinity increases from left to right across a period. This trend in $E A$ is due to the increase in effective nuclear charge from left to right (i.e., it becomes progressively easier to add a negatively charged electron as the positive charge of the element's nucleus increases). There are also periodic interruptions of the upward trend of $E A$ from left to right, similar to those observed for $I E_{1}$, although they do not occur for the same elements. For example, the $E A$ of a Group 2A element is lower than that for the corresponding Group 1A element, and the EA of a Group 5A element is lower than that for the corresponding Group 4A element. These exceptions to the trend are due to the electron configurations of the elements involved.

It is harder to add an electron to a Group 2 A element $\left(n s^{2}\right)$ than to the Group 1A element $\left(n s^{1}\right)$ in the same period because the electron added to the Group 2A element is placed in an orbital of higher energy (a $p$ orbital versus an $s$ orbital). Likewise, it is harder to add an electron to a Group 5A element $\left(n s^{2} n p^{3}\right)$ than to the corresponding Group 4A element $\left(n s^{2} n p^{2}\right)$ because the electron added to the Group 5A element must be placed in an orbital that already contains an electron. Figure 7.11 illustrates these points.

Just as more than one electron can be removed from an atom, more than one electron can also be added to an atom. While many first electron affinities are positive, subsequent electron

Think About It The first ionization energies of Na and Mg are 496 and $738 \mathrm{~kJ} / \mathrm{mol}$, respectively. The second ionization energies of Na and Mg are 4562 and $1451 \mathrm{~kJ} / \mathrm{mol}$, respectively.

Student Annotation: Some books define electron affinity as $\Delta H$, rather than the negative of $\Delta H$ for the process of adding an electron. This simply changes the sign of $E A$ relative to what we show here.

Student Annotation: Although IE and EA both increase from left to right across a period, an increase in IE means that it is less likely that an electron will be removed from an atom. An increase in $E A$, on the other hand, means that it is more likely that an electron will be accepted by an atom.

Student Annotation: There is a much less significant and less regular variation in electron affinities from top to bottom within a group. See Figure 7.11(a).

(a)

(b)

Figure 7.10 (a) Electron affinities ( $\mathrm{kJ} / \mathrm{mol}$ ) of the main group elements. (b) Electron affinity as a function of atomic number.
affinities are always negative. Considerable energy is required to overcome the repulsive forces between the electron and the negatively charged ion. The addition of two electrons to a gaseous oxygen atom can be represented as:

| Process | $\Delta \boldsymbol{H}(\mathbf{k J} / \mathbf{m o l})$ | Electron Affinity |
| :--- | :---: | ---: |
| $\mathrm{O}(g)+e^{-} \longrightarrow \mathrm{O}^{-}(g)$ | -141 | $E A_{1}=141 \mathrm{~kJ} / \mathrm{mol}$ |
| $\mathrm{O}^{-}(g)+e^{-} \longrightarrow \mathrm{O}^{2-}(g)$ | 744 | $E A_{2}=-744 \mathrm{~kJ} / \mathrm{mol}$ |

The term second electron affinity may seem like something of a misnomer, because an anion in the gas phase has no real "affinity" for an electron. As will be discussed in Chapter 8, a significantly endothermic process such as the addition of an electron to a gaseous $\mathrm{O}^{-}$ion happens only in concert with one or more exothermic processes that more than compensate for the required energy input.

Sample Problem 7.5 lets you practice using the periodic table to compare the electron affinities of elements.

Figure 7.11 (a) It is easier to add an electron to an $s$ orbital than to add one to a $p$ orbital with the same principal quantum number. (b) Within a $p$ subshell, it is easier to add an electron to an empty orbital than to add one to an orbital that already contains an electron.

## Sample Problem 7.5

For each pair of elements, indicate which one you would expect to have the greater first electron affinity, $E A_{1}$ : (a) Al or Si , (b) Si or P .

Strategy Consider the effective nuclear charge and electron configuration to compare the electron affinities. The effective nuclear charge increases from left to right in a period (thus generally increasing $E A$ ), and it is more difficult to add an electron to a partially occupied orbital than to an empty one. Writing out orbital diagrams for the valence electrons is helpful for this type of problem.

Setup (a) Al is in Group 3A and Si is beside it in Group 4A. Al has three valence electrons ( $[\mathrm{Ne}] 3 s^{2} 3 p^{1}$ ), and Si has four valence electrons ( $[\mathrm{Ne}] 3 s^{2} 3 p^{2}$ ).
(b) P is in Group 5A (to the right of Si ), so it has five valence electrons $\left([\mathrm{Ne}] 3 s^{2} 3 p^{3}\right)$.

Solution (a) $E A_{1}(\mathrm{Si})>E A_{1}(\mathrm{Al})$ because Si is to the right of Al and therefore has a greater effective nuclear charge.
(b) $E A_{1}(\mathrm{Si})>E A_{1}(\mathrm{P})$ because although P is to the right of Si in the third period of the periodic table (giving P the larger $Z_{\text {eff }}$ ), adding an electron to a P atom requires placing it in a $3 p$ orbital that is partially occupied. The energy cost of pairing electrons outweighs the energy advantage of adding an electron to an atom with a larger effective nuclear charge.

Practice Problem A Would you expect Mg or Al to have the higher $E A_{1}$ ?
$\boldsymbol{H}$ Practice Problem B Why is the $E A_{1}$ for Ge greater than the $E A_{1}$ for As?

## Metallic Character

Metals tend to

- Be shiny, lustrous, and malleable
- Be good conductors of both heat and electricity
- Have low ionization energies (so they commonly form cations)
- Form ionic compounds with chlorine (metal chlorides)
- Form basic, ionic compounds with oxygen (metal oxides)

Nonmetals, on the other hand, tend to

- Vary in color and lack the shiny appearance associated with metals
- Be brittle, rather than malleable
- Be poor conductors of both heat and electricity
- Form acidic, molecular compounds with oxygen
- Have high electron affinities (so they commonly form anions)

Metallic character increases from top to bottom in a group and decreases from left to right within a period.

Metalloids are elements with properties intermediate between those of metals and nonmetals. Because the definition of metallic character depends on a combination of properties, there may be some variation in the elements identified as metalloids in different sources. Astatine (At), for example, is listed as a metalloid in some sources and a nonmetal in others.

Valence orbital diagram for Al

Valence orbital diagram for Si

Valence orbital diagram for P

Think About It The first electron affinities of Al, Si, and P are 42.5, 134 , and $72.0 \mathrm{~kJ} / \mathrm{mol}$, respectively.

## FAQ You May Be Wondering...

## What Causes the Periodic Trends in Properties?

Many of the periodic trends in properties of the elements can be explained using Coulomb's law, which states that the force $(F)$ between two charged objects ( $Q_{1}$ and $Q_{2}$ ) is directly proportional to the product of the two charges and inversely proportional to the distance ( $d$ ) between the objects squared. Recall that the energy between two oppositely charged particles $\left(E_{\mathrm{el}}\right)$ is inversely proportional to $d$ [ 14 Section 5.1, Equation 5.2]. The SI unit of force is the newton ( $1 \mathrm{~N}=1 \mathrm{~kg} \cdot \mathrm{~m} / \mathrm{s}^{2}$ ), and the SI unit of energy is the joule $\left(1 \mathrm{~J}=1 \mathrm{~kg} \cdot \mathrm{~m}^{2} / \mathrm{s}^{2}\right)$.

When the charges have opposite signs, $F$ is negative-indicating an attractive force between the objects. When the charges have the same sign, $F$ is positive-indicating a repulsive force. Table 7.3 shows how the magnitude of the attractive force between two oppositely charged objects at a fixed distance from each other varies with changes in the magnitudes of the charges.

Sample Problem 7.6 illustrates how Coulomb's law can be used to compare the magnitudes of attractive forces between charged objects.

$$
F \propto \frac{Q_{1} \times Q_{2}}{d^{2}}
$$

TABLE 7.3 Attractive Force between Oppositely Charged Objects at a Fixed Distance $(d=1)$ from Each Other

| $\mathbf{Q}_{\mathbf{1}}$ | $\boldsymbol{Q}_{\mathbf{2}}$ | Attractive force is proportional to |
| :---: | :---: | :---: |
| +1 | -1 | 1 |
| +2 | -2 | 4 |
| +3 | -3 | 9 |

The product of a positive number and a negative number is a negative number. When we are simply comparing the magnitudes of attractive forces, however, it is unnecessary to include the sign.

## Sample Problem 7.6

For carbon and nitrogen, use the effective nuclear charges given in Figure 7.7 and the atomic radii given in Figure 7.6 to compare the attractive force between the nucleus in each atom and the valence electron that would be removed by the first ionization.

Strategy Use Coulomb's law to calculate a number to which the attractive force will be proportional in each case.

Setup From Figure 7.7, the effective nuclear charges of C and N are 3.14 and 3.83, respectively, and the radii of C and N are 77 pm and 75 pm , respectively. The first ionization energies are $1086 \mathrm{~kJ} / \mathrm{mol}(\mathrm{C})$ and $1402 \mathrm{~kJ} / \mathrm{mol}(\mathrm{N})$. The charge on the valence electron in each case is -1 .
Solution For C: $F \propto \frac{3.14 \times(-1)}{(77 \mathrm{pm})^{2}}=-5.3 \times 10^{-4}$
For $\mathrm{N}: F \propto \frac{3.83 \times(-1)}{(75 \mathrm{pm})^{2}}=-6.8 \times 10^{-4}$
Note that in this type of comparison, it doesn't matter what units we use for the distance between the charges. We are not trying to calculate a particular attractive force, only to compare the magnitudes of these two attractive forces.

Think About It Remember that the negative sign simply indicates that the force is attractive rather than repulsive. The calculated number for nitrogen is about 28 percent larger than that for carbon.

Practice Problem A Between which two charges is the attractive force larger: +3.26 and -1.15 separated by a distance of 1.5 pm , or +2.84 and -3.63 separated by a distance of 2.5 pm ?

HPractice Problem B What must the distance be between charges of +2.25 and -1.86 for the attractive force between them to be the same as that between charges of +4.06 and -2.11 separated by a distance of 2.16 pm ?

## Checkpoint 7.4 Periodic Trends in Properties of Atoms

7.4.1 Arrange the elements $\mathrm{Ca}, \mathrm{Sr}$, and Ba in order of increasing $I E_{1}$.
a) $\mathrm{Ca}<\mathrm{Sr}<\mathrm{Ba}$
b) $\mathrm{Ba}<\mathrm{Sr}<\mathrm{Ca}$
c) $\mathrm{Ba}<\mathrm{Ca}<\mathrm{Sr}$
d) $\mathrm{Sr}<\mathrm{Ba}<\mathrm{Ca}$
e) $\mathrm{Sr}<\mathrm{Ca}<\mathrm{Ba}$
7.4.2 Arrange the elements $\mathrm{Li}, \mathrm{Be}$, and B in order of increasing $I E_{2}$.
a) $\mathrm{Li}<\mathrm{Be}<\mathrm{B}$
b) $\mathrm{Li}<\mathrm{B}<\mathrm{Be}$
c) $\mathrm{Be}<\mathrm{B}<\mathrm{Li}$
d) $\mathrm{Be}<\mathrm{Li}<\mathrm{B}$
e) $\mathrm{B}<\mathrm{Be}<\mathrm{Li}$
7.4.3 For each of the following pairs of elements, indicate which will have the greater $E A_{1}$ : Rb or $\mathrm{Sr}, \mathrm{C}$ or $\mathrm{N}, \mathrm{O}$ or F :
a) $\mathrm{Rb}, \mathrm{C}, \mathrm{O}$
b) $\mathrm{Sr}, \mathrm{N}, \mathrm{F}$
c) $\mathrm{Sr}, \mathrm{C}, \mathrm{F}$
d) $\mathrm{Sr}, \mathrm{N}, \mathrm{O}$
e) $\mathrm{Rb}, \mathrm{C}, \mathrm{F}$
7.4.4 Which element, K or Ca , will have the greater $I E_{1}$, which will have the greater $I E_{2}$, and which will have the greater $E A_{1}$ ?
a) $\mathrm{Ca}, \mathrm{K}, \mathrm{K}$
b) $\mathrm{K}, \mathrm{K}, \mathrm{Ca}$
c) $\mathrm{K}, \mathrm{Ca}, \mathrm{K}$
d) $\mathrm{Ca}, \mathrm{Ca}, \mathrm{K}$
e) $\mathrm{Ca}, \mathrm{Ca}, \mathrm{Ca}$

### 7.5 Electron Configuration of Ions

Because many ionic compounds are made up of monatomic anions and cations, it is helpful to know how to write the electron configurations of these ionic species. Just as for atoms, we use the Pauli exclusion principle and Hund's rule to write the ground-state electron configurations of cations and anions.

Recall from Chapter 2 that we can use the periodic table to predict the charges on many of the ions formed by main group elements. Elements in Groups 1A and 2A, for example, form ions with charges of +1 and +2 , respectively. Elements in Groups 6A and 7A form ions with charges of -2 and -1 , respectively. Knowing something about electron configurations enables us to explain these charges.

## Ions of Main Group Elements

In Section 7.4, we learned about the tendencies of atoms to lose or gain electrons. In every period of the periodic table, the element with the highest $I E_{1}$ is the Group 8A element, the noble gas. [See Figure 7.8(b).] Also, Group 8A is the only group in which none of the members has any tendency to accept an electron; that is, they all have negative EA values. [See Figure 7.10(b).] High ionization energies and low electron affinities make the noble gases almost completely unreactive. Ultimately, the cause of this lack of reactivity is electron configuration. The $1 s^{2}$ configuration of He and the $n s^{2} n p^{6}(n \geq 2)$ valence electron configurations of the other noble gases are extraordinarily stable. Other main group elements tend to either lose or gain the number of electrons needed to achieve the same number of electrons as the nearest noble gas. Species with identical electron configurations are called isoelectronic.

To write the electron configuration of an ion formed by a main group element, we first write the configuration for the atom and either add or remove the appropriate number of electrons. Electron configurations for the sodium and chloride ions are

> Na: $1 s^{2} 2 s^{2} 2 p^{6} 3 s^{1} \longrightarrow \mathrm{Na}^{+}: 1 s^{2} 2 s^{2} 2 p^{6} \quad(10$ electrons total, isoelectronic with Ne$)$
> Cl: $1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2} 3 p^{5} \longrightarrow \mathrm{Cl}^{-}: 1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2} 3 p^{6} \quad(18$ electrons total, isoelectronic with Ar$)$

We can also write electron configurations for ions using the noble gas core.

$$
\begin{gathered}
\mathrm{Na}:[\mathrm{Ne}] 3 s^{1} \longrightarrow \mathrm{Na}^{+}:[\mathrm{Ne}] \\
\mathrm{Cl}:[\mathrm{Ne}] 3 s^{2} 3 p^{5} \longrightarrow \mathrm{Cl}^{-}:[\mathrm{Ne}] 3 s^{2} 3 p^{6} \text { or }[\mathrm{Ar}]
\end{gathered}
$$

Sample Problem 7.7 gives you some practice writing electron configurations for the ions of main group elements.

Student Annotation: It is a common error to mistake species with the same valence electron configuration for isoelectronic species. For example, $\mathrm{F}^{-}$and Ne are isoelectronic. $\mathrm{F}^{-}$and $\mathrm{Cl}^{-}$are not.

Think About It Be sure to add electrons to form an anion, and remove electrons to form a cation

## Sample Problem 7.7

Write electron configurations for the following ions of main group elements: (a) $\mathrm{N}^{3-}$, (b) $\mathrm{Ba}^{2+}$, and (c) $\mathrm{Be}^{2+}$.

Strategy First write electron configurations for the atoms. Then add electrons (for anions) or remove electrons (for cations) to account for the charge.
Setup (a) $\mathrm{N}^{3-}$ forms when $\mathrm{N}\left(1 s^{2} 2 s^{2} 2 p^{3}\right.$ or $\left.[\mathrm{He}] 2 s^{2} 2 p^{3}\right)$, a main group nonmetal, gains three electrons.
(b) $\mathrm{Ba}^{2+}$ forms when $\mathrm{Ba}\left(1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2} 3 p^{6} 4 s^{2} 3 d^{10} 4 p^{6} 5 s^{2} 4 d^{10} 5 p^{6} 6 s^{2}\right.$ or [Xe] $\left.6 s^{2}\right)$ loses two electrons.
(c) $\mathrm{Be}^{2+}$ forms when $\mathrm{Be}\left(1 s^{2} 2 s^{2}\right.$ or $\left.[\mathrm{He}] 2 s^{2}\right)$ loses two electrons.

Solution (a) $[\mathrm{He}] 2 s^{2} 2 p^{6}$ or $[\mathrm{Ne}]$
(b) $[\mathrm{Kr}] 5 s^{2} 4 d^{10} 5 p^{6}$ or $[\mathrm{Xe}]$
(c) $1 s^{2}$ or $[\mathrm{He}]$

Practice Problem A Write electron configurations for (a) $\mathrm{O}^{2-}$, (b) $\mathrm{Ca}^{2+}$, and (c) $\mathrm{Se}^{2-}$.
EPractice Problem B List all the species (atoms and/or ions) that are likely to have the following electron configuration: $1 s^{2} 2 s^{2} 2 p^{6}$.

## Ions of $\boldsymbol{d}$-Block Elements

Recall from Section 6.8 that the $4 s$ orbital fills before the $3 d$ orbitals for the elements in the first row of the $d$-block ( Sc to Zn ) [ 14 Section 6.8]. Following the pattern for writing electron configurations for main group ions, then, we might expect the two electrons lost in the formation of the $\mathrm{Fe}^{2+}$ ion to come from the $3 d$ subshell. It turns out, though, that an atom always loses electrons first from the shell with the highest value of $n$. In the case of Fe , that would be the $4 s$ subshell.

$$
\mathrm{Fe}:[\mathrm{Ar}] 4 s^{2} 3 d^{6} \longrightarrow \mathrm{Fe}^{2+}:[\mathrm{Ar}] 3 d^{6}
$$

Iron can also form the $\mathrm{Fe}^{3+}$ ion, in which case the third electron is removed from the $3 d$ subshell.

$$
\mathrm{Fe}:[\mathrm{Ar}] 4 s^{2} 3 d^{6} \longrightarrow \mathrm{Fe}^{3+}:[\mathrm{Ar}] 3 d^{5}
$$

In general, when a $d$-block element becomes an ion, it loses electrons first from the $n s$ subshell and then from the $(n-1) d$ subshell.

Sample Problem 7.8 gives you some practice writing electron configurations for the ions of $d$-block elements.

## Sample Problem 7.8

Write electron configurations for the following ions of $d$-block elements: (a) $\mathrm{Zn}^{2+}$, (b) $\mathrm{Mn}^{2+}$, and (c) $\mathrm{Cr}^{3+}$.
Strategy First write electron configurations for the atoms. Then add electrons (for anions) or remove electrons (for cations) to account for the charge. The electrons removed from a $d$-block element must come first from the outermost $s$ subshell, not the partially filled $d$ subshell.
Setup (a) $\mathrm{Zn}^{2+}$ forms when $\mathrm{Zn}\left(1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2} 3 p^{6} 4 s^{2} 3 d^{10}\right.$ or $\left.[\mathrm{Ar}] 4 s^{2} 3 d^{10}\right)$ loses two electrons.
(b) $\mathrm{Mn}^{2+}$ forms when $\mathrm{Mn}\left(1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2} 3 p^{6} 4 s^{2} 3 d^{5}\right.$ or $\left.[\mathrm{Ar}] 4 s^{2} 3 d^{5}\right)$ loses two electrons.
(c) $\mathrm{Cr}^{3+}$ forms when $\mathrm{Cr}\left(1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2} 3 p^{6} 4 s^{1} 3 d^{5}\right.$ or $\left.[\mathrm{Ar}] 4 s^{1} 3 d^{5}\right)$ loses three electrons-one from the $4 s$ subshell and two from the $3 d$ subshell.

Solution (a) $[\mathrm{Ar}] 3 d^{10}$
(b) $[\mathrm{Ar}] 3 d^{5}$
(c) $[\mathrm{Ar}] 3 d^{3}$

Practice Problem A Write electron configurations for (a) $\mathrm{Co}^{3+}$, (b) $\mathrm{Cu}^{2+}$, and (c) $\mathrm{Ag}^{+}$.
HPractice Problem B What common $d$-block ion (see Figure 2.14) is isoelectronic with $\mathrm{Zn}^{2+}$ ?

## Checkpoint 7.5 Electron Configuration of Ions

7.5.1 Which of the following ions are isoelectronic with a noble gas? (Select all that apply.)
a) $\mathrm{Mn}^{2+}$
b) $\mathrm{Ca}^{2+}$

### 7.6 Ionic Radius

When an atom gains or loses one or more electrons to become an ion, its radius changes. The ionic radius, the radius of a cation or an anion, affects the physical and chemical properties of an ionic compound. The three-dimensional structure of an ionic compound, for example, depends on the relative sizes of its cations and anions.

## Comparing Ionic Radius with Atomic Radius

When an atom loses an electron and becomes a cation, its radius decreases due in part to a reduction in electron-electron repulsions (and consequently a reduction in shielding) in the valence shell. A significant decrease in radius occurs when all of an atom's valence electrons are removed. This is the case with ions of most main group elements, which are isoelectronic with the noble gases preceding them. Consider Na , which loses its $3 s$ electron to become $\mathrm{Na}^{+}$:

## Multimedia

Periodic Table—atomic and ionic radii.

Valence orbitals in Na and in $\mathrm{Na}^{+}$

Figure 7.12 A comparison of atomic and ionic radii (in picometers) for main group elements and their common ions (those that are isoelectronic with noble gases).

The valence electron of Na has a principal quantum number of $n=3$. When it has been removed, the resulting $\mathrm{Na}^{+}$ion no longer has any electrons in the $n=3$ shell. The outermost electrons of the $\mathrm{Na}^{+}$ion have a principal quantum number of $n=2$. Because the value of $n$ determines the distance from the nucleus, this corresponds to a smaller radius.

When an atom gains one or more electrons and becomes an anion, its radius increases due to increased electron-electron repulsions. Adding an electron causes the rest of the electrons in the valence shell to spread out and take up more space to maximize the distance between them.

Figure 7.12 shows the ionic radii for those ions of main group elements that are isoelectronic with noble gases and compares them to the radii of the parent atoms. Note that the ionic radius, like the atomic radius, increases from top to bottom in a group.

## Isoelectronic Series

An isoelectronic series is a series of two or more species that have identical electron configurations, but different nuclear charges. For example, $\mathrm{O}^{2-}, \mathrm{F}^{-}$, and Ne constitute an isoelectronic series. Although these three species have identical electron configurations, they have different radii. In an isoelectronic series, the species with the smallest nuclear charge (i.e., the smallest atomic number $Z$ ) will have the largest radius. The species with the largest nuclear charge (i.e., the largest $Z$ ) will have the smallest radius.

Sample Problem 7.9 shows how to identify members of an isoelectronic series and how to arrange them according to radius.

## Sample Problem 7.9

Identify the isoelectronic series in the following group of species, and arrange them in order of increasing radius: $\mathrm{K}^{+}, \mathrm{Ne}, \mathrm{Ar}, \mathrm{Kr}, \mathrm{P}^{3-}, \mathrm{S}^{2-}$, and $\mathrm{Cl}^{-}$.

Strategy Isoelectronic series are species with identical electron configurations but different nuclear charges. Determine the number of electrons in each species. The radii of isoelectronic series members decreases with increasing nuclear charge.

Setup The number of electrons in each species is as follows: $18\left(\mathrm{~K}^{+}\right), 10(\mathrm{Ne}), 18(\mathrm{Ar}), 36(\mathrm{Kr})$, $18\left(\mathrm{P}^{3-}\right), 18\left(\mathrm{~S}^{2-}\right)$, and $18\left(\mathrm{Cl}^{-}\right)$. The nuclear charges of the species with 18 electrons are $+19\left(\mathrm{~K}^{+}\right)$, $+18(\mathrm{Ar}),+15\left(\mathrm{P}^{3-}\right),+16\left(\mathrm{~S}^{2-}\right)$, and $+17\left(\mathrm{Cl}^{-}\right)$.

Solution The isoelectronic series includes $\mathrm{K}^{+}, \mathrm{Ar}, \mathrm{P}^{3-}, \mathrm{S}^{2-}$, and $\mathrm{Cl}^{-}$. In order of increasing radius: $\mathrm{K}^{+}<\mathrm{Ar}<\mathrm{Cl}^{-}<\mathrm{S}^{2-}<\mathrm{P}^{3-}$.

Practice Problem A Arrange the following isoelectronic series in order of increasing radius: $\mathrm{Se}^{2-}$, $\mathrm{Br}^{-}, \mathrm{Kr}$, and $\mathrm{Rb}^{+}$.

HPractice Problem B List all the common ions that are isoelectronic with Ne .

Think About It Consult
Figure 7.12 to check your result. With identical electron configurations, the attractive force between the valence electrons and the nucleus will be strongest for the largest nuclear charge. Thus, the larger the nuclear charge, the closer in the valence electrons will be pulled and the smaller the radius will be.

## Checkpoint 7.6 Ionic Radius

7.6.1 Which of the following species are isoelectronic with Kr? (Select all that apply.)
a) He
b) Ne
c) Ar

Periodic Table-properties of alkali and alkaline earth metals.

Figure 7.13 Formation of NaCl from its constituent elements. Note that although the charges are not all shown, the solid consists of a three-dimensional array of alternating oppositely-charged ions.

### 7.7 Periodic Trends in Chemical Properties of the Main Group Elements

Ionization energy and electron affinity enable us to understand the types of reactions that elements undergo and the types of compounds they form. These two parameters actually measure similar things. Ionization energy is a measure of how powerfully an atom attracts its own electrons, while electron affinity is a measure of how powerfully an atom can attract electrons from another source. As a very simple example of how this helps us understand a chemical reaction, consider the combination of a sodium atom and a chlorine atom, shown in Figure 7.13.

Sodium, with its low ionization energy, has a relatively weak attraction for its one valence electron. Chlorine, with its energetically favorable electron affinity, has the ability to attract electrons from another source. In this case, the electron that is loosely held by the Na atom, and powerfully attracted by the Cl atom, is transferred from Na to Cl , thus producing a sodium ion $\left(\mathrm{Na}^{+}\right)$and a chloride ion $\left(\mathrm{Cl}^{-}\right)$. According to Coulomb's law, oppositely charged objects attract each other. The positively charged sodium ion and the negatively charged chloride ion are drawn together by electrostatic attraction, and the result is the formation of the solid ionic compound sodium chloride ( NaCl ).

## General Trends in Chemical Properties

Before we examine the elements in individual groups, let's identify some overall trends. We have said that elements in the same group resemble one another in chemical behavior because they have similar valence electron configurations. This statement, although correct in the general sense, must be applied with caution. Chemists have long known that the properties of the first member of each group ( $\mathrm{Li}, \mathrm{Be}, \mathrm{B}, \mathrm{C}, \mathrm{N}, \mathrm{O}$, and F) are different from those of the rest of the members of the same group. Lithium, for example, exhibits many, but not all, of the properties characteristic of the Group 1A (alkali) metals. For example, unlike the other Group 1A elements, Li reacts with the $\mathrm{O}_{2}$ and $\mathrm{N}_{2}$ in air to form a simple oxide $\left(\mathrm{Li}_{2} \mathrm{O}\right)$ and nitride $\left(\mathrm{Li}_{3} \mathrm{~N}\right)$, respectively. Similarly, beryllium is a somewhat atypical member of Group 2A (alkaline earth metals) in that it forms covalent compounds, and so on. The differences can be attributed to the unusually small size of the first element in each group (see Figure 7.6).

Another trend in the chemical behavior of main group elements is the diagonal relationship. Diagonal relationships refer to similarities between pairs of elements in different groups and periods of the periodic table. Specifically, the first three members of the second period ( $\mathrm{Li}, \mathrm{Be}$, and B ) exhibit many similarities to the elements located diagonally below them in the periodic table $(\mathrm{Mg}$, Al , and Si$)$. The reason for this phenomenon is the similarity of charge densities of their cations. (Charge density is the charge on an ion divided by its volume.) Cations with comparable charge densities react similarly with anions and therefore form the same types of compounds. Thus, the chemistry of lithium resembles that of magnesium in some ways; the same holds for beryllium and aluminum and for boron and silicon. Each of these pairs is said to exhibit a diagonal relationship.

A comparison of the properties of elements in the same group is most valid if the elements in question have a similar metallic (or nonmetallic) character. The elements in Groups 1A and 2A, for example, are all metals, whereas those in Groups 7A and 8A are all nonmetals. We have to be more careful when comparing the elements of Groups 3A through 6A, though, because a single group may contain metals, metalloids, and nonmetals. In these groups, we should expect a greater variation in chemical properties even though all group members have similar valence electron configurations.

## Hydrogen (1s ${ }^{1}$ )

There is no completely suitable position for hydrogen in the periodic table (it really belongs in a group by itself). Traditionally hydrogen is shown at the top of Group 1A, because, like the alkali metals, it has a single $s$ valence electron and forms a cation with a charge of $+1\left(\mathrm{H}^{+}\right)$, which is hydrated in solution. On the other hand, hydrogen also forms the hydride ion $\left(\mathrm{H}^{-}\right)$ in ionic compounds such as NaH and $\mathrm{CaH}_{2}$. In this respect, hydrogen resembles the members of Group 7A (halogens), all of which form -1 anions ( $\mathrm{F}^{-}, \mathrm{Cl}^{-}, \mathrm{Br}^{-}$, and $\mathrm{I}^{-}$) in ionic compounds. Ionic hydrides react with water to produce hydrogen gas and the corresponding metal hydroxides:

$$
\begin{aligned}
& 2 \mathrm{NaH}(s)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{NaOH}(a q)+2 \mathrm{H}_{2}(g) \\
& \mathrm{CaH}_{2}(s)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{Ca}(\mathrm{OH})_{2}(a q)+2 \mathrm{H}_{2}(g)
\end{aligned}
$$

The most important compound of hydrogen is water, which forms when hydrogen burns in air:

$$
2 \mathrm{H}_{2}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l)
$$

## Properties of the Active Metals

## Group 1A Elements ( $n s^{1}, n \geq 2$ )

Figure 7.14 shows samples of the Group 1A elements. These elements all have low ionization energies, making it easy for them to become $\mathrm{M}^{+}$ions. In fact, these metals are so reactive that they are never found in nature in the pure elemental state. They react with water to produce hydrogen gas and the corresponding metal hydroxide:

$$
2 \mathrm{M}(s)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{MOH}(a q)+\mathrm{H}_{2}(g)
$$

Lithium

Rubidium

Sodium

Cesium

Potassium

Figure 7.14 Group 1A elements.

Student Annotation: Because they have less metallic character than the other Group 2A elements, beryllium and magnesium form some molecular compounds such as $\mathrm{BeH}_{2}$ and $\mathrm{MgH}_{2}$.
where $M$ denotes an alkali metal. When exposed to air, they gradually lose their shiny appearance as they react with oxygen to form metal oxides. Lithium forms lithium oxide (containing the oxide ion, $\mathrm{O}^{2-}$ ):

$$
4 \mathrm{Li}(s)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{Li}_{2} \mathrm{O}(s)
$$

The other alkali metals all form oxides or peroxides (containing the peroxide ion, $\mathrm{O}_{2}^{2-}$ ):

$$
2 \mathrm{Na}(s)+\mathrm{O}_{2}(g) \longrightarrow \mathrm{Na}_{2} \mathrm{O}_{2}(s)
$$

Potassium, rubidium, and cesium also form superoxides (containing the superoxide ion, $\mathrm{O}_{2}^{-}$):

$$
\mathrm{K}(s)+\mathrm{O}_{2}(g) \longrightarrow \mathrm{KO}_{2}(s)
$$

The type of oxide that forms when an alkali metal reacts with oxygen has to do with the stability of the various oxides. Because these oxides are all ionic compounds, their stability depends on how strongly the cations and anions attract one another. Lithium tends to form predominantly the oxide because lithium oxide is more stable than lithium peroxide.

## Group 2A Elements ( $n s^{2}, n \geq 2$ )

Figure 7.15 shows samples of the Group 2A elements. As a group, the alkaline earth metals are somewhat less reactive than the alkali metals. Both the first and the second ionization energies decrease (and metallic character increases) from beryllium to barium. Group 2A elements tend to form $\mathrm{M}^{2+}$ ions, where M denotes an alkaline earth metal atom.

The reactions of alkaline earth metals with water vary considerably. Beryllium does not react with water; magnesium reacts slowly with steam; and calcium, strontium, and barium react vigorously with cold water.

Figure 7.15 Group 2A elements.

Beryllium

Calcium

Strontium

Magnesium

Barium

$$
\begin{aligned}
& \mathrm{Ca}(s)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{Ca}(\mathrm{OH})_{2}(s)+\mathrm{H}_{2}(g) \\
& \mathrm{Sr}(s)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{Sr}(\mathrm{OH})_{2}(s)+\mathrm{H}_{2}(g) \\
& \mathrm{Ba}(s)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{Ba}(\mathrm{OH})_{2}(a q)+\mathrm{H}_{2}(g)
\end{aligned}
$$

The reactivity of the alkaline earth metals toward oxygen also increases from Be to Ba . Beryllium and magnesium form oxides ( BeO and MgO ) only at elevated temperatures, whereas $\mathrm{CaO}, \mathrm{SrO}$, and BaO form at room temperature.

Magnesium reacts with aqueous acid to produce hydrogen gas:

$$
\mathrm{Mg}(s)+2 \mathrm{H}^{+}(a q) \longrightarrow \mathrm{Mg}^{2+}(a q)+\mathrm{H}_{2}(g)
$$

Calcium, strontium, and barium also react with aqueous acid solutions to produce hydrogen gas. However, because the metals also react with water, the two different reactions (with $\mathrm{H}^{+}$and with $\mathrm{H}_{2} \mathrm{O}$ ) occur simultaneously.

## Properties of Other Main Group Elements

## Group 3A Elements ( $n s^{2} n p^{1}, n \geq 2$ )

Figure 7.16 shows samples of the first four Group 3A elements. Boron, the first member of the group, is a metalloid; the others ( $\mathrm{Al}, \mathrm{Ga}, \mathrm{In}$, and Tl ) are metals. Boron does not form binary ionic compounds and is unreactive toward both oxygen and water. Aluminum, the next element in the group, readily forms aluminum oxide when exposed to air:

$$
4 \mathrm{Al}(s)+3 \mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{Al}_{2} \mathrm{O}_{3}(s)
$$

The aluminum oxide forms a protective coating, preventing the underlying metal from reacting further. This fact makes it possible to use aluminum for structural materials, such as aluminum siding and the shells of airplanes. Without the protective coating, layer after layer of Al atoms would become oxidized, and the structure would eventually crumble.

Student Annotation: Carbon, being a nonmetal, achieves its +4 oxidation state without actually losing four electrons, which would be very "expensive" in terms of the energy required. For the same reason, compounds containing metals in very high oxidation states also tend to be molecular rather than ionic.

Aluminum forms the $\mathrm{Al}^{3+}$ ion. It reacts with hydrochloric acid according to the equation:

$$
2 \mathrm{Al}(s)+6 \mathrm{H}^{+}(a q) \longrightarrow 2 \mathrm{Al}^{3+}(a q)+3 \mathrm{H}_{2}(g)
$$

The other Group 3A metals ( Ga , In , and Tl ) can form both $\mathrm{M}^{+}$and $\mathrm{M}^{3+}$ ions. As we move down the group, the $\mathrm{M}^{+}$ion becomes the more stable of the two.

The metallic elements in Group 3A also form many molecular compounds. For example, aluminum reacts with hydrogen to form $\mathrm{AlH}_{3}$, which has properties similar to those of $\mathrm{BeH}_{2}$. The progression of properties across the second row of the periodic table illustrates the gradual shift from metallic to nonmetallic character in the main group elements.

## Group 4A Elements ( $n s^{2} n p^{2}, n \geq 2$ )

Figure 7.17 shows samples of the Group 4A elements. Carbon, the first member of the group, is a nonmetal, whereas silicon and germanium, the next two members, are metalloids. Tin and lead, the last two members of the group, are metals. They do not react with water, but they do react with aqueous acid to produce hydrogen gas:

$$
\begin{aligned}
& \mathrm{Sn}(s)+2 \mathrm{H}^{+}(a q) \longrightarrow \mathrm{Sn}^{2+}(a q)+\mathrm{H}_{2}(g) \\
& \mathrm{Pb}(s)+2 \mathrm{H}^{+}(a q) \longrightarrow \mathrm{Pb}^{2+}(a q)+\mathrm{H}_{2}(g)
\end{aligned}
$$

The Group 4A elements form compounds in both the +2 and +4 oxidation states. For carbon and silicon, the +4 oxidation state is the more stable one. For example, $\mathrm{CO}_{2}$ is more stable than CO , and $\mathrm{SiO}_{2}$ is a stable compound, but SiO does not exist under ordinary conditions. As we move down the group, however, the relative stability of the two oxidation states is reversed. In tin compounds the +4 oxidation state is only slightly more stable than the +2 oxidation state. In lead compounds the +2 oxidation state is the more stable one. The outer electron configuration of lead is $6 s^{2} 6 p^{2}$, and lead tends to lose only the $6 p$ electrons to form $\mathrm{Pb}^{2+}$ rather than both the $6 p$ and $6 s$ electrons to form $\mathrm{Pb}^{4+}$.

## Group 5A Elements ( $n s^{2} n p^{3}, n \geq 2$ )

Figure 7.18 shows samples of the Group 5A elements. Nitrogen and phosphorus are nonmetals, arsenic and antimony are metalloids, and bismuth is a metal. Because Group 5A contains elements in all three categories, we expect greater variation in their chemical properties.

Figure 7.17 Group 4A elements.

Figure 7.18 Group 5A elements.

Elemental nitrogen is a diatomic gas $\left(\mathrm{N}_{2}\right)$. It forms a variety of oxides $\left(\mathrm{NO}, \mathrm{N}_{2} \mathrm{O}, \mathrm{NO}_{2}, \mathrm{~N}_{2} \mathrm{O}_{4}\right.$, and $\mathrm{N}_{2} \mathrm{O}_{5}$ ), all of which are gases except for $\mathrm{N}_{2} \mathrm{O}_{5}$, which is a solid at room temperature. Nitrogen has a tendency to accept three electrons to form the nitride ion $\left(\mathrm{N}^{3-}\right)$. Most metal nitrides, such as $\mathrm{Li}_{3} \mathrm{~N}$ and $\mathrm{Mg}_{3} \mathrm{~N}_{2}$, are ionic compounds. Phosphorus exists as individual $\mathrm{P}_{4}$ molecules (white phosphorus) or chains of $\mathrm{P}_{4}$ molecules (red phosphorus). It forms two solid oxides with the formulas $\mathrm{P}_{4} \mathrm{O}_{6}$ and $\mathrm{P}_{4} \mathrm{O}_{10}$. The industrially important oxoacids nitric acid and phosphoric acid form when $\mathrm{N}_{2} \mathrm{O}_{5}$ and $\mathrm{P}_{4} \mathrm{O}_{10}$, respectively, react with water:

$$
\begin{gathered}
\mathrm{N}_{2} \mathrm{O}_{5}(s)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{HNO}_{3}(\mathrm{aq}) \\
\mathrm{P}_{4} \mathrm{O}_{10}(s)+6 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 4 \mathrm{H}_{3} \mathrm{PO}_{4}(\mathrm{aq})
\end{gathered}
$$

Arsenic, antimony, and bismuth have extensive three-dimensional structures. Bismuth is far less reactive than metals in the preceding groups.

## Group 6A Elements ( $n s^{2} n p^{4}, n \geq 2$ )

Figure 7.19 shows samples of the first three Group 6A elements. The first three members of the group (oxygen, sulfur, and selenium) are nonmetals, whereas the last two (tellurium and polonium) are metalloids. Oxygen is a colorless, odorless, diatomic gas; elemental sulfur and selenium exist as the molecules $\mathrm{S}_{8}$ and $\mathrm{Se}_{8}$, respectively; and tellurium and polonium have more extensive three-dimensional structures. (Polonium is a radioactive element that is difficult to study in the laboratory.) Oxygen has a tendency to accept two electrons to form the oxide ion $\left(\mathrm{O}^{2-}\right)$ in many compounds. Sulfur, selenium, and tellurium also form ions by accepting two electrons: $\mathrm{S}^{2-}, \mathrm{Se}^{2-}$, and $\mathrm{Te}^{2-}$. The elements in Group 6A (especially oxygen) form a large number of molecular compounds with nonmetals. The important compounds of sulfur are $\mathrm{SO}_{2}, \mathrm{SO}_{3}$, and $\mathrm{H}_{2} \mathrm{~S}$. Sulfuric acid, an oxoacid, forms when sulfur trioxide reacts with water:

$$
\mathrm{SO}_{3}(g)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}_{2} \mathrm{SO}_{4}(a q)
$$

Student Annotation: The bismuth shown on the cover appears colorful because of a thin surface layer of bismuth oxide $\left(\mathrm{B}_{2} \mathrm{O}_{3}\right)$.

Figure 7.19 Group 6A elements.

## Group 7A Elements $\left(n s^{2} n p^{5}, n \geq 2\right)$

Figure 7.20 shows samples of the first four Group 7A elements. All the halogens are nonmetals with the general formula $X_{2}$, where X denotes a halogen element. Like the Group 1A metals, the Group 7A nonmetals are too reactive to be found in nature in the elemental form. (Astatine, the last member of Group 7A, is radioactive. Very little is known about its properties.)

The halogens have high ionization energies and large, energetically favorable electron affinities. Anions derived from the halogens $\left(\mathrm{F}^{-}, \mathrm{Cl}^{-}, \mathrm{Br}^{-}\right.$, and $\left.\mathrm{I}^{-}\right)$are called halides. The vast majority of alkali metal halides are ionic compounds. The halogens also form many molecular compounds among themselves, such as ICl and $\mathrm{BrF}_{3}$, and with nonmetals in other groups, such as $\mathrm{NF}_{3}, \mathrm{PCl}_{5}$, and $\mathrm{SF}_{6}$. The halogens react with hydrogen to form hydrogen halides:

$$
\mathrm{H}_{2}(g)+\mathrm{X}_{2}(g) \longrightarrow 2 \mathrm{HX}(g)
$$

This reaction is explosive when it involves fluorine, but it becomes less and less violent as we substitute chlorine, bromine, and iodine. The hydrogen halides dissolve in water to form hydrohalic acids. Hydrofluoric acid (HF) is a weak acid (meaning it is a weak electrolyte), but the other hydrohalic acids $(\mathrm{HCl}, \mathrm{HBr}$, and HI$)$ are all strong acids (strong electrolytes).

Figure 7.20 Group 7A elements.

## Group 8A Elements ( $n s^{2} n p^{6}, n \geq 2$ )

Figure 7.21 shows samples of the Group 8A elements. All the noble gases exist as monatomic species. With the exception of helium, which has the electron configuration $1 s^{2}$, their atoms have completely filled outer $n s$ and $n p$ subshells. Their electron configurations give the noble gases their great stability. The Group 8A ionization energies are among the highest of all the elements (see Figure 7.8). Their electron affinities are all less than zero (Figure 7.10), so they have no tendency to accept extra electrons.

For years the noble gases were called inert gases because they were not known to react with anything. Beginning in 1963, however, compounds were prepared from xenon and krypton by exposing them to very strong oxidizing agents such as fluorine and oxygen. Some of the compounds that have been prepared are $\mathrm{XeF}_{4}, \mathrm{XeO}_{3}, \mathrm{XeOF}_{4}$, and $\mathrm{KrF}_{2}$. Although the chemistry of the noble gases is interesting, their compounds are not involved in any natural biological processes and they currently have no major commercial applications.

## Comparison of Group 1A and Group 1B Elements

Although the outer electron configurations of Groups 1A and 1B are similar (members of both groups have a single valence electron in an $s$ orbital), their chemical properties are very different.

The first ionization energies of $\mathrm{Cu}, \mathrm{Ag}$, and Au are 745,731 , and $890 \mathrm{~kJ} / \mathrm{mol}$, respectively. Because these values are considerably larger than those of the alkali metals, the Group 1B elements are much less reactive. The higher ionization energies of the Group 1B elements result from incomplete shielding of the nucleus by the inner $d$ electrons (compared with the more effective

Helium

Argon

Neon

Student Annotation: Note that the common ions formed by the other main group elements are those that make them isoelectronic with a noble gas. In Group 1A elements, for example, each atom loses one electron to become isoelectronic with the noble gas that immediately precedes it; in Group 7A elements, each atom gains one electron to become isoelectronic with the noble gas that immediately follows it; and so on.

Figure 7.21 Discharge tubes containing Group 8A elements.

Xenon
shielding by the completely filled noble gas cores). Consequently, the outer $s$ electrons of the Group 1B elements are more strongly attracted by the nucleus. In fact, copper, silver, and gold are so unreactive that they are usually found in the uncombined state in nature. The inertness, rarity, and attractive appearance of these metals make them valuable in the manufacture of coins and jewelry. For this reason, these metals are also known as "coinage metals." The differences in the chemistry of the elements in Group 2A from that of the elements in Group 2B can be explained in a similar way.

X-ray image of a human skeleton

## Bringing Chemistry to Life

## Radioactive Bone

One of the consequences of two chemical species having similar properties is that human physiology sometimes mistakes one species for another. Healthy bones require constant replenishment of calcium. Our dietary calcium comes primarily from dairy products but can also be found in some vegetables-especially dark, leafy greens such as spinach and kale. Strontium-90, a radioactive isotope, is found in the fallout of atomic bomb explosions and is a component in the waste generated by nuclear power facilities. Strontium- 90 released into the atmosphere will eventually settle on land and water, and it can reach our bodies through ingestion-especially of vegetation-and through the inhalation of airborne particles. Because calcium and strontium are chemically similar, $\mathrm{Sr}^{2+}$ ions are mistaken by the body for $\mathrm{Ca}^{2+}$ ions and are incorporated into the bones. Constant exposure to the radiation emitted by strontium- 90 affects not only the bone and surrounding soft tissue, but also the bone marrow, damaging and destroying stem cells vital to the immune system. Such long-term exposure leads to an increased risk of leukemia and other cancers.

Ca and Sr , being in the same group, have similar chemical properties.

## Variation in Properties of Oxides Within a Period

One way to compare the properties of the main group elements across a period is to examine the properties of a series of similar compounds. Because oxygen combines with almost all elements, we will compare the properties of oxides of the third-period elements to see how metals differ from metalloids and nonmetals. Some elements in the third period ( $\mathrm{P}, \mathrm{S}$, and Cl ) form several types of oxides, but for simplicity we will consider only those oxides in which the elements have the highest oxidation number. Table 7.4 lists a few general characteristics of these oxides and some specific physical properties of the oxides of third-period elements.

The tendency of oxygen to form the oxide ion is greatly favored when oxygen combines with metals that have low ionization energies, such as those in Groups 1A and 2A and aluminum. Thus, $\mathrm{Na}_{2} \mathrm{O}, \mathrm{MgO}$, and $\mathrm{Al}_{2} \mathrm{O}_{3}$ are ionic compounds, as evidenced by their high melting points and boiling points. They have extensive three-dimensional structures in which each cation is surrounded by a specific number of anions, and vice versa. As the ionization energies of the elements increase from

TABLE 7.4 Some Properties of Oxides of the Third-Period Elements

|  | $\mathrm{Na}_{2} \mathrm{O}$ | MgO | $\mathrm{Al}_{2} \mathrm{O}_{3}$ | $\mathrm{SiO}_{2}$ | $\mathrm{P}_{4} \mathrm{O}_{10}$ | $\mathrm{SO}_{3}$ | $\mathrm{Cl}_{2} \mathrm{O}_{7}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Type of compound | $\checkmark$ | Ionic | $\longrightarrow$ |  | - | olecular |  |

| Melting point ( ${ }^{\circ} \mathrm{C}$ ) | 1275 | 2800 | 2045 | 1610 | 580 | 16.8 | -91.5 |
| Boiling point ( ${ }^{\circ} \mathrm{C}$ ) | ? | 3600 | 2980 | 2230 | ? | 44.8 | 82 |
| Acid-base nature | Basic | Basic | Amphoteric |  | - | Acidic |  |

left to right, so does the molecular nature of the oxides that form. Silicon is a metalloid; its oxide $\left(\mathrm{SiO}_{2}\right)$ also has a huge three-dimensional network, although it is not an ionic compound. The oxides of phosphorus, sulfur, and chlorine are molecular compounds composed of small discrete units. The weak attractions among these molecules result in relatively low melting points and boiling points.

Most oxides can be classified as acidic or basic depending on whether they produce acids or bases when dissolved in water (or whether they react as acids or bases). Some oxides are amphoteric, which means that they display both acidic and basic properties. The first two oxides of the third period, $\mathrm{Na}_{2} \mathrm{O}$ and MgO , are basic oxides. For example, $\mathrm{Na}_{2} \mathrm{O}$ reacts with water to form the base sodium hydroxide:

$$
\mathrm{Na}_{2} \mathrm{O}(s)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{NaOH}(a q)
$$

Magnesium oxide is quite insoluble; it does not react with water to any appreciable extent. However, it does react with acids in a manner that resembles an acid-base reaction:

$$
\mathrm{MgO}(s)+2 \mathrm{HCl}(a q) \longrightarrow \mathrm{MgCl}_{2}(a q)+\mathrm{H}_{2} \mathrm{O}(l)
$$

The products of this reaction are a salt $\left(\mathrm{MgCl}_{2}\right)$ and water, the same kind of products that are obtained in an acid-base neutralization.

Aluminum oxide is even less soluble than magnesium oxide. It, too, does not react with water, but it exhibits the properties of a base by reacting with acids:

$$
\mathrm{Al}_{2} \mathrm{O}_{3}(s)+6 \mathrm{HCl}(a q) \longrightarrow 2 \mathrm{AlCl}_{3}(a q)+3 \mathrm{H}_{2} \mathrm{O}(l)
$$

It also exhibits acidic properties by reacting with bases:

$$
\mathrm{Al}_{2} \mathrm{O}_{3}(s)+2 \mathrm{NaOH}(a q)+3 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{NaAl}(\mathrm{OH})_{4}(a q)
$$

Thus, $\mathrm{Al}_{2} \mathrm{O}_{3}$ is classified as an amphoteric oxide because it has properties of both acids and bases. Other amphoteric oxides are $\mathrm{ZnO}, \mathrm{BeO}$, and $\mathrm{Bi}_{2} \mathrm{O}_{3}$.

Silicon dioxide is insoluble and does not react with water. It has acidic properties, however, because it reacts with a very concentrated aqueous base:

$$
\mathrm{SiO}_{2}(s)+2 \mathrm{OH}^{-}(a q) \longrightarrow \mathrm{SiO}_{3}^{2-}(a q)+\mathrm{H}_{2} \mathrm{O}(l)
$$

For this reason, concentrated aqueous, strong bases such as sodium hydroxide $(\mathrm{NaOH})$ should not be stored in Pyrex glassware, which is made of $\mathrm{SiO}_{2}$.

The remaining third-period oxides $\left(\mathrm{P}_{4} \mathrm{O}_{10}, \mathrm{SO}_{3}\right.$, and $\left.\mathrm{Cl}_{2} \mathrm{O}_{7}\right)$ are acidic. They react with water to form phosphoric acid, sulfuric acid, and perchloric acid, respectively:

$$
\begin{aligned}
\mathrm{P}_{4} \mathrm{O}_{10}(s)+6 \mathrm{H}_{2} \mathrm{O}(a q) & \longrightarrow 4 \mathrm{H}_{3} \mathrm{PO}_{4}(a q) \\
\mathrm{SO}_{3}(g)+\mathrm{H}_{2} \mathrm{O}(l) & \longrightarrow 2 \mathrm{H}_{2} \mathrm{SO}_{4}(a q) \\
\mathrm{Cl}_{2} \mathrm{O}_{7}(l)+\mathrm{H}_{2} \mathrm{O}(l) & \longrightarrow 2 \mathrm{HClO}_{4}(a q)
\end{aligned}
$$

This brief examination of oxides of the third-period elements shows that as the metallic character of the elements decreases from left to right across the period, their oxides change from basic to amphoteric to acidic. Metal oxides are usually basic, and most oxides of nonmetals are acidic. The intermediate properties of the oxides (as demonstrated by the amphoteric oxides) are exhibited by elements whose positions are intermediate within the period. Because the metallic character of the elements increases from top to bottom within a group of main group elements, the oxides of elements with higher atomic numbers are more basic than the lighter elements.

## Applying What You've Learned

In 1949, the Australian psychiatrist John Cade published the results of his studies showing that lithium was useful in the treatment of "manic episodes," one of the phases of what is known today as bipolar disorder. Although the research had shown real promise, its publication coincided with news of the lithium poisoning and resulting deaths of a group of cardiac patients that had used lithium chloride as a dietary salt substitute. Reports of this disaster prompted drug manufacturers to withdraw all lithium salts from the market, and for a time, any medical use of lithium was viewed as too dangerous even to consider. Additional research in Europe and the United States resulted in the gradual acceptance of lithium as a potentially valuable psychiatric therapy. The FDA approved lithium carbonate $\left(\mathrm{Li}_{2} \mathrm{CO}_{3}\right)$ in 1970 for the treatment of manic illness, and in 1974 for the treatment of bipolar disorder.

## Problems:

a) Without referring to a periodic table, write the electron configuration of lithium $(Z=3)$. [ 144 Sample Problem 7.2]
b) Referring only to a periodic table, arrange Li and the other alkali metals (not including Fr ) in order of increasing atomic radius. [ 14 Sample Problem 7.3]
c) Again referring only to the periodic table, arrange the members of Group 1A (not including Fr ) in order of increasing ionization energy $\left(I E_{1}\right)$. [ $\mathrm{K4}$ Sample Problem 7.4]
d) Write the electron configuration for each of the alkali metal cations.
[ 144 Sample Problem 7.7]
e) For each alkali metal cation in part (d), identify an isoelectronic series consisting of a noble gas and, where appropriate, one or more common ions (see Figure 2.14). [14 Sample Problem 7.8] List each series in order of increasing radius. [ 14 Sample Problem 7.9]

## Chapter Summary

## Section 7.1

- The modern periodic table was devised independently by Dmitri Mendeleev and Lothar Meyer in the nineteenth century. The elements that were known at the time were grouped based on their physical and chemical properties. Using his arrangements of the elements, Mendeleev successfully predicted the existence of elements that had not yet been discovered.
- Early in the twentieth century, Henry Moseley refined the periodic table with the concept of the atomic number, thus resolving a few inconsistencies in the tables proposed by Mendeleev and Meyer.
- Elements in the same group of the periodic table tend to have similar physical and chemical properties.

## Section 7.2

- The periodic table can be divided into the main group elements (also known as the representative elements) and the transition metals. It is further divided into smaller groups or columns of elements that all have the same configuration of valence electrons.
- The 18 columns of the periodic table are labeled 1A through 8A ( $s$ - and $p$-block elements) and 1B through 8B ( $d$-block elements), or by the numbers 1 through 18.

## Section 7.3

- Effective nuclear charge $\left(Z_{\mathrm{eff}}\right)$ is the nuclear charge that is "felt" by the valence electrons. It is usually lower than the nuclear charge due to shielding by the core electrons.
- According to Coulomb's law, the attractive force $(F)$ between two oppositely charged particles $\left(Q_{1}\right.$ and $\left.Q_{2}\right)$ is directly proportional to the product of the charges and inversely proportional to the distance $(d)$ between the objects squared: $\left(F \propto Q_{1} \cdot Q_{2} / d^{2}\right)$.

## Section 7.4

- Atomic radius is the distance between an atom's nucleus and its valence shell. The atomic radius of a metal atom is defined as the metallic radius, which is one-half the distance between adjacent, identical nuclei in a metal solid. The atomic radius of a nonmetal is defined as the covalent radius, which is one-half the distance between adjacent, identical nuclei in a molecule. In general, atomic radii decrease from left to right across a period of the periodic table and increase from top to bottom down a group.
- Ionization energy (IE) is the energy required to remove an electron from a gaseous atom. The first ionization energy $\left(I E_{1}\right)$ is smaller than subsequent ionization energies [e.g., second $\left(I E_{2}\right)$, third $\left(I E_{3}\right)$, and so on]. The first ionization of any atom removes a valence electron. Ionization energies increase dramatically when core electrons are being removed.
- First ionization energies ( $I E_{1}$ values) tend to increase across a period and decrease down a group. Exceptions to this trend can be explained based upon the electron configuration of the element.
- Electron affinity $(\boldsymbol{E A})$ is the energy released when an atom in the gas phase accepts an electron. $E A$ is equal to $-\Delta H$ for the process $\mathrm{A}(g)+e^{-} \longrightarrow \mathrm{A}^{-}(g)$.
- Electron affinities tend to increase across a period. As with first ionization energies, exceptions to the trend can be explained based on the electron configuration of the element.
- Metals tend to be shiny, lustrous, malleable, ductile, and conducting (for both heat and electricity). Metals typically lose electrons to form cations, and they tend to form ionic compounds (including basic oxides).
- Nonmetals tend to be brittle and not good conductors (for either heat or electricity). They can gain electrons to form anions but they commonly form molecular compounds (including acidic oxides).
- In general, metallic character decreases across a period and increases down a group of the periodic table. Metalloids are elements with properties intermediate between metals and nonmetals.

## Section 7.5

- Ions of main group elements are isoelectronic with noble gases. When a $d$-block element loses one or more electrons, it loses them first from the shell with the highest principal quantum number (e.g., electrons in the $4 s$ subshell are lost before electrons in the $3 d$ subshell).

## Section 7.6

- Ionic radius is the distance between the nucleus and valence shell of a cation or an anion. A cation is smaller than its parent atom. An anion is larger than its parent atom.
- An isoelectronic series consists of one or more ions and a noble gas, all of which have identical electron configurations. Within an isoelectronic series, the greater the nuclear charge, the smaller the radius.

## Section 7.7

- A diagonal relationship describes similarities in the chemical properties of elements that are in different groups, but that are positioned diagonally from each other in the periodic table.
- Although members of a group in the periodic table exhibit similar chemical and physical properties, the first member of each group tends to be significantly different from the other members. Hydrogen is essentially a group unto itself.
- The alkali metals (Group 1A) tend to be highly reactive toward oxygen, water, and acid. Group 2A metals are less reactive than Group 1A metals, but the heavier members all react with water to produce metal hydroxides and hydrogen gas. Groups that contain both metals and nonmetals (e.g., Groups 4A, 5A, and 6A) tend to show greater variability in their physical and chemical properties.
- Amphoteric oxides, such as $\mathrm{Al}_{2} \mathrm{O}_{3}$, are those that exhibit both acidic and basic behavior.

## Questions and Problems

## Section 7.1: Development of the Periodic Table

## Review Questions

7.1 Briefly describe the significance of Mendeleev's periodic table.
7.2 What is Moseley's contribution to the modern periodic table?
7.3 Describe the general layout of a modern periodic table.
7.4 What is the most important relationship among elements in the same group in the periodic table?

## Section 7.2: The Modern Periodic Table

## Review Questions

4.5 Classify each of the following elements as a metal, a nonmetal, or a metalloid: As, $\mathrm{Xe}, \mathrm{Fe}, \mathrm{Li}, \mathrm{B}, \mathrm{Cl}, \mathrm{Ba}, \mathrm{P}, \mathrm{I}, \mathrm{Si}$.
7.6 Compare the physical and chemical properties of metals and nonmetals.
7.7 Draw a rough sketch of a periodic table (no details are required). Indicate regions where metals, nonmetals, and metalloids are located.
7.8 What is a main group element? Give names and symbols of four main group elements.
7.9 Without referring to a periodic table, write the name and give the symbol for one element in each of the following groups: $1 \mathrm{~A}, 2 \mathrm{~A}$, $3 \mathrm{~A}, 4 \mathrm{~A}, 5 \mathrm{~A}, 6 \mathrm{~A}, 7 \mathrm{~A}, 8 \mathrm{~A}$, transition metals.
7.10 Indicate whether the following elements exist as atomic species, molecular species, or extensive three-dimensional structures in their most stable states at room temperature, and write the molecular or empirical formula for each one: phosphorus, iodine, magnesium, neon, carbon, sulfur, cesium, and oxygen.
7.11 You are given a sample of a dark, shiny solid and asked to determine whether it is the nonmetal iodine or a metallic element. What test could you do that would enable you to answer the question without destroying the sample?
7.12 What are valence electrons? For main group elements, the number of valence electrons of an element is equal to its group number. Show that this is true for the following elements: $\mathrm{Al}, \mathrm{Sr}, \mathrm{K}, \mathrm{Br}, \mathrm{P}$, S, C.
7.13 Write the outer electron configurations for the (a) alkali metals, (b) alkaline earth metals, (c) halogens, (d) noble gases.
7.14 Use the first-row transition metals $(\mathrm{Sc}$ to Cu$)$ as an example to illustrate the characteristics of the electron configurations of transition metals.
7.15 Arsenic is not an essential element for the human body. Based on its position in the periodic table, suggest a reason for its toxicity.

## Problems

7.16 In the periodic table, the element hydrogen is sometimes grouped with the alkali metals and sometimes with the halogens. Explain why hydrogen can resemble the Group 1A and the Group 7A elements.
7.17 A neutral atom of a certain element has 16 electrons. Consulting only the periodic table, identify the element and write its groundstate electron configuration.

E7.18 Group the following electron configurations in pairs that would represent elements with similar chemical properties:
(a) $1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2}$
(b) $1 s^{2} 2 s^{2} 2 p^{3}$
(c) $1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2} 3 p^{6} 4 s^{2} 3 d^{10} 4 p^{6}$
(d) $1 s^{2} 2 s^{2}$
(e) $1 s^{2} 2 s^{2} 2 p^{6}$
(f) $1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2} 3 p^{3}$

E7.19 Group the following electron configurations in pairs that would represent elements with similar chemical properties:
(a) $1 s^{2} 2 s^{2} 2 p^{5}$
(b) $1 s^{2} 2 s^{1}$
(c) $1 s^{2} 2 s^{2} 2 p^{6}$
(d) $1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2} 3 p^{5}$
(e) $1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2} 3 p^{6} 4 s^{1}$
(f) $1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2} 3 p^{6} 4 s^{2} 3 d^{10} 4 p^{6}$
§7.20 Without referring to a periodic table, write the electron configuration of elements with the following atomic numbers: (a) 9 , (b) 20 , (c) 26 , (d) 33 .
7.21 Specify the group of the periodic table in which each of the following elements is found: (a) $[\mathrm{Ne}] 3 s^{1}$, (b) $[\mathrm{Ne}] 3 s^{2} 3 p^{3}$, (c) $[\mathrm{Ne}] 3 s^{2} 3 p^{6}$, (d) $[\mathrm{Ar}] 4 s^{2} 3 d^{8}$.

## Section 7.3: Effective Nuclear Charge

Review Questions
E17.22 Explain the term effective nuclear charge.
7.23 Explain why the atomic radius of Be is smaller than that of Li .

## Problems

7.24 The electron configuration of B is $1 s^{2} 2 s^{2} 2 p^{1}$. (a) If each core electron (that is, the $1 s$ electrons) were totally effective in shielding the valence electrons (that is, the $2 s$ and $2 p$ electrons) from the nucleus and the valence electrons did not shield one another, what would be the shielding constant $(\sigma)$ and the effective nuclear charge ( $Z_{\text {eff }}$ ) for the $2 s$ and $2 p$ electrons? (b) In reality, the shielding constants for the $2 s$ and $2 p$ electrons in B are slightly different. They are 2.42 and 2.58 , respectively. Calculate $Z_{\text {eff }}$ for these electrons, and explain the differences from the values you determined in part (a).
7.25 The electron configuration of C is $1 s^{2} 2 s^{2} 2 p^{2}$. (a) If each core electron (that is, the $1 s$ electrons) were totally effective in shielding the valence electrons (that is, the $2 s$ and $2 p$ electrons) from the nucleus and the valence electrons did not shield one another, what would be the shielding constant $(\sigma)$ and the effective nuclear charge ( $Z_{\text {eff }}$ ) for the $2 s$ and $2 p$ electrons? (b) In reality, the shielding constants for the $2 s$ and $2 p$ electrons in C are slightly different. They are 2.78 and 2.86 , respectively. Calculate $Z_{\text {eff }}$ for these electrons, and explain the differences from the values you determined in part (a).

## Section 7.4: Periodic Trends in Properties of Elements

## Review Questions

7.26 Define atomic radius. Does the size of an atom have a precise meaning?
7.27 How does atomic radius change (a) from left to right across a period and (b) from top to bottom in a group?
7.28 Define ionization energy. Explain why ionization energy measurements are usually made when atoms are in the gaseous state. Why is the second ionization energy always greater than the first ionization energy for any element?
7.29 Sketch the outline of the periodic table, and show group and period trends in the first ionization energy of the elements. What types of elements have the highest ionization energies and what types have the lowest ionization energies?
7.30 (a) Define electron affinity. (b) Explain why electron affinity measurements are made with gaseous atoms. (c) Ionization energy is always a positive quantity, whereas electron affinity may be either positive or negative. Explain.
7.31 Explain the trends in electron affinity from aluminum to chlorine (see Figure 7.10).

## Problems

\$7.32 On the basis of their positions in the periodic table, select the atom with the larger atomic radius in each of the following pairs:
(a) $\mathrm{Na}, \mathrm{Si}$; (b) $\mathrm{Ba}, \mathrm{Be}$;
; (c) $\mathrm{N}, \mathrm{F}$; (d) $\mathrm{Br}, \mathrm{Cl}$;
(e) $\mathrm{Ne}, \mathrm{Kr}$.
\$7.33 Arrange the following atoms in order of increasing atomic radius: $\mathrm{Na}, \mathrm{Al}, \mathrm{P}, \mathrm{Cl}, \mathrm{Mg}$.
\$7.34 Which is the largest atom in the third period of the periodic table?
§7.35 Which is the smallest atom in Group 7A?
\$7.36 Based on size, identify the spheres shown as $\mathrm{Na}, \mathrm{Mg}, \mathrm{O}$, and S .

7.37 Based on size, identify the spheres shown as $\mathrm{K}, \mathrm{Ca}, \mathrm{S}$, and Se .

7.38 Why is the radius of the lithium atom considerably larger than the radius of the hydrogen atom?
7.39 Use the second period of the periodic table as an example to show that the size of atoms decreases as we move from left to right. Explain the trend.
\$7.40 Arrange the following in order of increasing first ionization energy: $\mathrm{Na}, \mathrm{Cl}, \mathrm{Al}, \mathrm{S}$, and Cs .
7.41 Arrange the following in order of increasing first ionization energy: F, K, P, Ca, and Ne.
7.42 Use the third period of the periodic table as an example to illustrate the change in first ionization energies of the elements as we move from left to right. Explain the trend.
7.43 In general, the first ionization energy increases from left to right across a given period. Aluminum, however, has a lower first ionization energy than magnesium. Explain.
7.44 The first and second ionization energies of K are 419 and $3052 \mathrm{~kJ} /$ mol , and those of Ca are 590 and $1145 \mathrm{~kJ} / \mathrm{mol}$, respectively Compare their values and comment on the differences.
7.45 Two atoms have the electron configurations $1 s^{2} 2 s^{2} 2 p^{6}$ and $1 s^{2} 2 s^{2} 2 p^{6} 3 s^{1}$. The first ionization energy of one is $2080 \mathrm{~kJ} / \mathrm{mol}$, and that of the other is $496 \mathrm{~kJ} / \mathrm{mol}$. Match each ionization energy with one of the given electron configurations. Justify your choice.

G7.46 A hydrogen-like ion is an ion containing only one electron. The energies of the electron in a hydrogen-like ion are given by

$$
E_{n}=-\left(2.18 \times 10^{-18} \mathrm{~J}\right) Z^{2}\left(\frac{1}{n^{2}}\right)
$$

where $n$ is the principal quantum number and $Z$ is the atomic number of the element. Calculate the ionization energy (in $\mathrm{kJ} / \mathrm{mol}$ ) of the $\mathrm{He}^{+}$ion.
\& 7.47 Plasma is a state of matter consisting of positive gaseous ions and electrons. In the plasma state, a mercury atom could be stripped of its 80 electrons and therefore would exist as $\mathrm{Hg}^{80+}$. Use the equation in Problem 7.46 to calculate the energy required for the last ionization step, that is,

$$
\mathrm{Hg}^{79+}(\mathrm{g}) \longrightarrow \mathrm{Hg}^{80+}(\mathrm{g})+e^{-}
$$

\$7.48 Arrange the elements in each of the following groups in order of increasing electron affinity: (a) $\mathrm{Li}, \mathrm{Na}, \mathrm{K}$; (b) $\mathrm{F}, \mathrm{Cl}, \mathrm{Br}, \mathrm{I}$.
7.49 Specify which of the following elements you would expect to have the greatest electron affinity: $\mathrm{He}, \mathrm{K}, \mathrm{Co}, \mathrm{S}, \mathrm{Cl}$.
7.50 Considering their electron affinities, do you think it is possible for the alkali metals to form an anion like $\mathrm{M}^{-}$, where M represents an alkali metal?
7.51 Explain why alkali metals have a greater affinity for electrons than alkaline earth metals.

## Section 7.5: Electron Configuration of Ions

## Review Questions

7.52 How does the electron configuration of ions derived from main group elements give them stability?
7.53 What do we mean when we say that two ions or an atom and an ion are isoelectronic?
7.54 Is it possible for the atoms of one element to be isoelectronic with the atoms of another element? Explain.
7.55 Give three examples of first-row transition metal ( Se to Cu ) ions that are isoelectronic with argon.

## Problems

\&7.56 $\mathrm{A} \mathrm{M}^{2+}$ ion derived from a metal in the first transition metal series has four electrons in the $3 d$ subshell. What element might M be?
7.57 A metal ion with a net +3 charge has five electrons in the $3 d$ subshell. Identify the metal.
\$7.58 Write the ground-state electron configurations of the following ions: (a) $\mathrm{Li}^{+}$, (b) $\mathrm{H}^{-}$, (c) $\mathrm{N}^{3-}$, (d) $\mathrm{F}^{-}$, (e) $\mathrm{S}^{2-}$, (f) $\mathrm{Al}^{3+}$, (g) $\mathrm{Se}^{2-}$, (h) $\mathrm{Br}^{-}$, (i) $\mathrm{Rb}^{+}$, (j) $\mathrm{Sr}^{2+}$, (k) $\mathrm{Sn}^{2+}$, (l) $\mathrm{Te}^{2-}$, (m) $\mathrm{Ba}^{2+}$, (n) $\mathrm{Pb}^{2+}$, (o) $\mathrm{In}^{3+}$, (p) $\mathrm{Tl}^{+}$, (q) $\mathrm{Tl}^{3+}$.
7.59 Write the ground-state electron configurations of the following ions, which play important roles in biochemical processes in our bodies: (a) $\mathrm{Na}^{+}$, (b) $\mathrm{Mg}^{2+}$, (c) $\mathrm{Cl}^{-}$, (d) $\mathrm{K}^{+}$, (e) $\mathrm{Ca}^{2+}$, (f) $\mathrm{Fe}^{2+}$, (g) $\mathrm{Cu}^{2+}$, (h) $\mathrm{Zn}^{2+}$.
7.60 Write the ground-state electron configurations of the following transition metal ions: (a) $\mathrm{Sc}^{3+}$, (b) $\mathrm{Ti}^{4+}$, (c) $\mathrm{V}^{5+}$, (d) $\mathrm{Cr}^{3+}$, (e) $\mathrm{Mn}^{2+}$, (f) $\mathrm{Fe}^{2+}$, (g) $\mathrm{Fe}^{3+}$, (h) $\mathrm{Co}^{2+}$, (i) $\mathrm{Ni}^{2+}$, (j) $\mathrm{Cu}^{+}$, (k) $\mathrm{Cu}^{2+}$, (1) $\mathrm{Ag}^{+}$, (m) $\mathrm{Au}^{+}$, (n) $\mathrm{Au}^{3+}$, (o) $\mathrm{Pt}^{2+}$.
7.61 Name the ions with three charges that have the following electron configurations: (a) $[\mathrm{Ar}] 3 d^{3}$, (b) $[\mathrm{Ar}]$, (c) $[\mathrm{Kr}] 4 d^{6}$, (d) $[\mathrm{Xe}] 4 f^{14} 5 d^{6}$.
\$7.62 Which of the following species are isoelectronic with each other: $\mathrm{C}, \mathrm{Cl}^{-}, \mathrm{Mn}^{2+}, \mathrm{B}^{-}, \mathrm{Ar}, \mathrm{Zn}, \mathrm{Fe}^{3+}, \mathrm{Ge}^{2+}$ ?
7.63 Group the species that are isoelectronic: $\mathrm{Be}^{2+}, \mathrm{F}^{-}, \mathrm{Fe}^{2+}, \mathrm{N}^{3-}, \mathrm{He}$, $\mathrm{S}^{2-}, \mathrm{Co}^{3+}, \mathrm{Ar}$.
7.64 Thallium ( Tl ) is a neurotoxin and exists mostly in the $\mathrm{Tl}(\mathrm{I})$ oxidation state in its compounds. Aluminum (Al), which causes anemia and dementia, is only stable in the $\mathrm{Al}(\mathrm{III})$ form. The first, second, and third ionization energies of Tl are 589,1971 , and $2878 \mathrm{~kJ} / \mathrm{mol}$, respectively. The first, second, and third ionization energies of Al are $577.5,1817$, and $2745 \mathrm{~kJ} / \mathrm{mol}$, respectively. Plot the ionization energies of Al and Tl versus atomic number and explain the trends.

## Section 7.6: Ionic Radius

## Review Questions

7.65 Define ionic radius. How does the size of an atom change when it is converted to (a) an anion and (b) a cation?
7.66 Explain why, for isoelectronic ions, the anions are larger than the cations.

## Problems

\$7.67 Indicate which one of the two species in each of the following pairs is smaller: (a) $\mathrm{Cl}^{\text {or }} \mathrm{Cl}^{-}$, (b) Na or $\mathrm{Na}^{+}$, (c) $\mathrm{O}^{2-}$ or $\mathrm{S}^{2-}$, (d) $\mathrm{Mg}^{2+}$ or $\mathrm{Al}^{3+}$, (e) $\mathrm{Au}^{+}$or $\mathrm{Au}^{3+}$.
\$7.68 List the following ions in order of increasing ionic radius: $\mathrm{N}^{3-}$, $\mathrm{Na}^{+}, \mathrm{F}^{-}, \mathrm{Mg}^{2+}, \mathrm{O}^{2-}$.
7.69 Explain which of the following cations is larger, and why: $\mathrm{Cu}^{+}$ or $\mathrm{Cu}^{2+}$.
¢ 7.70 Explain which of the following anions is larger, and why: $\mathrm{Se}^{2-}$ or $\mathrm{Te}^{2-}$.
7.71 Both $\mathrm{Mg}^{2+}$ and $\mathrm{Ca}^{2+}$ are important biological ions. One of their functions is to bind to the phosphate group of ATP molecules or amino acids of proteins. For Group 2A metals in general, the tendency for binding to the anions increases in the order $\mathrm{Ba}^{2+}<$ $\mathrm{Sr}^{2+}<\mathrm{Ca}^{2+}<\mathrm{Mg}^{2+}$. Explain this trend.

## Section 7.7: Periodic Trends in Chemical Properties of the Main Group Elements

## Review Questions

7.72 Why do members of a group exhibit similar chemical properties?
7.73 Which elements are more likely to form acidic oxides? Basic oxides? Amphoteric oxides?

## Problems

E7.74 Give the physical states (gas, liquid, or solid) of the main group elements in the fourth period $(\mathrm{K}, \mathrm{Ca}, \mathrm{Ga}, \mathrm{Ge}, \mathrm{As}, \mathrm{Se}, \mathrm{Br})$ at room temperature.
§7.75 The boiling points of neon and krypton are $-246.1^{\circ} \mathrm{C}$ and $-153.2^{\circ} \mathrm{C}$, respectively. Using these data, estimate the boiling point of argon.
7.76 Use the alkali metals and alkaline earth metals as examples to show how we can predict the chemical properties of elements simply from their electron configurations.
7.77 Based on your knowledge of the chemistry of the alkali metals, predict some of the chemical properties of francium, the last member of the group.
7.78 As a group, the noble gases are very stable chemically (only Kr and Xe are known to form compounds). Why?
7.79 Why are Group 1B elements more stable than Group 1A elements even though they seem to have the same outer electron configuration, $n s^{1}$, where $n$ is the principal quantum number of the outermost shell?
7.80 How do the chemical properties of oxides change from left to right across a period? How do they change from top to bottom within a particular group?

E7.81 Write balanced equations for the reactions between each of the following oxides and water: (a) $\mathrm{Li}_{2} \mathrm{O}$, (b) CaO , (c) $\mathrm{SO}_{3}$.
7.82 Write formulas for and name the binary hydrogen compounds of the second-period elements (Li to F). Describe how the physical and chemical properties of these compounds change from left to right across the period.
7.83 Which oxide is more basic, MgO or BaO ? Why?

## Additional Problems

7.84 State whether each of the following properties of the main group elements generally increases or decreases (a) from left to right across a period and (b) from top to bottom within a group: metallic character, atomic size, ionization energy, acidity of oxides.
7.85 Referring to the periodic table, name (a) the halogen in the fourth period, (b) an element similar to phosphorus in chemical properties, (c) the most reactive metal in the fifth period, (d) an element that has an atomic number smaller than 20 and is similar to strontium.

H7.86 Write equations representing the following processes:
(a) The electron affinity of $\mathrm{S}^{-}$
(b) The third ionization energy of titanium
(c) The electron affinity of $\mathrm{Mg}^{2+}$
(d) The ionization energy of $\mathrm{O}^{2-}$
7.87 Arrange the following isoelectronic species in order of increasing ionization energy: $\mathrm{O}^{2-}, \mathrm{F}^{-}, \mathrm{Na}^{+}, \mathrm{Mg}^{2+}$.
7.88 Write the empirical (or molecular) formulas of compounds that the elements in the third period (sodium to chlorine) should form with (a) molecular oxygen and (b) molecular chlorine. In each case indicate whether you would expect the compound to be ionic or molecular in character.
7.89 Element M is a shiny and highly reactive metal (melting point $63^{\circ} \mathrm{C}$ ), and element X is a highly reactive nonmetal (melting point $-7.2^{\circ} \mathrm{C}$ ). They react to form a compound with the
empirical formula MX, a colorless, brittle white solid that melts at $734^{\circ} \mathrm{C}$. When dissolved in water or when in the molten state, the substance conducts electricity. When chlorine gas is bubbled through an aqueous solution containing MX, a reddish-brown liquid appears and $\mathrm{Cl}^{-}$ions are formed. From these observations, identify M and X . (You may need to consult a handbook of chemistry for the melting-point values.)

E 7.90 Match each of the elements on the right with its description on the left:
(a) A dark-red liquid
(b) A colorless gas that burns in oxygen gas
(c) A metal that reacts violently with water
(d) A shiny metal that is used in jewelry
(e) An inert gas

Calcium (Ca)
Gold (Au) Hydrogen $\left(\mathrm{H}_{2}\right)$
Argon (Ar)
Bromine ( $\mathrm{Br}_{2}$ )
7.91 Arrange the following species in isoelectronic pairs: $\mathrm{O}^{+}, \mathrm{Ar}, \mathrm{S}^{2-}$, $\mathrm{Ne}, \mathrm{Zn}, \mathrm{Cs}^{+}, \mathrm{N}^{3-}, \mathrm{As}^{3+}, \mathrm{N}, \mathrm{Xe}$.
§7.92 In which of the following are the species written in decreasing order by size of radius: (a) $\mathrm{Be}, \mathrm{Mg}, \mathrm{Ba}$, (b) $\mathrm{N}^{3-}, \mathrm{O}^{2-}, \mathrm{F}^{-}$, (c) $\mathrm{Tl}^{3+}$, $\mathrm{Tl}^{2+}, \mathrm{Tl}^{+}$?
7.93 Which of the following properties show a clear periodic variation: (a) first ionization energy, (b) molar mass of the elements, (c) number of isotopes of an element, (d) atomic radius?

E 7.94 When carbon dioxide is bubbled through a clear calcium hydroxide solution, the solution appears milky. Write an equation for the reaction, and explain how this reaction illustrates that $\mathrm{CO}_{2}$ is an acidic oxide.
7.95 You are given four substances: a fuming red liquid, a dark metallic-looking solid, a pale-yellow gas, and a yellow-green gas that attacks glass. You are told that these substances are the first four members of Group 7A, the halogens. Name each one.
7.96 For each pair of elements listed, give three properties that show their chemical similarity: (a) sodium and potassium and (b) chlorine and bromine.
7.97 Name the element that forms compounds, under appropriate conditions, with every other element in the periodic table except $\mathrm{He}, \mathrm{Ne}$, and Ar.
7.98 Explain why the first electron affinity of sulfur is $200 \mathrm{~kJ} / \mathrm{mol}$ but the second electron affinity is $-649 \mathrm{~kJ} / \mathrm{mol}$.
7.99 The $\mathrm{H}^{-}$ion and the He atom have two $1 s$ electrons each. Which of the two species is larger? Explain.

H7.100 Predict the products of the following oxides with water: $\mathrm{Na}_{2} \mathrm{O}, \mathrm{BaO}$, $\mathrm{CO}_{2}, \mathrm{~N}_{2} \mathrm{O}_{5}, \mathrm{P}_{4} \mathrm{O}_{10}, \mathrm{SO}_{3}$. Write an equation for each of the reactions. Specify whether the oxides are acidic, basic, or amphoteric.

E7.101 Write the formulas and names of the oxides of the secondperiod elements (Li to N ). Identify the oxides as acidic, basic, or amphoteric. Use the highest oxidation state of each element.
$\$ 7.102$ State whether each of the following elements is a gas, liquid, or solid under atmospheric conditions. Also state whether it exists in the elemental form as atoms, molecules, or a three-dimensional network: $\mathrm{Mg}, \mathrm{Cl}, \mathrm{Si}, \mathrm{Kr}, \mathrm{O}, \mathrm{I}, \mathrm{Hg}, \mathrm{Br}$.
7.103 What factors account for the unique nature of hydrogen?

E 7.104 The air in a manned spacecraft or submarine needs to be purified of exhaled carbon dioxide. Write equations for the reactions between carbon dioxide and (a) lithium oxide $\left(\mathrm{Li}_{2} \mathrm{O}\right)$, (b) sodium peroxide $\left(\mathrm{Na}_{2} \mathrm{O}_{2}\right)$, and (c) potassium superoxide $\left(\mathrm{KO}_{2}\right)$.
7.105 The formula for calculating the energies of an electron in a hydrogen-like ion is given in Problem 7.46. This equation can be applied only to one-electron atoms or ions. One way to modify it for more complex species is to replace $Z$ with $Z-\sigma$ or $Z_{\text {eff }}$. Calculate the value of $\sigma$ if the first ionization energy of helium is $3.94 \times 10^{-18} \mathrm{~J}$ per atom. (Disregard the minus sign in the given equation in your calculation.)
7.106 Why do noble gases have negative electron affinity values?

H7.107 The atomic radius of K is 227 pm and that of $\mathrm{K}^{+}$is 138 pm . Calculate the percent decrease in volume that occurs when $\mathrm{K}(g)$ is converted to $\mathrm{K}^{+}(g)$. (The volume of a sphere is $\frac{4}{3} \pi r^{3}$, where $r$ is the radius of the sphere.)
$\Psi 7.108$ The atomic radius of $F$ is 72 pm and that of $\mathrm{F}^{-}$is 133 pm . Calculate the percent increase in volume that occurs when $\mathrm{F}(g)$ is converted to $\mathrm{F}^{-}(g)$. (See Problem 7.107 for the volume of a sphere.)

H7.109 A technique called photoelectron spectroscopy is used to measure the ionization energy of atoms. A gaseous sample is irradiated with UV light, and electrons are ejected from the valence shell. The kinetic energies of the ejected electrons are measured. Because the energy of the UV photon and the kinetic energy of the ejected electron are known, we can write

$$
h v=I E+\frac{1}{2} m u^{2}
$$

where $v$ is the frequency of the UV light, and $m$ and $u$ are the mass and velocity of the electron, respectively. In one experiment the kinetic energy of the ejected electron from potassium is found to be $5.34 \times 10^{-19} \mathrm{~J}$ using a UV source of wavelength 162 nm . Calculate the ionization energy of potassium. How can you be sure that this ionization energy corresponds to the electron in the valence shell (that is, the most loosely held electron)?
§ 7.110 The energy needed for the following process is $1.96 \times 10^{4} \mathrm{~kJ} / \mathrm{mol}$ :

$$
\mathrm{Li}(g) \longrightarrow \mathrm{Li}^{3+}(g)+3 e^{-}
$$

If the first ionization energy of lithium is $520 \mathrm{~kJ} / \mathrm{mol}$, calculate the second ionization energy of lithium, that is, the energy required for the process

$$
\mathrm{Li}^{+}(g) \longrightarrow \mathrm{Li}^{2+}(g)+e^{-}
$$

(Hint: You need the equation in Problem 7.46.)
7.111 A student is given samples of three elements, $X, Y$, and $Z$, which could be an alkali metal, a member of Group 4A, or a member of Group 5A. She makes the following observations: Element X has a metallic luster and conducts electricity. It reacts slowly with hydrochloric acid to produce hydrogen gas. Element Y is a light yellow solid that does not conduct electricity. Element Z has a metallic luster and conducts electricity. When exposed to air, it slowly forms a white powder. A solution of the white powder in water is basic. What can you conclude about the elements from these observations?
7.112 What is the electron affinity of the $\mathrm{Na}^{+}$ion?
7.113 The ionization energies of sodium (in $\mathrm{kJ} / \mathrm{mol}$ ), starting with the first and ending with the eleventh, are 496, 4562, 6910, 9543, $13,354,16,613,20,117,25,496,28,932,141,362,159,075$. Plot the log of ionization energy ( $y$ axis) versus the number of ionization ( $x$ axis); for example, log 496 is plotted versus 1 (labeled $I E_{1}$, the first ionization energy), $\log 4562$ is plotted versus 2 (labeled $I E_{2}$, the second ionization energy), and so on. (a) Label $I E_{1}$ through $I E_{11}$ with the electrons in orbitals such as $1 s, 2 s, 2 p$, and $3 s$. (b) What can you deduce about electron shells from the breaks in the curve?
7.114 Experimentally, the electron affinity of an element can be determined by using a laser light to ionize the anion of the element in the gas phase:

$$
\mathrm{X}^{-}(g)+h v \longrightarrow \mathrm{X}(g)+e^{-}
$$

Referring to Figure 7.10, calculate the photon wavelength (in nm ) corresponding to the electron affinity for chlorine. In what region of the electromagnetic spectrum does this wavelength fall?
7.115 Explain, in terms of their electron configurations, why $\mathrm{Fe}^{2+}$ is more easily oxidized to $\mathrm{Fe}^{3+}$ than $\mathrm{Mn}^{2+}$ is to $\mathrm{Mn}^{3+}$.
7.116 Write the formulas and names of the hydrides of the following second-period elements: Li, C, N, O, F. Predict their reactions with water.

E 7.117 Based on knowledge of the electronic configuration of titanium, state which of the following compounds of titanium is unlikely to exist: $\mathrm{K}_{3} \mathrm{TiF}_{6}, \mathrm{~K}_{2} \mathrm{Ti}_{2} \mathrm{O}_{5}, \mathrm{TiCl}_{3}, \mathrm{~K}_{2} \mathrm{TiO}_{4}, \mathrm{~K}_{2} \mathrm{TiF}_{6}$.

H7.118 In halogen displacement reactions a halogen element can be generated by oxidizing its anions with a halogen element that lies above it in the periodic table. This means that there is no way to prepare elemental fluorine, because it is the first member of Group 7A. Indeed, for years the only way to prepare elemental fluorine was to oxidize $\mathrm{F}^{-}$ions by electrolytic means. Then, in 1986, a chemist reported that by combining potassium hexafluoromanganate(IV) $\left(\mathrm{K}_{2} \mathrm{MnF}_{6}\right)$ with antimony pentafluoride $\left(\mathrm{SbF}_{5}\right)$ at $150^{\circ} \mathrm{C}$, he had generated elemental fluorine. Balance the following equation representing the reaction:

$$
\mathrm{K}_{2} \mathrm{MnF}_{6}+\mathrm{SbF}_{5} \longrightarrow \mathrm{KSbF}_{6}+\mathrm{MnF}_{3}+\mathrm{F}_{2}
$$

7.119 Write a balanced equation for the preparation of (a) molecular oxygen, (b) ammonia, (c) carbon dioxide, (d) molecular hydrogen, (e) calcium oxide. Indicate the physical state of the reactants and products in each equation.

E7.120 Write chemical formulas for oxides of nitrogen with the following oxidation numbers: $+1,+2,+3,+4,+5$. (Hint: There are two oxides of nitrogen with a +4 oxidation number.)
7.121 Most transition metal ions are colored. For example, a solution of $\mathrm{CuSO}_{4}$ is blue. How would you show that the blue color is due to the hydrated $\mathrm{Cu}^{2+}$ ions and not the $\mathrm{SO}_{4}^{2-}$ ions?
7.122 In general, atomic radius and ionization energy have opposite periodic trends. Why?
7.123 Explain why the electron affinity of nitrogen is approximately zero, while the elements on either side, carbon and oxygen, have substantial positive electron affinities.

E 7.124 Consider the halogens chlorine, bromine, and iodine. The melting point and boiling point of chlorine are $-101.5^{\circ} \mathrm{C}$ and $-34.0^{\circ} \mathrm{C}$ and those of iodine are $113.7^{\circ} \mathrm{C}$ and $184.3^{\circ} \mathrm{C}$, respectively. Thus chlorine is a gas and iodine is a solid under room conditions. Estimate the melting point and boiling point of bromine. Compare your values with those from the webelements.com website.
7.125 Although it is possible to determine the second, third, and higher ionization energies of an element, the same cannot usually be done with the electron affinities of an element. Explain.
\$7.126 Little is known of the chemistry of astatine, the last member of Group 7A. Describe the physical characteristics that you would expect this halogen to have. Predict the products of the reaction between sodium astatide (NaAt) and sulfuric acid. (Hint: Sulfuric acid is an oxidizing agent.)
7.127 As discussed in the chapter, the atomic mass of argon is greater than that of potassium. This observation created a problem in the early development of the periodic table because it meant that argon should be placed after potassium. (a) How was this difficulty resolved? (b) From the following data, calculate the average atomic masses of argon and potassium: Ar-36 (35.9675 amu, 0.337 percent), Ar-38 (37.9627 amu, 0.063 percent), Ar-40 ( $39.9624 \mathrm{amu}, 99.60$ percent), K-39 ( $38.9637 \mathrm{amu}, 93.258$ percent), K-40 (39.9640 amu, 0.0117 percent), K-41 (40.9618 amu, 6.730 percent).

H7.128 Calculate the maximum wavelength of light (in nm ) required to ionize a single sodium atom.
7.129 Predict the atomic number and ground-state electron configuration of the next member of the alkali metals after francium.
7.130 Why do elements that have high ionization energies also have more positive electron affinities? Which group of elements would be an exception to this generalization?

E 7.131 The first four ionization energies of an element are approximately $738,1450,7.7 \times 10^{3}$, and $1.1 \times 10^{4} \mathrm{~kJ} / \mathrm{mol}$. To which periodic group does this element belong? Explain your answer.
7.132 Some chemists think that helium should properly be called "helon." Why? What does the ending in helium (-ium) suggest?
7.133 (a) The formula of the simplest hydrocarbon is $\mathrm{CH}_{4}$ (methane). Predict the formulas of the simplest compounds formed between hydrogen and the following elements: silicon, germanium, tin, and lead. (b) Sodium hydride $(\mathrm{NaH})$ is an ionic compound. Would you expect rubidium hydride $(\mathrm{RbH})$ to be more or less ionic than NaH ? (c) Predict the reaction between radium ( Ra ) and water. (d) When exposed to air, aluminum forms a tenacious oxide $\left(\mathrm{Al}_{2} \mathrm{O}_{3}\right)$ coating that protects the metal from corrosion. Which metal in Group 2A would you expect to exhibit similar properties? (See Page 278.)

F7.134 Match each of the elements on the right with its description on the left:
(a) A pale yellow gas that reacts with water.

Nitrogen $\left(\mathrm{N}_{2}\right)$
(b) A soft metal that reacts with water to produce hydrogen.
(c) A metalloid that is hard and has a high melting point.

Boron (B) Fluorine ( $\mathrm{F}_{2}$ ) Aluminum (Al) Sodium (Na)
(d) A colorless, odorless gas.
(e) A metal that is more reactive than iron, but does not corrode in air.
7.135 Write at least two paragraphs describing the importance of the periodic table. Pay particular attention to the significance of the position of an element in the table and how the position relates to the chemical and physical properties of the element.
7.136 On one graph, plot the effective nuclear charge (shown in parentheses) and atomic radius (see Figure 7.6) versus atomic number for the second-period elements: $\mathrm{Li}(1.28), \mathrm{Be}(1.91)$, $\mathrm{B}(2.42), \mathrm{C}(3.14), \mathrm{N}(3.83), \mathrm{O}(4.45), \mathrm{F}(5.10), \mathrm{Ne}(5.76)$. Comment on the trends.
7.137 One allotropic form of an element X is a colorless crystalline solid. The reaction of X with an excess amount of oxygen produces a colorless gas. This gas dissolves in water to yield an acidic solution. Choose one of the following elements that matches X: (a) sulfur, (b) phosphorus, (c) carbon, (d) boron, (e) silicon.

G 7.138 The ionization energy of a certain element is $412 \mathrm{~kJ} / \mathrm{mol}$. When the atoms of this element are in the first excited state, however, the ionization energy is only $126 \mathrm{~kJ} / \mathrm{mol}$. Based on this information, calculate the wavelength of light emitted in a transition from the first excited state to the ground state.
7.139 One way to estimate the effective charge $\left(Z_{\text {eff }}\right)$ of a many-electron atom is to use the equation $I E_{1}=(1312 \mathrm{~kJ} / \mathrm{mol})\left(Z_{\text {eff }}^{2} / n^{2}\right)$, where $I E_{1}$ is the first ionization energy and $n$ is the principal quantum number of the shell in which the electron resides. Use this equation to calculate the effective charges of $\mathrm{Li}, \mathrm{Na}$, and K. Also calculate $Z_{\text {eff }} / n$ for each metal. Comment on your results.
7.140 Use your knowledge of thermochemistry to calculate the $\Delta H$ for the following processes: $\left(\right.$ a) $\mathrm{Cl}^{-}(g) \longrightarrow \mathrm{Cl}^{+}(g)+2 e^{-}$and (b) $\mathrm{K}^{+}(g)+2 e^{-} \longrightarrow \mathrm{K}^{-}(g)$.
7.141 To prevent the formation of oxides, peroxides, and superoxides, alkali metals are sometimes stored in an inert atmosphere. Which of the following gases should not be used for lithium: $\mathrm{Ne}, \mathrm{Ar}$, $\mathrm{N}_{2}, \mathrm{Kr}$ ? Explain. (Hint: As mentioned in the chapter, Li and Mg exhibit a diagonal relationship. Compare the common compounds of these two elements.)

## Pre-Professional Practice Exam Problems: Physical and Biological Sciences

These questions are not based on a descriptive passage.

1. A halogen has valence electrons in which orbitals?
a) $s$
b) $s$ and $p$
c) $p$
d) $s$, $p$, and $d$
2. How many subshells does a shell with principal quantum number $n$ contain?
a) $n$
b) $n^{2}$
c) $n-1$
d) $2 n-1$
3. In a shell that contains an $f$ subshell, what is the ratio of $f$ orbitals to $s$ orbitals?
a) $14: 1$
b) $7: 1$
c) $7: 3$
d) $7: 5$
4. What is the maximum number of electrons that can be in the $n=3$ shell?
a) 2
b) 6
c) 8
d) 18

## What Chemical Bonds Have to Do with Explosives

When the Swedish chemist Alfred Nobel died in 1896, his will specified that the bulk of his considerable fortune was to be used to establish the prizes that bear his name. The prizes, given annually in five categories (Chemistry, Physics, Physiology or Medicine, Literature, and Peace), are intended to recognize significant contributions to the betterment of humankind. In life, Nobel had been a prolific scientist and entrepreneur. He held more than 300 patents, including the one for dynamite, a stabilized form of the explosive nitroglycerin. His extensive work on the development and manufacture of explosives earned him the title "merchant of death" and was the cause of personal tragedy when his younger brother was killed in an explosion at one of the family's factories.

Ironically, toward the end of his life, Nobel developed heart-disease related chest pain (angina pectoris) and was directed by his physician to take nitroglycerin orally, which Nobel refused to do. Glyceryl trinitrate, the name used by the medical community-perhaps to avoid the impression that doctors are prescribing explosives to patients-still is widely used to treat the symptoms of heart disease and other medical conditions. One of the more recently developed and intriguing uses of nitroglycerin is its placement in the tip of a condom to stimulate an erection.

Both the explosive nature of nitroglycerin and its effectiveness in treating such conditions as heart disease and erectile dysfunction can be illuminated by an understanding of the basic concepts of chemical bonding.

Student Annotation: A sixth prize, the Nobel Memorial Prize in Economics, is awarded along with the others but was not specified in Nobel's will, and it is not really a Nobel Prize.

Nitroglycerin

At the end of this chapter, you will be able to answer a series of questions about nitric oxide and nitroglycerin [ $n$ Page 329].

## In This Chapter, You Will Learn:

About two different types of chemical bonds, called ionic and covalent. You will also learn how to represent atoms and atomic ions using Lewis dot symbols and how to represent molecules and polyatomic ions using Lewis structures.

## Before you begin, you should review

- Atomic radius [K4 Section 7.4]
- Ions of main group elements [K4 Section 7.5]

Student Annotation: Remember that for two species to be isoelectronic they must have exactly the same electron configuration [144 Section 7.5].

Student Annotation: As we will see shortly [ $D$ Section 8.8], a larger nonmetal atom (one in the third period or beyond) can actually form as many bonds as the total number of dots in its Lewis dot symbol.

### 8.1 Lewis Dot Symbols

The development of the periodic table and the concept of electron configuration gave chemists a way to explain the formation of compounds. The explanation, formulated by Gilbert Lewis, ${ }^{1}$ is that atoms combine to achieve a more stable electron configuration. Maximum stability results when an atom is isoelectronic with a noble gas.

When atoms interact to form compounds, it is their valence electrons that actually interact. Therefore, it is helpful to have a method for depicting the valence electrons of the atoms involved. This can be done using Lewis dot symbols. A Lewis dot symbol consists of the element's symbol surrounded by dots, where each dot represents a valence electron. For the main group elements, the number of dots in the Lewis dot symbol is the same as the group number, as shown in Figure 8.1. (Because they have incompletely filled inner shells, transition metals typically are not represented with Lewis dot symbols.)

Figure 8.1 shows that dots are placed above and below as well as to the left and right of the symbol. The exact order in which the dots are placed around the element symbol is not important, but the number of dots is. Thus, any of the following would be correct for the Lewis dot symbol for boron:

$$
\dot{\mathrm{B}} \quad \quad \dot{\mathrm{~B}} . \quad \cdot \dot{\mathrm{B}} \quad \quad \dot{\mathrm{~B}}
$$

When writing Lewis dot symbols, though, we do not "pair" dots until absolutely necessary. Thus, we would not represent boron with a pair of dots on one side and a single dot on another.

For main group metals such as Na or Mg , the number of dots in the Lewis dot symbol is the number of electrons that are lost when the atom forms a cation that is isoelectronic with the preceding noble gas. For nonmetals of the second period (B through F), the number of unpaired dots is the number of bonds the atom can form.

In addition to atoms, we can also represent atomic ions with Lewis dot symbols. To do so, we simply add (for anions) or subtract (for cations) the appropriate number of dots from the Lewis dot symbol of the atom and include the ion's charge.

Sample Problem 8.1 shows how to use Lewis dot symbols to represent atomic ions.

## Sample Problem 8.1

Write Lewis dot symbols for (a) fluoride ion $\left(\mathrm{F}^{-}\right)$, (b) potassium ion $\left(\mathrm{K}^{+}\right)$, and (c) sulfide ion $\left(\mathrm{S}^{2-}\right)$.
Strategy Starting with the Lewis dot symbol for each element, add dots (for anions) or remove dots (for cations) as needed to achieve the correct charge on each ion. Don't forget to include the appropriate charge on the Lewis dot symbol.
Setup The Lewis dot symbols for $\mathrm{F}, \mathrm{K}$, and S are $: \underset{\mathrm{:}}{\mathrm{~F}} \cdot, \mathrm{~K}$, and $\cdot \stackrel{\mathrm{S}}{\cdot} \cdot$, respectively.
Solution (a) $[\ddot{\mathrm{E}} .:]^{-}$
(b) $\mathrm{K}^{+}$
(c) $[: \ddot{S}:]^{2-}$

Practice Problem A Write Lewis dot symbols for (a) $\mathrm{Ca}^{2+}$, (b) $\mathrm{N}^{3-}$, and (c) $\mathrm{I}^{-}$.
FPractice Problem B Indicate the charge on each of the ions represented by the following Lewis dot symbols: (a) $[: \ddot{O} \cdot \cdot]$ ?, (b) $H^{?}$, and (c) $[\ddot{\ddot{P}}]^{?}$.

[^22]

## Checkpoint 8.1 Lewis Dot Symbols

8.1.1 Using only a periodic table, determine the correct Lewis dot symbol for a silicon (Si) atom.
a) $: \mathrm{Si}:$
b) $\cdot \dot{S i} \cdot$
c) $: \dot{\mathrm{Si}}$ -
d) $\cdot \mathrm{Si} \cdot$
e) $: \mathrm{Si}$
8.1.2 Using only a periodic table, determine the correct Lewis dot symbol for the bromide ion $\left(\mathrm{Br}^{-}\right)$.
a) $[\ddot{\mathrm{B}} \mathrm{r} \cdot]^{-}$
b) $[: \ddot{\mathrm{B}} \mathrm{r}]^{-}$
c) $[\ddot{\mathrm{B} \cdot} \cdot]^{-}$
d) $[\mathrm{Br} \cdot]^{-}$
e) $[: \ddot{\mathrm{Br}}:]^{-}$
8.1.3 To which group does element X belong if its Lewis symbol is $\cdot \ddot{\mathrm{X}} \cdot$ ?
a) 1 A
b) 2 A
c) 3 A
d) 4 A
e) 5 A
f) 6 A
g) 7 A
h) It is not possible to tell.
8.1.4 To which group does element $Y$ belong if the Lewis symbol for its anion is $[\ddot{\mathrm{Y}}:]^{m-}$, where $m$ represents the charge?
a) 4 A
b) 5 A
c) 6 A
d) 7 A
e) It is not possible to tell.

### 8.2 Ionic Bonding

Recall from Chapter 7 that atoms of elements with low ionization energies tend to form cations, while those with high positive electron affinities tend to form anions. Ionic bonding refers to the electrostatic attraction that holds these oppositely charged ions together in an ionic compound, such as $\mathrm{K}^{+}$and $\mathrm{I}^{-}$in potassium iodide (KI), the "iodizing" ingredient in iodized salt. The electron configuration of potassium is $[\mathrm{Ar}] 4 s^{1}$, and that of iodine is $[\mathrm{Kr}] 5 s^{2} 4 d^{10} 5 p^{5}$. When potassium and iodine atoms come into contact with each other, the valence electron of potassium is transferred to the iodine atom. We can imagine these processes taking place separately and represent each process using Lewis dot symbols.

$$
\begin{aligned}
\cdot \mathrm{K} & \rightarrow \mathrm{~K}^{+}+e^{-} \\
: \ddot{\mathrm{I}} .+e^{-} & \rightarrow\left[\ddot{\mathrm{I}: \cdot]^{-}}\right.
\end{aligned}
$$

Figure 8.1 Lewis dot symbols of the main group elements.

Student Annotation: lodized salt is used to prevent the devastating effects of iodine deficiency disorders, which include stillbirths, birth defects, and mental retardation.

Student Annotation: Remember that the electron affinity, EA, is the energy released when a gaseous atom accepts an electron. A positive $E A$ corresponds to a negative $\Delta H$ for the process [ 14 Section 7.4]. Hess's law says that we can add the $\Delta H$ values for the individual steps to determine the overall $\Delta H$ [ 14 Section 5.5].

Student Annotation: Recall that a lattice is a three-dimensional array of interspersed cations and anions [ 14 Section 2.7].

The sum of these two equations is

$$
\mathrm{K} \cdot+: \ddot{\mathrm{I}} \cdot \rightarrow \mathrm{~K}^{+}+\left[\ddot{\ddot{\mathrm{I}} \cdot]^{-}}\right.
$$

The electrostatic attraction between the resulting cation and anion draws them together to form the electrically neutral compound KI.

The net energy change associated with the formation of $\mathrm{K}^{+}$and $\mathrm{I}^{-}$ions is endothermic; that is, energy must be supplied for the overall transfer of an electron from K to I to take place. The ionization of potassium requires the input of $419 \mathrm{~kJ} / \mathrm{mol}$, and the electron affinity of iodine is only $295 \mathrm{~kJ} / \mathrm{mol}$ [ 144 Section 7.4]. If a mole of KI were to form as we have described it, an input of $[419+(-295)]=124 \mathrm{~kJ}$ of energy would be required. Ionic compounds do form, though, and often in vigorous reactions. In fact, the formation of ionic bonds is highly exothermic and more than compensates for the energy input required to transfer electrons from metal atoms to nonmetal atoms. We can quantify the energy change associated with the formation of ionic bonds with lattice energy.

## Lattice Energy

Lattice energy is the amount of energy required to convert a mole of ionic solid to its constituent ions in the gas phase. For example, the lattice energy of potassium iodide is $632 \mathrm{~kJ} / \mathrm{mol}$. Thus, it takes 632 kJ of energy to convert 1 mole of $\mathrm{KI}(s)$ to 1 mole each of $\mathrm{K}^{+}(g)$ and $\mathrm{I}^{-}(g)$.

$$
\mathrm{KI}(s) \longrightarrow \mathrm{K}^{+}(g)+\mathrm{I}^{-}(g) \quad \Delta H=632 \mathrm{~kJ} / \mathrm{mol}
$$

The magnitude of lattice energy is a measure of an ionic compound's stability. The greater the lattice energy, the more stable the compound. Table 8.1 lists the lattice energies for some ionic compounds.

Lattice energy depends on the magnitudes of the charges and on the distance between them. For example, LiI, NaI, and KI all have the same anion $\left(\mathrm{I}^{-}\right)$and all have cations with the same charge $(+1)$. The trend in their lattice energies $(\mathrm{LiI}>\mathrm{NaI}>\mathrm{KI})$ can be explained on the basis of ionic radius. The radii of alkali metal ions increase as we move down a group in the periodic table $\left(r_{\mathrm{Li}+}<r_{\mathrm{Na}+}<r_{\mathrm{K}+}\right)$ [/4 Section 7.6]. Knowing the radius of each ion, we can use Coulomb's law to compare the attractive forces between the ions in these three compounds:

LiI, with the smallest distance between ions, has the strongest attractive forces. It should therefore have the largest lattice energy. KI, with the largest distance between ions, has the weakest attractive forces, and should have the smallest lattice energy. NaI has an intermediate distance between ions and should have an intermediate lattice energy. Thus, Coulomb's law correctly predicts the relative magnitudes of the lattice energies of LiI, NaI, and KI.

Now consider the compounds LiF and MgO . With the distances between ions roughly equal $(0.76+1.33=2.09$ for LiF versus $0.72+1.40=2.12 \AA$ for MgO$)$ and the magnitude of each

| TABLE 8.1 | Lattice Energies of Selected Ionic Compounds |  |
| :---: | :---: | :---: |
| Compound | Lattice Energy (kJ/mol) | Melting Point ( ${ }^{\circ} \mathrm{C}$ ) |
| LiF | 1017 | 845 |
| LiCl | 860 | 610 |
| LiBr | 787 | 550 |
| LiI | 732 | 450 |
| NaCl | 787 | 801 |
| NaBr | 736 | 750 |
| NaI | 686 | 662 |
| KCl | 699 | 772 |
| KBr | 689 | 735 |
| KI | 632 | 680 |
| $\mathrm{MgCl}_{2}$ | 2527 | 714 |
| $\mathrm{Na}_{2} \mathrm{O}$ | 2570 | Sub |
| $\mathrm{MgO}^{*}$ | 3890 | 2800 |

* $\mathrm{Na}_{2} \mathrm{O}$ sublimes at $1275^{\circ} \mathrm{C}$.
charge increased by a factor of 2 in MgO as compared to LiF , the lattice energy of MgO is roughly four times as large as that of LiF:

Sample Problem 8.2 shows how to use ionic radii and Coulomb's law to compare lattice energies for ionic compounds.

## Sample Problem 8.2

Arrange $\mathrm{MgO}, \mathrm{CaO}$, and SrO in order of increasing lattice energy.
Strategy Consider the charges on the ions and the distances between them. Apply Coulomb's law to determine the relative lattice energies.

Setup $\mathrm{MgO}, \mathrm{CaO}$, and SrO all contain the same anion $\left(\mathrm{O}^{2-}\right)$, and all contain cations with the same charge ( +2 ). In this case, then, the distance between ions will determine the relative lattice energies. Recall that lattice energy increases as the distance between ions decreases (because the force between oppositely charged particles increases as the distance between them decreases). Because all three compounds contain the same anion, we need only consider the radii of the cations when determining the distance between ions. From Figure 7.6 , the ionic radii are $0.72 \AA\left(\mathrm{Mg}^{2+}\right), 1.00 \AA\left(\mathrm{Ca}^{2+}\right)$, and $1.18 \AA\left(\mathrm{Sr}^{2+}\right)$.

Think About It $\mathrm{Mg}, \mathrm{Ca}$, and Sr are all Group 2A metals, so we could have predicted this result without knowing their radii. Recall that ionic radii increase as we move down a column in the periodic table, and charges that are farther apart are more easily separated (meaning the lattice energy will be smaller). The lattice energies of $\mathrm{SrO}, \mathrm{CaO}$, and MgO are 3217, 3414, and $3890 \mathrm{~kJ} / \mathrm{mol}$, respectively.

Media Player/MPEG Animation: Figure 8.3, Born-Haber Cycle, pp. 304-305.

Solution MgO has the smallest distance between ions, whereas SrO has the largest distance between ions. Therefore, in order of increasing lattice energy: $\mathrm{SrO}<\mathrm{CaO}<\mathrm{MgO}$.

Practice Problem A Determine which compound has the larger lattice energy: $\mathrm{MgCl}_{2}$ or $\mathrm{SrCl}_{2}$.
EPractice Problem B Arrange the compounds $\mathrm{NaF}, \mathrm{MgO}$, and AlN in order of increasing lattice energy.

Although lattice energy is a useful measure of an ionic compound's stability, it is not a quantity that we can measure directly. Instead, we use various thermodynamic quantities that can be measured, and calculate lattice energy using Hess's law [ 14 Section 5.5].

## The Born-Haber Cycle

We have described the formation of an ionic compound as though it happens when gaseous ions coalesce into a solid. In fact, the reactions that produce ionic solids generally do not occur this way. Figure 8.2 illustrates the formation of sodium chloride $(\mathrm{NaCl})$ from its constituent elements.

We can imagine the reaction of $\mathrm{Na}(s)$ and $\mathrm{Cl}_{2}(g)$ to form $\mathrm{NaCl}(s)$ as taking place in a series of steps for which most of the energy changes can be measured directly (See Table 8.2). Using these energy changes and the enthalpy of formation for NaCl , we can calculate the lattice energy using Hess's law. This method of determining the lattice energy is known as the Born-Haber cycle.

The net reaction resulting from the series of steps in Table 8.2 is

$$
\mathrm{Na}(s)+\frac{1}{2} \mathrm{Cl}_{2}(g) \longrightarrow \mathrm{Na}^{+}(g)+\mathrm{Cl}^{-}(g)
$$

The final step in the formation of $\mathrm{NaCl}(g)$ would be the coalescence of $\mathrm{Na}^{+}(g)+\mathrm{Cl}^{-}(g)$. This is the step for which we cannot measure the energy change directly. However, we can measure the standard heat of formation of $\mathrm{NaCl}(s)$. (It is tabulated in Appendix 2 as $-410.9 \mathrm{~kJ} / \mathrm{mol}$.) Although the formation of $\mathrm{NaCl}(s)$ from its constituent elements is not actually a step in our imaginary process, knowing its value enables us to calculate the lattice energy of NaCl . Figure 8.3 illustrates how this is done using all of these thermodynamic data and Hess's law.

Sample Problem 8.3 shows how to use the Born-Haber cycle to calculate the lattice energy.

## Sample Problem 8.3

Using data from Figures 7.8 and 7.10 and Appendix 2, calculate the lattice energy of cesium chloride ( CsCl ).

Strategy Using Figure 8.3 as a guide, combine the pertinent thermodynamic data and use Hess's law to calculate the lattice energy.

Setup From Figure 7.8, $I E_{1}(\mathrm{Cs})=376 \mathrm{~kJ} / \mathrm{mol}$. From Figure 7.10, $E A_{1}(\mathrm{Cl})=349.0 \mathrm{~kJ} / \mathrm{mol}$. From Appendix $2, \Delta H_{\mathrm{f}}^{\circ}[\mathrm{Cs}(g)]=76.50 \mathrm{~kJ} / \mathrm{mol}, \Delta H_{\mathrm{f}}^{\circ}[\mathrm{Cl}(g)]=121.7 \mathrm{~kJ} / \mathrm{mol}$, and $\Delta H_{\mathrm{f}}^{\circ}[\mathrm{CsCl}(s)]=$ $-422.8 \mathrm{~kJ} / \mathrm{mol}$. Because we are interested in magnitudes only, we can use the absolute values of the thermodynamic data. And, because only the standard heat of formation of $\mathrm{CsCl}(s)$ is a negative number, it is the only one for which the sign changes.

## Solution

$$
\begin{gathered}
\left\{\Delta H_{\mathrm{f}}^{\circ}[\mathrm{Cs}(g)]+\Delta H_{\mathrm{f}}^{\circ}[\mathrm{Cl}(g)]+I E_{1}(\mathrm{Cs})+\left|\Delta H_{\mathrm{f}}^{\circ}[\mathrm{CsCl}(s)]\right|\right\}-E A_{1}(\mathrm{Cl})=\text { lattice energy } \\
=(76.50 \mathrm{~kJ} / \mathrm{mol}+121.7 \mathrm{~kJ} / \mathrm{mol}+376 \mathrm{~kJ} / \mathrm{mol}+422.8 \mathrm{~kJ} / \mathrm{mol})-349.0 \mathrm{~kJ} / \mathrm{mol} \\
=648 \mathrm{~kJ} / \mathrm{mol}
\end{gathered}
$$

Practice Problem A Using data from Figures 7.8 and 7.10 and Appendix 2, calculate the lattice energy of rubidium iodide (RbI).

GPractice Problem B The lattice energy of MgO is $3890 \mathrm{~kJ} / \mathrm{mol}$, and the second ionization energy $\left(I E_{2}\right)$ of Mg is $1450.6 \mathrm{~kJ} / \mathrm{mol}$. Using these data, as well as data from Figures 7.8 and 7.10 and Appendix 2, determine the second electron affinity for oxygen, $E A_{2}(\mathrm{O})$.

Figure 8.2 Sodium metal and chlorine gas combine to produce sodium chloride in a highly exothermic reaction.
TABLE 8.2 $\quad$ Hypothetical Steps in the Formation of $\mathrm{Na}^{+}(g)$ and $\mathrm{Cl}^{-}(g)$ from $\mathrm{Na}(s)$ and $\mathrm{Cl}_{2}(g)$

| Chemical Equation | Energy Change (kJ/mol) |
| :--- | :---: |
| $\mathrm{Na}(s) \longrightarrow \mathrm{Na}(g)$ | $107.7^{*}$ |
| $\frac{1}{2} \mathrm{Cl}_{2}(g) \longrightarrow \mathrm{Cl}(g)$ | $121.7^{\dagger}$ |
| $\mathrm{Na}(g) \longrightarrow \mathrm{Na}^{+}(g)+e^{-}$ | $495.9^{\ddagger}$ |
| $\mathrm{Cl}(g)+e^{-} \longrightarrow \mathrm{Cl}^{-}(g)$ | $-349^{\S}$ |

*Standard heat of formation $\left(\Delta H_{\mathrm{f}}^{\mathrm{o}}\right)$ of $\mathrm{Na}(g)$ from Appendix 2.
${ }^{\dagger}$ Standard heat of formation $\left(\Delta H_{\mathrm{f}}^{\mathrm{o}}\right)$ of $\mathrm{Cl}(\mathrm{g})$ from Appendix 2.
${ }^{*}$ First ionization energy $\left(I E_{1}\right)$ of Na from Figure 7.8.
${ }^{8} \Delta H^{\circ}$ for this process is negative. (Recall that by definition, $E A$ is the amount of energy released [ 14 Section 7.4]. This $\Delta H$ is equal to $-E A$.)

## Checkpoint 8.2 Ionic Bonding

8.2.1 Will the lattice energy of KF be larger or smaller than that of LiF , larger or smaller than that of KCl , and larger or smaller than that of KI?
a) larger, larger, and smaller
b) smaller, larger, and smaller
c) smaller, larger, and larger
d) smaller, smaller, and smaller
e) larger, smaller, and larger
8.2.2 Using the following data, calculate the lattice energy of KF : $\Delta H_{\mathrm{f}}^{\circ}[\mathrm{K}(g)]=89.99 \mathrm{~kJ} / \mathrm{mol}, \Delta H_{\mathrm{f}}^{\circ}[\mathrm{F}(g)]=80.0 \mathrm{~kJ} / \mathrm{mol}$, $I E_{1}(\mathrm{~K})=418.8 \mathrm{~kJ} / \mathrm{mol}, \Delta H_{\mathrm{f}}^{\circ}[\mathrm{KF}(\mathrm{s})]=-547 \mathrm{~kJ} / \mathrm{mol}$, and $E A_{1}(\mathrm{~F})=328 \mathrm{~kJ} / \mathrm{mol}$.
a) $808 \mathrm{~kJ} / \mathrm{mol}$
b) $-286 \mathrm{~kJ} / \mathrm{mol}$
c) $261 \mathrm{~kJ} / \mathrm{mol}$
d) $1355 \mathrm{~kJ} / \mathrm{mol}$
e) $-261 \mathrm{~kJ} / \mathrm{mol}$
8.2.3 Lattice energies are graphed for three series of compounds in which the ion charges are $+2,-2 ;+2,-1$; and $+1,-1$. The ions in each series of compounds are separated by different distances. Identify the series.

a) red $+2,-2$; blue $+1,-1$; green $+2,-1$
b) red $+2,-2$; blue $+2,-1$; green $+1,-1$
c) red $+2,-1$; blue $+2,-2$; green $+1,-1$
d) red $+1,-1$; blue $+2,-1$; green $+2,-2$
e) red $+2,-1$; blue $+1,-1$; green $+2,-2$

## Figure 8.3

## Born-Haber Cycle

## Step 4

The first ionization energy of sodium, $I E_{1}(\mathrm{Na})$, gives the amount of energy required to convert 1 mole of $\mathrm{Na}(g)$ to 1 mole of $\mathrm{Na}^{+}(\mathrm{g})$ :

$$
\begin{aligned}
\mathrm{Na}(g) & \longrightarrow \mathrm{Na}^{+}(g)+e^{-} \\
& \longrightarrow++e
\end{aligned}
$$

## Step 3

The tabulated value of $\Delta H_{\mathrm{f}}^{\circ}$ for $\mathrm{Cl}(g)$ gives the amount of energy needed to convert $\frac{1}{2}$ mole of $\mathrm{Cl}_{2}(g)$ to 1 mole of $\mathrm{Cl}(\mathrm{g})$ :

$$
\frac{1}{2} \mathrm{Cl}_{2}(g) \longrightarrow \mathrm{Cl}(g)
$$

## Step 2

The tabulated value of $\Delta H_{\mathrm{f}}^{\circ}$ for $\mathrm{Na}(g)$ gives the amount of energy needed to convert 1 mole of $\mathrm{Na}(s)$ to 1 mole of $\mathrm{Na}(g)$ :

$$
\mathrm{Na}(s) \longrightarrow \mathrm{Na}(g)
$$

## Step 1

The tabulated value of $\Delta H_{\mathrm{f}}^{\circ}$ for $\mathrm{NaCl}(s)$ gives us the energy produced when 1 mole of Na and $\frac{1}{2}$ mole of $\mathrm{Cl}_{2}$ combine to form 1 mole of NaCl :

$$
\mathrm{Na}(s)+\frac{1}{2} \mathrm{Cl}_{2}(g) \longrightarrow \mathrm{NaCl}(s)
$$

Step 1 in the Born-Haber cycle involves converting 1 mole of NaCl into 1 mole of Na and $\frac{1}{2}$ mole of $\mathrm{Cl}_{2}$ (the reverse of the $\Delta H_{\mathrm{f}}^{\circ}$ reaction):

$$
\mathrm{NaCl}(s) \longrightarrow \mathrm{Na}(s)+\frac{1}{2} \mathrm{Cl}_{2}(g)
$$

Therefore, $\Delta H$ for step 1 is $-\Delta H_{\mathrm{f}}^{\circ}[\mathrm{NaCl}(s)]$

## Step 5

The electron affinity of chlorine, $E A(\mathrm{Cl})$, gives the amount of energy produced when 1 mole of $\mathrm{Cl}(g)$ is converted to 1 mole of $\mathrm{Cl}^{-}(g)$ :

## What's the point?

Lattice energy is the energy required to convert 1 mole of an ionic solid into its constituent ions in the gas phase. In the case of NaCl , the equation representing the process is

$$
\mathrm{NaCl}(s) \longrightarrow \mathrm{Na}^{+}(g)+\mathrm{Cl}^{-}(g)
$$

Lattice energy is not a quantity that we can measure directly. Rather, we determine lattice energy by combining tabulated values of a series of quantities that can be measured directly. Although the steps in the Born-Haber cycle are not necessarily the steps that actually take place, because they combine to give the correct overall process, the energy changes associated with them can be used (with Hess's law) to determine the overall energy change.

Student Annotation: For the sake of simplicity, the shared pair of electrons can be represented by a dash, rather than by two dots: $\mathrm{H}-\mathrm{H}$.

Student Annotation: For nearly all elements, achieving a noble gas electron configuration results in eight electrons around each atom-hence the name octet rule.

Student Annotation: Lewis structures are also referred to as Lewis dot structures. In this book, we will use the term Lewis structure to avoid confusion with the term Lewis dot symbol.

Student Annotation: For H, the octet rule dictates that it have two electrons, giving it the electron configuration of the noble gas He .

### 8.3 Covalent Bonding

We learned in Section 8.2 that ionic compounds tend to form between metals and nonmetals when electrons are transferred from an element with a low ionization energy (the metal) to one with a high electron affinity (the nonmetal). When compounds form between elements with more similar properties, electrons are not transferred from one element to another but instead are shared to give each atom a noble gas electron configuration. It was Gilbert Lewis who first suggested that a chemical bond involves atoms sharing electrons, and this approach is known as the Lewis theory of bonding.

Lewis theory depicts the formation of the bond in $\mathrm{H}_{2}$ as

$$
\mathrm{H} \cdot+\cdot \mathrm{H} \rightarrow \mathrm{H}: \mathrm{H}
$$

In essence, two H atoms move close enough to each other to share the electron pair. Although there are still two atoms and just two electrons, this arrangement allows each H atom to "count" both electrons as its own and to "feel" as though it has the noble gas electron configuration of helium. This type of arrangement, where two atoms share a pair of electrons, is known as covalent bonding, and the shared pair of electrons constitutes the covalent bond. In a covalent bond, each electron in a shared pair is attracted to the nuclei of both atoms. It is this attraction that holds the two atoms together.

Lewis summarized much of his theory of chemical bonding with the octet rule. According to the octet rule, atoms will lose, gain, or share electrons to achieve a noble gas electron configuration. This rule enables us to predict many of the formulas for compounds consisting of specific elements. The octet rule holds for nearly all the compounds made up of second period elements and is therefore especially important in the study of organic compounds, which contain mostly $\mathrm{C}, \mathrm{N}$, and O atoms.

As with ionic bonding, covalent bonding of many-electron atoms involves only the valence electrons. Consider the fluorine molecule ( $\mathrm{F}_{2}$ ). The electron configuration of F is $1 s^{2} 2 s^{2} 2 p^{5}$. The $1 s$ electrons are low in energy and stay near the nucleus most of the time, so they do not participate in bond formation. Thus, each F atom has seven valence electrons (the two $2 s$ and five $2 p$ electrons). According to Figure 8.1, there is only one unpaired electron on F , so the formation of the $\mathrm{F}_{2}$ molecule can be represented as follows:

$$
: \ddot{\mathrm{F}} \cdot+\text { + } \ddot{\mathrm{F}}: \longrightarrow \text { :̣̈: }: \ddot{\mathrm{F}}: \text { or }: \ddot{\mathrm{F}}-\ddot{\mathrm{F}}:
$$

Only two valence electrons participate in the bond that forms $\mathrm{F}_{2}$. The other, nonbonding electrons, are called lone pairs-pairs of valence electrons that are not involved in covalent bond formation. Thus, each F in $\mathrm{F}_{2}$ has three lone pairs of electrons.

## Lewis Structures

The structures used to represent molecules held together by covalent bonds, such as $\mathrm{H}_{2}$ and $\mathrm{F}_{2}$, are called Lewis structures. A Lewis structure is a representation of covalent bonding in which shared electron pairs are shown either as dashes or as pairs of dots between two atoms, and lone pairs are shown as pairs of dots on individual atoms. Only valence electrons are shown in a Lewis structure.

To draw the Lewis structure of the water molecule, recall that the Lewis dot symbol for oxygen has two unpaired dots (Figure 8.1), meaning that it has two unpaired electrons and can form two bonds. Because hydrogen has only one electron, it can form only one covalent bond. Thus, the Lewis structure for water is

$$
\mathrm{H}: \ddot{O}: \mathrm{H} \quad \text { or } \quad \mathrm{H}-\ddot{\mathrm{O}}-\mathrm{H}
$$

In this case, the O atom has two lone pairs. The hydrogen atom has no lone pairs because its only valence electron is used to form a covalent bond.

In the $\mathrm{F}_{2}$ and $\mathrm{H}_{2} \mathrm{O}$ molecules, the $\mathrm{F}, \mathrm{H}$, and O atoms each achieve a stable noble gas configuration by sharing electrons, thus illustrating the octet rule:

The octet rule works best for elements in the second period of the periodic table. These elements have only $2 s$ and $2 p$ valence subshells, which can hold a total of eight electrons. When an atom of one of these elements forms a covalent compound, it can attain the noble gas electron configuration $[\mathrm{Ne}]$ by sharing electrons with other atoms in the same compound. In Section 8.8 , we will discuss some important exceptions to the octet rule.

## Multiple Bonds

Atoms can form several different types of covalent bonds, such as single bonds and multiple bonds. In a single bond, two atoms are held together by one electron pair. Multiple bonds form, on the other hand, when two atoms share two or more pairs of electrons. A multiple bond in which the atoms share two pairs of electrons is called a double bond. Double bonds are found in molecules such as carbon dioxide $\left(\mathrm{CO}_{2}\right)$ and ethylene $\left(\mathrm{C}_{2} \mathrm{H}_{4}\right)$ :

A triple bond arises when two atoms share three pairs of electrons, as in molecules such as nitrogen $\left(\mathrm{N}_{2}\right)$ and acetylene $\left(\mathrm{C}_{2} \mathrm{H}_{2}\right)$ :

In ethylene and acetylene, all the valence electrons are used in bonding; there are no lone pairs on the carbon atoms. In fact, with the important exception of carbon monoxide ( CO ), most stable molecules containing carbon do not have lone pairs on the carbon atoms.

Multiple bonds are shorter than single bonds. Bond length is defined as the distance between the nuclei of two covalently bonded atoms in a molecule (Figure 8.4). Table 8.3 lists some experimentally determined bond lengths. For a given pair of atoms, such as carbon and nitrogen, triple bonds are shorter than double bonds, and double bonds are shorter than single bonds. The shorter multiple bonds are also stronger than single bonds, as we will see in Section 8.9.

## Comparison of Ionic and Covalent Compounds

Ionic and covalent compounds differ markedly in their general physical properties because of differences in the nature of their bonds. There are two types of attractive forces in covalent compounds, the intramolecular bonding force that holds the atoms together in a molecule, and the intermolecular forces between molecules. Bond enthalpy, discussed in Section 8.9, can be used to quantify the intramolecular bonding force. Intermolecular forces are usually quite weak compared to the forces holding atoms together within a molecule, so molecules of a covalent compound are not held together tightly. As a result, covalent compounds are usually gases, liquids, or lowmelting solids.

On the other hand, the electrostatic forces holding ions together in an ionic compound are usually very strong, so ionic compounds are solids at room temperature and have high melting points. Many ionic compounds are soluble in water, and the resulting aqueous solutions conduct electricity because the compounds are strong electrolytes. Most covalent compounds are insoluble in water, or if they do dissolve, their aqueous solutions generally do not conduct electricity, because the compounds are nonelectrolytes. Molten ionic compounds conduct electricity because they contain mobile cations and anions; liquid or molten covalent compounds do not conduct electricity because no ions are present. Table 8.4 compares some of the properties of a typical ionic compound, sodium chloride $(\mathrm{NaCl})$, with those of a covalent compound, carbon tetrachloride $\left(\mathrm{CCl}_{4}\right)$.

Figure 8.4 Bond length is the distance between the nuclei of two bonded atoms.

TABLE 8.3
Average Bond Lengths of Some Common Single, Double, and Triple Bonds

| Bond <br> Type | Bond <br> Length (pm) |
| :--- | :---: |
| $\mathrm{C}-\mathrm{H}$ | 107 |
| $\mathrm{O}-\mathrm{H}$ | 96 |
| $\mathrm{C}-\mathrm{O}$ | 143 |
| $\mathrm{C}=\mathrm{O}$ | 121 |
| $\mathrm{C} \equiv \mathrm{O}$ | 113 |
| $\mathrm{C}-\mathrm{C}$ | 154 |
| $\mathrm{C}=\mathrm{C}$ | 133 |
| $\mathrm{C} \equiv \mathrm{C}$ | 120 |
| $\mathrm{C}-\mathrm{N}$ | 143 |
| $\mathrm{C}=\mathrm{N}$ | 138 |
| $\mathrm{C} \equiv \mathrm{N}$ | 116 |
| $\mathrm{~N}-\mathrm{N}$ | 147 |
| $\mathrm{~N}=\mathrm{N}$ | 124 |
| $\mathrm{~N} \equiv \mathrm{~N}$ | 110 |
| $\mathrm{~N}-\mathrm{O}$ | 136 |
| $\mathrm{~N}=\mathrm{O}$ | 122 |
| $\mathrm{O}-\mathrm{O}$ | 148 |
| $\mathrm{O}=\mathrm{O}$ | 121 |

| TABLE 8.4 | Comparison of Some Properties of an Ionic Compound $(\mathrm{NaCl})$ <br> and a Covalent Compound $\left(\mathrm{CCl}_{4}\right)$ |  |
| :--- | :--- | :--- |
| Property | $\mathbf{N a C l}$ | $\mathrm{CCl}_{4}$ |
| Appearance | White solid | Colorless liquid |
| Melting point $\left({ }^{\circ} \mathrm{C}\right)$ | 801 | -23 |
| Molar heat of fusion* $(\mathrm{kJ} / \mathrm{mol})$ | 30.2 | 2.5 |
| Boiling point $\left({ }^{\circ} \mathrm{C}\right)$ | 1413 | 76.5 |
| Molar heat of vaporization* $(\mathrm{kJ} / \mathrm{mol})$ | 600 | 30 |
| Density $\left(\mathrm{g} / \mathrm{cm}^{3}\right)$ | 2.17 | 1.59 |
| Solubility in water | High | Very low |
| Electrical conductivity |  |  |
| Solid | Poor | Poor |
| Liquid | Good | Poor |
| Aqueous | Good | Poor |

*The molar heat of fusion and molar heat of vaporization are the amounts of heat needed to melt 1 mole of the solid and to vaporize 1 mole of the liquid, respectively.

### 8.4 Electronegativity and Polarity

So far, we have described chemical bonds as either ionic, when they occur between a metal and a nonmetal, or covalent, when they occur between nonmetals. In fact, ionic and covalent bonds are simply the extremes in a spectrum of bonding. Bonds that fall between these two extremes are polar, meaning that electrons are shared but are not shared equally. Such bonds are referred to as polar covalent bonds. The following shows a comparison of the different types of bonds, where M and X represent two different elements:

Student Annotation: In fact, the transfer of electrons in NaF is nearly complete. Even in an ionic bond, the electrons in question spend a small amount of time near the cation.

Figure 8.5 Electron density maps show the distribution of charge in a covalent species $\left(\mathrm{H}_{2}\right)$, a polar covalent species (HF), and an ionic species ( NaF ). The most electron-rich regions are red; the most electron-poor regions are blue.

| $\mathrm{M}: \mathrm{X}$ | $\mathrm{M}^{\delta+} \mathrm{X}^{\delta-}$ | $\mathrm{M}^{+} \mathrm{X}^{-}$ |
| :---: | :---: | :---: |
| Pure covalent bond <br> together by equally shared <br> electrons | Polar covalent bond <br> Partially charged <br> atoms held together by <br> unequally shared electrons | Oppositely charged ions <br> held together by <br> electrostatic attraction |

To illustrate the spectrum of bonding, let's consider three substances: $\mathrm{H}_{2}, \mathrm{HF}$, and NaF . In the $\mathrm{H}_{2}$ molecule, where the two bonding atoms are identical, the electrons are shared equally. That is, the electrons in the covalent bond spend roughly the same amount of time in the vicinity of each H atom. In the HF molecule, on the other hand, where the two bonding atoms are different, the electrons are not shared equally. They spend more time in the vicinity of the F atom than in the vicinity of the H atom. (The $\delta$ symbol is used to denote partial charges on the atoms.) In NaF , the electrons are not shared at all but rather are transferred from sodium to fluorine.

One way to visualize the distribution of electrons in species such as $\mathrm{H}_{2}, \mathrm{HF}$, and NaF is to use electrostatic potential models (Figure 8.5). These models show regions where electrons spend a lot of time in red, and regions where electrons spend very little time in blue. (Regions where electrons spend a moderate amount of time appear in green.)

## Electronegativity

Electronegativity is the ability of an atom in a compound to draw electrons to itself. It determines where electrons in a compound spend most of their time. Elements with high electronegativity have a greater tendency to attract electrons than do elements with low electronegativity. Electronegativity is related to electron affinity and ionization energy. An atom such as fluorine, which has a high electron affinity (tends to accept electrons) and a high ionization energy (does not lose electrons easily), has a high electronegativity. Sodium, on the other hand, has a low electron affinity, a low ionization energy, and therefore a low electronegativity.

Electronegativity is a relative concept, meaning that an element's electronegativity can be measured only in relation to the electronegativity of other elements. Linus Pauling ${ }^{2}$ devised a method for calculating the relative electronegativities of most elements. These values are shown in Figure 8.6. In general, electronegativity increases from left to right across a period in the periodic table, as the metallic character of the elements decreases. Within each group, electronegativity decreases with increasing atomic number and increasing metallic character. The transition metals do not follow these trends. The most electronegative elements (the halogens, oxygen, nitrogen, and sulfur) are found in the upper right-hand corner of the periodic table, and the least electronegative elements (the alkali and alkaline earth metals) are clustered near the lower left-hand corner. These trends are readily apparent in the graph in Figure 8.7.

2. Linus Carl Pauling (1901-1994). American chemist. Regarded by many as the most influential chemist of the twentieth century. Pauling received the Nobel Prize in Chemistry in 1954 for his work on protein structure, and the Nobel Peace Prize in 1962 for his tireless campaign against the testing and proliferation of nuclear arms. He is the only person ever to have received two unshared Nobel Prizes.

Figure 8.6 Electronegativities of common elements.

Figure 8.7 Variation of electronegativity with atomic number.

Think About It By convention, the difference in electronegativity is always calculated by subtracting the smaller number from the larger one, so the result is always positive.

Electronegativity and electron affinity are related but distinct concepts. Both indicate the tendency of an atom to attract electrons. Electron affinity, however, refers to an isolated atom's ability to attract an additional electron in the gas phase, whereas electronegativity refers to the ability of an atom in a chemical bond (with another atom) to attract the shared electrons. Electron affinity, moreover, is an experimentally measurable quantity, whereas electronegativity is an estimated number that cannot be measured directly.

Atoms of elements with widely different electronegativities tend to form ionic compounds with each other because the atom of the less electronegative element gives up its electrons to the atom of the more electronegative element. Atoms of elements with comparable electronegativities tend to form polar covalent bonds, or simply polar bonds, with each other because the shift in electron density from one atom to the other is usually small. Only atoms of the same element, which have the same electronegativity, can be joined by a pure covalent bond.

There is no sharp distinction between nonpolar covalent and polar covalent or between polar covalent and ionic, but the following guidelines can help distinguish among them:

- A bond between atoms whose electronegativities differ by less than 0.5 is generally considered purely covalent or nonpolar.
- A bond between atoms whose electronegativities differ by the range of 0.5 to 2.0 is generally considered polar covalent.
- A bond between atoms whose electronegativities differ by 2.0 or more is generally considered ionic.

Sometimes chemists describe bonds using the term percent ionic character [ $\quad \mathrm{Page}$ 312]. A purely ionic bond would have 100 percent ionic character (although no such bond is known). A purely covalent, nonpolar bond has 0 percent ionic character.

Sample Problem 8.4 shows how to use electronegativities to identify a chemical bond as nonpolar, polar, or ionic.

## Sample Problem 8.4

Classify the following bonds as nonpolar, polar, or ionic: (a) the bond in ClF , (b) the bond in CsBr , and (c) the carbon-carbon double bond in $\mathrm{C}_{2} \mathrm{H}_{4}$.

Strategy Using the information in Figure 8.6, determine which bonds have identical, similar, and widely different electronegativities.

Setup Electronegativity values from Figure 8.6 are: $\mathrm{Cl}(3.0), \mathrm{F}(4.0), \mathrm{Cs}(0.7), \mathrm{Br}(2.8), \mathrm{C}(2.5)$.
Solution (a) The difference between the electronegativities of F and Cl is $4.0-3.0=1.0$, making the bond in ClF polar.
(b) In CsBr , the difference is $2.8-0.7=2.1$, making the bond ionic.
(c) In $\mathrm{C}_{2} \mathrm{H}_{4}$, the two atoms are identical. (Not only are they the same element, but each C atom is bonded to two H atoms.) The carbon-carbon double bond in $\mathrm{C}_{2} \mathrm{H}_{4}$ is nonpolar.

Practice Problem A Classify the following bonds as nonpolar, polar, or ionic: (a) the bonds in $\mathrm{H}_{2} \mathrm{~S}$, (b) the $\mathrm{H}-\mathrm{O}$ bonds in $\mathrm{H}_{2} \mathrm{O}_{2}$, and (c) the $\mathrm{O}-\mathrm{O}$ bond in $\mathrm{H}_{2} \mathrm{O}_{2}$.
$\$$ Practice Problem B Electrostatic potential maps are shown for HCl and LiH . Determine which diagram is which. (The H atom is shown on the left in both.)

## TABLE 8.5 Bond Lengths and Dipole Moments of the Hydrogen Halides

| Molecule | Bond Length (Å) | Dipole Moment (D) |
| :---: | :---: | :---: |
| HF | 0.92 | 1.82 |
| HCl | 1.27 | 1.08 |
| HBr | 1.41 | 0.82 |
| HI | 1.61 | 0.44 |

## Dipole Moment, Partial Charges, and Percent Ionic Character

The shift of electron density in a polar bond is symbolized by placing a crossed arrow (a dipole arrow) above the Lewis structure to indicate the direction of the shift. For example,

$$
\overrightarrow{\mathrm{H}-\mathrm{P}}:
$$

The consequent charge separation can be represented as

$$
\stackrel{\delta}{\mathrm{H}}-\ddot{\mathrm{F}}:{ }^{\delta-}
$$

A quantitative measure of the polarity of a bond is its dipole moment $(\boldsymbol{\mu})$, which is calculated as the product of the charge $(Q)$ and the distance $(r)$ between the charges:

$$
\begin{equation*}
\mu=Q \times r \tag{Equation 8.1}
\end{equation*}
$$

For a diatomic molecule containing a polar bond to be electrically neutral, the partial positive and partial negative charges must have the same magnitude. Therefore, the $Q$ term in Equation 8.1 refers to the magnitude of the partial charges and the calculated value of $\mu$ is always positive. Dipole moments are usually expressed in debye units (D), named for Peter Debye. ${ }^{3}$ In terms of more familiar SI units,

$$
1 \mathrm{D}=3.336 \times 10^{-30} \mathrm{C} \cdot \mathrm{~m}
$$

where C is coulombs and m is meters. Table 8.5 lists several polar diatomic molecules, their bond lengths, and their experimentally measured dipole moments.

Sample Problem 8.5 shows how to use bond lengths and dipole moments to determine the magnitude of the partial charges in a polar diatomic molecule.

## Sample Problem 8.5

Burns caused by hydrofluoric acid $[\mathrm{HF}(a q)]$ are unlike any other acid burns and present unique medical complications. HF solutions typically penetrate the skin and damage internal tissues, including bone, often with minimal surface damage. Less concentrated solutions actually can cause greater injury than more concentrated ones by penetrating more deeply before causing injury, thus delaying the onset of symptoms and preventing timely treatment. Determine the magnitude of the partial positive and partial negative charges in the HF molecule.

Strategy Rearrange Equation 8.1 to solve for $Q$. Convert the resulting charge in coulombs to charge in units of electronic charge.

Setup According to Table 8.5, $\mu=1.82 \mathrm{D}$ and $r=0.92 \AA$ for HF. The dipole moment must be converted from debye to $\mathrm{C} \cdot \mathrm{m}$ and the distance between the ions must be converted to meters.

$$
\begin{gathered}
\mu=1.82 \mathrm{D} \times \frac{3.336 \times 10^{-30} \mathrm{C} \cdot \mathrm{~m}}{1 \mathrm{D}}=6.07 \times 10^{-30} \mathrm{C} \cdot \mathrm{~m} \\
r=0.92 \AA \times \frac{1 \times 10^{-10} \mathrm{~m}}{1 \AA}=9.2 \times 10^{-11} \mathrm{~m}
\end{gathered}
$$

(Continued)

[^23]Student Annotation: The distance, $r_{\text {, }}$ between partial charges in a polar diatomic molecule is the bond length expressed in meters. Bond lengths are usually given in angstroms ( $\AA$ ) or picometers (pm), so it is generally necessary to convert to meters.

Student Annotation: We usually express the charge on an electron as -1 . This refers to units of electronic charge. However, remember that the charge on an electron can also be expressed in coulombs [ 14 Section 2.2]. The conversion factor between the two is necessary to calculate dipole moments: $1 \mathrm{e}^{-}=1.6022 \times 10^{-19} \mathrm{C}$.

Student Annotation: Hydrofluoric acid has several important industrial applications, including the etching of glass and the manufacture of electronic components.

## Think About It Calculated

 partial charges should always be less than 1 . If a "partial" charge were 1 or greater, it would indicate that at least one electron had been transferred from one atom to the other. Remember that polar bonds involve unequal sharing of electrons, not a complete transfer of electrons.Think About lt A purely covalent bond (in a homonuclear diatomic molecule such as $\mathrm{H}_{2}$ ) would have 0 percent ionic character. In theory, a purely ionic bond would be expected to have 100 percent ionic character, although no such bond is known.

Solution In coulombs:

$$
Q=\frac{\mu}{r}=\frac{6.07 \times 10^{-30} \mathrm{C} \cdot \mathrm{~m}}{9.2 \times 10^{-11} \mathrm{~m}}=6.598 \times 10^{-20} \mathrm{C}
$$

In units of electronic charge:

$$
6.598 \times 10^{-20} \mathrm{C} \times \frac{1 e^{-}}{1.6022 \times 10^{-19} \mathrm{C}}=0.41 e^{-}
$$

Therefore, the partial charges in HF are +0.41 and -0.41 on H and F , respectively.

$$
{ }^{+0.41} \mathrm{H}-\ddot{\mathrm{F}}:{ }^{-0.41}
$$

Practice Problem A Using data from Table 8.5, determine the magnitude of the partial charges in HBr .
EPractice Problem B Given that the partial charges on C and O in carbon monoxide are +0.020 and -0.020 , respectively, calculate the dipole moment of CO. (The distance between the partial charges, $r$, is 113 pm .)

Although the designations "covalent," "polar covalent," and "ionic" can be useful, sometimes chemists wish to describe and compare chemical bonds with more precision. For this purpose, we can use Equation 8.1 to calculate the dipole moment we would expect if the charges on the atoms were discrete instead of partial; that is, if an electron had actually been transferred from one atom to the other. Comparing this calculated dipole moment with the measured value gives us a quantitative way to describe the nature of a bond using the term percent ionic character, which is defined as the ratio of observed $\mu$ to calculated $\mu$, multiplied by 100 .

Equation 8.2 percent ionic character $=\frac{\mu \text { (observed) }}{\mu(\text { calculated assuming discrete charges) }} \times 100 \%$
Figure 8.8 illustrates the relationship between percent ionic character and the electronegativity difference in a heteronuclear diatomic molecule.

Sample Problem 8.6 shows how to calculate percent ionic character using Equation 8.2.

## Sample Problem 8.6

Using data from Table 8.5, calculate the percent ionic character of the bond in HI .
Strategy Use Equation 8.1 to calculate the dipole moment in HI assuming that the charges on H and $I$ are +1 and -1 , respectively; and use Equation 8.2 to calculate percent ionic character. The magnitude of the charges must be expressed as coulombs $\left(1 e^{-}=1.6022 \times 10^{-19} \mathrm{C}\right)$; the bond length ( $r$ ) must be expressed as meters ( $1 \AA=1 \times 10^{-10} \mathrm{~m}$ ); and the calculated dipole moment should be expressed as debyes ( $1 \mathrm{D}=3.336 \times 10^{-30} \mathrm{C} \cdot \mathrm{m}$ ).
Setup From Table 8.5, the bond length in HI is $1.61 \AA\left(1.61 \times 10^{-10} \mathrm{~m}\right)$ and the measured dipole moment of HI is 0.44 D .

Solution The dipole moment we would expect if the magnitude of charges were $1.6022 \times 10^{-19} \mathrm{C}$ is

$$
\mu=Q \times r=\left(1.6022 \times 10^{-19} \mathrm{C}\right) \times\left(1.61 \times 10^{-10} \mathrm{~m}\right)=2.58 \times 10^{-29} \mathrm{C} \cdot \mathrm{~m}
$$

Converting to debyes gives

$$
2.58 \times 10^{-29} \mathrm{C}-\mathrm{m} \times \frac{1 \mathrm{D}}{3.336 \times 10^{-30} \mathrm{C}-\mathrm{m}}=7.73 \mathrm{D}
$$

The percent ionic character of the $\mathrm{H}-\mathrm{I}$ bond is

$$
\frac{0.44 \mathrm{D}}{7.73 \mathrm{D}} \times 100 \%=5.7 \%
$$

Practice Problem A Using data from Table 8.5, calculate the percent ionic character of the bond in HF.
GPractice Problem B Using information from Figure 7.12, and given that the NaI bond has 59.7 percent ionic character, determine the measured dipole moment of NaI .

## Checkpoint 8.4 Electronegativity and Polarity

8.4.1 In which of the following molecules are the bonds most polar?
a) $\mathrm{H}_{2} \mathrm{Se}$
b) $\mathrm{H}_{2} \mathrm{O}$
c) $\mathrm{CO}_{2}$
d) $\mathrm{BCl}_{3}$
e) $\mathrm{PCl}_{5}$
8.4.2 Using data from Table 8.5, calculate the magnitude of the partial charges in HI .
a) 0.39
b) 1.8
c) 0.057
d) 0.60
e) 0.15
8.4.3 Arrange molecules A through E in order of increasing percent ionic character.

a) A $<$ B $<$ C $<$ D $<$ E
b) A $=$ B $<$ C $<$ D $<$ E
c) $\mathrm{A}=\mathrm{B}<\mathrm{C}<\mathrm{D}=\mathrm{E}$
d) $\mathrm{A}<\mathrm{B}<\mathrm{C}<$ D $=$ E
e) $\mathrm{A}<\mathrm{B}=\mathrm{C}=\mathrm{D}<\mathrm{E}$
8.4.4 Using data from Table 8.5, calculate the percent ionic character of HCl .
a) 85.0 percent
b) 6.10 percent
c) 17.7 percent
d) 2.03 percent
e) 20.3 percent

### 8.5 Drawing Lewis Structures

Although the octet rule and Lewis structures alone do not present a complete picture of covalent bonding, they do help us account for some of the properties of molecules. In addition, Lewis structures provide a starting point for the bonding theories that we will examine in Chapter 9. It is crucial, therefore, that you learn a system for drawing correct Lewis structures for molecules and polyatomic ions. The basic steps are as follows:

Figure 8.8 Relationship between percent ionic character and electronegativity difference.

Student Annotation: H cannot be a central atom because it only forms one covalent bond.

1. From the molecular formula, draw the skeletal structure of the compound, using chemical symbols and placing bonded atoms next to one another. For simple compounds, this step is fairly easy. Often there will be a unique central atom surrounded by a group of other identical atoms. In general, the least electronegative atom will be the central atom. Draw a single covalent bond (dash) between the central atom and each of the surrounding atoms. (For more complex compounds whose structures might not be obvious, you may need to be given information in addition to the molecular formula.)
2. Count the total number of valence electrons present. Remember that an element's group number $(1 \mathrm{~A}-8 \mathrm{~A})$ gives the number of valence electrons it contributes to the total number. For polyatomic ions, add electrons to the total number to account for negative charges; subtract electrons from the total number to account for positive charges.
3. For each bond (dash) in the skeletal structure, subtract two electrons from the total valence electrons (determined in step 2) to determine the number of remaining electrons.
4. Use the remaining electrons to complete the octets of the terminal atoms (those bonded to the central atom) by placing pairs of electrons on each atom. (Remember that an H atom only requires two electrons to complete its valence shell.) If there is more than one type of terminal atom, complete the octets of the most electronegative atoms first.
5. If any electrons remain after step 4, place them in pairs on the central atom.
6. If the central atom has fewer than eight electrons after completing steps 1 to 5 , move one or more pairs from the terminal atoms to form multiple bonds between the central atom and the terminal atoms.

Student Annotation: To summarize the process of drawing Lewis structures:

1. Draw the skeletal structure
2. Count the valence electrons.
3. Subtract two electrons for each bond.
4. Distribute the remaining electrons.
5. Complete the octets of all atoms.
6. Use multiple bonds if necessary.

Student Annotation: Like Lewis dot symbols for atomic anions, Lewis structures for polyatomic anions are enclosed by square brackets.

## Steps for Drawing Lewis Structures

| Step | $\mathrm{CH}_{4}$ | $\mathrm{CCl}_{4}$ | $\mathrm{H}_{2} \mathrm{O}$ | $\mathrm{O}_{2}$ | $\mathrm{CN}^{-}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 1 |  |  | $\mathrm{H}-\mathrm{O}-\mathrm{H}$ | $\mathrm{O}-\mathrm{O}$ | $\mathrm{C}-\mathrm{N}$ |
| 2 | 8 | 32 | 8 | 12 | 10 |
| 3 | $8-8=0$ | $32-8=24$ | $8-4=4$ | $12-2=10$ | $10-2=8$ |

| 6 | - | - | - | $\bigcirc$ | $[\mathrm{C} \equiv \mathrm{N}]^{-}$ |

Sample Problem 8.7 shows how to draw a Lewis structure.

## Sample Problem 8.7

Draw the Lewis structure for carbon disulfide $\left(\mathrm{CS}_{2}\right)$.
Strategy Use the procedure described in steps 1 through 6 above for drawing Lewis structures.

## Setup

Step 1: C and S have identical electronegativities. We will draw the skeletal structure with the unique atom, C , at the center.

$$
S-C-S
$$

Step 2: The total number of valence electrons is 16 , six from each $S$ atom and four from the $C$ atom $[2(6)+4=16]$.
Step 3: Subtract four electrons to account for the bonds in the skeletal structure, leaving us 12 electrons to distribute.
Step 4: Distribute the 12 remaining electrons as three lone pairs on each S atom.

$$
: \ddot{S}-C-\ddot{S}:
$$

Step 5: There are no electrons remaining after step 4, so step 5 does not apply.
Step 6: To complete carbon's octet, use one lone pair from each $S$ atom to make a double bond to the C atom.

## Solution

$\because \mathrm{S}=\mathrm{C}=\dot{\mathrm{S}} \cdot$

Practice Problem A Draw the Lewis structure for $\mathrm{NF}_{3}$.
HPractice Problem B Draw the Lewis structure for $\mathrm{ClO}_{3}^{-}$.

## Checkpoint 8.5 Drawing Lewis Structures

8.5.1 Identify the correct Lewis structure for formic acid $(\mathrm{HCOOH})$.
a) $\mathrm{H}-\ddot{\mathrm{C}}-\ddot{\mathrm{O}}-\ddot{\mathrm{O}}-\mathrm{H}$
b) $\mathrm{H}-\ddot{\mathrm{O}}=\mathrm{C}=\ddot{\mathrm{O}}-\mathrm{H}$
c) $\mathrm{H}-\ddot{\mathrm{O}}-\ddot{\mathrm{C}}-\ddot{\mathrm{O}}-\mathrm{H}$
d) $\mathrm{H}-\stackrel{\text { O: }}{\mathrm{C}}-\stackrel{\mathrm{O}}{\mathrm{O}}-\mathrm{H}$
8.5.2 Identify the correct Lewis structure for hydrogen peroxide $\left(\mathrm{H}_{2} \mathrm{O}_{2}\right)$.
a) $\mathrm{H}-\ddot{\mathrm{O}}=\ddot{\mathrm{O}}-\mathrm{H}$
b) $\mathrm{H}-\mathrm{O} \equiv \mathrm{O}-\mathrm{H}$
c) $\mathrm{H}-\ddot{\mathrm{O}}-\ddot{\mathrm{O}}-\mathrm{H}$
d) $\mathrm{H}=\mathrm{O}=\mathrm{O}=\mathrm{H}$
e) $\mathrm{H}-\mathrm{H}-\ddot{\mathrm{O}}-\ddot{\mathrm{O}}$ :

### 8.6 Lewis Structures and Formal Charge

So far you have learned two different methods of electron "bookkeeping." In Chapter 4, you learned about oxidation numbers [ 14 Section 4.4], and in Section 8.4, you learned how to calculate partial charges. There is one additional commonly used method of electron bookkeepingnamely, formal charge, which can be used to determine the most plausible Lewis structures when more than one possibility exists for a compound. Formal charge is determined by comparing the number of electrons associated with an atom in a Lewis structure with the number of electrons that would be associated with the isolated atom. In an isolated atom, the number of electrons associated with the atom is simply the number of valence electrons. (As usual, we need not be concerned with the core electrons.)

To determine the number of electrons associated with an atom in a Lewis structure, keep in mind the following:

- All the atom's nonbonding electrons are associated with the atom.
- Half of the atom's bonding electrons are associated with the atom.

$$
\text { formal charge }=\text { valence electrons }- \text { associated electrons }
$$

Equation 8.3
An atom's formal charge is calculated as follows: We can illustrate the concept of formal charge using the ozone molecule $\left(\mathrm{O}_{3}\right)$. Use the step-by-step method for drawing Lewis structures to draw the Lewis structure for ozone, and then determine the formal charge on each O atom by subtracting the number of associated electrons from the number of valence electrons.

Think About It Counting the total number of valence electrons should be relatively simple to do, but it is often done hastily and is therefore a potential source of error in this type of problem. Remember that the number of valence electrons for each element is equal to the group number of that element.

Multimedia
Chemical Bonding-formal charge calculations.

Student Annotation: While you are new at determining formal charges, it may be helpful to draw Lewis structures with all dots, rather than dashes. This can make it easier to see how many electrons are associated with each atom.

## (0) 0.0 )

Remember that for the purpose of counting associated electrons, those shared by two atoms are evenly split between them.

Think About lt The sum of formal charges $(+1)+(-1)+$ $(-1)+(0)=-1$ is equal to the overall charge on the nitrate ion.

As with oxidation numbers, the sum of the formal charges must equal the overall charge on the species [ 14 Section 4.4]. Because $\mathrm{O}_{3}$ is a molecule, its formal charges must sum to zero. For ions, the formal charges must sum to the overall charge on the ion.

Formal charges do not represent actual charges on atoms in a molecule. In the $\mathrm{O}_{3}$ molecule, for example, there is no evidence that the central atom bears a net +1 charge or that one of the terminal atoms bears a -1 charge. Assigning formal charges to the atoms in the Lewis structure merely helps us keep track of the electrons involved in bonding in the molecule.

Sample Problem 8.8 lets you practice determining formal charges.

## Sample Problem 8.8

The widespread use of fertilizers has resulted in the contamination of some groundwater with nitrates, which are potentially harmful. Nitrate toxicity is due primarily to its conversion in the body to nitrite $\left(\mathrm{NO}_{2}^{-}\right)$, which interferes with the ability of hemoglobin to transport oxygen. Determine the formal charges on each atom in the nitrate ion $\left(\mathrm{NO}_{3}^{-}\right)$.

Strategy Use steps 1 through 6 on page 314 for drawing Lewis stuctures to draw the Lewis structure of $\mathrm{NO}_{3}^{-}$. For each atom, subtract the associated electrons from the valence electrons.

## Setup

The N atom has five valence electrons and four associated electrons (one from each single bond and two from the double bond). Each singly bonded O atom has six valence electrons and seven associated electrons (six in three lone pairs and one from the single bond). The doubly bonded O atom has six valence electrons and six associated electrons (four in two lone pairs and two from the double bond).

Solution The formal charges are as follows: +1 ( N atom), -1 (singly bonded O atoms), and 0 (doubly bonded O atom).

Practice Problem A Determine the formal charges on each atom in the carbonate ion $\left(\mathrm{CO}_{3}^{2-}\right)$.
EPractice Problem B Determine the formal charges and use them to determine the overall charge, if any, on the species represented by the following Lewis structure:

Sometimes, there is more than one possible skeletal arrangement of atoms for the Lewis structure for a given species. In such cases, we often can select the best skeletal arrangement by using formal charges and the following guidelines:

- For molecules, a Lewis structure in which all formal charges are zero is preferred to one in which there are nonzero formal charges.
- Lewis structures with small formal charges $(0$ and $\pm 1)$ are preferred to those with large formal charges ( $\pm 2, \pm 3$, and so on).
- The best skeletal arrangement of atoms will give rise to Lewis structures in which the formal charges are consistent with electronegativities. For example, the more electronegative atoms should have the more negative formal charges.

Sample Problem 8.9 shows how formal charge can be used to determine the best skeletal arrangement of atoms for the Lewis structure of a molecule or polyatomic ion.

## Sample Problem 8.9

Formaldehyde $\left(\mathrm{CH}_{2} \mathrm{O}\right)$, which can be used to preserve biological specimens, is commonly sold as a $37 \%$ aqueous solution. Use formal charges to determine which skeletal arrangement of atoms shown here is the best choice for the Lewis structure of $\mathrm{CH}_{2} \mathrm{O}$.

Strategy Complete the Lewis structures for each of the $\mathrm{CH}_{2} \mathrm{O}$ skeletons shown and determine the formal charges on the atoms in each one.

Setup The completed Lewis structures for the skeletons shown are:

In the structure on the left, the formal charges are as follows:
Both H atoms: 1 valence $e^{-}-1$ associated $e^{-}$(from single bond) $=0$
C atom: 4 valence $e^{-}-5$ associated $e^{-}$(two in the lone pair, one from the single bond, and two from the double bond) $=-1$
O atom: 6 valence $e^{-}-5$ associated $e^{-}$(two from the lone pair, one from the single bond, and two from the double bond) $=+1$

$$
\begin{array}{lc} 
& \mathrm{H}-\ddot{\mathrm{C}}=\ddot{\mathrm{O}}-\mathrm{H} \\
\text { Formal charges } & 0
\end{array}-1+1 \quad 0
$$

In the structure on the right, the formal charges are as follows:
Both H atoms: 1 valence $e^{-}-1$ associated $e^{-}$(from single bond) $=0$
C atom: 4 valence $e^{-}-4$ associated $e^{-}$(one from each single bond, and two from the double bond) $=0$
O atom: 6 valence $e^{-}-6$ associated $e^{-}$(four from the two lone pairs and two from the double bond) $=0$

Formal charges all zero
Solution Of the two possible arrangements, the structure on the left has an O atom with a positive formal charge, which is inconsistent with oxygen's high electronegativity. Therefore, the structure on the right, in which both H atoms are attached directly to the C atom and all atoms have a formal charge of zero, is the better choice for the Lewis structure of $\mathrm{CH}_{2} \mathrm{O}$.

Practice Problem A Two possible arrangements are shown for the Lewis structure of a carboxyl group, -COOH . Use formal charges to determine which of the two arrangements is better.

$$
-\ddot{\mathrm{C}}-\ddot{\mathrm{O}}=\ddot{\mathrm{O}}-\mathrm{H}
$$

EPractice Problem B Use Lewis structures and formal charges to determine the best skeletal arrangement of atoms in $\mathrm{NCl}_{2}^{-}$.

Think About It For a molecule, formal charges of zero are preferred. When there are nonzero formal charges, they should be consistent with the electronegativities of the atoms in the molecule. A positive formal charge on oxygen, for example, is inconsistent with oxygen's high electronegativity.

## Checkpoint 8.6 Lewis Structures and Formal Charge

8.6.1 Determine the formal charges on $\mathrm{H}, \mathrm{C}$, and N , respectively, in HCN.
a) $0,+1$, and -1
b) $-1,+1$, and 0
c) $0,-1$, and +1
d) $0,+1$, and +1
e) 0,0 , and 0
8.6.2 Which of the Lewis structures shown is most likely preferred for $\mathrm{NCO}^{-}$?
a) $[: \stackrel{+}{\mathrm{N}}=\mathrm{C}=\dot{\mathrm{O}} \cdot]^{-}$
b) $[\ddot{\mathrm{N}}-\mathrm{C} \equiv \mathrm{O}:]^{-}$
c) $[\mathrm{N} \equiv \mathrm{C}-\ddot{O}:]$
d) $[\ddot{\mathrm{N}}-\mathrm{C}=\ddot{\mathrm{O}} \cdot]^{-}$
e) $[\stackrel{\square}{\mathrm{N}}=\mathrm{C}-\ddot{\mathrm{O}}:]^{-}$

### 8.7 Resonance

Our drawing of the Lewis structure for ozone $\left(\mathrm{O}_{3}\right)$ satisfied the octet rule for the central O atom because we placed a double bond between it and one of the two terminal $O$ atoms. In fact, we can put the double bond at either end of the molecule, as shown by the following two equivalent Lewis structures:

$$
\dot{\mathrm{O}}=\ddot{\mathrm{O}}-\ddot{\mathrm{O}}: \quad \longleftrightarrow \quad: \ddot{\mathrm{O}}-\ddot{\mathrm{O}}=\dot{\mathrm{O}} \dot{\dot{C}}
$$

A single bond between O atoms should be longer than a double bond between O atoms, but experimental evidence indicates that both of the bonds in $\mathrm{O}_{3}$ are equal in length ( 128 pm ). Because neither one of these two Lewis structures accounts for the known bond lengths in $\mathrm{O}_{3}$, we use both Lewis structures to represent the ozone molecule.

Each of the Lewis structures is called a resonance structure. A resonance structure is one of two or more Lewis structures for a single molecule that cannot be represented accurately by only one Lewis structure. The double-headed arrow indicates that the structures shown are resonance structures. Like the medieval European traveler to Africa who described a rhinoceros as a cross between a griffin and a unicorn (two familiar but imaginary animals), we describe ozone, a real molecule, in terms of two familiar but nonexistent structures.

A common misconception about resonance is that a molecule such as ozone somehow shifts quickly back and forth from one resonance structure to the other. Neither resonance structure, though, adequately represents the actual molecule, which has its own unique, stable structure. "Resonance" is a human invention, designed to address the limitations of a simple bonding model. To extend the animal analogy, a rhinoceros is a distinct, real creature, not some oscillation between the mythical griffin and unicorn!

The carbonate ion provides another example of resonance:

According to experimental evidence, all three carbon-oxygen bonds in $\mathrm{CO}_{3}^{2-}$ are equivalent. Therefore, the properties of the carbonate ion are best explained by considering its resonance structures together.

The concept of resonance applies equally well to organic systems. A good example is the benzene molecule $\left(\mathrm{C}_{6} \mathrm{H}_{6}\right)$ :

If one of these resonance structures corresponded to the actual structure of benzene, there would be two different bond lengths between adjacent C atoms, one with the properties of a single bond and the other with the properties of a double bond. In fact, the distance between all adjacent C
atoms in benzene is 140 pm , which is shorter than a $\mathrm{C}-\mathrm{C}$ bond ( 154 pm ) and longer than a $\mathrm{C}=\mathrm{C}$ bond (133 pm).

A simpler way of drawing the structure of the benzene molecule and other compounds containing the benzene ring is to show only the skeleton and not the carbon and hydrogen atoms. By this convention, the resonance structures are represented by

Note that the C atoms at the corners of the hexagon and the H atoms are not shown, although they are understood to be there. Only the bonds between the C atoms are shown.

Resonance structures differ only in the positions of their electrons-not in the positions of their atoms. Thus, $: \stackrel{N}{N}=\mathrm{N}=0^{\circ}$. and $: \mathrm{N} \equiv \mathrm{N}-\ddot{O}$ : are resonance structures of each other, whereas $: \mathrm{N}=\mathrm{N}=\dot{O}^{\circ}$ and $: \stackrel{\mathrm{N}}{\mathrm{N}}=\mathrm{O}=\mathrm{N} \dot{\mathrm{n}}$ are not.

Sample Problem 8.10 shows how to draw resonance structures.

## Sample Problem 8.10

High oil and gasoline prices have renewed interest in alternative methods of producing energy, including the "clean" burning of coal. Part of what makes "dirty" coal dirty is its high sulfur content. Burning dirty coal produces sulfur dioxide $\left(\mathrm{SO}_{2}\right)$, among other pollutants. Sulfur dioxide is oxidized in the atmosphere to form sulfur trioxide $\left(\mathrm{SO}_{3}\right)$, which subsequently combines with water to produce sulfuric acid-a major component of acid rain. Draw all possible resonance structures of sulfur trioxide.

Strategy Draw two or more Lewis structures for $\mathrm{SO}_{3}$ in which the atoms are arranged the same way but the electrons are arranged differently.

Setup Following the steps for drawing Lewis structures, we determine that a correct Lewis structure for $\mathrm{SO}_{3}$ contains two sulfur-oxygen single bonds and one sulfur-oxygen double bond.

But the double bond can be put in any one of three positions in the molecule.

Practice Problem A Draw all possible resonance structures for the nitrate ion $\left(\mathrm{NO}_{3}^{-}\right)$.
EPractice Problem B Draw three resonance structures for the thiocyanate ion ( $\mathrm{NCS}^{-}$), and determine the formal charges in each resonance structure. Based on formal charges, list the resonance structures in order of increasing relative importance.

Student Annotation: The representation of organic compounds is discussed in more detail in Chapter 10.

Think About It Always make sure that resonance structures differ only in the positions of the electrons, not in the positions of the atoms.

## Checkpoint 8.7 Resonance

8.7.1 Indicate which of the following are resonance structures of : $\ddot{\mathrm{C}} \mathrm{l}-\mathrm{Be}-\ddot{\mathrm{C}} \mathrm{l}$ : (select all that apply).
a) $: \stackrel{C l}{C l}=\mathrm{Be}=\mathrm{CI} \dot{C}$
b) $: \mathrm{Cl} \equiv \mathrm{Be}-\ddot{\mathrm{C}}:$
c) $: \mathrm{Be} \equiv \mathrm{Cl}-\ddot{\mathrm{C}}!$ :
d) : $\mathrm{C} \mathrm{l} \mid-\mathrm{Be} \equiv \mathrm{Cl}$ :
e) $: \mathrm{Be}=\mathrm{Cl}=\mathrm{Cl}!$
8.7.2 How many resonance structures can be drawn for the nitrite ion $\left(\mathrm{NO}_{2}^{-}\right)$? ( N and O must obey the octet rule.)
a) 1
b) 2
c) 3
d) 4
e) 5

### 8.8 Exceptions to the Octet Rule

The octet rule almost always holds for second-period elements. Exceptions to the octet rule fall into three categories:

1. The central atom has fewer than eight electrons due to a shortage of electrons.
2. The central atom has fewer than eight electrons due to an odd number of electrons.
3. The central atom has more than eight electrons.

## Incomplete Octets

In some compounds the number of electrons surrounding the central atom in a stable molecule is fewer than eight. Beryllium, for example, which is the Group 2A element in the second period, has the electron configuration $[\mathrm{He}] 2 s^{2}$. Thus, it has two valence electrons in the $2 s$ orbital. In the gas phase, beryllium hydride $\left(\mathrm{BeH}_{2}\right)$ exists as discrete molecules. The Lewis structure of $\mathrm{BeH}_{2}$ is

$$
\mathrm{H}-\mathrm{Be}-\mathrm{H}
$$

Only four electrons surround the Be atom, so there is no way to satisfy the octet rule for beryllium in this molecule.

Elements in Group 3A also tend to form compounds in which they are surrounded by fewer than eight electrons. Boron, for example, has the electron configuration $[\mathrm{He}] 2 s^{2} 2 p^{1}$, so it has only three valence electrons. Boron reacts with the halogens to form a class of compounds having the general formula $\mathrm{BX}_{3}$, where X is a halogen atom. Thus, there are only six electrons around the boron atom in boron trifluoride:

We actually can satisfy the octet rule for boron in $\mathrm{BF}_{3}$ by using a lone pair on one of the F atoms to form a double bond between the F atom and boron. This gives rise to three additional resonance structures:

Although these resonance structures result in boron carrying a negative formal charge while fluorine carries a positive formal charge, a situation that is inconsistent with the electronegativities of the atoms involved, the experimentally determined bond length in $\mathrm{BF}_{3}(130.9 \mathrm{pm})$ is shorter than a single bond ( 137.3 pm ). The shorter bond length would appear to support the idea behind the three resonance structures.

On the other hand, boron trifluoride combines with ammonia in a reaction that is better represented using the Lewis structure in which boron has only six valence electrons around it:

It seems, then, that the properties of $\mathrm{BF}_{3}$ are best explained by all four resonance structures.
The $\mathrm{B}-\mathrm{N}$ bond in $\mathrm{F}_{3} \mathrm{~B}-\mathrm{NH}_{3}$ is different from the covalent bonds discussed so far in the sense that both electrons are contributed by the N atom. This type of bond is called a coordinate covalent bond (also referred to as a dative bond), which is defined as a covalent bond in which one of the atoms donates both electrons. Although the properties of a coordinate covalent bond do not differ from those of a normal covalent bond (i.e., the electrons are shared in both cases), the distinction is useful for keeping track of valence electrons and assigning formal charges.

## Odd Numbers of Electrons

Some molecules, such as nitrogen dioxide $\left(\mathrm{NO}_{2}\right)$, contain an odd number of electrons.

$$
: \dot{O}=\dot{\mathrm{N}}-\ddot{\mathrm{O}}:
$$

Because we need an even number of electrons for every atom in a molecule to have a complete octet, the octet rule cannot be obeyed for all the atoms in these molecules. Molecules with an odd number of electrons are sometimes referred to as free radicals (or just radicals). Many radicals are highly reactive, because there is a tendency for the unpaired electron to form a covalent bond with an unpaired electron on another molecule. When two nitrogen dioxide molecules collide, for example, they form dinitrogen tetroxide, a molecule in which the octet rule is satisfied for both the N and O atoms.

## Bringing Chemistry to Life

## The Power of Radicals

Beginning about a week after the September 11, 2001 attacks, letters containing anthrax bacteria were mailed to several news media offices and to two U.S. senators. Of the 22 people who subsequently contracted anthrax, five died. Anthrax is a spore-forming bacterium (Bacillus anthracis) and, like smallpox, is classified by the CDC as a Category A bioterrorism agent. Spore-forming bacteria are notoriously difficult to kill, making the cleanup of the buildings contaminated by anthrax costly and time-consuming. The American Media Inc. (AMI) building in Boca Raton, Florida, was not deemed safe to enter until July of 2004, after it had been treated with chlorine dioxide $\left(\mathrm{ClO}_{2}\right)$, the only structural fumigant approved by the Environmental Protection Agency (EPA) for anthrax decontamination. The effectiveness of $\mathrm{ClO}_{2}$ in killing anthrax and other hardy biological agents stems in part from its being a radical, meaning that it contains an odd number of electrons.

Sample Problem 8.11 lets you practice drawing Lewis structures for species with odd numbers of electrons.

## Sample Problem 8.11

Draw the Lewis structure of chlorine dioxide $\left(\mathrm{ClO}_{2}\right)$.
Strategy The skeletal structure is

$$
\mathrm{O}-\mathrm{Cl}-\mathrm{O}
$$

This puts the unique atom, Cl , in the center and puts the more electronegative O atoms in terminal positions.

Setup There are a total of 19 valence electrons (seven from the Cl and six from each of the two O atoms). We subtract four electrons to account for the two bonds in the skeleton, leaving us with 15 electrons to distribute as follows: three lone pairs on each O atom, one lone pair on the Cl atom, and the last remaining electron also on the Cl atom.

Solution : $\ddot{\mathrm{O}}-\ddot{\mathrm{C}} \mathrm{l}-\ddot{\mathrm{O}}:$

Practice Problem A Draw the Lewis structure for the OH species.
EPractice Problem B Draw the Lewis structure for the $\mathrm{NS}_{2}$ molecule.

The American Media Inc. building in Boca Raton, Florida.

Severe flooding in New Orleans after Hurricane Katrina in 2005.

Think About It $\mathrm{ClO}_{2}$ is used primarily to bleach wood pulp in the manufacture of paper, but it is also used to bleach flour, disinfect drinking water, and deodorize certain industrial facilities. Recently, it has been used to eradicate the toxic mold in homes in New Orleans that were damaged by the devastating floodwaters of Hurricane Katrina in 2005.

Student Annotation: The OH species is a radical, not to be confused with the hydroxide ion $\left(\mathrm{OH}^{-}\right)$.

## Expanded Octets

Atoms of the second-period elements cannot have more than eight valence electrons around them, but atoms of elements in and beyond the third period of the periodic table can. In addition to the $3 s$ and $3 p$ orbitals, elements in the third period also have $3 d$ orbitals that can be used in bonding. These orbitals enable an atom to form an expanded octet. One compound in which there is an
expanded octet is sulfur hexafluoride, a very stable compound. The electron configuration of sulfur is $[\mathrm{Ne}] 3 s^{2} 3 p^{4}$. In $\mathrm{SF}_{6}$, each of sulfur's 6 valence electrons forms a covalent bond with a fluorine atom, so there are 12 electrons around the central sulfur atom:

In Chapter 9 we will see that these 12 electrons, or six bonding pairs, are accommodated in six orbitals that originate from the one $3 s$, the three $3 p$, and two of the five $3 d$ orbitals. Sulfur also forms many compounds in which it does obey the octet rule. In sulfur dichloride, for instance, $S$ is surrounded by only eight electrons:

$$
: \ddot{\mathrm{C}} \mid-\ddot{S}-\ddot{\mathrm{C}} \mathrm{C}:
$$

Sample Problems 8.12 and 8.13 involve compounds that do not obey the octet rule.

## Sample Problem 8.12

Draw the Lewis structure of boron triiodide $\left(\mathrm{BI}_{3}\right)$.
Strategy Follow the step-by-step procedure for drawing Lewis structures. The skeletal structure is

$$
\stackrel{I}{\mid}
$$

Setup There are a total of 24 valence electrons in $\mathrm{BI}_{3}$ (three from the B and seven from each of the three I atoms). We subtract six electrons to account for the three bonds in the skeleton, leaving 18 electrons to distribute as three lone pairs on each I atom.

## Solution

$$
\begin{gathered}
: \mathrm{Ï:} \\
: \ddot{\mathrm{I}}-\mathrm{B}-\mathrm{Ï:}
\end{gathered}
$$

Think About lt Boron is one of the elements that does not always follow the octet rule. Like $\mathrm{BF}_{3}$, however, $\mathrm{BI}_{3}$ can be drawn with a double bond to satisfy the octet of boron. This gives rise to a total of four resonance structures:

Practice Problem A Draw the Lewis structure of beryllium fluoride $\left(\mathrm{BeF}_{2}\right)$.

GPractice Problem B Draw the Lewis structure of boron trichloride $\left(\mathrm{BCl}_{3}\right)$.

Student Annotation: $\mathrm{BeF}_{2}$ is also known as beryllium difluoride, but because this is the only compound that beryllium forms with fluorine, the name beryllium fluoride is unambiguous.

Think About It Always make sure that the number of electrons represented in your final Lewis structure matches the total number of valence electrons you are supposed to have.

## Sample Problem 8.13

Draw the Lewis structure of arsenic pentafluoride $\left(\mathrm{AsF}_{5}\right)$.
Strategy Follow the steps for drawing Lewis structures. The skeletal structure already has more than an octet around the As atom.

Setup There are 40 total valence electrons [five from As (Group 5A) and seven from each of the five F atoms (Group 7A)]. We subtract 10 electrons to account for the five bonds in the skeleton, leaving 30 to be distributed. Next, place three lone pairs on each F atom, thereby completing all their octets and using up all the electrons.

## Solution

Practice Problem A Draw the Lewis structure of phosphorus pentachloride $\left(\mathrm{PCl}_{5}\right)$.
SPractice Problem B Draw the Lewis structure of antimony pentafluoride $\left(\mathrm{SbF}_{5}\right)$.

When drawing Lewis structures of compounds containing a central atom from the third period and beyond, the octet rule may be satisfied for all the atoms before all the valence electrons have been used up. When this happens, the extra electrons should be placed as lone pairs on the central atom. Sample Problem 8.14 illustrates this approach.

## Sample Problem 8.14

Draw the Lewis structure of xenon tetrafluoride $\left(\mathrm{XeF}_{4}\right)$.
Strategy Follow the steps for drawing Lewis structures. The skeletal structure is

Setup There are 36 total valence electrons (eight from Xe and seven from each of the four F atoms). We subtract eight electrons to account for the bonds in the skeleton, leaving 28 to distribute. We first complete the octets of all four F atoms. When this is done, four electrons remain, so we place two lone pairs on the Xe atom.

Solution

Think About lt Atoms beyond the second period can accommodate more than an octet of electrons, whether those electrons are used in bonds or reside on the atom as lone pairs.

Practice Problem A Draw the Lewis structure of the iodine tetrachloride ion $\left(\mathrm{ICl}_{4}^{-}\right)$.
EPractice Problem B Draw the Lewis structure of krypton difluoride $\left(\mathrm{KrF}_{2}\right)$.

## Checkpoint 8.8 Exceptions to the Octet Rule

8.8.1 In which of the following species does the central atom not obey the octet rule?
a) $\mathrm{ClO}_{2}^{-}$
b) $\mathrm{CO}_{2}$
c) $\mathrm{BrO}_{3}^{-}$
d) HCN
e) $\mathrm{ICl}_{4}^{-}$
8.8.2 Which elements cannot have more than an octet of electrons? (Select all that apply.)
a) N
b) C
c) S
d) Br
e) O
8.8.3 In which species does the central atom obey the octet rule? (Select all that apply.)
a) $I_{3}^{-}$
b) $\mathrm{BH}_{3}$
c) $\mathrm{AsF}_{6}^{-}$
d) $\mathrm{NO}_{2}$
e) $\mathrm{ClO}_{2}^{-}$
8.8.4 How many lone pairs are there on the central atom in the Lewis structure of $\mathrm{ICl}_{2}^{-}$?
a) 0
b) 1
c) 2
d) 3
e) 4

You May Be Wondering...

## Which Is More Important: Formal Charge or the Octet Rule?

We have learned that although central atoms from the third period (and beyond) often obey the octet rule, it is not necessary for them to do so. Rather, they can have what we call "expanded octets," meaning they are surrounded by more than eight electrons.

The sulfate ion $\left(\mathrm{SO}_{4}^{2-}\right)$, for example, can be represented by a resonance structure that obeys the octet rule (structure I), or by a structure that does not (structure II):

Structure I

Structure II

In structure I, although the octet rule is obeyed for the central atom, there are nonzero formal charges (shown in blue) on all the atoms. In structure II, by relocating a lone pair from each of two oxygen atoms and creating two double bonds, we change three of the formal charges to zero.

Which of these structures is better (or "more important") has been the subject of some debate among educators over the past two decades. Although some chemists may have a strong preference for one or the other, it is important for you to understand that both are valid Lewis structures and you should be able to draw both types of structures.

Sample Problem 8.15 gives you some practice drawing resonance structures for species that can obey the octet rule but also can be drawn with expanded octets to minimize formal charges.

## Sample Problem 8.15

Draw two resonance structures for sulfurous acid $\left(\mathrm{H}_{2} \mathrm{SO}_{3}\right)$ : one that obeys the octet rule for the central atom, and one that minimizes the formal charges. Determine the formal charge on each atom in both structures.

Strategy Begin by drawing the skeletal structure and counting the total number of valence electrons. Use the steps outlined in Section 8.5 to draw the first structure and reposition one or more lone pairs to adjust the formal charges for the second structure.

Setup The skeletal structure is

Note that each hydrogen in an oxoacid is attached to an oxygen atom and not directly to the central atom. The total number of valence electrons is 26 (six from S , six from each O , and one from each H ).

Solution Following the procedure outlined on page 314, we get the first structure:

From the top O atom, which has three lone pairs, we reposition one lone pair to create a double bond between O and S to get the second structure:

Incorporating the double bond results in every atom having a formal charge of zero.

Practice Problem A Draw three resonance structures for the hydrogen sulfite ion $\left(\mathrm{HSO}_{3}^{-}\right)$—one that obeys the octet rule for the central atom, and two that expand the octet of the central atom. Calculate the formal charges on all atoms in each structure and determine which, if any, of the resonance structures has formal charges that are inconsistent with the elements' electronegativities.

HPractice Problem B Draw two resonance structures for each species-one that obeys the octet rule, and one in which the formal charge on the central atom is zero: $\mathrm{PO}_{4}^{3-}, \mathrm{HClO}_{3}, \mathrm{SO}_{3}, \mathrm{SO}_{2}$.

Think About It In some species, such as the sulfate ion, it is possible to incorporate too many double bonds. Structures with three and four double bonds to sulfur would give formal charges on S and O that are inconsistent with the electronegativities of these elements. In general, if you are trying to minimize formal charges by expanding the central atom's octet, only add enough double bonds to make the formal charge on the central atom zero.

### 8.9 Bond Enthalpy

One measure of the stability of a molecule is its bond enthalpy, which is the enthalpy change associated with breaking a particular bond in 1 mole of gaseous molecules. (Bond enthalpies in solids and liquids are affected by neighboring molecules.) The experimentally determined bond enthalpy of the diatomic hydrogen molecule, for example, is

$$
\mathrm{H}_{2}(g) \longrightarrow \mathrm{H}(g)+\mathrm{H}(g) \quad \Delta H^{\circ}=436.4 \mathrm{~kJ} / \mathrm{mol}
$$

According to this equation, breaking the covalent bonds in 1 mole of gaseous $\mathrm{H}_{2}$ molecules requires 436.4 kJ of energy. For the less stable chlorine molecule,

$$
\mathrm{Cl}_{2}(g) \longrightarrow \mathrm{Cl}(g)+\mathrm{Cl}(g) \quad \Delta H^{\circ}=242.7 \mathrm{~kJ} / \mathrm{mol}
$$

Bond enthalpies can also be directly measured for heteronuclear diatomic molecules, such as HCl ,

$$
\mathrm{HCl}(g) \longrightarrow \mathrm{H}(g)+\mathrm{Cl}(g) \quad \Delta H^{\circ}=431.9 \mathrm{~kJ} / \mathrm{mol}
$$

as well as for molecules containing multiple bonds:

$$
\begin{array}{ll}
\mathrm{O}_{2}(g) \longrightarrow \mathrm{O}(g)+\mathrm{O}(g) & \Delta H^{\circ}=498.7 \mathrm{~kJ} / \mathrm{mol} \\
\mathrm{~N}_{2}(g) \longrightarrow \mathrm{N}(g)+\mathrm{N}(g) & \Delta H^{\circ}=941.4 \mathrm{~kJ} / \mathrm{mol}
\end{array}
$$

Measuring the strength of covalent bonds in polyatomic molecules is more complicated. For example, measurements show that the energy needed to break the first $\mathrm{O}-\mathrm{H}$ bond in $\mathrm{H}_{2} \mathrm{O}$ is different from that needed to break the second $\mathrm{O}-\mathrm{H}$ bond:

$$
\begin{aligned}
\mathrm{H}_{2} \mathrm{O}(g) \longrightarrow \mathrm{H}(g)+\mathrm{OH}(g) & \Delta H^{\circ}=502 \mathrm{~kJ} / \mathrm{mol} \\
\mathrm{OH}(g) \longrightarrow \mathrm{H}(g)+\mathrm{O}(g) & \Delta H^{\circ}=427 \mathrm{~kJ} / \mathrm{mol}
\end{aligned}
$$

In each case, an $\mathrm{O}-\mathrm{H}$ bond is broken, but the first step requires the input of more energy than the second. The difference between the two $\Delta H^{\circ}$ values suggests that the second $\mathrm{O}-\mathrm{H}$ bond itself undergoes change, because of the changes in its chemical environment.

We can now understand why the bond enthalpy of the same $\mathrm{O}-\mathrm{H}$ bond in two different molecules, such as methanol $\left(\mathrm{CH}_{3} \mathrm{OH}\right)$ and water $\left(\mathrm{H}_{2} \mathrm{O}\right)$, will not be the same: their environments are different. For polyatomic molecules, therefore, we speak of the average bond enthalpy of a particular bond. For example, we can measure the enthalpy of the $\mathrm{O}-\mathrm{H}$ bond in 10 different polyatomic molecules and obtain the average $\mathrm{O}-\mathrm{H}$ bond enthalpy by dividing the sum of the bond enthalpies by 10. Table 8.6 lists the average bond enthalpies of a number of diatomic and polyatomic molecules. As we noted earlier, triple bonds are stronger than double bonds, and double bonds are stronger than single bonds.

A comparison of the thermochemical changes that take place during a number of reactions reveals a strikingly wide variation in the enthalpies of different reactions. For example, the combustion of hydrogen gas in oxygen gas is fairly exothermic:

$$
\mathrm{H}_{2}(g)+\frac{1}{2} \mathrm{O}_{2}(g) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l) \quad \Delta H^{\circ}=-285.8 \mathrm{~kJ} / \mathrm{mol}
$$

The formation of glucose from carbon dioxide and water, on the other hand, best achieved by photosynthesis, is highly endothermic:

$$
6 \mathrm{CO}_{2}(g)+6 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}(s)+6 \mathrm{O}_{2}(g) \quad \Delta H^{\circ}=2801 \mathrm{~kJ} / \mathrm{mol}
$$

We can account for such variations by looking at the stability of individual reactant and product molecules. After all, most chemical reactions involve the making and breaking of bonds. Therefore, knowing the bond enthalpies and hence the stability of molecules reveals something about the thermochemical nature of the reactions that molecules undergo.

In many cases, it is possible to predict the approximate enthalpy of a reaction by using the average bond enthalpies. Because energy is always required to break chemical bonds and chemical bond formation is always accompanied by a release of energy, we can estimate the enthalpy of a reaction by counting the total number of bonds broken and formed in the reaction and recording all the corresponding enthalpy changes. The enthalpy of reaction in the gas phase is given by

$$
\begin{array}{rr}
\Delta H^{\circ} & =\Sigma \mathrm{BE}(\text { reactants })-\Sigma \mathrm{BE}(\text { products }) \\
& =\text { total energy input } \text { (to break bonds) }- \text { total energy released }(\text { by bond formation } 8.4
\end{array}
$$

*Bond enthalpies shown in red are for diatomic molecules
${ }^{\dagger}$ The $\mathrm{C}=\mathrm{O}$ bond enthalpy in $\mathrm{CO}_{2}$ is $799 \mathrm{~kJ} / \mathrm{mol}$.

Student Annotation: To many students Equation 8.4 appears to be backward. Ordinarily you calculate a change as final minus initial. Here we are determining the difference between the amount of heat we have to add to break reactant bonds and the amount of heat released when product bonds form. The sign of the final answer tells us if the process is endothermic $(+)$ or exothermic $(-)$ overall.
where BE stands for average bond enthalpy and $\Sigma$ is the summation sign. As written, Equation 8.4 takes care of the sign convention for $\Delta H^{\circ}$. Thus, if the total energy input needed to break bonds in the reactants is less than the total energy released when bonds are formed in the products, then $\Delta H^{\circ}$ is negative and the reaction is exothermic [Figure 8.9(a)]. On the other hand, if less energy is released (bond making) than absorbed (bond breaking), $\Delta H^{\circ}$ is positive and the reaction is endothermic [Figure 8.9(b)].

If all the reactants and products are diatomic molecules, then the equation for the enthalpy of reaction will yield accurate results because the bond enthalpies of diatomic molecules are accurately known. If some or all of the reactants and products are polyatomic molecules, the equation will yield only approximate results because the bond enthalpies used will be averages.

Sample Problem 8.16 shows how to estimate enthalpies of reaction using bond enthalpies.

## Sample Problem 8.16

Use bond enthalpies from Table 8.6 to estimate the enthalpy of reaction for the combustion of methane:

$$
\mathrm{CH}_{4}(g)+2 \mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(l)
$$

Strategy Draw Lewis structures to determine what bonds are to be broken and what bonds are to be formed.

Bonds to break: $4 \mathrm{C}-\mathrm{H}$ and $2 \mathrm{O}=\mathrm{O}$.
Bonds to form: $2 \mathrm{C}=\mathrm{O}$ and $4 \mathrm{H}-\mathrm{O}$.
Bond enthalpies from Table 8.6: $414 \mathrm{~kJ} / \mathrm{mol}(\mathrm{C}-\mathrm{H}), 498.7 \mathrm{~kJ} / \mathrm{mol}(\mathrm{O}=\mathrm{O}), 799 \mathrm{~kJ} / \mathrm{mol}(\mathrm{C}=\mathrm{O}$ in $\mathrm{CO}_{2}$ ), and $460 \mathrm{~kJ} / \mathrm{mol}(\mathrm{H}-\mathrm{O})$.

Solution
$[4(414 \mathrm{~kJ} / \mathrm{mol})+2(498.7 \mathrm{~kJ} / \mathrm{mol})]-[2(799 \mathrm{~kJ} / \mathrm{mol})+4(460 \mathrm{~kJ} / \mathrm{mol})]=-785 \mathrm{~kJ} / \mathrm{mol}$.

Practice Problem A Use bond enthalpies from Table 8.6 to estimate the enthalpy of reaction for the combination of carbon monoxide and oxygen to produce carbon dioxide:

$$
2 \mathrm{CO}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{CO}_{2}(g)
$$

EPPractice Problem B Using the following chemical equation, data from Table 8.6, and data from Appendix 2, determine the $\mathrm{P}-\mathrm{Cl}$ bond enthalpy:

$$
\mathrm{PH}_{3}(g)+3 \mathrm{HCl}(g) \longrightarrow \mathrm{PCl}_{3}(g)+3 \mathrm{H}_{2}(g)
$$

Student Annotation: Remember that heats of reaction are expressed in $\mathrm{kJ} / \mathrm{mol}$, where the "per mole" refers to per mole of reaction as written [14 Section 5.3].
Student Annotation: Don't skip the step of drawing Lewis structures. This is the only way to know for certain what types and numbers of bonds must be broken and formed.

## Think About It Use Equation

 5.19 [ 14 Section 5.6] and data from Appendix 2 to calculate this enthalpy of reaction again; then compare your results using the two approaches. The difference in this case is due to two things: Most tabulated bond enthalpies are averages and, by convention, we show the product of combustion as liquid water-but average bond enthalpies apply to species in the gas phase, where there is little or no influence exerted by neighboring molecules.Figure 8.9 Enthalpy changes in (a) an exothermic reaction and (b) an endothermic reaction. The $\Delta H^{\circ}$ values are calculated using Equation 5.19 and tabulated $\Delta H_{\mathrm{f}}^{\circ}$ values from Appendix 2.

## Checkpoint 8.9 Bond Enthalpy

8.9.1 Use data from Table 8.6 to estimate $\Delta H_{\mathrm{rxn}}$ for the decomposition of hydrogen peroxide to form water and oxygen.

$$
\mathrm{H}_{2} \mathrm{O}_{2}(l) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)+\frac{1}{2} \mathrm{O}_{2}(g)
$$

a) $-71 \mathrm{~kJ} / \mathrm{mol}$
b) $+357 \mathrm{~kJ} / \mathrm{mol}$
c) $-357 \mathrm{~kJ} / \mathrm{mol}$
d) $-107 \mathrm{~kJ} / \mathrm{mol}$
e) $+71 \mathrm{~kJ} / \mathrm{mol}$
8.9.2 Use data from Table 8.6 to estimate $\Delta H_{\mathrm{rxn}}$ for the reaction of fluorine and chlorine to produce CIF.

$$
\mathrm{F}_{2}(g)+\mathrm{Cl}_{2}(g) \longrightarrow 2 \mathrm{ClF}(g)
$$

a) $-77.5 \mathrm{~kJ} / \mathrm{mol}$
b) $-206.6 \mathrm{~kJ} / \mathrm{mol}$
c) $206.6 \mathrm{~kJ} / \mathrm{mol}$
d) $-13.6 \mathrm{~kJ} / \mathrm{mol}$
e) $13.6 \mathrm{~kJ} / \mathrm{mol}$
8.9.3 Use bond enthalpies to determine $\Delta H_{\mathrm{rxn}}$ for the reaction shown.

a) $-1139 \mathrm{~kJ} / \mathrm{mol}$
b) $+1139 \mathrm{~kJ} / \mathrm{mol}$
c) $-346 \mathrm{~kJ} / \mathrm{mol}$
d) $+114 \mathrm{~kJ} / \mathrm{mol}$
e) $-114 \mathrm{~kJ} / \mathrm{mol}$
8.9.4 Use bond enthalpies to determine $\Delta H_{\mathrm{rxn}}$ for the reaction shown.

a) $-1028 \mathrm{~kJ} / \mathrm{mol}$
b) $-200 \mathrm{~kJ} / \mathrm{mol}$
c) $-392 \mathrm{~kJ} / \mathrm{mol}$
d) $+392 \mathrm{~kJ} / \mathrm{mol}$
e) $+200 \mathrm{~kJ} / \mathrm{mol}$

## Applying What You've Learned

Researchers in the early 1990s made the sensational announcement that nitric oxide (NO), which had long been thought of only as a component of air pollution, turns out to play an important role in human physiology. They found that NO serves as a signal molecule, being produced in vivo and regulating a wide variety of cell functions in the body including in the cardiovascular, nervous, and immune systems.

The discovery of the biological role of nitric oxide has shed light on how nitroglycerin works as a drug. For many years, nitroglycerin tablets have been prescribed for cardiac patients to relieve the pain caused by brief interruptions in the flow of blood to the heart, although how it worked was not understood. We now know that nitroglycerin produces nitric oxide in the body, which causes muscles to relax and allows the arteries to dilate.

Research continues to uncover the role nitric oxide plays in biological processes, and medicine continues to find new uses for this molecule.

## Problems:

a) Without consulting Figure 8.1, give the Lewis dot symbols for N and O . [ IA Sample Problem 8.1]
b) Classify the bond in NO as nonpolar, polar, or ionic. [ KA Sample Problem 8.4]
c) Given the experimentally determined dipole moment $(0.16 \mathrm{D})$ and the bond length ( $1.15 \AA$ ), determine the magnitude of the partial charges in the NO molecule. [ KA Sample Problem 8.5]
d) Draw the Lewis structures for NO and for nitroglycerin $\left(\mathrm{C}_{3} \mathrm{H}_{5} \mathrm{~N}_{3} \mathrm{O}_{9}\right)$. [ 14 Sample Problem 8.7]
e) Determine the formal charges on each atom in NO and in nitroglycerin. [144 Sample Problem 8.8]
f) Nitroglycerin decomposes explosively to give carbon dioxide, water, nitrogen, and oxygen. Given the balanced equation for this reaction,

$$
\mathrm{C}_{3} \mathrm{H}_{5}\left(\mathrm{NO}_{3}\right)_{3} \longrightarrow 3 \mathrm{CO}_{2}+2.5 \mathrm{H}_{2} \mathrm{O}+1.5 \mathrm{~N}_{2}+0.25 \mathrm{O}_{2}
$$

use bond enthalpies to estimate $\Delta H^{\circ}$ for the reaction. [14 Sample Problem 8.16]

## Chapter Summary

## Section 8.1

- A Lewis dot symbol depicts an atom or an atomic ion of a main group element with dots (representing the valence electrons) arranged around the element's symbol. Main group atoms lose or gain one or more electrons to become isoelectronic with noble gases.

## Section 8.2

- The electrostatic attraction that holds ions together in an ionic compound is referred to as ionic bonding.
- Lattice energy is the amount of energy required to convert a mole of ionic solid to its constituent ions in the gas phase. Lattice energy cannot be measured directly, but is determined using the Born-Haber cycle and thermodynamic quantities that can be measured directly.

## Section 8.3

- According to the Lewis theory of bonding, covalent bonding results when atoms share valence electrons. The atoms in molecules and those in polyatomic ions are held together by covalent bonds.
- According to the octet rule, atoms will lose, gain, or share electrons to achieve a noble gas configuration. Pairs of valence electrons that are not involved in the covalent bonding in a molecule or polyatomic ion (i.e., valence electrons that are not shared) are called lone pairs.
- Lewis structures are drawn to represent molecules and polyatomic ions, showing the arrangement of atoms and the positions of all valence electrons. Lewis structures represent the shared pairs of valence electrons either as two dots, $\cdot \cdot$, or as a single dash, - . Any unshared electrons are represented as dots.
- One shared pair of electrons between atoms constitutes a single bond. Multiple bonds form between atoms that share more than one pair of electrons. Two shared pairs constitute a double bond, and three shared pairs constitute a triple bond.

## Section 8.4

- Bonds in which electrons are not shared equally are polar and are referred to as polar covalent bonds.
- Electronegativity is an atom's ability to draw shared electrons toward itself. Bonds between elements of widely different electronegativities ( $\Delta \geq 2.0$ ) are ionic. Covalent bonds between atoms with significantly different electronegativities $(0.5 \leq \Delta<2.0)$ are polar. Bonds between atoms with very similar electronegativities $(\Delta<0.5)$ are nonpolar.
- Percent ionic character quantifies the polarity of a bond, and is determined by comparing the measured dipole moment to the one predicted by assuming that the bonded atoms have discrete charges.
- The dipole moment $(\boldsymbol{\mu})$ is a quantitative measure of the polarity of a bond.

## Section 8.5

- Lewis structures of molecules or polyatomic ions can be drawn using the following step-by-step procedure:

1. Use the molecular formula to draw the skeletal structure.
2. Count the total number of valence electrons, adding electrons to account for a negative charge and subtracting electrons to account for a positive charge.
3. Subtract two electrons for each bond in the skeletal structure.
4. Distribute the remaining valence electrons to complete octets, completing the octets of the more electronegative atoms first.
5. Place any remaining electrons on the central atom.
6. Include double or triple bonds, if necessary, to complete the octets of all atoms.

## Section 8.6

- Formal charge is a way of keeping track of the valence electrons in a species. Formal charges should be consistent with electronegativities and can be used to determine the best arrangement of atoms and electrons for a Lewis structure.

## Section 8.7

- Resonance structures are two or more equally correct Lewis structures that differ in the positions of the electrons but not in the positions of the atoms. Different resonance structures of a compound can be separated by a resonance arrow, $\longleftrightarrow$.

## Section 8.8

- In an ordinary covalent bond, each atom contributes one electron to the shared pair of electrons. In cases where just one of the atoms contributes both of the electrons, the bond is called a coordinate covalent bond or a dative bond.
- A species that contains an odd number of electrons is called a free radical.

## Section 8.9

- Bond enthalpy is the energy required to break 1 mole of a particular type of bond. Bond enthalpies are a measure of the stability of covalent bonds and can be used to estimate the enthalpy change for a reaction.

## Key Words

Bond enthalpy, 325
Born-Haber cycle, 302
Coordinate covalent bond, 320
Covalent bond, 306
Covalent bonding, 306
Dative bond, 320
Dipole moment ( $\mu$ ), 311

Double bond, 307
Electronegativity, 309
Formal charge, 315
Free radical, 321
Ionic bonding, 299
Lattice energy, 300
Lewis dot symbol, 298

Lewis structure, 306
Lewis theory of bonding, 306
Lone pair, 306
Multiple bond, 307
Nonpolar, 310
Octet rule, 306
Percent ionic character, 312

Polar, 308
Polar covalent bond, 308
Resonance structure, 318
Single bond, 307
Triple bond, 307

## Key Equations

8.1 $\mu=Q \times r$
8.2 percent ionic character $=\frac{\mu \text { (observed) }}{\mu(\text { calculated assuming discrete charges) }}=100 \%$
8.3 formal charge $=$ valence electrons - associated electrons
$8.4 \Delta H^{\circ}=\Sigma \mathrm{BE}($ reactants $)-\Sigma \mathrm{BE}$ (products)

## Questions and Problems

## Section 8.1: Lewis Dot Symbols

## Review Questions

8.1 What is a Lewis dot symbol? What elements do we generally represent with Lewis symbols?
8.2 Use the second member of each group from Group 1A to Group 7A to show that the number of valence electrons on an atom of the element is the same as its group number.

G8.3 Without referring to Figure 8.1, write Lewis dot symbols for atoms of the following elements: (a) Be , (b) K , (c) Ca , (d) Ga , (e) O , (f) Br , (g) N , (h) I, (i) As, (j) F.

G18.4 Write Lewis dot symbols for the following ions: (a) $\mathrm{Li}^{+}$, (b) $\mathrm{Cl}^{-}$, (c) $\mathrm{S}^{2-}$, (d) $\mathrm{Sr}^{2+}$, (e) $\mathrm{N}^{3-}$.
8.5 Write Lewis dot symbols for the following atoms and ions: (a) I, (b) $\mathrm{I}^{-}$, (c) S , (d) $\mathrm{S}^{2-}$, (e) P , (f ) $\mathrm{P}^{3-}$, (g) Na , (h) $\mathrm{Na}^{+}$, (i) Mg , (j) $\mathrm{Mg}^{2+}$, (k) Al , (l) $\mathrm{As}^{3+}$, (m) Pb , (n) $\mathrm{Pb}^{2+}$.

## Section 8.2: Ionic Bonding

## Visualizing Chemistry

Figure 8.3
VC 8.1 What additional information would you need to calculate the lattice energy for a compound if the charges on the cation and anion were +2 and -1 , respectively, rather than +1 and -1 ?
a) No additional information is needed.
b) $I E_{2}$ of the cation.
c) $I E_{2}$ of the cation and $E A_{2}$ of the anion.

VC 8.2 What additional information would you need to calculate the lattice energy for a compound if the charges on the cation and anion were +2 and -2 , respectively, rather than +1 and -1 ?
a) No additional information is needed.
b) $I E_{2}$ of the cation.
c) $I E_{2}$ of the cation and $E A_{2}$ of the anion.

VC 8.3 How would the magnitude of the lattice energy calculated using the Born-Haber cycle change if the charges on the cation and anion were +2 and -2 , respectively, rather than +1 and -1 ?
a) Lattice energy would increase.
b) Lattice energy would decrease.
c) Whether lattice energy would increase or decrease depends on the relative magnitudes of $I E_{2}$ of the cation and $E A_{2}$ of the anion.
VC 8.4 What law enables us to use the Born-Haber cycle to calculate lattice energy?
a) Coulomb's law.
b) Hess's law.
c) Law of multiple proportions.

## Review Questions

8.6 Explain what ionic bonding is.
8.7 Explain how ionization energy and electron affinity determine whether atoms of elements will combine to form ionic compounds.
8.8 Name five metals and five nonmetals that are very likely to form ionic compounds. Write formulas for compounds that might result from the combination of these metals and nonmetals. Name these compounds.
8.9 Name one ionic compound that contains only nonmetallic elements.
8.10 Name one ionic compound that contains a polyatomic cation and a polyatomic anion (see Table 2.9).
8.11 Explain why ions with charges greater than $\pm 3$ are seldom found in ionic compounds.
8.12 The term molar mass was introduced in Chapter 3. Molar mass is numerically equivalent to molecular mass, although the units are different, for a covalent compound. What is the advantage of using the term molar mass when we discuss ionic compounds?
8.13 In which of the following states would NaCl be electrically conducting: (a) solid, (b) molten (that is, melted), (c) dissolved in water? Explain.
8.14 Beryllium forms a compound with chlorine that has the empirical formula $\mathrm{BeCl}_{2}$. How would you determine whether it is an ionic compound? (The compound is not soluble in water.)
8.15 What is lattice energy, and what does it indicate about the stability of an ionic compound?
8.16 Explain how the lattice energy of an ionic compound such as KCl can be determined using the Born-Haber cycle. On what law is this procedure based?

E 8.17 Specify which compound in each of the following pairs of ionic compounds should have the higher lattice energy: (a) KCl or MgO , (b) LiF or LiBr , (c) $\mathrm{Mg}_{3} \mathrm{~N}_{2}$ or NaCl . Explain your choice.

E 8.18 Specify which compound in each of the following pairs of ionic compounds should have the higher lattice energy: (a) AlN or CaO , (b) NaF or CsF , (c) $\mathrm{MgCl}_{2}$ or $\mathrm{MgF}_{2}$. Explain your choice.

## Problems

8.19 An ionic bond is formed between a cation $\mathrm{A}^{+}$and an anion $\mathrm{B}^{-}$. Based on Coulomb's law

$$
E \propto \frac{Q_{1} \times Q_{2}}{d}
$$

how would the energy of the ionic bond be affected by the following changes: (a) doubling the radius of $\mathrm{A}^{+}$, (b) tripling the charge on $\mathrm{A}^{+}$, (c) doubling the charges on $\mathrm{A}^{+}$and $\mathrm{B}^{-}$, (d) decreasing the radii of $\mathrm{A}^{+}$and $\mathrm{B}^{-}$to half their original values?
8.20 Give the empirical formulas and names of the compounds formed from the following pairs of ions: (a) $\mathrm{Rb}^{+}$and $\mathrm{I}^{-}$, (b) $\mathrm{Cs}^{+}$and $\mathrm{SO}_{4}^{2-}$, (c) $\mathrm{Sr}^{2+}$ and $\mathrm{N}^{3-}$, (d) $\mathrm{Al}^{3+}$ and $\mathrm{S}^{2-}$.
8.21 Use Lewis dot symbols to show the transfer of electrons between the following atoms to form cations and anions: (a) Na and F , (b) K and S, (c) Ba and O, (d) Al and N.

E 8.22 Write the Lewis dot symbols of the reactants and products in the following reactions. (First balance the equations.)
(a) $\mathrm{Sr}+\mathrm{Se} \longrightarrow \mathrm{SrSe}$
(c) $\mathrm{Li}+\mathrm{N}_{2} \longrightarrow \mathrm{Li}_{3} \mathrm{~N}$
(b) $\mathrm{Ca}+\mathrm{H}_{2} \longrightarrow \mathrm{CaH}_{2}$
(d) $\mathrm{Al}+\mathrm{S} \longrightarrow \mathrm{Al}_{2} \mathrm{~S}_{3}$

E8.23 Use the Born-Haber cycle outlined in Section 8.2 for NaCl to calculate the lattice energy of LiCl . Use data from Figures 7.8 and 7.10 and Appendix 2.
8.24 Calculate the lattice energy of $\mathrm{CaCl}_{2}$. Use data from Figures 7.8 and 7.10 and Appendix 2. (The second ionization energy of Ca , $I E_{2}$, is $1145 \mathrm{~kJ} / \mathrm{mol}$.)

## Section 8.3: Covalent Bonding

## Review Questions

8.25 Describe Lewis's contribution to our understanding of the covalent bond.
8.26 Use an example to illustrate each of the following terms: lone pair, Lewis structure, octet rule, bond length.
8.27 What is the difference between a Lewis symbol and a Lewis structure?
8.28 How many lone pairs are on the underlined atoms in these compounds: $\mathrm{HBr}, \mathrm{H}_{2} \underline{\mathrm{~S}}, \underline{\mathrm{CH}_{4}}$ ?
8.29 Compare single, double, and triple bonds in a molecule, and give an example of each. For the same bonding atoms, how does the bond length change from single bond to triple bond?
8.30 Compare the properties of ionic compounds and covalent compounds.
8.31 Summarize the essential features of the Lewis octet rule. The octet rule applies mainly to the second period elements. Explain.

## Problems

Ef 8.32 For each of the following pairs of elements, state whether the binary compound they form is likely to be ionic or covalent. Write the empirical formula and name of the compound:
(a) I and Cl , (b) Mg and F .
8.33 For each of the following pairs of elements, state whether the binary compound they form is likely to be ionic or covalent. Write the empirical formula and name of the compound:
(a) B and F, (b) K and Br.

## Section 8.4: Electronegativity and Polarity

## Review Questions

8.34 Define electronegativity, and explain the difference between electronegativity and electron affinity. Describe in general how the electronegativities of the elements change according to their position in the periodic table.
8.35 What is a polar covalent bond? Name two compounds that contain one or more polar covalent bonds.

## Problems

8.36 List the following bonds in order of increasing ionic character: the lithium-to-fluorine bond in LiF , the potassium-to-oxygen bond in $\mathrm{K}_{2} \mathrm{O}$, the nitrogen-to-nitrogen bond in $\mathrm{N}_{2}$, the sulfur-to-oxygen bond in $\mathrm{SO}_{2}$, the chlorine-to-fluorine bond in $\mathrm{ClF}_{3}$.

E 8.37 Arrange the following bonds in order of increasing ionic character: carbon to hydrogen, fluorine to hydrogen, bromine to hydrogen, sodium to chlorine, potassium to fluorine, lithium to chlorine.

I 8.38 Four atoms are arbitrarily labeled D, E, F, and G. Their electronegativities are as follows: $\mathrm{D}=3.8, \mathrm{E}=3.3, \mathrm{~F}=2.8$, and $\mathrm{G}=1.3$. If the atoms of these elements form the molecules DE, DG, EG, and DF, how would you arrange these molecules in order of increasing covalent bond character?
8.39 List the following bonds in order of increasing ionic character: cesium to fluorine, chlorine to chlorine, bromine to chlorine, silicon to carbon.

E 8.40 Classify the following bonds as covalent, polar covalent, or ionic, and explain: (a) the CC bond in $\mathrm{H}_{3} \mathrm{CCH}_{3}$, (b) the KI bond in KI , (c) the NB bond in $\mathrm{H}_{3} \mathrm{NBCl}_{3}$, (d) the CF bond in $\mathrm{CF}_{4}$.
E.41 Classify the following bonds as covalent, polar covalent, or ionic, and explain: (a) the SiSi bond in $\mathrm{Cl}_{3} \mathrm{SiSiCl}_{3}$, (b) the SiCl bond in $\mathrm{Cl}_{3} \mathrm{SiSiCl}_{3}$, (c) the CaF bond in $\mathrm{CaF}_{2}$, (d) the NH bond in $\mathrm{NH}_{3}$.

## Section 8.5: Drawing Lewis Structures

## Problems

E 8.42 Draw Lewis structures for the following molecules and ions: (a) $\mathrm{NCl}_{3}$, (b) OCS , (c) $\mathrm{H}_{2} \mathrm{O}_{2}$, (d) $\mathrm{CH}_{3} \mathrm{COO}^{-}$, (e) $\mathrm{CN}^{-}$, (f) $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{NH}_{3}^{+}$.

E8.43 Draw Lewis structures for the following molecules and ions: (a) $\mathrm{OF}_{2}$, (b) $\mathrm{N}_{2} \mathrm{~F}_{2}$, (c) $\mathrm{Si}_{2} \mathrm{H}_{6}$, (d) $\mathrm{OH}^{-}$, (e) $\mathrm{CH}_{2} \mathrm{ClCOO}^{-}$, (f) $\mathrm{CH}_{3} \mathrm{NH}_{3}^{+}$.

G8.44 Draw Lewis structures for the following molecules: (a) ICl ,
(b) $\mathrm{PH}_{3}$, (c) $\mathrm{P}_{4}$ (each P is bonded to three other P atoms), (d) $\mathrm{H}_{2} \mathrm{~S}$, (e) $\mathrm{N}_{2} \mathrm{H}_{4}$, (f) $\mathrm{HClO}_{3}$.
8.45 Draw Lewis structures for the following molecules: (a) $\mathrm{COBr}_{2}$ (C is bonded to O and Br atoms), (b) $\mathrm{H}_{2} \mathrm{Se}$, (c) $\mathrm{NH}_{2} \mathrm{OH}$,
(d) $\mathrm{CH}_{3} \mathrm{NH}_{2}$, (e) $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{Br}$, (f) $\mathrm{NCl}_{3}$.

## Section 8.6: Lewis Structures and Formal Charge

## Review Questions

8.46 Explain the concept of formal charge. Do formal charges represent an actual separation of charges?

## Problems

H8.47 Draw Lewis structures for the following ions: (a) $\mathrm{NO}_{2}^{+}$, (b) $\mathrm{SCN}^{-}$, (c) $\mathrm{S}_{2}^{2-}$, (d) $\mathrm{ClF}_{2}^{+}$. Show formal charges.

E 8.48 Draw Lewis structures for the following ions: (a) $\mathrm{O}_{2}^{2-}$, (b) $\mathrm{C}_{2}^{2-}$, (c) $\mathrm{NO}^{+}$, (d) $\mathrm{NH}_{4}^{+}$. Show formal charges.
8.49 The skeletal structure of acetic acid shown here is correct, but some of the bonds are wrong. (a) Identify the incorrect bonds and explain what is wrong with them. (b) Write the correct Lewis structure for acetic acid.

8.50 The following Lewis structures are incorrect. Explain what is wrong with each one, and give a correct Lewis structure for the molecule. (Relative positions of atoms are shown correctly.)
(a) $\mathrm{H}-\ddot{\mathrm{C}}=\ddot{\mathrm{N}}$
(d)

(g)

(b) $\mathrm{H}=\mathrm{C}=\mathrm{C}=\mathrm{H}$
(e) $\mathrm{H}-\ddot{\mathrm{O}}=\ddot{\mathrm{F}}$ :
(c) $\ddot{O}-\mathrm{Sn}-\ddot{O}$
(f)

## Section 8.7: Resonance

## Review Questions

G 8.51 What is a resonance structure? Is it possible to isolate one resonance structure of a compound for analysis? Explain.
8.52 What are the rules for writing resonance structures?

## Problems

8.53 Draw Lewis structures for the following species, including all resonance forms, and show formal charges: (a) $\mathrm{HCO}_{2}^{-}$, (b) $\mathrm{CH}_{2} \mathrm{NO}_{2}^{-}$. The relative positions of the atoms are as follows:

|  | O | H | O |
| :---: | :---: | :---: | :---: |
| H | C | C | N |
|  | O | H | O |

E8.54 Draw three resonance structures for the chlorate ion $\left(\mathrm{ClO}_{3}^{-}\right)$. Show formal charges.

Ef8.55 Draw three resonance structures for hydrazoic acid $\left(\mathrm{HN}_{3}\right)$. The atomic arrangement is HNNN. Show formal charges.

E 8.56 Draw two resonance structures for diazomethane $\left(\mathrm{CH}_{2} \mathrm{~N}_{2}\right)$. Show formal charges. The skeletal structure of the molecule is

```
H
    C N N
```

H
8.57 Draw three reasonable resonance structures for the $\mathrm{OCN}^{-}$ion. Show formal charges and rank the importance of the structures.
8.58 Draw three resonance structures for the molecule $\mathrm{N}_{2} \mathrm{O}$ in which the atoms are arranged in the order NNO. Indicate formal charges and arrange the resonance structures in order of increasing relative importance.
8.59 Draw a resonance structure of the adenine molecule shown here, which is part of the DNA structure. Show all the lone pairs and label the formal charges.

## Section 8.8: Exceptions to the Octet Rule

## Review Questions

8.60 Why does the octet rule not hold for many compounds containing elements in the third period of the periodic table and beyond?
8.61 Give three examples of compounds that do not satisfy the octet rule. Write a Lewis structure for each.
8.62 Because fluorine has seven valence electrons $\left(2 s^{2} 2 p^{5}\right)$, seven covalent bonds in principle could form around the atom. Such a compound might be $\mathrm{FH}_{7}$ or $\mathrm{FCl}_{7}$. These compounds have never been prepared. Why?
8.63 What is a coordinate covalent bond? Is it different from an ordinary covalent bond?
8.64 Because the central atom in each case is from the same group of the periodic table, the Lewis structures we draw for $\mathrm{SO}_{2}$ and $\mathrm{O}_{3}$ are essentially the same. Explain why we can draw a resonance structure for $\mathrm{SO}_{2}$ in which the formal charge on the central atom is zero, but we cannot do this for $\mathrm{O}_{3}$.
8.65 What is the advantage of drawing the Lewis structures of oxoanions and oxoacids using expanded octets?

## Problems

8.66 The $\mathrm{AlI}_{3}$ molecule has an incomplete octet around Al. Draw three resonance structures of the molecule in which the octet rule is satisfied for both the Al and the I atoms. Show formal charges.
8.67 In the vapor phase, beryllium chloride consists of discrete $\mathrm{BeCl}_{2}$ molecules. Is the octet rule satisfied for Be in this compound? If not, can you form an octet around Be by drawing another resonance structure? How plausible is this structure?
8.68 Of the noble gases, only $\mathrm{Kr}, \mathrm{Xe}$, and Rn are known to form a few compounds with O and/or F . Write Lewis structures for the following molecules: (a) $\mathrm{XeF}_{2}$, (b) $\mathrm{XeF}_{4}$, (c) $\mathrm{XeF}_{6}$, (d) $\mathrm{XeOF}_{4}$, (e) $\mathrm{XeO}_{2} \mathrm{~F}_{2}$. In each case Xe is the central atom.
8.69 Write a Lewis structure for $\mathrm{SbCl}_{5}$. Does this molecule obey the octet rule?

E8.70 Write Lewis structures for $\mathrm{SeF}_{4}$ and $\mathrm{SeF}_{6}$. Is the octet rule satisfied for Se?

E8.71 Write Lewis structures for the reaction

$$
\mathrm{AlCl}_{3}+\mathrm{Cl}^{-} \longrightarrow \mathrm{AlCl}_{4}^{-}
$$

What kind of bond joins Al and Cl in the product?
8.72 Draw two resonance structures for the bromate ion $\left(\mathrm{BrO}_{3}^{-}\right)$, one that obeys the octet rule and one in which the formal charge on the central atom is zero.
8.73 Draw two resonance structures for the sulfite ion $\left(\mathrm{SO}_{3}^{2-}\right)$, one that obeys the octet rule and one in which the formal charge on the central atom is zero.

## Section 8.9: Bond Enthalpy

## Review Questions

8.74 What is bond enthalpy? Bond enthalpies of polyatomic molecules are average values, whereas those of diatomic molecules can be accurately determined. Why?
8.75 Explain why the bond enthalpy of a molecule is usually defined in terms of a gas-phase reaction. Why are bond-breaking processes always endothermic and bond-forming processes always exothermic?

## Problems

8.76 From the following data, calculate the average bond enthalpy for the $\mathrm{N}-\mathrm{H}$ bond:

$$
\begin{array}{cl}
\mathrm{NH}_{3}(g) \longrightarrow \mathrm{NH}_{2}(g)+\mathrm{H}(g) & \Delta H^{\circ}=435 \mathrm{~kJ} / \mathrm{mol} \\
\mathrm{NH}_{2}(g) \longrightarrow \mathrm{NH}(g)+\mathrm{H}(g) & \Delta H^{\circ}=381 \mathrm{~kJ} / \mathrm{mol} \\
\mathrm{NH}(g) \longrightarrow \mathrm{N}(g)+\mathrm{H}(g) & \Delta H^{\circ}=360 \mathrm{~kJ} / \mathrm{mol}
\end{array}
$$

8.77 For the reaction

$$
\mathrm{O}(g)+\mathrm{O}_{2}(g) \longrightarrow \mathrm{O}_{3}(g) \quad \Delta H^{\circ}=-107.2 \mathrm{~kJ} / \mathrm{mol}
$$

Calculate the average bond enthalpy in $\mathrm{O}_{3}$.
E 8.78 The bond enthalpy of $\mathrm{F}_{2}(g)$ is $156.9 \mathrm{~kJ} / \mathrm{mol}$. Calculate $\Delta H_{\mathrm{f}}^{\circ}$ for $\mathrm{F}(g)$.
8.79 For the reaction

$$
2 \mathrm{C}_{2} \mathrm{H}_{6}(g)+7 \mathrm{O}_{2}(g) \longrightarrow 4 \mathrm{CO}_{2}(g)+6 \mathrm{H}_{2} \mathrm{O}(g)
$$

(a) Predict the enthalpy of reaction from the average bond enthalpies in Table 8.6. (b) Calculate the enthalpy of reaction from the standard enthalpies of formation (see Appendix 2) of the reactant and product molecules, and compare the result with your answer for part (a).
8.80 Use average bond enthalpies from Table 8.6 to estimate $\Delta H_{\mathrm{rxn}}$ for the following reaction.

8.81 Use average bond enthalpies from Table 8.6 to estimate $\Delta H_{\mathrm{rxn}}$ for the following reaction.

## Additional Problems

$\boldsymbol{\$} 8.82$ Classify the following substances as ionic compounds or covalent compounds containing discrete molecules: $\mathrm{CH}_{4}, \mathrm{KF}, \mathrm{CO}, \mathrm{SiCl}_{4}$, $\mathrm{BaCl}_{2}$.
8.83 Which of the following are ionic compounds and which are covalent compounds: $\mathrm{RbCl}, \mathrm{PF}_{5}, \mathrm{BrF}_{3}, \mathrm{KO}_{2}, \mathrm{CI}_{4}$ ?

EI 8.84 Match each of the following energy changes with one of the processes given: ionization energy, electron affinity, bond enthalpy, and standard enthalpy of formation.
(a) $\mathrm{F}(g)+e^{-} \longrightarrow \mathrm{F}^{-}(g)$
(c) $\mathrm{Na}(g) \longrightarrow \mathrm{Na}^{+}(g)+e^{-}$
(b) $\mathrm{F}_{2}(g) \longrightarrow 2 \mathrm{~F}(g)$
(d) $\mathrm{Na}(s)+\frac{1}{2} \mathrm{~F}_{2}(g) \longrightarrow \mathrm{NaF}(s)$
8.85 The formulas for the fluorides of the third-period elements are $\mathrm{NaF}, \mathrm{MgF}_{2}, \mathrm{AlF}_{3}, \mathrm{SiF}_{4}, \mathrm{PF}_{5}, \mathrm{SF}_{6}$, and $\mathrm{ClF}_{3}$. Classify these compounds as covalent or ionic.

E 8.86 Use ionization energy (see Figure 7.8) and electron affinity (see Figure 7.10) values to calculate the energy change (in $\mathrm{kJ} / \mathrm{mol}$ ) for the following reactions:
(a) $\mathrm{Li}(g)+\mathrm{I}(g) \longrightarrow \mathrm{Li}^{+}(g)+\mathrm{I}^{-}(g)$
(b) $\mathrm{Na}(g)+\mathrm{F}(g) \longrightarrow \mathrm{Na}^{+}(g)+\mathrm{F}^{-}(g)$
(c) $\mathrm{K}(g)+\mathrm{Cl}(g) \longrightarrow \mathrm{K}^{+}(g)+\mathrm{Cl}^{-}(g)$
8.87 Describe some characteristics of an ionic compound such as KF that would distinguish it from a covalent compound such as benzene $\left(\mathrm{C}_{6} \mathrm{H}_{6}\right)$.
f 8.88 Write Lewis structures for $\mathrm{BrF}_{3}, \mathrm{ClF}_{5}$, and $\mathrm{IF}_{7}$. Identify those in which the octet rule is not obeyed.
8.89 Write three reasonable resonance structures for the azide ion $\mathrm{N}_{3}^{-}$ in which the atoms are arranged as NNN. Show formal charges.

E 8.90 The amide group plays an important role in determining the structure of proteins:

Draw another resonance structure for this group. Show formal charges.
8.91 Give an example of an ion or molecule containing Al that (a) obeys the octet rule, (b) has an expanded octet, and (c) has an incomplete octet.

E 8.92 Draw four reasonable resonance structures for the $\mathrm{PO}_{3} \mathrm{~F}^{2-}$ ion. The central P atom is bonded to the three O atoms and to the F atom. Show formal charges.
©8.93 Attempts to prepare the compounds $\mathrm{CF}_{2}, \mathrm{LiO}_{2}, \mathrm{CsCl}_{2}$, and $\mathrm{PI}_{5}$ as stable species under atmospheric conditions have failed. Suggest possible reasons for the failure.
\& 8.94 Draw reasonable resonance structures for the following ions: (a) $\mathrm{HSO}_{4}^{-}$, (b) $\mathrm{PO}_{4}^{3-}$, (c) $\mathrm{HPO}_{3}^{2-}$, (d) $\mathrm{IO}_{3}^{-}$.

E18.95 Are the following statements true or false? (a) Formal charges represent an actual separation of charges. (b) $\Delta H_{\mathrm{rxn}}^{\circ}$ can be estimated from the bond enthalpies of reactants and products. (c) All second-period elements obey the octet rule in their compounds. (d) The resonance structures of a molecule can be separated from one another in the laboratory.
8.96 A rule for drawing plausible Lewis structures is that the central atom is generally less electronegative than the surrounding atoms. Explain why this is so.

E8.97 Using the following information and the fact that the average $\mathrm{C}-\mathrm{H}$ bond enthalpy is $414 \mathrm{~kJ} / \mathrm{mol}$, estimate the standard enthalpy of formation of methane $\left(\mathrm{CH}_{4}\right)$.

$$
\begin{aligned}
\mathrm{C}(s) \longrightarrow \mathrm{C}(g) & \Delta H_{\mathrm{rxn}}^{\circ}=716 \mathrm{~kJ} / \mathrm{mol} \\
2 \mathrm{H}_{2}(g) \longrightarrow 4 \mathrm{H}(g) & \Delta H_{\mathrm{rxn}}^{\circ}=872.8 \mathrm{~kJ} / \mathrm{mol}
\end{aligned}
$$

H8.98 Based on changes in enthalpy, which of the following reactions will occur more readily?
(a) $\mathrm{Cl}(g)+\mathrm{CH}_{4}(g) \longrightarrow \mathrm{CH}_{3} \mathrm{Cl}(g)+\mathrm{H}(g)$
(b) $\mathrm{Cl}(g)+\mathrm{CH}_{4}(g) \longrightarrow \mathrm{CH}_{3}(g)+\mathrm{HCl}(g)$

E 8.99 Which of the following molecules has the shortest nitrogen-tonitrogen bond: $\mathrm{N}_{2} \mathrm{H}_{4}, \mathrm{~N}_{2} \mathrm{O}, \mathrm{N}_{2}, \mathrm{~N}_{2} \mathrm{O}_{4}$ ? Explain.

E 8.100 Most organic acids can be represented as RCOOH , where COOH is the carboxyl group and R is the rest of the molecule. [For example, R is $\mathrm{CH}_{3}$ in acetic acid $\left(\mathrm{CH}_{3} \mathrm{COOH}\right)$.] (a) Draw a Lewis structure for the carboxyl group. (b) Upon ionization, the carboxyl group is converted to the carboxylate group $\left(\mathrm{COO}^{-}\right)$. Draw resonance structures for the carboxylate group.
8.101 Which of the following species are isoelectronic: $\mathrm{NH}_{4}^{+}, \mathrm{C}_{6} \mathrm{H}_{6}, \mathrm{CO}$, $\mathrm{CH}_{4}, \mathrm{~N}_{2}, \mathrm{~B}_{3} \mathrm{~N}_{3} \mathrm{H}_{6}$ ?
8.102 The following is a simplified (skeletal) structure of the amino acid histidine. Draw a complete Lewis structure of the molecule.

8.103 The following is a simplified (skeletal) structure of the amino acid tryptophan. Draw a complete Lewis structure of the molecule.

E 8.104 The following species have been detected in interstellar space: (a) CH , (b) OH , (c) $\mathrm{C}_{2}$, (d) HNC , (e) HCO. Draw Lewis structures for these species.
8.105 The amide ion $\left(\mathrm{NH}_{2}^{-}\right)$is a Brønsted base. Use Lewis structures to represent the reaction between the amide ion and water.
8.106 Draw Lewis structures for the following organic molecules: (a) tetrafluoroethylene $\left(\mathrm{C}_{2} \mathrm{~F}_{4}\right)$, (b) propane $\left(\mathrm{C}_{3} \mathrm{H}_{8}\right)$, (c) butadiene $\left(\mathrm{CH}_{2} \mathrm{CHCHCH}_{2}\right)$, (d) propyne $\left(\mathrm{CH}_{3} \mathrm{CCH}\right)$, (e) benzoic acid $\left(\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COOH}\right)$. (To draw $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COOH}$, replace an H atom in benzene with a COOH group.)
8.107 The triiodide ion $\left(\mathrm{I}_{3}^{-}\right)$in which the I atoms are arranged in a straight line is stable, but the corresponding $\mathrm{F}_{3}^{-}$ion does not exist. Explain.
8.108 Compare the bond enthalpy of $\mathrm{F}_{2}$ with the overall energy change for the following process:

$$
\mathrm{F}_{2}(g) \longrightarrow \mathrm{F}^{+}(g)+\mathrm{F}^{-}(g)
$$

Which is the preferred dissociation for $\mathrm{F}_{2}$, energetically speaking?
8.109 Methyl isocyanate $\left(\mathrm{CH}_{3} \mathrm{NCO}\right)$ is used to make certain pesticides. In December 1984, water leaked into a tank containing this substance at a chemical plant, producing a toxic cloud that killed thousands of people in Bhopal, India. Draw Lewis structures for $\mathrm{CH}_{3} \mathrm{NCO}$, showing formal charges.

E 8.110 The chlorine nitrate $\left(\mathrm{ClONO}_{2}\right)$ molecule is believed to be involved in the destruction of ozone in the Antarctic stratosphere. Draw a plausible Lewis structure for this molecule.
8.111 Several resonance structures for the molecule $\mathrm{CO}_{2}$ are shown here. Explain why some of them are likely to be of little importance in describing the bonding in this molecule.
(a) $: \stackrel{\mathrm{O}}{\mathrm{O}}=\mathrm{C}=\dot{\mathrm{O}}$.
(c) $: \mathrm{O} \equiv \ddot{\mathrm{C}}-\dot{\mathrm{O}}$.
(b) $: \mathrm{O} \equiv \mathrm{C}-\ddot{\mathrm{O}}:$
(d) : $\ddot{O}-\mathrm{C}-\ddot{\mathrm{O}}:$
8.112 For each of the following organic molecules draw a Lewis structure in which the carbon atoms are bonded to each other by single bonds: (a) $\mathrm{C}_{2} \mathrm{H}_{6}$, (b) $\mathrm{C}_{4} \mathrm{H}_{10}$, (c) $\mathrm{C}_{5} \mathrm{H}_{12}$. For parts (b) and (c), show only structures in which each C atom is bonded to no more than two other C atoms.
8.113 Draw Lewis structures for the following chlorofluorocarbons (CFCs), which are partly responsible for the depletion of ozone in the stratosphere: (a) $\mathrm{CFCl}_{3}$, (b) $\mathrm{CF}_{2} \mathrm{Cl}_{2}$, (c) $\mathrm{CHF}_{2} \mathrm{Cl}$, (d) $\mathrm{CF}_{3} \mathrm{CHF}_{2}$.
8.114 Draw Lewis structures for the following organic molecules: $\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{~F}, \mathrm{C}_{3} \mathrm{H}_{6}, \mathrm{C}_{4} \mathrm{H}_{8}$. In each there is one $\mathrm{C}=\mathrm{C}$ bond, and the rest of the carbon atoms are joined by $\mathrm{C}-\mathrm{C}$ bonds.

G8.115 Calculate $\Delta H^{\circ}$ for the reaction

$$
\mathrm{H}_{2}(g)+\mathrm{I}_{2}(g) \longrightarrow 2 \mathrm{HI}(g)
$$

using (a) Equation 8.4 and (b) Equation 5.19, given that $\Delta H_{\mathrm{f}}^{\circ}$ for $\mathrm{I}_{2}(g)$ is $61.0 \mathrm{~kJ} / \mathrm{mol}$.

G 8.116 Draw Lewis structures for the following organic molecules: (a) methanol $\left(\mathrm{CH}_{3} \mathrm{OH}\right)$; (b) ethanol $\left(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}\right)$; (c) tetraethyl lead $\left[\mathrm{Pb}\left(\mathrm{CH}_{2} \mathrm{CH}_{3}\right)_{4}\right]$, which is used in "leaded gasoline";
(d) methylamine $\left(\mathrm{CH}_{3} \mathrm{NH}_{2}\right)$, which is used in tanning;
(e) mustard gas $\left(\mathrm{ClCH}_{2} \mathrm{CH}_{2} \mathrm{SCH}_{2} \mathrm{CH}_{2} \mathrm{Cl}\right)$, a poisonous gas used in World War I; (f) urea [ $\left(\mathrm{NH}_{2}\right)_{2} \mathrm{CO}$ ], a fertilizer; and (g) glycine $\left(\mathrm{NH}_{2} \mathrm{CH}_{2} \mathrm{COOH}\right)$, an amino acid.
8.117 Write Lewis structures for the following four isoelectronic species: (a) CO , (b) $\mathrm{NO}^{+}$, (c) $\mathrm{CN}^{-}$, (d) $\mathrm{N}_{2}$. Show formal charges.

E 8.118 Oxygen forms three types of ionic compounds in which the anions are oxide $\left(\mathrm{O}^{2-}\right)$, peroxide $\left(\mathrm{O}_{2}^{2-}\right)$, and superoxide $\left(\mathrm{O}_{2}^{-}\right)$. Draw Lewis structures of these ions.
8.119 Comment on the correctness of the statement, "All compounds containing a noble gas atom violate the octet rule."
8.120 Write three resonance structures for (a) the cyanate ion $\left(\mathrm{NCO}^{-}\right)$ and (b) the isocyanate ion $\left(\mathrm{CNO}^{-}\right)$. In each case, rank the resonance structures in order of increasing importance.

F 8.121 (a) From the following data calculate the bond enthalpy of the $\mathrm{F}_{2}^{-}$ion.

$$
\begin{array}{ll}
\mathrm{F}_{2}(g) \longrightarrow 2 \mathrm{~F}(g) & \Delta H_{\mathrm{rxn}}^{\circ}=156.9 \mathrm{~kJ} / \mathrm{mol} \\
\mathrm{~F}^{-}(g) \longrightarrow \mathrm{F}(g)+e^{-} & \Delta H_{\mathrm{rx}}^{\circ}=333 \mathrm{~kJ} / \mathrm{mol} \\
\mathrm{~F}_{2}^{-}(g) \longrightarrow \mathrm{F}_{2}(g)+e^{-} & \Delta H_{\mathrm{rxn}}^{\circ}=290 \mathrm{~kJ} / \mathrm{mol}
\end{array}
$$

(b) Explain the difference between the bond enthalpies of $\mathrm{F}_{2}$ and $\mathrm{F}_{2}^{-}$.

E 8.122 The resonance concept is sometimes described by analogy to a mule, which is a cross between a horse and a donkey. Compare this analogy with the one used in this chapter, that is, the description of a rhinoceros as a cross between a griffin and a unicorn. Which description is more appropriate? Why?
8.123 The $\mathrm{N}-\mathrm{O}$ bond distance in nitric oxide is 115 pm , which is intermediate between a triple bond ( 106 pm ) and a double bond (120 pm). (a) Draw two resonance structures for NO, and comment on their relative importance. (b) Is it possible to draw a resonance structure having a triple bond between the atoms?
8.124 Although nitrogen dioxide $\left(\mathrm{NO}_{2}\right)$ is a stable compound, there is a tendency for two such molecules to combine to form dinitrogen tetroxide $\left(\mathrm{N}_{2} \mathrm{O}_{4}\right)$. Why? Draw four resonance structures of $\mathrm{N}_{2} \mathrm{O}_{4}$, showing formal charges.
8.125 In the gas phase, aluminum chloride exists as a dimer (a unit of two) with the formula $\mathrm{Al}_{2} \mathrm{Cl}_{6}$. Its skeletal structure is given by

Complete the Lewis structure and indicate the coordinate covalent bonds in the molecule. Does this dimer possess a dipole moment? Explain.

E 8.126 Draw a Lewis structure for nitrogen pentoxide $\left(\mathrm{N}_{2} \mathrm{O}_{5}\right)$ in which each N is bonded to three O atoms.

EI8.127 The hydroxyl radical $(\mathrm{OH})$ plays an important role in atmospheric chemistry. It is highly reactive and has a tendency to combine with an H atom from other compounds, causing them to break up. Thus OH is sometimes called a "detergent" radical because it helps to clean up the atmosphere. (a) Draw the Lewis structure for the radical. (b) Refer to Table 8.6 and explain why the radical has a high affinity for H atoms. (c) Estimate the enthalpy change for the following reaction:

$$
\mathrm{OH}(g)+\mathrm{CH}_{4}(g) \longrightarrow \mathrm{CH}_{3}(g)+\mathrm{H}_{2} \mathrm{O}(g)
$$

(d) The radical is generated when sunlight hits water vapor. Calculate the maximum wavelength (in nm ) required to break an $\mathrm{O}-\mathrm{H}$ bond in $\mathrm{H}_{2} \mathrm{O}$.
E. 8.128 Vinyl chloride $\left(\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{Cl}\right)$ differs from ethylene $\left(\mathrm{C}_{2} \mathrm{H}_{4}\right)$ in that one of the H atoms is replaced with a Cl atom. Vinyl chloride is used to prepare poly(vinyl chloride), which is an important polymer used in pipes. (a) Draw the Lewis structure of vinyl chloride.
(b) The repeating unit in poly(vinyl chloride) is $-\mathrm{CH}_{2}-\mathrm{CHCl}-$. Draw a portion of the molecule showing three such repeating units. (c) Calculate the enthalpy change when $1.0 \times 10^{3} \mathrm{~kg}$ of vinyl chloride forms poly(vinyl chloride).

E8.129 Experiments show that it takes $1656 \mathrm{~kJ} / \mathrm{mol}$ to break all the bonds in methane $\left(\mathrm{CH}_{4}\right)$ and $4006 \mathrm{~kJ} / \mathrm{mol}$ to break all the bonds in propane $\left(\mathrm{C}_{3} \mathrm{H}_{8}\right)$. Based on these data, calculate the average bond enthalpy of the $\mathrm{C}-\mathrm{C}$ bond.
§8.130 In 1998 scientists using a special type of electron microscope were able to measure the force needed to break a single chemical bond. If $2.0 \times 10^{-9} \mathrm{~N}$ was needed to break a $\mathrm{C}-$ Si bond, estimate the bond enthalpy in $\mathrm{kJ} / \mathrm{mol}$. Assume that the bond has to be stretched by a distance of $2 \AA\left(2 \times 10^{-10} \mathrm{~m}\right)$ before it is broken.
Gy 8.131 The American chemist Robert S. Mulliken suggested a different definition for the electronegativity ( EN ) of an element, given by

$$
\mathrm{EN}=\frac{I E_{1}+E A}{2}
$$

where $I E_{1}$ is the first ionization energy and $E A$ is the electron affinity of the element. Calculate the electronegativities of $\mathrm{O}, \mathrm{F}$, and Cl using the preceding equation. Compare the electronegativities of these elements on the Mulliken and Pauling scales. (To convert to the Pauling scale, divide each EN value by $230 \mathrm{~kJ} / \mathrm{mol}$.)

E 8.132 Among the common inhaled anesthetics are:
Halothane $\left(\mathrm{CF}_{3} \mathrm{CHClBr}\right) \quad$ Isoflurane $\left(\mathrm{CF}_{3} \mathrm{CHClOCHF}_{2}\right)$ Enflurane $\left(\mathrm{CHFClCF}_{2} \mathrm{OCHF}_{2}\right)$ Methoxyflurane $\left(\mathrm{CHCl}_{2} \mathrm{CF}_{2} \mathrm{OCH}_{3}\right)$ Draw Lewis structures of these molecules.
8.133 A student in your class claims that magnesium oxide actually consists of $\mathrm{Mg}^{+}$and $\mathrm{O}^{-}$ions, not $\mathrm{Mg}^{2+}$ and $\mathrm{O}^{2-}$ ions. Suggest some experiments one could do to show that your classmate is wrong.
8.134 From the lattice energy of KCl in Table 8.6, and the ionization energy of K and electron affinity on Cl in Figures 7.8 and 7.10, respectively, calculate the $\Delta H^{\circ}$ for the reaction

$$
\mathrm{K}(g)+\mathrm{Cl}(g) \longrightarrow \mathrm{KCl}(s)
$$

Ef8.135 The species $\mathrm{H}_{3}^{+}$is the simplest polyatomic ion. The geometry of the ion is that of an equilateral triangle. (a) Draw three resonance structures to represent the ion. (b) Given the following information

$$
\begin{aligned}
2 \mathrm{H}+\mathrm{H}^{+} & \mathrm{H}_{3}^{+} \\
\mathrm{H}_{2} & \Delta \mathrm{H}
\end{aligned} \begin{aligned}
& \Delta H^{\circ}=-849 \mathrm{~kJ} / \mathrm{mol} \\
& \Delta H^{\circ}=436.4 \mathrm{~kJ} / \mathrm{mol}
\end{aligned}
$$

calculate $\Delta H^{\circ}$ for the reaction

$$
\mathrm{H}^{+}+\mathrm{H}_{2} \longrightarrow \mathrm{H}_{3}^{+}
$$

E 8.136 The bond enthalpy of the $\mathrm{C}-\mathrm{N}$ bond in the amide group of proteins (see Problem 8.90) can be treated as an average of $\mathrm{C}-\mathrm{N}$ and $\mathrm{C}=\mathrm{N}$ bonds. Calculate the maximum wavelength of light needed to break the bond.
8.137 In 1999 an unusual cation containing only nitrogen ( $\mathrm{N}_{5}^{+}$) was prepared. Draw three resonance structures of the ion, showing formal charges. (Hint: The N atoms are joined in a linear fashion.)
8.138 Write the formulas of the binary hydrides for the second-period elements from Li to F. Identify the bonding in each as covalent, polar covalent, or ionic.
8.139 Using Table 8.6, compare the following bond enthalpies: $\mathrm{C}-\mathrm{C}$ in $\mathrm{C}_{2} \mathrm{H}_{6}, \mathrm{~N}-\mathrm{N}$ in $\mathrm{N}_{2} \mathrm{H}_{4}$, and $\mathrm{O}-\mathrm{O}$ in $\mathrm{H}_{2} \mathrm{O}_{2}$. What effect do lone pairs on adjacent atoms appear to have on bond enthalpy?
8.140 Do a Web search of the following ionic compounds and give brief descriptions of their medical uses: $\mathrm{AgNO}_{3}, \mathrm{BaSO}_{4}, \mathrm{CaSO}_{4}, \mathrm{KI}$, $\mathrm{Li}_{2} \mathrm{CO}_{3}, \mathrm{Mg}(\mathrm{OH})_{2}, \mathrm{NaHCO}_{3}, \mathrm{NaF}, \mathrm{TiO}_{2}, \mathrm{ZnO}$.

## Pre-Professional Practice Exam Problems: Physical and Biological Sciences

Nitrous oxide $\left(\mathrm{N}_{2} \mathrm{O}\right)$ is an anesthetic commonly used for dental procedures. Because of the euphoria caused by inhaling it, $\mathrm{N}_{2} \mathrm{O}$ is commonly known as "laughing gas." It is licensed for use as a food additive and as an aerosol propellant. It is used to displace air from potato chip bags to extend shelf life and as the propellant in whipped cream canisters. In recent years $\mathrm{N}_{2} \mathrm{O}$ has become popular as a recreational drug, due in part to its ready availability to consumers. Although $\mathrm{N}_{2} \mathrm{O}$ is legal, it is regulated by the FDA; its sale and distribution for the purpose of human consumption are not permitted.

| Bond | Bond Enthalpy (kJ/mol) |
| :--- | :---: |
| $\mathrm{N}-\mathrm{O}$ | 176 |
| $\mathrm{~N}=\mathrm{O}$ | 607 |
| $\mathrm{~N}-\mathrm{N}$ | 193 |
| $\mathrm{~N}=\mathrm{N}$ | 418 |
| $\mathrm{~N} \equiv \mathrm{~N}$ | 941.4 |
| $\mathrm{O}=\mathrm{O}$ | 498.7 |

1. Which of the following Lewis structures are possible for $\mathrm{N}_{2} \mathrm{O}$ ?
$: N \equiv N-\ddot{\mathrm{O}}:$
I
$\dot{\mathrm{N}}=\mathrm{N}=\dot{\mathrm{O}} \dot{\circ}$
II
$\dot{\mathrm{N}}=\mathrm{O}=\mathrm{N}^{\dot{\prime}}$
III
$: \ddot{\mathrm{N}}-\mathrm{O}-\ddot{\mathrm{N}}$ :
IV
a) I only
b) I and II
c) I, II, and III
d) I, II, III, and IV
2. Use formal charges to choose the best of the resonance structures shown.
a) I
b) II
c) III
d) IV
3. Using the best resonance structure and the average bond enthalpies given, determine the $\Delta H_{\mathrm{f}}^{\circ}$ for $\mathrm{N}_{2} \mathrm{O}$.
a) $73 \mathrm{~kJ} / \mathrm{mol}$
b) $-73 \mathrm{~kJ} / \mathrm{mol}$
c) $166 \mathrm{~kJ} / \mathrm{mol}$
d) $-166 \mathrm{~kJ} / \mathrm{mol}$
4. Why does the calculated $\Delta H_{\mathrm{f}}^{\circ}$ value differ from the tabulated value of $81.56 \mathrm{~kJ} / \mathrm{mol}$ ?
a) The tabulated value is wrong.
b) None of the resonance structures depicts the bonds realistically.
c) To a reasonable number of significant figures, the calculated and tabulated values are the same.
d) Using bond enthalpies gives only an estimate of $\Delta H_{\mathrm{rxn}}^{\circ}$.

Molecules responsible for the aroma of a substance, such as freshly-baked pie, have distinctive shapes. Their shapes enable molecules to stimulate our sense of smell.

## How Molecular Shape Affects Our Perception of the World

Research has revealed that the geometry or shape of a molecule determines some of its important properties. The 2004 Nobel Prize in Physiology or Medicine was awarded to Richard Axel and Linda Buck for their discoveries of odorant receptors and the organization of the olfactory system. Their work shed new light on how our sense of smell works. Although it is somewhat more complicated than can be explained in detail here, the odor of a molecule depends in large part on which of the olfactory receptors it stimulates. Olfactory receptors are specialized proteins, located on hairlike cilia in the back of the nose. Stimulation of a receptor triggers an electrical signal that travels along nerve fibers to the brain, where the scent is identified. Which olfactory receptors a molecule stimulates depends on its shape.

We are thought to have receptors for at least seven different, fundamental scents: floral, pepperminty, musky, pungent, camphorlike, ethereal, and putrid. Different parts of a larger molecule may have distinctly different shapes, enabling it to stimulate more than one type of olfactory receptor. This results in the perception of a combination of odors. For example, parts of the benzaldehyde molecule are shaped such that they stimulate the camphorlike, floral, and pepperminty receptors. This is a combination that we perceive as the smell of almonds. Such combinations enable us to recognize thousands of different smells.

This discussion illustrates the importance of molecular geometry to the most enigmatic of our senses-smell. Many biochemical processes are specific in that they depend on the shapes of the molecules involved. Chemical bonding theories help us to predict and/ or explain these shapes.

Benzaldehyde

At the end of this chapter, you will be able to answer several questions about the geometry and structure of a molecule with a distinctive, musky odor [ m Page 378].

## In This Chapter, You Will Learn:

How to determine the three-dimensional shape of a molecule and how the interactions of atomic orbitals give rise to chemical bonds.

## Before you begin, you should review

- Shapes of atomic orbitals [ 144 Section 6.7]
- Electron configurations of atoms [ 14 Section 6.8]
- Drawing Lewis structures [1/4 Section 8.5]

Student Annotation: Any atom that is bonded to two or more other atoms can be considered a "central" atom.

Triple bond

### 9.1 Molecular Geometry

Many familiar chemical and biochemical processes depend heavily on the three-dimensional shapes of the molecules and/or ions involved. Our sense of smell is one example; the effectiveness of a particular drug is another. Although the shape of a molecule or polyatomic ion must be determined experimentally, we can predict their shapes reasonably well using Lewis structures [14 Section 8.5] and the valence-shell electron-pair repulsion (VSEPR) model. In this section, we will focus primarily on determining the shapes of molecules of the general type $\mathrm{AB}_{x}$, where A is a central atom surrounded by $x \mathrm{~B}$ atoms and $x$ can have integer values of 2 to 6 . For example, $\mathrm{NH}_{3}$ is an $\mathrm{AB}_{3}$ molecule in which A is nitrogen, B is hydrogen, and $x=3$. Its Lewis structure is shown in the margin.

Table 9.1 lists examples of each type of $\mathrm{AB}_{x}$ molecule and polyatomic ion that we will consider. Throughout this chapter, we will discuss concepts that apply both to molecules and to polyatomic ions, but we will usually refer to them collectively as "molecules."

Having the molecular formula alone is insufficient to predict the shape of a molecule. For instance, $\mathrm{AB}_{2}$ molecules may be linear or bent:

Linear

Bent

Moreover, $\mathrm{AB}_{3}$ molecules may be planar, pyramidal, or T-shaped:

Trigonal planar

Trigonal pyramidal

T-shaped

To determine shape, we must start with a correct Lewis structure and apply the VSEPR model.

## The VSEPR Model

The basis of the VSEPR model is that electron pairs in the valence shell of an atom repel one another. As we learned in Chapter 8, there are two types of electron pairs: bonding pairs and nonbonding pairs (also known as lone pairs). Furthermore, bonding pairs may be found in single bonds or in multiple bonds. For clarity, we will refer to electron domains instead of electron pairs when we use the VSEPR model. An electron domain in this context is a lone pair or a bond, regardless of whether the bond is single, double, or triple. Consider the following examples:

|  | $\begin{gathered} \mathrm{CO}_{2} \\ : \mathrm{O}=\mathrm{C}=0 \dot{O} \end{gathered}$ | $: \begin{gathered} \mathrm{O}_{3} \\ : \mathrm{O}=\ddot{\mathrm{O}}-\ddot{O}: \end{gathered}$ |  |  |  |

## TABLE 9.1

Examples of $\mathrm{AB}_{x}$ Molecules and Polyatomic Ions

| $\mathrm{AB}_{2}$ | $\mathrm{BeCl}_{2}, \mathrm{SO}_{2}, \mathrm{H}_{2} \mathrm{O}, \mathrm{NO}_{2}^{-}$ |
| :--- | :--- |
| $\mathrm{AB}_{3}$ | $\mathrm{BF}_{3}, \mathrm{NH}_{3}, \mathrm{ClF}_{3}, \mathrm{SO}_{3}^{2-}$ |
| $\mathrm{AB}_{4}$ | $\mathrm{CCl}_{4}, \mathrm{NH}_{4}^{+}, \mathrm{SF}_{4}, \mathrm{XeF}_{4}, \mathrm{ClO}_{4}^{-}$ |
| $\mathrm{AB}_{5}$ | $\mathrm{PCl}_{5}, \mathrm{IF}_{5}, \mathrm{SbF}_{5}, \mathrm{BrF}_{5}$ |
| $\mathrm{AB}_{6}$ | $\mathrm{SF}_{6}, \mathrm{UF}_{6}, \mathrm{TiCl}_{6}^{3-}$ |

Note the number of electron domains on the central atom in each molecule. The VSEPR model predicts that because these electron domains repel one another, they will arrange themselves to be as far apart as possible, thus minimizing the repulsive interactions between them.

We can visualize the arrangement of electron domains using balloons, as shown in Figure 9.1. Like the B atoms in our $\mathrm{AB}_{x}$ molecules, the balloons are all connected to a central, fixed point, which represents the central atom (A). When they are as far apart as possible, they adopt the five geometries shown in the figure. When there are only two balloons, they orient themselves to point in opposite directions [Figure 9.1(a)]. With three balloons the arrangement is a trigonal plane [Figure 9.1(b)]. With four balloons the arrangement adopted is a tetrahedron [Figure 9.1(c)]. With five balloons, three of them adopt positions in a trigonal plane whereas the other two point opposite to each other, forming an axis that is perpendicular to the trigonal plane [Figure 9.1(d)]. This geometry is called a trigonal bipyramid. Finally, with six balloons the arrangement is an octahedron, which is essentially a square bipyramid [Figure 9.1(e)]. Each of the $\mathrm{AB}_{x}$ molecules we consider will have one of these five electron-domain geometries: linear, trigonal planar, tetrahedral, trigonal bipyramidal, or octahedral.

Media Player/ MPEG Content
Chemical bonding-VSEPR and molecular geometry (interactive).

Student Annotation: It would be impossible to overstate the importance of being able to draw Lewis structures correctly, especially for students who will go on to study organic chemistry.

Figure 9.2 Five geometries of $\mathrm{AB}_{x}$ molecules in which all the electron domains are bonds.

## Electron-Domain Geometry and Molecular Geometry

It is important to distinguish between the electron-domain geometry, which is the arrangement of electron domains (bonds and lone pairs) around the central atom, and the molecular geometry, which is the arrangement of bonded atoms. Figure 9.2 illustrates the molecular geometries of $\mathrm{AB}_{x}$ molecules in which all the electron domains are bonds-that is, there are no lone pairs on any of the central atoms. In these cases, the molecular geometry is the same as the electron-domain geometry.

In an $\mathrm{AB}_{x}$ molecule, a bond angle is the angle between two adjacent $\mathrm{A}-\mathrm{B}$ bonds. In an $\mathrm{AB}_{2}$ molecule there are only two bonds and therefore only one bond angle, and, provided that there are no lone pairs on the central atom, the bond angle is $180^{\circ} . \mathrm{AB}_{3}$ and $\mathrm{AB}_{4}$ molecules have three and four bonds, respectively. However, in each case there is only one bond angle possible between any two $A-B$ bonds. In an $A B_{3}$ molecule, the bond angle is $120^{\circ}$, and in an $A B_{4}$ molecule, the bond angle is $109.5^{\circ}$-again, provided that there are no lone pairs on the central atoms. Similarly, in an $\mathrm{AB}_{6}$ molecule the bond angles between adjacent bonds are all $90^{\circ}$. (The angle between any two $\mathrm{A}-\mathrm{B}$ bonds that point in opposite directions is $180^{\circ}$.)
$\mathrm{AB}_{5}$ molecules contain two different bond angles between adjacent bonds. The reason for this is that, unlike those in the other $\mathrm{AB}_{x}$ molecules, the positions occupied by bonds in a trigonal bipyramid are not all equivalent. The three bonds that are arranged in a trigonal plane are referred to as equatorial. The bond angle between any two of the three equatorial bonds is $120^{\circ}$. The two bonds that form an axis perpendicular to the trigonal plane are referred to as axial. The bond angle between either of the axial bonds and any one of the equatorial bonds is $90^{\circ}$. (As in the case of the $\mathrm{AB}_{6}$ molecule, the angle between any two $\mathrm{A}-\mathrm{B}$ bonds that point in opposite directions is $180^{\circ}$.) Figure 9.2 illustrates all these bond angles. The angles shown in the figure are the bond angles that are observed when all the electron domains on the central atom are identical. As we will see later in this section, the bond angles in many molecules will differ slightly from these ideal values.

When the central atom in an $\mathrm{AB}_{x}$ molecule bears one or more lone pairs, the electron-domain geometry and the molecular geometry are no longer the same. However, we still use the electrondomain geometry as a first step in determining the molecular geometry. The first step in determining the molecular geometry of $\mathrm{O}_{3}$ (or any species), for example, is to draw its Lewis structure. Two different resonance structures can be drawn for $\mathrm{O}_{3}$ :

$$
: \dot{\mathrm{O}}=\ddot{\mathrm{O}}-\ddot{\mathrm{O}}: \quad \longleftrightarrow \quad: \ddot{\mathrm{O}}-\ddot{\mathrm{O}}=\dot{\mathrm{O}}
$$

Either one can be used to determine its geometry.
The next step is to count the electron domains on the central atom. In this case, there are three: one single bond, one double bond, and one lone pair. Using the VSEPR model, we first determine the electron-domain geometry. According to the information in Figure 9.2, three electron domains on the central atom will be arranged in a trigonal plane. Molecular geometry, however, is dictated by the arrangement of atoms. If we consider only the positions of the three atoms in this molecule, the molecular geometry (the molecule's shape) is bent.

Electron-domain geometry: trigonal planar

Molecular geometry: bent

In addition to the five basic geometries depicted in Figure 9.2, you must be familiar with how molecular geometry can differ from electron-domain geometry. Table 9.2 shows the common

## TABLE 9.2

| Molecular |
| :---: |
| Geometry | Example

\end{tabular}

molecular geometries where there are one or more lone pairs on the central atom. Note the positions occupied by the lone pairs in the trigonal bipyramidal electron-domain geometry. When there are lone pairs on the central atom in a trigonal bipyramid, the lone pairs preferentially occupy equatorial positions because repulsion is greater when the angle between electron domains is $90^{\circ}$ or less. Placing a lone pair in an axial position would put it at $90^{\circ}$ to three other electron domains. Placing it in an equatorial position puts it at $90^{\circ}$ to only two other domains, thus minimizing the number of strong repulsive interactions.

All positions are equivalent in the octahedral geometry, so one lone pair on the central atom can occupy any of the positions. If there is a second lone pair in this geometry, though, it must occupy the position opposite the first. This arrangement minimizes the repulsive forces between the two lone pairs (they are $180^{\circ}$ apart instead of $90^{\circ}$ apart).

In summary, the steps to determine the electron-domain and molecular geometries are as follows:

1. Draw the Lewis structure of the molecule or polyatomic ion.
2. Count the number of electron domains on the central atom.
3. Determine the electron-domain geometry by applying the VSEPR model.
4. Determine the molecular geometry by considering the positions of the atoms only.

Sample Problem 9.1 shows how to determine the shape of a molecule or polyatomic ion.

## Sample Problem 9.1

Determine the shapes of (a) $\mathrm{SO}_{3}$ and (b) $\mathrm{ICl}_{4}^{-}$.
Strategy Use Lewis structures and the VSEPR model to determine first the electron-domain geometry and then the molecular geometry (shape).

Setup (a) The Lewis structure of $\mathrm{SO}_{3}$ is:

There are three electron domains on the central atom: one double bond and two single bonds.
(b) The Lewis structure of $\mathrm{ICl}_{4}^{-}$is:

There are six electron domains on the central atom in $\mathrm{ICl}_{4}^{-}$: four single bonds and two lone pairs.

## Solution

(a) According to the VSEPR model, three electron domains will be arranged in a trigonal plane. Since there are no lone pairs on the central atom in $\mathrm{SO}_{3}$, the molecular geometry is the same as the electron-domain geometry. Therefore, the shape of $\mathrm{SO}_{3}$ is trigonal planar.

Electron-domain geometry: trigonal planar $\longrightarrow$ Molecular geometry: trigonal planar
(b) Six electron domains will be arranged in an octahedron. Two lone pairs on an octahedron will be located on opposite sides of the central atom, making the shape of $\mathrm{ICl}_{4}^{-}$square planar.

Think About It Compare these results with the information in Figure 9.2 and Table 9.2. Make sure that you can draw Lewis structures correctly. Without a correct Lewis structure, you will be unable to determine the shape of a molecule.

Electron-domain geometry: octahedral

$\longrightarrow$

Molecular geometry: square planar

Practice Problem A Determine the shapes of (a) $\mathrm{CO}_{2}$ and (b) $\mathrm{SCl}_{2}$.
HPractice Problem B (a) From what group must the terminal atoms come in an $\mathrm{AB}_{x}$ molecule where the central atom is from Group 6A, for the electron-domain geometry and the molecular geometry both to be trigonal planar? (b) From what group must the terminal atoms come in an $\mathrm{AB}_{x}$ molecule where the central atom is from Group 7A, for the electron-domain geometry to be octahedral and the molecular geometry to be square pyramidal?

## Deviation from Ideal Bond Angles

Some electron domains are better than others at repelling neighboring domains. As a result, the bond angles may be slightly different from those shown in Figure 9.2. For example, the electrondomain geometry of ammonia $\left(\mathrm{NH}_{3}\right)$ is tetrahedral, so we might predict the $\mathrm{H}-\mathrm{N}-\mathrm{H}$ bond angles to be $109.5^{\circ}$. In fact, the bond angles are about $107^{\circ}$, slightly smaller than predicted. The lone pair on the nitrogen atom repels the $\mathrm{N}-\mathrm{H}$ bonds more strongly than the bonds repel one another. It therefore "squeezes" them closer together than the ideal tetrahedral angle of $109.5^{\circ}$.

In effect, a lone pair takes up more space than the bonding pairs. This can be understood by considering the attractive forces involved in determining the location of the electron pairs. A lone pair on a central atom is attracted only to the nucleus of that atom. A bonding pair of electrons, on the other hand, is simultaneously attracted by the nuclei of both of the bonding atoms. As a result, the lone pair has more freedom to spread out and greater capacity to repel other electron domains. Also, because they contain more electron density, multiple bonds repel more strongly than single bonds. Consider the bond angles in each of the following examples:

## Geometry of Molecules with More Than One Central Atom

Thus far we have considered the geometries of molecules having only one central atom. We can determine the overall geometry of more complex molecules by treating them as though they have multiple central atoms. Methanol $\left(\mathrm{CH}_{3} \mathrm{OH}\right)$, for example, has a central C atom and a central O atom, as shown in the following Lewis structure:

Both the C and the O atoms are surrounded by four electron domains. In the case of C , they are three $\mathrm{C}-\mathrm{H}$ bonds and one $\mathrm{C}-\mathrm{O}$ bond. In the case of O , they are one $\mathrm{O}-\mathrm{C}$ bond, one $\mathrm{O}-\mathrm{H}$ bond, and two lone pairs. In each case, the electron-domain geometry is tetrahedral. However, the molecular geometry of the C part of the molecule is tetrahedral, whereas the molecular geometry of the O part of the molecule is bent. Note that although the Lewis structure makes it appear as though there is a $180^{\circ}$ angle between the $\mathrm{O}-\mathrm{C}$ and $\mathrm{O}-\mathrm{H}$ bonds, the angle is actually approximately $109.5^{\circ}$, the angle in a tetrahedral arrangement of electron domains.

Sample Problem 9.2 shows how to determine when bond angles differ from ideal values.

## Sample Problem 9.2

Acetic acid, the substance that gives vinegar its characteristic smell and sour taste, is sometimes used in combination with corticosteroids to treat certain types of ear infections. Its Lewis structure is

Student Annotation: When we specify the geometry of a particular portion of a molecule, we refer to it as the geometry "about" a particular atom. In methanol, for example, we say that the geometry is tetrahedral about the C atom and bent about the O atom.

Think About It Compare these answers with the information in Figure 9.2 and Table 9.2.

Determine the molecular geometry about each of the central atoms, and determine the approximate value of each of the bond angles in the molecule. Which if any of the bond angles would you expect to be smaller than the ideal values?

Strategy Identify the central atoms and count the number of electron domains around each of them. Use the VSEPR model to determine each electron-domain geometry, and the information in Table 9.2 to determine the molecular geometry about each central atom.

Setup The leftmost C atom is surrounded by four electron domains: one $\mathrm{C}-\mathrm{C}$ bond and three $\mathrm{C}-\mathrm{H}$ bonds. The middle C atom is surrounded by three electron domains: one $\mathrm{C}-\mathrm{C}$ bond, one $\mathrm{C}-\mathrm{O}$ bond, and one $\mathrm{C}=\mathrm{O}$ (double) bond. The O atom is surrounded by four electron domains: one $\mathrm{O}-\mathrm{C}$ bond, one $\mathrm{O}-\mathrm{H}$ bond, and two lone pairs.

Solution The electron-domain geometry of the leftmost C is tetrahedral. Because all four electron domains are bonds, the molecular geometry of this part of the molecule is also tetrahedral. The electrondomain geometry of the middle C is trigonal planar. Again, because all the domains are bonds, the molecular geometry is also trigonal planar. The electron-domain geometry of the O atom is tetrahedral. Because two of the domains are lone pairs, the molecular geometry about the O atom is bent.

Bond angles are determined using electron-domain geometry. Therefore, the approximate bond angles about the leftmost C are $109.5^{\circ}$, those about the middle C are $120^{\circ}$, and those about the O are $109.5^{\circ}$. The angle between the two single bonds on the middle carbon will be less than $120^{\circ}$ because the double bond repels the single bonds more strongly than they repel each other. Likewise, the bond angle between the two bonds on the O will be less than $109.5^{\circ}$ because the lone pairs on O repel the single bonds more strongly than they repel each other and push the two bonding pairs closer together. The angles are labeled as follows:

Practice Problem A Ethanolamine $\left(\mathrm{HOCH}_{2} \mathrm{CH}_{2} \mathrm{NH}_{2}\right)$ has a smell similar to ammonia and is commonly found in biological tissues. Its Lewis structure is

Determine the molecular geometry about each central atom and label all the bond angles. Cite any expected deviations from ideal bond angles.

EfPractice Problem B The bond angle in $\mathrm{NH}_{3}$ is significantly smaller than the ideal bond angle of $109.5^{\circ}$ because of the lone pair on the central atom. Explain why the bond angle in $\mathrm{SO}_{2}$ is very close to $120^{\circ}$ despite there being a lone pair on the central atom.

## Checkpoint 9.1 Molecular Geometry

9.1.1 What are the electron-domain geometry and molecular geometry of $\mathrm{CO}_{3}^{2-}$ ?
a) tetrahedral, trigonal planar
b) tetrahedral, trigonal pyramidal
c) trigonal pyramidal, trigonal pyramidal
d) trigonal planar, trigonal planar
e) tetrahedral, tetrahedral
9.1.2 What are the electron-domain geometry and molecular geometry of $\mathrm{ClO}_{3}^{-}$?
a) tetrahedral, trigonal planar
b) tetrahedral, trigonal pyramidal
c) trigonal pyramidal, trigonal pyramidal
d) trigonal planar, trigonal planar
e) tetrahedral, tetrahedral
9.1.3 What is the approximate value of the bond angle indicated?

a) $<90^{\circ}$
b) $<109.5^{\circ}$
c) $>109.5^{\circ}$
d) $>120^{\circ}$
e) $<120^{\circ}$
9.1.4 What is the approximate value of the bond angle indicated?
9.1.5 Which of the following shows a deviation from ideal bond angles that is not possible for an $\mathrm{AB}_{x}$ molecule?

Seesaw-

### 9.2 Molecular Geometry and Polarity

Molecular geometry is tremendously important in understanding the physical and chemical behavior of a substance. Molecular polarity, for example, is one of the most important consequences of molecular geometry, because molecular polarity influences physical, chemical, and biological properties. Recall from Section 8.4 that a bond between two atoms of different electronegativities is polar and that a diatomic molecule containing a polar bond is a polar molecule. Whether a molecule made up of three or more atoms is polar depends not only on the polarity of the individual bonds, but also on its molecular geometry.

Each of the $\mathrm{CO}_{2}$ and $\mathrm{H}_{2} \mathrm{O}$ molecules contains two identical atoms bonded to a central atom and two polar bonds. However, only one of these molecules is polar. To understand why, think of each individual bond dipole as a vector. The overall dipole moment of the molecule is determined by vector addition of the individual bond dipoles.

In the case of $\mathrm{CO}_{2}$, we have two identical vectors pointing in opposite directions. When the vectors are placed on a Cartesian coordinate system, they have no $y$ component and their $x$ components are equal in magnitude but opposite in sign. The sum of these two vectors is zero in both the $x$ and $y$ directions. Thus, although the bonds in $\mathrm{CO}_{2}$ are polar, the molecule is nonpolar.

The vectors representing the bond dipoles in water, although equal in magnitude and opposite in the $x$ direction, are not opposite in the $y$ direction. Therefore, although their $x$ components sum to zero, their $y$ components do not. This means that there is a net resultant dipole and $\mathrm{H}_{2} \mathrm{O}$ is polar.

Chemical bonding-molecular geometry and polarity (interactive).

Student Annotation: Recall that we can represent an individual bond dipole using a crossed arrow that points toward the more electronegative atom [144 Section 8.4].

# Can More Complex Molecules Contain Polar Bonds and Still Be Nonpolar? 

In $\mathrm{AB}_{x}$ molecules where $x \geq 3$, it may be less obvious whether the individual bond dipoles cancel one another. Consider the molecule $\mathrm{BF}_{3}$, for example, which has a trigonal planar geometry:

We will simplify the math in this analysis by assigning the vectors representing the three identical $\mathrm{B}-\mathrm{F}$ bonds an arbitrary magnitude of 1.00 . The $x, y$ coordinates for the end of arrow 1 are ( $0,1.00$ ). Determining the coordinates for the ends of arrows 2 and 3 requires the use of trigonometric functions. You may have learned the mnemonic SOH CAH TOA, where the letters stand for

> Sin $=$ Opposite over Hypotenuse
> Cos $=$ Adjacent over Hypotenuse
> Tan $=$ Opposite over Adjacent

The $x$ coordinate for the end of arrow 2 corresponds to the length of the line opposite the $60^{\circ}$ angle. The hypotenuse of the triangle has a length of 1.00 (the arbitrarily assigned value). Therefore, using SOH ,

$$
\sin 60^{\circ}=0.866=\frac{\text { opposite }}{\text { hypotenuse }}=\frac{\text { opposite }}{1}
$$

so the $x$ coordinate for the end of arrow 2 is 0.866 .
The magnitude of the $y$ coordinate corresponds to the length of the line adjacent to the $60^{\circ}$ angle. Using TOA,

$$
\begin{aligned}
\tan 60^{\circ}=1.73 & =\frac{\text { opposite }}{\text { adjacent }}=\frac{0.866}{\text { adjacent }} \\
\text { adjacent } & =\frac{0.866}{1.73}=0.500
\end{aligned}
$$

so the $y$ coordinate for the end of arrow 2 is -0.500 . (The trigonometric formula gives us the length of the side. We know from the diagram that the sign of this $y$ component is negative.)

Arrow 3 is similar to arrow 2. Its $x$ component is equal in magnitude but opposite in sign, and its $y$ component is the same magnitude and sign as that for arrow 2. Therefore, the $x$ and $y$ coordinates for all three vectors are

|  | $x$ | $y$ |
| :--- | :---: | :---: |
| Arrow 1 | 0 | 1 |
| Arrow 2 | 0.866 | -0.500 |
| Arrow 3 | -0.866 | -0.500 |
| Sum $=$ | 0 | 0 |

Because the individual bond dipoles (represented here as the vectors) sum to zero, the molecule is nonpolar overall.

Although it is somewhat more complicated, a similar analysis can be done to show that all $x, y$, and $z$ coordinates sum to zero when there are four identical polar bonds arranged in a tetrahedron about a central atom. In fact, any time there are identical bonds symmetrically distributed around a central atom, with no lone pairs on the central atom, the molecule will be nonpolar overall, even if the bonds themselves are polar.

In cases where the bonds are distributed symmetrically around the central atom, the nature of the atoms surrounding the central atom determines whether the molecule is polar overall. For example, $\mathrm{CCl}_{4}$ and $\mathrm{CHCl}_{3}$ have the same molecular geometry (tetrahedral), but $\mathrm{CCl}_{4}$ is nonpolar because the bond dipoles cancel one another. In $\mathrm{CHCl}_{3}$, however, the bonds are not all

Dipole moments can be used to distinguish between molecules that have the same chemical formula but different arrangements of atoms. Such compounds are called structural isomers. For example, there are two structural isomers of dichloroethylene $\left(\mathrm{C}_{2} \mathrm{H}_{2} \mathrm{Cl}_{2}\right)$. Because the individual bond dipoles sum to zero in trans-dichloroethylene, the trans isomer is nonpolar:

$\Sigma x=0$
$\Sigma y=0$
overall: $\Sigma=0$
identical, and therefore the bond dipoles do not sum to zero. The $\mathrm{CHCl}_{3}$ molecule is polar.

Sample Problem 9.3 shows you how to determine whether a molecule is polar.

## Sample Problem 9.3

Determine whether (a) $\mathrm{PCl}_{5}$ and (b) $\mathrm{H}_{2} \mathrm{CO}$ (C double bonded to O ) are polar.
Strategy For each molecule, draw the Lewis structure, use the VSEPR model to determine its molecular geometry, and then determine whether the individual bond dipoles cancel.

Setup (a) The Lewis structure of $\mathrm{PCl}_{5}$ is

With five identical electron domains around the central atom, the electron-domain and molecular geometries are trigonal bipyramidal. The equatorial bond dipoles will cancel one another, just as in the case of $\mathrm{BF}_{3}$, and the axial bond dipoles will also cancel each other.
(b) The Lewis structure of $\mathrm{H}_{2} \mathrm{CO}$ is

The bond dipoles, although symmetrically distributed around the C atom, are not identical and therefore will not sum to zero.

Solution (a) $\mathrm{PCl}_{5}$ is nonpolar.
(b) $\mathrm{H}_{2} \mathrm{CO}$ is polar.

Think About It Make sure that your Lewis structures are correct and that you count electron domains on the central atom carefully. This will give you the correct electron-domain and molecular geometries. Molecular polarity depends both on individual bond dipoles and molecular geometry.

Practice Problem A Determine whether (a) $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ and (b) $\mathrm{XeF}_{4}$ are polar.
HPractice Problem B For which molecular geometries (linear, bent, trigonal planar, trigonal pyramidal, tetrahedral, square planar, T-shaped, seesaw-shaped, trigonal bipyramidal, square pyramidal, octahedral) can an $\mathrm{AB}_{x}$ molecule be nonpolar if there are (a) two different types of terminal atoms and (b) three different types of terminal atoms?

The bond dipoles in the cis isomer do not cancel one another, so cis-dichloroethylene is polar:

Because of the difference in polarity, these two isomers can be distinguished experimentally by measuring the dipole moment.

## How Are Electrons in Orbitals Represented?

In Chapter 6 we learned that although an electron is a particle with a known mass, it exhibits wavelike properties. The quantum mechanical model of the atom, which gives rise to the familiar shapes of $s$ and $p$ atomic orbitals, treats electrons in atoms as waves, rather than particles. Therefore, rather than use arrows to denote the locations and spins of electrons, we will adopt a convention whereby a singly occupied orbital will appear as a light color and a doubly occupied
orbital will appear as a darker version of the same color. In the representations of orbitals that follow, atomic $s$ orbitals will be represented as yellow, and atomic $p$ orbitals will be represented as light blue if singly occupied and darker blue if doubly occupied. (Empty $p$ orbitals will appear white.) When two electrons occupy the same atomic orbital, their spins are paired. Paired electrons occupy the same orbital and have opposite spins [ 14 Section 6.6].

## Checkpoint 9.2 Molecular Geometry and Polarity

9.2.1 Identify the polar molecules in the following group: $\mathrm{HBr}, \mathrm{CH}_{4}, \mathrm{CS}_{2}$.
a) HBr only
b) HBr and $\mathrm{CS}_{2}$

b) $\mathrm{SO}_{2}$ only
c) $\mathrm{XeF}_{2}$ only
d) $\mathrm{SO}_{2}$ and $\mathrm{XeF}_{2}$
e) $\mathrm{SO}_{2}$ and $\mathrm{NH}_{3}$

### 9.3 Valence Bond Theory

$\mathrm{H}-\mathrm{H}$
:ت̈.- F :
$\mathrm{H}-\ddot{\mathrm{F}}:$
Lewis dot structures of $\mathrm{H}_{2}, \mathrm{~F}_{2}$, and HF

The Lewis theory of chemical bonding provides a relatively simple way for us to visualize the arrangement of electrons in molecules. It is insufficient, however, to explain the differences between the covalent bonds in compounds such as $\mathrm{H}_{2}, \mathrm{~F}_{2}$, and HF. Although Lewis theory describes the bonds in these three molecules in exactly the same way, they really are quite different from one another, as evidenced by their bond lengths and bond enthalpies listed in Table 9.3. Understanding these differences and why covalent bonds form in the first place requires a bonding model that combines Lewis's notion of atoms sharing electron pairs and the quantum mechanical descriptions of atomic orbitals.

According to valence bond theory, atoms share electrons when an atomic orbital on one atom overlaps with an atomic orbital on the other. Each of the overlapping atomic orbitals must

## TABLE 9.3

## Bond Lengths and Bond Enthalpies of $\mathrm{H}_{2}, \mathrm{~F}_{2}$, and HF

|  | Bond Length (Å) | Bond Enthalpy (kJ/mol) |
| :--- | :---: | :---: |
| $\mathrm{H}_{2}$ | 0.74 | 436.4 |
| $\mathrm{~F}_{2}$ | 1.42 | 150.6 |
| HF | 0.92 | 568.2 |

contain a single, unpaired electron. Furthermore, the two electrons shared by the bonded atoms must have opposite spins [ 14 Section 6.6]. The nuclei of both atoms are attracted to the shared pair of electrons. It is this mutual attraction for the shared electrons that holds the atoms together.

The $\mathrm{H}-\mathrm{H}$ bond in $\mathrm{H}_{2}$ forms when the singly occupied $1 s$ orbitals of the two H atoms overlap:

Similarly, the $\mathrm{F}-\mathrm{F}$ bond in $\mathrm{F}_{2}$ forms when the singly occupied $2 p$ orbitals of the two F atoms overlap:

Recall that the ground-state electron configuration of the F atom is [He] $2 s^{2} 2 p^{5}$ [ KA Section 6.8]. (The ground-state orbital diagram of F is shown in the margin.)

We can also depict the formation of an $\mathrm{H}-\mathrm{F}$ bond using the valence bond model. In this case, the singly occupied $1 s$ orbital of the H atom overlaps with the singly occupied $2 p$ orbital of the F atom:

According to the quantum mechanical model, the sizes, shapes, and energies of the $1 s$ orbital of H and the $2 p$ orbital of F are different. Therefore, it is not surprising that the bonds in $\mathrm{H}_{2}, \mathrm{~F}_{2}$, and HF vary in strength and length.

HF
Ball-and-stick models

Student Annotation: Keep in mind that although there are still just two electrons, each atom "thinks" it owns them both, so when the singly occupied orbitals overlap, both orbitals end up doubly occupied.

Orbital diagram for F

Figure 9.3 The change in potential energy of two hydrogen atoms as a function of internuclear distance. The minimum potential energy ( $-436 \mathrm{~kJ} / \mathrm{mol}$ ) occurs when the distance between the nuclei is 74 pm . The yellow spheres represent the $1 s$ orbitals of hydrogen.

Student Annotation: Recall that the enthalpy change for a forward process and that for the reverse process differ only in sign: $\Delta H_{\text {formard }}=-\Delta H_{\text {reverse }}$ [144 Section 5.3].

Student Annotation: For you to understand the material in this section and Section 9.4, you must be able to draw orbital diagrams for ground-state electron configurations [14 Section 6.8].

Why do covalent bonds form? According to valence bond theory, a covalent bond will form between two atoms if the potential energy of the resulting molecule is lower than that of the isolated atoms. Simply put, this means that the formation of covalent bonds is exothermic. While this fact may not seem intuitively obvious, you know that energy must be supplied to a molecule to break covalent bonds [ 14 Section 8.9]. Because the formation of a bond is the reverse process, we should expect energy to be given off. Figure 9.3 illustrates how the potential energy of two hydrogen atoms varies with distance between the nuclei.

Valence bond theory also introduces the concept of directionality to chemical bonds. For example, we expect the bond formed by the overlap of a $p$ orbital to coincide with the axis along which the $p$ orbital lies. Consider the molecule $\mathrm{H}_{2} \mathrm{~S}$. Unlike the other molecules that we have encountered, $\mathrm{H}_{2} \mathrm{~S}$ does not have the bond angle that Lewis theory and the VSEPR model would lead us to predict. (With four electron domains on the central atom, we would expect the bond angle to be on the order of $109.5^{\circ}$.) In fact, the $\mathrm{H}-\mathrm{S}-\mathrm{H}$ bond angle is $92^{\circ}$. Looking at this in terms of valence bond theory, the central atom ( $S$ ) has two unpaired electrons, each of which resides in a $3 p$ orbital. The orbital diagram for the ground-state electron configuration of the S atom is

$$
\mathrm{S} \quad[\mathrm{Ne}] \begin{array}{|c|}
\hline 1 \downarrow \\
3 s^{2}
\end{array} \frac{1 \downarrow 1 \mid 1}{3 p^{4}}
$$

Remember that $p$ orbitals are mutually perpendicular, lying along the $x, y$, and $z$ axes [ 144 Section 6.7]. We can rationalize the observed bond angle by envisioning the overlap of each of the singly occupied $3 p$ orbitals with the $1 s$ orbital of a hydrogen atom:

In summary, the important features of valence bond theory are as follows:

- A bond forms when singly occupied atomic orbitals on two atoms overlap.
- The two electrons shared in the region of orbital overlap must be of opposite spin.
- Formation of a bond results in a lower potential energy for the system.

Sample Problem 9.4 shows how to use valence bond theory to explain the bonding in a molecule.

## Sample Problem 9.4

Hydrogen selenide $\left(\mathrm{H}_{2} \mathrm{Se}\right)$ is a foul-smelling gas that can cause eye and respiratory tract inflammation. The $\mathrm{H}-\mathrm{Se}-\mathrm{H}$ bond angle in $\mathrm{H}_{2} \mathrm{Se}$ is approximately $92^{\circ}$. Use valence bond theory to describe the bonding in this molecule.

Strategy Consider the central atom's ground-state electron configuration, and determine what orbitals are available for bond formation.

Setup The ground-state electron configuration of Se is $[\mathrm{Ar}] 4 s^{2} 3 d^{10} 4 p^{4}$. Its orbital diagram (showing only the $4 p$ orbitals) is

Solution Two of the $4 p$ orbitals are singly occupied and therefore available for bonding. The bonds in $\mathrm{H}_{2} \mathrm{Se}$ form as the result of the overlap of a hydrogen $1 s$ orbital with each of these orbitals on the Se atom.

Practice Problem A Use valence bond theory to describe the bonding in phosphine $\left(\mathrm{PH}_{3}\right)$, which has $\mathrm{H}-\mathrm{P}-\mathrm{H}$ bond angles of approximately $94^{\circ}$.

HPractice Problem B For which molecule(s) can we not use valence bond theory to explain the bonding: $\mathrm{SO}_{2}\left(\mathrm{O}-\mathrm{S}-\mathrm{O}\right.$ bond angle $\left.\sim 120^{\circ}\right), \mathrm{CH}_{4}\left(\mathrm{H}-\mathrm{C}-\mathrm{H}\right.$ bond angles $\left.=109.5^{\circ}\right)$, $\mathrm{AsH}_{3}\left(\mathrm{H}-\mathrm{As}-\mathrm{H}\right.$ bond angles $\left.=92^{\circ}\right)$ ? Explain.

## Checkpoint 9.3 Valence Bond Theory

a) O
b) Be
c) $B$
d) F
e) Ne
e) 6

### 9.4 Hybridization of Atomic Orbitals

Although valence bond theory is useful and can explain more of our experimental observations than Lewis bond theory, it fails to explain the bonding in many of the molecules that we encounter. According to valence bond theory, for example, an atom must have a singly occupied atomic orbital to form a bond with another atom. How then do we explain the bonding in $\mathrm{BeCl}_{2}$ ? The central atom, Be, has a ground-state electron configuration of $[\mathrm{He}] 2 s^{2}$, so it has no unpaired electrons. With no singly occupied atomic orbitals in its ground state, how does Be form two bonds?

Furthermore, in cases where the ground-state electron configuration of the central atom does have the required number of unpaired electrons, how do we explain the observed bond angles? Carbon, like sulfur, has two unpaired electrons in its ground state. Using valence bond theory as our guide, we might envision the formation of two covalent bonds with oxygen, as in $\mathrm{CO}_{2}$. If the two unpaired electrons on C (each residing in a $2 p$ orbital) were to form bonds, however, the $\mathrm{O}-\mathrm{C}-\mathrm{O}$ bond angle should be on the order of $90^{\circ}$, like the bond angle in $\mathrm{H}_{2} \mathrm{~S}$. In fact, the bond angle in $\mathrm{CO}_{2}$ is $180^{\circ}$ :

Think About lt Because the $4 p$ orbitals on the Se atom are all mutually perpendicular, we should expect the angles between bonds formed by their overlap to be approximately $90^{\circ}$.

$$
\begin{gathered}
: \ddot{\mathrm{C}} \mathrm{l}-\mathrm{Be}-\ddot{\mathrm{C}} \mathrm{l}: \\
\mathrm{BeCl}_{2}
\end{gathered}
$$

Student Annotation: The ground-state orbital diagram for C is:

Hybrid orbitals—orbital hybridization (interactive).

Student Annotation: Remember that Be is one of the atoms that does not obey the octet rule [ 144 Section 8.1]. The Lewis structure of $\mathrm{BeCl}_{2}$ is

$$
: \ddot{\mathrm{C}} \mathrm{l}-\mathrm{Be}-\ddot{\mathrm{C}} \mathrm{l} \mathrm{l}
$$

Orbital diagram for Cl

Student Annotation: Hybrid orbitals are another type of electron domain.

Actual bond angle is $180^{\circ}$.

Bond angle should be $90^{\circ}$.
To explain these and other observations, we need to extend our discussion of orbital overlap to include the concept of hybridization or mixing of atomic orbitals.

The idea of hybridization of atomic orbitals begins with the molecular geometry and works backward to explain the bonds and the observed bond angles in a molecule. To extend our discussion of orbital overlap and introduce the concept of hybridization of atomic orbitals, we first consider beryllium chloride $\left(\mathrm{BeCl}_{2}\right)$, which has two electron domains on the central atom. Using its Lewis structure (shown in the margin) and the VSEPR model, we predict that $\mathrm{BeCl}_{2}$ will have a $\mathrm{Cl}-\mathrm{Be}-\mathrm{Cl}$ bond angle of $180^{\circ}$. If this is true, though, how does Be form two bonds with no unpaired electrons, and why is the angle between the two bonds $180^{\circ}$ ?

To answer the first part of the question, we envision the promotion of one of the electrons in the $2 s$ orbital to an empty $2 p$ orbital. Recall that electrons can be promoted from a lower atomic orbital to a higher one [ $\mathrm{H4}$ Section 6.3]. The ground-state electron configuration is the one in which all the electrons occupy orbitals of the lowest possible energy. A configuration in which one or more electrons occupy a higher energy orbital is called an excited state. An excited state generally is denoted with an asterisk (e.g., $\mathrm{Be}^{*}$ for an excited-state Be atom). Showing only the valence orbitals, we can represent the promotion of one of the valence electrons of beryllium as

With one of its valence electrons promoted to the $2 p$ subshell, the Be atom now has two unpaired electrons and therefore can form two bonds. However, the orbitals in which the two unpaired electrons reside are different from each other, so we would expect bonds formed as a result of the overlap of these two orbitals (each with a $3 p$ orbital on a Cl atom) to be different:

Experimentally, though, the bonds in $\mathrm{BeCl}_{2}$ are identical in length and strength.

## Hybridization of $s$ and $p$ Orbitals

To explain how beryllium forms two identical bonds, we must mix the orbitals in which the unpaired electrons reside, thus yielding two equivalent orbitals. The mixing of beryllium's $2 s$ orbital with one of its $2 p$ orbitals, a process known as hybridization, yields two hybrid orbitals that are neither $s$ nor $p$, but have some character of each. The hybrid orbitals are designated $2 s p$ or simply $s p$.

Mixing of one $s$ orbital and one $p$ orbital to yield two $s p$ orbitals

Figure 9.4 (a) An atomic $s$ orbital (yellow) and one atomic $p$ orbital (blue) combine to form two $s p$ hybrid orbitals (green). The realistic hybrid orbital shapes are shown first. The thinner representations are used to keep diagrams clear. (b) The $2 s$ orbital and one of the $2 p$ orbitals on Be combine to form two $s p$ hybrid orbitals. Unoccupied orbitals are shown in white. Like any two electron domains, the hybrid orbitals on Be are $180^{\circ}$ apart. (c) The hybrid orbitals on Be each overlap with a singly occupied $3 p$ orbital on a Cl atom.

The mathematical combination of the quantum mechanical wave functions for an $s$ orbital and a $p$ orbital gives rise to two new, equivalent wave functions. As shown in Figure 9.4(a), each $s p$ hybrid orbital has one small lobe and one large lobe and, like any two electron domains on an atom, they are oriented in opposite directions with a $180^{\circ}$ angle between them. The figure shows the atomic and hybrid orbitals separately for clarity. Note that the hybrid orbitals are shown in two ways: the first is a more realistic shape, whereas the second is a simplified shape that we use to keep the figures clear and make the visualization of orbitals easier. Note also that the representations of hybrid orbitals are green. Figure 9.4(b) shows the locations of the atomic orbitals and the hybrid orbitals, respectively, relative to the beryllium nucleus.

With two $s p$ hybrid orbitals, each containing a single unpaired electron, we can see how the Be atom is able to form two identical bonds with two Cl atoms [Figure 9.4(c)]. Each of the singly occupied $s p$ hybrid orbitals on the Be atom overlaps with the singly occupied $3 p$ atomic orbital on aCl atom.

We can do a similar analysis of the bonds and the trigonal-planar geometry of boron trifluoride $\left(\mathrm{BF}_{3}\right)$. The ground-state electron configuration of the B atom is $[\mathrm{He}] 2 s^{2} 2 p^{1}$, containing just one unpaired electron. Promotion of one of the $2 s$ electrons to an empty $2 p$ orbital gives the three unpaired electrons needed to explain the formation of three bonds. The ground-state and excitedstate electron configurations can be represented by

Student Annotation: In picturing the shapes of the resulting hybrid orbitals it may help to remember that orbitals, like waves, can combine constructively or destructively. We can think of the large lobe of each sp hybrid orbital as the result of a constructive combination and the small lobe of each as the result of a destructive combination.

Student Annotation: The energy required to promote an electron in an atom is more than compensated for by the energy given off when a bond forms.

$\mathrm{BF}_{3}$

Figure 9.5 (a) An $s$ atomic orbital and two $p$ atomic orbitals combine to form three $s p^{2}$ hybrid orbitals. (b) The three $s p^{2}$ hybrid orbitals on B are arranged in a trigonal plane. (Empty atomic orbitals are shown in white.) (c) Hybrid orbitals on B overlap with $2 p$ orbitals on F .

Student Annotation: A hybrid orbital analysis starts with a known molecular geometry and known bond angles. It is not used to predict geometries.

Student Annotation: Empty unhybridized $p$ orbitals are important in certain types of bond formation, as we will see in Chapters 10 and 16.

$\mathrm{CH}_{4}$

(b)

Because the three bonds in $\mathrm{BF}_{3}$ are identical, we must hybridize the three singly occupied atomic orbitals (the one $s$ and two $p$ orbitals) to give three singly occupied hybrid orbitals:

Figure 9.5 illustrates the hybridization and bond formation in $\mathrm{BF}_{3}$.
In both cases (i.e., for $\mathrm{BeCl}_{2}$ and $\mathrm{BF}_{3}$ ), some but not all of the $p$ orbitals are hybridized. When the remaining unhybridized atomic $p$ orbitals do not contain electrons, as in the case of $\mathrm{BF}_{3}$, they will not be part of the discussion of bonding in this chapter. As we will see in Section 9.5, though, unhybridized atomic orbitals that do contain electrons are important in our description of the bonding in a molecule.

We can now apply the same kind of analysis to the methane molecule $\left(\mathrm{CH}_{4}\right)$. The Lewis structure of $\mathrm{CH}_{4}$ has four electron domains around the central carbon atom. This means that we need four hybrid orbitals, which in turn means that four atomic orbitals must be hybridized. The ground-state electron configuration of the C atom contains two unpaired electrons. Promotion of one electron from the $2 s$ orbital to the empty $2 p$ orbital yields the four unpaired electrons needed for the formation of four bonds:

Hybridization of the $s$ orbital and the three $p$ orbitals yields four hybrid orbitals designated $s p^{3}$. We can then place the electrons that were originally in the $s$ and $p$ atomic orbitals into the $s p^{3}$ hybrid orbitals.

The set of four $s p^{3}$ hybrid orbitals on carbon, like any four electron domains on a central atom, assumes a tetrahedral arrangement. Figure 9.6 illustrates how the hybridization of the C atom results in the formation of the four bonds and the $109.5^{\circ}$ bond angles observed in $\mathrm{CH}_{4}$.

## Hybridization of $s, p$, and $d$ Orbitals

Recall that elements in the third period of the periodic table and beyond do not necessarily obey the octet rule because they have $d$ orbitals that can hold additional electrons [ KH Section 8.5]. To explain the bonding and geometry of molecules in which there are more than four electron domains on the central atom, we must include $d$ orbitals in our hybridization scheme. $\mathrm{PCl}_{5}$, for example, has five electron domains around the P atom. To explain the five bonds in this molecule,

Figure 9.6 (a) An $s$ atomic orbital and three $p$ atomic orbitals combine to form four $s p^{3}$ hybrid orbitals. (b) The four $s p^{3}$ hybrid orbitals on C are arranged in a tetrahedron. (c) Hybrid orbitals on C overlap with $1 s$ orbitals on H. For clarity, the small lobes of the hybrid orbitals are not shown.
we will need five singly occupied hybrid orbitals. The ground-state electron configuration of the P atom is $[\mathrm{Ne}] 3 s^{2} 3 p^{3}$, which contains three unpaired electrons. In this case, though, because all three of the $p$ orbitals are occupied, promotion of an electron from the $3 s$ orbital to a $3 p$ orbital would not result in additional unpaired electrons. However, we can promote an electron from the $3 s$ orbital to an empty $3 d$ orbital, thus forming the five unpaired electrons needed:

Student Annotation: Note that the superscript numbers in hybrid orbital notation are used to designate the number of atomic orbitals that have undergone hybridization. When the superscript is 1 , it is not shown (analogous to the subscripts in chemical formulas).

Hybridization of the $s$ orbital, the three $p$ orbitals, and one of the $d$ orbitals yields hybrid orbitals that are designated $s p^{3} d$. After placing the five electrons in the five hybrid orbitals, we can rationalize the formation of five bonds in the molecule:

Mixing of one $s$ orbital, three $p$ orbitals, and one $d$ orbital to yield five $s p^{3} d$ orbitals
The $s p^{3} d$ orbitals have shapes similar to those we have seen for the $s p, s p^{2}$, and $s p^{3}$ hybrid orbitals; that is, one large lobe and one small lobe. In addition, the five hybrid orbitals adopt a trigonal bipyramidal arrangement, enabling us to explain the geometry and bond angles in $\mathrm{PCl}_{5}$ :

A similar analysis can be done with the $\mathrm{SF}_{6}$ molecule. The ground-state electron configuration of the S atom is $[\mathrm{Ne}] 3 s^{2} 3 p^{4}$, giving it only two unpaired electrons. To obtain the six unpaired electrons needed to form six $\mathrm{S}-\mathrm{F}$ bonds, we must promote $t w o$ electrons to empty $d$ orbitals: one from the $3 s$ orbital and one from the doubly occupied $3 p$ orbital. The resulting hybrid orbitals are designated $s p^{3} d^{2}$.

The six bonds in $\mathrm{SF}_{6}$ form, therefore, when each $s p^{3} d^{2}$ hybrid orbital on the S atom overlaps with a singly occupied $2 p$ orbital on an F atom:

Table 9.4 shows how the number of electron domains on a central atom corresponds to a set of hybrid orbitals. In general, the hybridized bonding in a molecule can be described using the following steps:

1. Draw the Lewis structure.
2. Count the number of electron domains on the central atom. This is the number of hybrid orbitals necessary to account for the molecule's geometry. (This is also the number of atomic orbitals that must undergo hybridization.)
3. Draw the ground-state orbital diagram for the central atom.
4. Maximize the number of unpaired valence electrons by promotion.
5. Combine the necessary number of atomic orbitals to generate the required number of hybrid orbitals.
6. Place electrons in the hybrid orbitals, putting one electron in each orbital before pairing any electrons.

Student Annotation: The electrons that you place in hybrid orbitals are those that originally resided in the atomic orbitals that have undergone hybridization.

TABLE 9.4
Number of Electron Domains and Hybrid Orbitals on Central Atom

| Number of Electron |  |  |
| :--- | :---: | :--- |
| Domains on Central Atom | 2 | 3 |

It is important to recognize that we do not use hybrid orbitals to predict molecular geometries, but rather to explain geometries that are already known. As we saw in Section 9.3, the bonding in many molecules can be explained without the use of hybrid orbitals. Hydrogen sulfide $\left(\mathrm{H}_{2} \mathrm{~S}\right)$, for example, has a bond angle of $92^{\circ}$. This bond angle is best explained without the use of hybrid orbitals.

Sample Problem 9.5 shows how to use hybridization to explain the bonding and geometry in a molecule.

## Sample Problem 9.5

Ammonia $\left(\mathrm{NH}_{3}\right)$ is a trigonal pyramidal molecule with $\mathrm{H}-\mathrm{N}-\mathrm{H}$ bond angles of about $107^{\circ}$. Describe the formation of three equivalent $\mathrm{N}-\mathrm{H}$ bonds, and explain the angles between them.

Strategy Starting with a Lewis structure, determine the number and type of hybrid orbitals necessary to rationalize the bonding in $\mathrm{NH}_{3}$.

Setup The Lewis structure of $\mathrm{NH}_{3}$ is

$$
\underset{\substack{\mathrm{H} \\ \mathrm{H}-\mathrm{N} \\ \hline 107^{\circ}}}{\mathrm{H}}
$$

The ground-state electron configuration of the N atom is $[\mathrm{He}] 2 s^{2} 2 p^{3}$. Its valence orbital diagram is

Solution Although the N atom has the three unpaired electrons needed to form three $\mathrm{N}-\mathrm{H}$ bonds, we would expect bond angles of $\sim 90^{\circ}\left(\right.$ not $107^{\circ}$ ) to form from the overlap of the three mutually perpendicular $2 p$ orbitals. Hybridization, therefore, is necessary to explain the bonding in $\mathrm{NH}_{3}$. (Recall from Section 9.3 that valence bond theory alone could be used to explain the bonding in $\mathrm{H}_{2} \mathrm{~S}$, where the bond angles are $\sim 90^{\circ}$-hybridization was unnecessary.) Although we often need to promote an electron to maximize the number of unpaired electrons, no promotion is necessary for the nitrogen in $\mathrm{NH}_{3}$. We already have the three unpaired electrons necessary, and the promotion of an electron from the $2 s$ orbital to one of the $2 p$ orbitals would not result in any additional unpaired electrons. Furthermore, there are no empty $d$ orbitals in the second shell. According to the Lewis structure, there are four electron domains on the central atom (three bonds and a lone pair of electrons). Four electron domains on the central atom require four hybrid orbitals, and four hybrid orbitals require the hybridization of four atomic orbitals: one $s$ and three $p$. This corresponds to $s p^{3}$ hybridization. Because the atomic orbitals involved in the hybridization contain a total of five electrons, we place five electrons in the resulting hybrid orbitals. This means that one of the hybrid orbitals will contain a lone pair of electrons:

Each $\mathrm{N}-\mathrm{H}$ bond is formed by the overlap between an $s p^{3}$ hybrid orbital on the N atom and the $1 s$ atomic orbital on an H atom. Because there are four electron domains on the central atom, we expect them to be arranged in a tetrahedron. In addition, because one of the electron domains is a lone pair, we expect the $\mathrm{H}-\mathrm{N}-\mathrm{H}$ bond angles to be slightly smaller than the ideal tetrahedral bond angle of $109.5^{\circ}$ :

Think About It This analysis agrees with the experimentally observed geometry and bond angles of $107^{\circ}$ in $\mathrm{NH}_{3}$.

Practice Problem A Use hybrid orbital theory to describe the bonding and explain the bond angles in bromine pentafluoride $\left(\mathrm{BrF}_{5}\right)$.

HPactice Problem B Use hybrid orbital theory to describe the bonding and explain the bond angles in $\mathrm{BeF}_{2}$ :

### 9.5 Hybridization in Molecules Containing

 Multiple BondsThe concept of valence bond theory and hybridization can also be used to describe the bonding in molecules containing double and triple bonds, such as ethylene $\left(\mathrm{C}_{2} \mathrm{H}_{4}\right)$ and acetylene $\left(\mathrm{C}_{2} \mathrm{H}_{2}\right)$. The Lewis structure of ethylene is

Each carbon atom is surrounded by three electron domains (two single bonds and one double bond). Thus, we expect the hybridization about each C atom to be $s p^{2}$, just like the B atom in $\mathrm{BF}_{3}$. Applying the procedure described in Section 9.4, we first maximize the number of unpaired electrons by promoting an electron from the $2 s$ orbital to the empty $2 p$ orbital:

We then hybridize the required number of atomic orbitals, which in this case is three (one for each electron domain on the C atom):

Multimedia
Chemical bonding—sigma-pi bonding.

Multimedia
Chemical bonding-sigma and pi bonding in benzene.

Figure 9.7 (a) A sigma bond forms when $s p^{2}$ hybrid orbitals on the C atoms overlap. Each C atom has one remaining unhybridized $p$ orbital. (b) The remaining $p$ orbitals overlap to form a pi bond.

The three equivalent $s p^{2}$ hybrid orbitals, arranged in a trigonal plane, enable us to explain the three bonds about each C atom. In this case, however, each C atom is left with a singly occupied, unhybridized atomic orbital. As we will see, it is the singly occupied $p$ orbitals not involved in hybridization that give rise to multiple bonds in molecules.

In the bonding schemes that we have described thus far, the overlap of atomic orbitals or hybrid orbitals occurs directly between the two nuclei involved in bonding. Such bonds, in which the shared electron density is concentrated directly along the internuclear axis, are called sigma ( $\boldsymbol{\sigma}$ ) bonds. The ethylene molecule (also known as ethene) contains five sigma bonds: one between the two C atoms (the result of the overlap of one of the $s p^{2}$ hybrid orbitals on each C atom) and four between the C and H atoms (each the result of the overlap of an $s p^{2}$ hybrid orbital on a C atom and the $1 s$ orbital on an H atom). The leftover unhybridized $p$ orbital is perpendicular to the plane in which the atoms of the molecule lie. Figure 9.7(a) illustrates the formation and the overlap of $s p^{2}$ hybrid orbitals and shows the positions of the remaining $p$ orbital on each C atom.

Remember that the shapes used to represent the atomic and hybrid orbitals are simplified to make visualization of the molecules easier. The actual shapes of both atomic and hybrid orbitals are such that when the $s p^{2}$ hybrid orbitals overlap to form a sigma bond between the two C atoms, the remaining unhybridized $p$ orbitals also overlap, although to a smaller extent. Figure 9.7(b) shows the overlap of the unhybridized $p$ orbitals on the two C atoms in ethylene. The resulting regions of electron density are concentrated above and below the plane of the molecule, in contrast to a sigma bond in which the electron density is concentrated directly along the internuclear axis. Bonds that form from the sideways overlap of $p$ orbitals are called $\boldsymbol{p i}(\boldsymbol{\pi})$ bonds. The two regions of overlap shown in Figure 9.7(b) together make up one pi bond. It is the formation of the pi bond that makes the ethylene molecule planar.

A sigma bond and a pi bond together constitute a double bond. Because the sideways overlap of $p$ orbitals is not as effective as the overlap of hybrid orbitals that point directly toward each other, the contribution of the pi bond to the overall strength of the bond is less than that of the sigma bond. The bond enthalpy of a carbon-carbon double bond ( $620 \mathrm{~kJ} / \mathrm{mol}$ ) is greater than that of a carbon-carbon single bond ( $347 \mathrm{~kJ} / \mathrm{mol}$ ), but it is not twice as large [ 1 k Section 8.9].

Sample Problem 9.6 shows how to use a Lewis structure to determine the number of sigma and pi bonds in a molecule.

## Sample Problem 9.6

Thalidomide $\left(\mathrm{C}_{13} \mathrm{H}_{10} \mathrm{~N}_{2} \mathrm{O}_{4}\right)$ is a sedative and antiemetic that was widely prescribed during the 1950 s, although not in the United States, for pregnant women suffering from morning sickness. Its use was largely discontinued when it was determined to be responsible for thousands of devastating birth defects. Determine the number of carbon-carbon sigma bonds and the total number of pi bonds in thalidomide.

Thalidomide
Strategy Use the Lewis structure to determine the number of single and double bonds. Then, to convert the number of single and double bonds to the number of sigma and pi bonds, remember that a single bond typically is composed of a sigma bond, whereas a double bond is usually composed of one sigma bond and one pi bond.

Setup There are nine carbon-carbon single bonds and three carbon-carbon double bonds. Overall there are seven double bonds in the molecule (three $\mathrm{C}=\mathrm{C}$ and four $\mathrm{C}=\mathrm{O}$ ).

Solution Thalidomide contains 12 carbon-carbon sigma bonds and a total of seven pi bonds (three in carbon-carbon double bonds and four in carbon-oxygen double bonds).

Practice Problem A The active ingredient in Tylenol and a host of other over-the-counter pain relievers is acetaminophen $\left(\mathrm{C}_{8} \mathrm{H}_{9} \mathrm{NO}_{2}\right)$. Determine the total number of sigma and pi bonds in the acetaminophen molecule.

Acetaminophen
EfPractice Problem B Determine the total number of sigma and pi bonds in a molecule of aspirin $\left(\mathrm{C}_{9} \mathrm{H}_{8} \mathrm{O}_{4}\right)$.

Aspirin

Because the $p$ orbitals that form pi bonds must be parallel to each other, pi bonds restrict the rotation of a molecule in a way that sigma bonds do not. For example, the molecule 1,2dichloroethane exists as a single isomer. Although we can draw the molecule in several different ways, including the two shown in Figure 9.8(a), all of them are equivalent because the molecule can rotate freely about the sigma bond between the two carbon atoms.

On the other hand, 1,2-dichloroethylene exists as two distinct isomers-cis and trans-as shown in Figure 9.8(b). The double bond between the carbon atoms consists of one sigma bond and one pi bond. The pi bond restricts rotation about the sigma bond, making the molecules rigid, planar, and not interchangeable. To change one isomer into the other, the pi bond would have to be broken and rotation would have to occur about the sigma bond and the pi bond. This process would require a significant input of energy.

Student Annotation: For more on the history of thalidomide, see pages 387 and 438 .

Think About It The Lewis structure given for thalidomide is one of two possible resonance structures. Draw the other resonance structure, and count sigma and pi bonds again. Make sure you get the same answer.

Student Annotation: Remember that isomers are molecules with the same chemical formula but different structural arrangements of atoms (Section 9.2).

(a)

(b)

The acetylene molecule $\left(\mathrm{C}_{2} \mathrm{H}_{2}\right)$ is linear. Because each carbon atom has two electron domains around it in the Lewis structure, the carbon atoms are $s p$ hybridized. As before, promotion of an electron first maximizes the number of unpaired electrons:

The $2 s$ orbital and one of the $2 p$ orbitals then mix to form two $s p$ hybrid orbitals:

This leaves two unhybridized $p$ orbitals (each containing an electron) on each C atom. Figure 9.9 shows the sigma and pi bonds in the acetylene molecule (also known as ethyne). Just as one sigma bond and one pi bond make up a double bond, one sigma bond and two pi bonds make up a triple bond. Figure 9.10 (pp. 366-67) summarizes the formation of bonds in ethane, ethylene, and acetylene.

Sample Problem 9.7 shows how hybrid orbitals and pi bonds can be used to explain the bonding in formaldehyde, a molecule with a carbon-oxygen double bond.

## Sample Problem 9.7

In addition to its use in aqueous solution as a preservative for laboratory specimens, formaldehyde gas is used as an antibacterial fumigant. Use hybridization to explain the bonding in formaldehyde $\left(\mathrm{CH}_{2} \mathrm{O}\right)$.

Strategy Draw the Lewis structure of formaldehyde, determine the hybridization of the C and O atoms, and describe the formation of the sigma and pi bonds in the molecule.

Setup The Lewis structure of formaldehyde is

The C and O atoms each have three electron domains around them. [Carbon has two single bonds $(\mathrm{C}-\mathrm{H})$ and a double bond $(\mathrm{C}=\mathrm{O})$; oxygen has a double bond $(\mathrm{O}=\mathrm{C})$ and two lone pairs.]

Solution Three electron domains correspond to $s p^{2}$ hybridization. For carbon, promotion of an electron from the $2 s$ orbital to the empty $2 p$ orbital is necessary to maximize the number of unpaired electrons. For oxygen, no promotion is necessary. Each undergoes hybridization to produce $s p^{2}$ hybrid orbitals; and each is left with a singly occupied, unhybridized $p$ orbital:

A sigma bond is formed between the C and O atoms by the overlap of one of the $s p^{2}$ hybrid orbitals from each of them. Two more sigma bonds form between the C atom and the H atoms by the overlap of carbon's remaining $s p^{2}$ hybrid orbitals with the $1 s$ orbital on each H atom. Finally, the remaining $p$ orbitals on C and O overlap to form a pi bond:

Practice Problem A Use valence bond theory and hybrid orbitals to explain the bonding in hydrogen cyanide (HCN).
\$Practice Problem B Use valence bond theory and hybrid orbitals to explain the bonding in diatomic nitrogen $\left(\mathrm{N}_{2}\right)$.

Student Annotation: The two lone pairs on the O atom are the electrons in the doubly occupied $s p^{2}$ hybrid orbitals.

Figure 9.10

## Formation of Pi Bonds in Ethylene and Acetylene

$2 s$ and $2 p$ atomic orbitals on two C atoms

In ethylene $\left(\mathrm{C}_{2} \mathrm{H}_{4}\right)$ the C atoms are $s p^{2}$-hybridized.

In acetylene $\left(\mathrm{C}_{2} \mathrm{H}_{2}\right)$ the C atoms are $s p$-hybridized.

In ethane $\left(\mathrm{C}_{2} \mathrm{H}_{6}\right)$ the C atoms are $s p^{3}$-hybridized.

Overlap of $s p^{2}$ hybrid orbitals forms a sigma bond between the two C atoms.

Overlap of $s p$ hybrid orbitals forms a sigma bond between the two C atoms.

Overlap of $s p^{3}$ hybrid orbitals forms a sigma bond between the two C atoms.

Using the more realistic shape shows how $p$ orbitals overlap.

Each C atom forms three sigma bonds with H atoms.

Each C atom forms two sigma bonds with H atoms. Each C atom has one leftover unhybridized $p$ orbital.

Each C atom forms one sigma bond with an H atom. Each C atom has two leftover unhybridized $p$ orbitals.

## What's the point?

When carbon is $s p^{2}$ - or $s p$-hybridized, parallel, unhybridized $p$ orbitals interact to form pi bonds. Each pi bond consists of two lobes as a result of the overlap.

d) $3 p_{y}$ and $3 p_{z}$
e) $2 p_{x}$ and $3 p_{x}$

### 9.6 Molecular Orbital Theory

Although the bonding theories we have seen thus far provide simple and effective ways for us to visualize molecules and to predict their shapes and bond angles, Lewis structures and valence bond theory do not enable us to describe or predict some important properties of molecules. Diatomic oxygen, for example, exhibits a property called paramagnetism. Paramagnetic species are attracted by magnetic fields, whereas diamagnetic species are weakly repelled by them. Such magnetic properties are the result of a molecule's electron configuration. Species in which all the electrons are paired are diamagnetic, whereas species that contain one or more unpaired electrons are paramagnetic. Because $\mathrm{O}_{2}$ exhibits paramagnetism, it must contain unpaired electrons. According to the Lewis structure of $\mathrm{O}_{2}$ (shown in the margin) and the valence bond theory description of $\mathrm{O}_{2}$, however, all the electrons in $\mathrm{O}_{2}$ are paired. Another bonding theory, called molecular orbital theory, is needed to describe the paramagnetism of $\mathrm{O}_{2}$ and other important molecular properties.

According to molecular orbital theory, the atomic orbitals involved in bonding actually combine to form new orbitals that are the "property" of the entire molecule, rather than of the atoms forming the bonds. These new orbitals are called molecular orbitals. In molecular orbital theory, electrons shared by atoms in a molecule reside in the molecular orbitals.

Molecular orbitals are like atomic orbitals in several ways: they have specific shapes and specific energies, and they can each accommodate a maximum of two electrons. As was the case with atomic orbitals, two electrons residing in the same molecular orbital must have opposite spins, as required by the Pauli exclusion principle. And, like hybrid orbitals, the number of molecular orbitals we get is equal to the number of atomic orbitals we combine.

Our treatment of molecular orbital theory in this book will be limited to descriptions of bonding in diatomic molecules consisting of elements from the first two periods of the periodic table (H through Ne).

## Bonding and Antibonding Molecular Orbitals

To begin our discussion, we consider $\mathrm{H}_{2}$, the simplest homonuclear diatomic molecule. According to valence bond theory, an $\mathrm{H}_{2}$ molecule forms when two H atoms are close enough for their $1 s$ atomic orbitals to overlap. According to molecular orbital theory, two H atoms come together to form $\mathrm{H}_{2}$ when their $1 s$ atomic orbitals combine to give molecular orbitals. Figure 9.11 shows the $1 s$

atomic orbitals of the isolated H atoms and the molecular orbitals that result from their constructive and destructive combinations. The constructive combination of the two $1 s$ orbitals gives rise to a molecular orbital [Figure 9.11(b)] that lies along the internuclear axis, directly between the two H nuclei. Just as electron density shared between two nuclei in overlapping atomic orbitals drew the nuclei together, electron density in a molecular orbital that lies between two nuclei will draw them together, too. Thus, this molecular orbital is referred to as a bonding molecular orbital.

The destructive combination of the $1 s$ atomic orbitals also gives rise to a molecular orbital that lies along the internuclear axis, but, as Figure 9.11(c) shows, this molecular orbital, which consists of two lobes, does not lie in between the two nuclei. Electron density in this molecular orbital would actually pull the two nuclei in opposite directions, rather than toward each other. This is referred to as an antibonding molecular orbital.

## $\boldsymbol{\sigma}$ Molecular Orbitals

Molecular orbitals that lie along the internuclear axis (such as the bonding and antibonding molecular orbitals in $\mathrm{H}_{2}$ ) are referred to as $\sigma$ molecular orbitals. Specifically, the bonding molecular orbital formed by the combination of two $1 s$ atomic orbitals is designated $\sigma_{1 s}$ and the antibonding orbital is designated $\sigma_{1 s}^{*}$, where the asterisk distinguishes an antibonding orbital from a bonding orbital. Figure 9.11 (d) summarizes the combination of two $1 s$ atomic orbitals to yield two molecular orbitals: one bonding and one antibonding.

Like atomic orbitals, molecular orbitals have specific energies. The combination of two atomic orbitals of equal energy, such as two $1 s$ orbitals on two H atoms, yields one molecular orbital that is lower in energy (bonding) and one molecular orbital that is higher in energy (antibonding) than the original atomic orbitals. The bonding molecular orbital in $\mathrm{H}_{2}$ is concentrated between the nuclei, along the internuclear axis. Electron density in this molecular orbital both attracts the nuclei and shields them from each other, stabilizing the molecule. Thus, the bonding molecular orbital is lower in energy than the isolated atomic orbitals. In contrast, the antibonding molecular orbital has most of its electron density outside the internuclear region. Electron density in this orbital does not shield one nucleus from the other, which increases the nuclear repulsions and makes the antibonding molecular orbital higher in energy than the isolated atomic orbitals.

Showing all the molecular orbitals in a molecule can make for a very complicated picture. Rather than represent molecules with pictures of their molecular orbitals, we generally use diagrams in which molecular orbitals are represented with boxes placed at the appropriate relative energy levels. Figure 9.12 shows the energies of the $\sigma_{1 s}$ and $\sigma_{1 s}^{*}$ molecular orbitals in $\mathrm{H}_{2}$, relative to the energy of the original $1 s$ orbitals on two isolated H atoms. Like atomic orbitals, molecular orbitals fill in order of increasing energy. Note that the electrons that originally resided in the atomic orbitals both occupy the lowest-energy molecular orbital, $\sigma_{1 s}$, with opposite spins.

We can construct a similar molecular orbital diagram for the hypothetical molecule $\mathrm{He}_{2}$. Like the H atom, the He atom has a $1 s$ orbital (unlike H , though, the $1 s$ orbital on He has two electrons, not one). The combination of $1 s$ orbitals to form molecular orbitals in $\mathrm{He}_{2}$ is essentially the same as what we have described for $\mathrm{H}_{2}$. The placement of electrons is shown in Figure 9.13.

Figure 9.11 (a) Two $s$ atomic orbitals combine to give two sigma molecular orbitals. (b) One of the molecular orbitals is lower in energy than the original atomic orbitals (darker), and (c) one is higher in energy (lighter). The two light yellow lobes make up one molecular orbital. (d) Atomic and molecular orbitals shown relative to the H nuclei.

Multimedia
Chemical bonding-formation of molecular orbitals.

Student Annotation: The designations $\sigma$ and $\pi$ are used in molecular orbital theory just as they are in valence bond theory: $\sigma$ refers to electron density along the internuclear axis, and $\pi$ refers to electron density that influences both nuclei but that does not lie directly along the internuclear axis.

Student Annotation: This molecular orbital diagram shows the two H atoms having electrons with paired spins ( $\uparrow$ and $\downarrow$ ). H atoms whose electrons have parallel spins ( $\uparrow$ and $\uparrow$ or $\downarrow$ and $\downarrow$ ) actually repel one another and will not bond to form $\mathrm{H}_{2}$.

Student Annotation: When we draw molecular orbital diagrams, we need only show the valence orbitals and electrons.

Figure 9.12 Relative energies of atomic orbitals in H and molecular orbitals in $\mathrm{H}_{2}$.

$\mathrm{He}_{2}$ molecule
Figure 9.13 Relative energies of atomic orbitals in He and molecular orbitals in $\mathrm{He}_{2}$.

## Bond Order

With molecular orbital diagrams such as those for $\mathrm{H}_{2}$ and $\mathrm{He}_{2}$, we can begin to see the power of molecular orbital theory. For a diatomic molecule described using molecular orbital theory, we can calculate the bond order. The value of the bond order indicates, qualitatively, how stable a molecule is. The higher the bond order, the more stable the molecule. Bond order is calculated in the following way:

In the case of $\mathrm{H}_{2}$, where both electrons reside in the $\sigma_{1 s}$ orbital, the bond order is $[(2-0) / 2]=1$. In the case of $\mathrm{He}_{2}$, where the two additional electrons reside in the $\sigma_{1 s}^{*}$ orbital, the bond order is $[(2-2) / 2]=0$. Molecular orbital theory predicts that a molecule with a bond order of zero will not exist and $\mathrm{He}_{2}$, in fact, does not exist under ordinary conditions.

We can do similar analyses of the molecules $\mathrm{Li}_{2}$ and $\mathrm{Be}_{2}$. (The Li and Be atoms have groundstate electron configurations of $[\mathrm{He}] 2 s^{1}$ and $[\mathrm{He}] 2 s^{2}$, respectively.) The $2 s$ atomic orbitals also combine to form the corresponding $\sigma$ and $\sigma^{*}$ molecular orbitals. Figure 9.14 shows the molecular orbital diagrams and bond orders for $\mathrm{Li}_{2}$ and $\mathrm{Be}_{2}$.

As predicted by molecular orbital theory, $\mathrm{Li}_{2}$, with a bond order of 1 , is a stable molecule, whereas $\mathrm{Be}_{2}$, with a bond order of 0 , does not exist.

## $\pi$ Molecular Orbitals

To consider diatomic molecules beyond $\mathrm{Be}_{2}$, we must also consider the combination of $p$ atomic orbitals. Like $s$ orbitals, $p$ orbitals combine both constructively, to give bonding molecular orbitals that are lower in energy than the original atomic orbitals, and destructively, to give antibonding

molecular orbitals that are higher in energy than the original atomic orbitals. However, the orientations of $p_{x}, p_{y}$, and $p_{z}$ orbitals give rise to two different types of molecular orbitals: $\sigma$ molecular orbitals, in which the regions of electron density in the bonding and antibonding molecular orbitals lie along the internuclear axis, and $\pi$ molecular orbitals, in which the regions of electron density affect both nuclei but do not lie along the internuclear axis.

Orbitals that lie along the internuclear axis, as the $2 p_{x}$ orbitals do in Figure 9.15(a), point directly toward each other and combine to form $\sigma$ molecular orbitals. Figure 9.15(b) shows the combination of two $2 p_{x}$ atomic orbitals to give two molecular orbitals designated $\sigma_{2 p x}$ and $\sigma_{2 p_{x}}^{*}$. Figure 9.15(c) shows the relative energies of these molecular orbitals.

Orbitals that are aligned parallel to each other, like the $2 p_{y}$ and $2 p_{z}$ orbitals shown in Figure 9.15(a), combine to form $\pi$ molecular orbitals. These bonding molecular orbitals are designated $\pi_{2 p_{y}}$ and $\pi_{2 p_{z}}$; the corresponding antibonding molecular orbitals are designated $\pi_{2 p_{y}}^{*}$ and $\pi_{2 p_{z}}^{*}$. Often we refer to the molecular orbitals collectively using the designations $\pi_{2 p_{y, z}}$ and $\pi_{2 p_{y, z}}^{*}$. Figure 9.16(a) shows the constructive and destructive combination of parallel $p$ orbitals. Figure 9.16(b) shows the locations of the molecular orbitals resulting from the combination of $p_{y}$, and $p_{z}$ orbitals relative to the two atomic nuclei. Again, electron density in the resulting bonding molecular orbitals serves to hold the nuclei together, whereas electron density in the antibonding molecular orbitals does not.

Just as the $p$ atomic orbitals within a particular shell are higher in energy than the $s$ orbital in the same shell, all the molecular orbitals resulting from the combination of $p$ atomic orbitals are higher in energy than the molecular orbitals resulting from the combination of $s$ atomic orbitals. To understand better the relative energy levels of the molecular orbitals resulting from $p$-orbital combinations, consider the fluorine molecule ( $\mathrm{F}_{2}$ ).

Figure 9.15 (a) Two sets of $2 p$ orbitals. (b) The $p$ atomic orbitals that point toward each other $\left(p_{x}\right)$ combine to give bonding and antibonding $\sigma$ molecular orbitals. (c) The antibonding $\sigma$ molecular orbital is higher in energy than the corresponding bonding $\sigma$ molecular orbital.

Figure 9.16 Parallel $p$ atomic orbitals combine to give $\pi$ molecular orbitals. (a) Bonding and antibonding molecular orbitals shown separately. (b) Bonding and antibonding molecular orbitals shown together relative to the two nuclei.

In general, molecular orbital theory predicts that the more effective the interaction or overlap of the atomic orbitals, the lower in energy will be the resulting bonding molecular orbital and the higher in energy will be the resulting antibonding molecular orbital. Thus, the relative energy levels of molecular orbitals in $\mathrm{F}_{2}$ can be represented by the diagram in Figure 9.17(a). The $p_{x}$ orbitals, which lie along the internuclear axis, overlap most effectively, giving the lowest-energy bonding molecular orbital and the highest-energy antibonding molecular orbital.

The order of orbital energies shown in Figure 9.17(a) assumes that $p$ orbitals interact only with other $p$ orbitals and $s$ orbitals interact only with other $s$ orbitals-that there is no significant interaction between $s$ and $p$ orbitals. In fact, the relatively smaller nuclear charges of boron, carbon, and nitrogen atoms cause their atomic orbitals to be held less tightly than those of atoms with larger nuclear charges, and some $s-p$ interaction does take place. This results in a change in the relative energies of the $\sigma_{2 p_{x}}$ and $\pi_{2 p_{y, z}}$ molecular orbitals. Although energies of several of the resulting molecular orbitals change, the most important of these changes is the energy of the $\sigma_{2 p}$ orbital, making it higher than the $\pi_{2 p_{y, z}}$ orbitals. The relative energy levels of molecular orbitals in the $\mathrm{B}_{2}$, $\mathrm{C}_{2}$, and $\mathrm{N}_{2}$ molecules can be represented by the diagram in Figure 9.17(b).

## Molecular Orbital Diagrams

Beginning with oxygen, the nuclear charge is sufficiently large to prevent the interaction of $s$ and $p$ orbitals. Thus, for $\mathrm{O}_{2}$ and $\mathrm{Ne}_{2}$, the order of molecular orbital energies is the same as that for $\mathrm{F}_{2}$, which is shown in Figure 9.17(a). Figure 9.18 gives the molecular orbital diagrams, magnetic properties, bond orders, and bond enthalpies for $\mathrm{Li}_{2}, \mathrm{~B}_{2}, \mathrm{C}_{2}, \mathrm{~N}_{2}, \mathrm{O}_{2}, \mathrm{~F}_{2}$, and $\mathrm{Ne}_{2}$. Note that the filling of molecular orbitals follows the same rules as the filling of atomic orbitals [ 14 Section 6.8]:

- Lower-energy orbitals fill first.
- Each orbital can accommodate a maximum of two electrons with opposite spins.
- Hund's rule is obeyed.

Figure 9.17 (a) Ordering of molecular orbital energies for $\mathrm{O}_{2}$ and $\mathrm{F}_{2}$. (b) Ordering of molecular orbital energies for $\mathrm{Li}_{2}, \mathrm{~B}_{2}, \mathrm{C}_{2}$, and $\mathrm{N}_{2}$. Bonding orbitals are darker; antibonding orbitals are lighter.

Figure 9.18 Molecular orbital diagrams for second-period homonuclear diatomic molecules.

There are several important predictions made by the molecular orbital diagrams in Figure 9.18. First, molecular orbital theory correctly predicts that $\mathrm{Ne}_{2}$, with a bond order of 0 , does not exist. Second, it correctly predicts the magnetic properties of the molecules that do exist. Both $\mathrm{B}_{2}$ and $\mathrm{O}_{2}$ are known to be paramagnetic. Third, although bond order is only a qualitative measure of bond strength, the calculated bond orders of the molecules correlate well with the measured bond enthalpies. The $\mathrm{N}_{2}$ molecule, with a bond order of 3 , has the largest bond enthalpy of the five molecules. The $\mathrm{B}_{2}$ and $\mathrm{F}_{2}$ molecules, each with a bond order of 1 , have the smallest bond enthalpies. Its ability to predict correctly the properties of molecules makes molecular orbital theory a powerful tool in the study of chemical bonding.

Sample Problem 9.8 shows how to use molecular orbital diagrams to determine the magnetic properties and bond order of the superoxide ion.

Think About It Experiments confirm that the superoxide ion is paramagnetic. Also, any time we add one or more electrons to an antibonding molecular orbital, as we did in this problem, we should expect the bond order to decrease. Electrons in antibonding orbitals cause a bond to be less stable.

## Sample Problem 9.8

The superoxide ion $\left(\mathrm{O}_{2}^{-}\right)$has been implicated in a number of degenerative conditions, including aging and Alzheimer's disease. Using molecular orbital theory, determine whether $\mathrm{O}_{2}^{-}$is paramagnetic or diamagnetic, and then calculate its bond order.

Strategy Start with the molecular orbital diagram for $\mathrm{O}_{2}$, add an electron, and then use the resulting diagram to determine the magnetic properties and bond order.

Setup The molecular orbital diagram for $\mathrm{O}_{2}$ is shown in Figure 9.18. The additional electron must be added to the lowest-energy molecular orbital available.

Molecular orbital diagram for $\mathrm{O}_{2}^{-}$
Solution In this case, either of the two singly occupied $\pi_{2 p}^{*}$ orbitals can accommodate an additional electron. This gives a molecular orbital diagram in which there is one unpaired electron, making $\mathrm{O}_{2}^{-}$paramagnetic. The new diagram has six electrons in bonding molecular orbitals and three in antibonding molecular orbitals. We can ignore the electrons in the $\sigma_{2 s}$ and $\sigma_{2 s}^{*}$ orbitals because their contributions to the bond order cancel each other. The bond order is $(6-3) / 2=1.5$.

Practice Problem A Use molecular orbital theory to determine whether $\mathrm{N}_{2}^{2-}$ is paramagnetic or diamagnetic, and then calculate its bond order.

EPractice Problem B Use molecular orbital theory to determine whether $\mathrm{F}_{2}^{2+}$ is paramagnetic or diamagnetic, and then calculate its bond order.

## Checkpoint 9.6 Molecular Orbital Theory

9.6.1 Calculate the bond order of $\mathrm{N}_{2}^{2+}$, and determine whether it is paramagnetic or diamagnetic.
a) 2, paramagnetic
b) 2, diamagnetic
c) 3, paramagnetic
d) 3, paramagnetic
e) 1, paramagnetic
9.6.2 Which of the following species is paramagnetic? (Select all that apply.)
a) $\mathrm{C}_{2}^{2-}$
b) $\mathrm{O}_{2}^{2+}$
c) $\mathrm{F}_{2}^{2+}$
d) $\mathrm{F}_{2}^{2-}$
e) $\mathrm{C}_{2}^{2+}$
9.6.3 Calculate the bond order of $\mathrm{He}_{2}^{+}$.
a) 0
b) 0.5
c) 1.0
d) 1.5
e) 2
9.6.4 Which if any of the following species has a bond order of 0 ? (Select all that apply.)
a) $\mathrm{B}_{2}^{2+}$
b) $\mathrm{Ne}_{2}^{2+}$
c) $\mathrm{F}_{2}^{2-}$
d) $\mathrm{He}_{2}^{2+}$
e) $\mathrm{H}_{2}^{2-}$

### 9.7 Bonding Theories and Descriptions of Molecules with Delocalized Bonding

The progression of bonding theories in this chapter illustrates the importance of model development. Scientists use models to understand experimental results and to predict future observations. A model is useful as long as it agrees with observation. When it fails to do so, it must be replaced with a new model. What follows is a synopsis of the strengths and weaknesses of the bonding theories presented in Chapters 8 and 9:

## Lewis Theory

Strength: The Lewis theory of bonding enables us to make qualitative predictions about bond strengths and bond lengths. Lewis structures are easy to draw and are widely used by chemists [ 14 Section 8.9].
Weakness: Lewis structures are two dimensional, whereas molecules are three dimensional. In addition, Lewis theory fails to account for the differences in bonds in compounds such as $\mathrm{H}_{2}, \mathrm{~F}_{2}$, and HF. It also fails to explain why bonds form.

## The Valence-Shell Electron-Pair Repulsion Model

Strength: The VSEPR model enables us to predict the shapes of many molecules and polyatomic ions.
Weakness: Because the VSEPR model is based on the Lewis theory of bonding, it also fails to explain why bonds form.

Valence Bond Theory
Strength: Valence bond theory describes the formation of covalent bonds as the overlap of atomic orbitals. Bonds form because the resulting molecule has a lower potential energy than the original, isolated atoms.
Weakness: Valence bond theory alone fails to explain the bonding in many molecules such as $\mathrm{BeCl}_{2}, \mathrm{BF}_{3}$, and $\mathrm{CH}_{4}$, in which the central atom in its ground state does not have enough unpaired electrons to form the observed number of bonds.

## Hybridization of Atomic Orbitals

Strength: The hybridization of atomic orbitals is not a separate bonding theory; rather, it is an extension of valence bond theory. Using hybrid orbitals, we can understand the bonding and geometry of more molecules, including $\mathrm{BeCl}_{2}, \mathrm{BF}_{3}$, and $\mathrm{CH}_{4}$.
Weakness: Valence bond theory and hybrid orbitals fail to predict some of the important properties of molecules, such as the paramagnetism of $\mathrm{O}_{2}$.

## Molecular Orbital Theory

Strength: Molecular orbital theory enables us to predict accurately the magnetic and other properties of molecules and ions.
Weakness: Pictures of molecular orbitals can be very complex.
Although molecular orbital theory is in many ways the most powerful of the bonding models, it is also the most complex, so we continue to use the other models when they do an adequate job of explaining or predicting the properties of a molecule. For example, if you need to predict the three-dimensional shape of an $\mathrm{AB}_{x}$ molecule on an exam, you should draw its Lewis structure and apply the VSEPR model. Don't try to draw its molecular orbital diagram. On the other hand, if you need to determine the bond order of a diatomic molecule or ion, you should draw a molecular orbital diagram. In general chemistry, it is best to use the simplest theory that can answer a particular question.

Because they remain useful, we don't discard the old models when we develop new ones. In fact, the bonding in some molecules, such as benzene $\left(\mathrm{C}_{6} \mathrm{H}_{6}\right)$, is best described using a combination of models. Benzene can be represented with two resonance structures [ 14 Section 8.7].

According to its Lewis structure and valence bond theory, the benzene molecule contains twelve $\sigma$ bonds (six carbon-carbon, and six carbon-hydrogen) and three $\pi$ bonds. From experimental evidence, however, we know that benzene does not have three single bonds and three double bonds
between carbon atoms. Rather, there are six equivalent carbon-carbon bonds. This is precisely the reason that two different Lewis structures are necessary to represent the molecule. Neither one alone accurately depicts the nature of the carbon-carbon bonds. In fact, the $\pi$ bonds in benzene are delocalized, meaning that they are spread out over the entire molecule, rather than confined between two specific atoms. (Bonds that are confined between two specific atoms are called localized bonds.) Valence bond theory does a good job of describing the localized $\sigma$ bonds in benzene, but molecular orbital theory does a better job of using delocalized $\pi$ bonds to describe the bonding scheme in benzene.

To describe the $\sigma$ bonds in benzene, begin with a Lewis structure and count the electron domains on the carbon atoms. (Either resonance structure will give the same result.) Each C atom has three electron domains around it (two single bonds and one double bond). Recall from Table 9.4 that an atom that has three electron domains is $s p^{2}$ hybridized. To obtain the three unpaired electrons necessary on each C atom, one electron from each C atom must be promoted from the doubly occupied $2 s$ orbital to an empty $2 p$ orbital:

This actually creates four unpaired electrons. Next, the orbitals are $s p^{2}$ hybridized, leaving one singly occupied, unhybridized $2 p$ orbital on each C atom:

The $s p^{2}$ hybrid orbitals adopt a trigonal planar arrangement and overlap with one another (and with $1 s$ orbitals on H atoms) to form the $\sigma$ bonds in the molecule.

The remaining unhybridized $2 p$ orbitals (one on each C atom) combine to form molecular orbitals. Because the $p$ orbitals are all parallel to one another, only $\pi_{2 p}$ and $\pi_{2 p}^{*}$ molecular orbitals form. The combination of these six $2 p$ atomic orbitals forms six molecular orbitals: three bonding and three antibonding. These molecular orbitals are delocalized over the entire benzene molecule:

In the ground state, the lower-energy bonding molecular orbitals contain all six electrons. The electron density in the delocalized $\pi$ molecular orbitals lies above and below the plane that contains all the atoms and the $\sigma$ bonds in the molecule:

Sample Problem 9.9 shows how to combine valence bond theory and molecular orbital theory to explain the bonding in the carbonate ion.

## Sample Problem 9.9

It takes three resonance structures to represent the carbonate ion $\left(\mathrm{CO}_{3}^{2-}\right)$ :

None of the three, though, is a completely accurate depiction. As with benzene, the bonds that are shown in the Lewis structure as one double and two single are actually three equivalent bonds. Use a combination of valence bond theory and molecular orbital theory to explain the bonding in $\mathrm{CO}_{3}^{2-}$.

Strategy Starting with the Lewis structure, use valence bond theory and hybrid orbitals to describe the $\sigma$ bonds. Then use molecular orbital theory to describe the delocalized $\pi$ bonding.

Setup The Lewis structure of the carbonate ion shows three electron domains around the central C atom, so the carbon must be $s p^{2}$ hybridized.

Solution Each of the $s p^{2}$ hybrid orbitals on the C atom overlaps with a singly occupied $p$ orbital on an O atom, forming the three $\sigma$ bonds. Each O atom has an additional, singly occupied $p$ orbital, perpendicular to the one involved in $\sigma$ bonding. The unhybridized $p$ orbital on C overlaps with the $p$ orbitals on O to form $\pi$ bonds, which have electron densities above and below the plane of the molecule. Because the species can be represented with resonance structures, we know that the $\pi$ bonds are delocalized.

Practice Problem A Use a combination of valence bond theory and molecular orbital theory to describe the bonding in ozone $\left(\mathrm{O}_{3}\right)$.

EPPractice Problem B Use a combination of valence bond theory and molecular orbital theory to describe the bonding in the nitrite ion $\left(\mathrm{NO}_{2}^{-}\right)$.

## Checkpoint 9.7 Bonding Theories and Descriptions of Molecules with Delocalized Bonding

9.7.1 Which of the following contain one or more delocalized $\pi$ bonds? (Select all that apply.)
a) $\mathrm{O}_{2}$
b) $\mathrm{CO}_{2}$
c) $\mathrm{NO}_{2}^{-}$
d) $\mathrm{CH}_{4}$
e) $\mathrm{CH}_{2} \mathrm{Cl}_{2}$
9.7.2 Which of the atoms in $\mathrm{BCl}_{3}$ need hybrid orbitals to describe the bonding in the molecule?
a) all four atoms
b) only the B atom
c) only the three Cl atoms
d) only the B atom and one Cl atom
e) only the B atom and two Cl atoms
9.7.3 Which of the following can hybrid orbitals be used for? (Select all that apply.)
a) to explain the geometry of a molecule
b) to explain how a central atom can form more bonds than the number of unpaired electrons in its ground-state configuration
c) to predict the geometry of a molecule
d) to explain the magnetic properties of a molecule
e) to predict the magnetic properties of a molecule
9.7.4 Which of the following enables us to explain the paramagnetism of $\mathrm{O}_{2}$ ?
a) Lewis theory
b) valence bond theory
c) valence-shell electron-pair repulsion
d) hybridization of atomic orbitals
e) molecular orbital theory

Student Annotation: Double bonds that appear in different places in different resonance structures represent delocalized $\pi$ bonds.

Think About It Although the Lewis structure of $\mathrm{CO}_{3}^{2-}$ shows three electron domains on one of the O atoms, we generally do not treat terminal atoms (those with single bonds to only one other atom) as though they are hybridized because it is unnecessary to do so.

## Applying What You've Learned

Recall from the beginning of the chapter that one of the fundamental scents for which we have olfactory receptors is musky. Musk is a familiar, provocative scent that has been part of the human experience for thousands of years. The primary odorous molecule in musk is muscone, a large,

Muscone cyclic, organic molecule. The natural source of musk is a gland on the abdomen of the mature male musk deer, a small species of deer native to the Himalayas. The practice of harvesting musk nearly wiped out the musk deer population.

In 1888, Albert Baur, while experimenting with explosives, stumbled onto some synthetic compounds that smelled like musk. Two of these compounds are shown below. (Note the similarity between the structure of musk Baur and that of TNT.) Musk ketone, the molecule that smelled closest to muscone, was far cheaper than natural musk, but it was toxic and hazardous to prepare. In the 1950 s, it was replaced with a series of synthetic musk compounds without the $\mathrm{NO}_{2}$ groups. These new compounds are widely used in the fragrance industry.

TNT

Musk Baur

Musk Ketone

## Problems:

a) How many carbon-carbon sigma bonds are there in musk ketone? How many carbon-carbon or carbon-oxygen pi bonds are there? [ 14 Sample Problem 9.6]
b) Determine the hybridization of the carbon atoms circled in red in the musk ketone molecule, and describe their geometries. [ 14 Sample Problem 9.5]
c) Of the pi bonds in the musk ketone molecule, which are localized and which are delocalized?
d) Describe the bonding in the six-membered ring portion of the musk ketone molecule using a combination of valence bond theory and molecular orbital theory.
[ KA Sample Problem 9.9]

## Chapter Summary

## Section 9.1

- According to the valence-shell electron-pair repulsion (VSEPR) model, electron pairs in the valence shell of an atom repel one another. An electron domain is a lone pair or a bond. Any bond (single, double, or triple) constitutes one electron domain.
- The arrangement of electron domains about a central atom, determined using the VSEPR model, is called the electron-domain geometry. The arrangement of atoms in a molecule is called the molecular geometry. The basic molecular geometries are linear, bent, trigonal planar, tetrahedral, trigonal pyramidal, trigonal bipyramidal, seesaw-shaped, T-shaped, octahedral, square pyramidal, and square planar.
- The bond angle is the angle between two adjacent bonds in a molecule or polyatomic ion. A trigonal bipyramid contains two types of bonds: axial and equatorial.

## Section 9.2

- The polarity of a molecule depends on the polarity of its individual bonds and on its molecular geometry. Even a molecule containing polar bonds may be nonpolar overall if the bonds are distributed symmetrically.
- Structural isomers are molecules with the same chemical formula, but different structural arrangements.

## Section 9.3

- According to valence bond theory, bonds form between atoms when atomic orbitals overlap, thus allowing the atoms to share valence electrons. A bond forms, furthermore, when the resulting molecule is lower in energy than the original, isolated atoms.

## Section 9.4

- To explain the bonding in some molecules, we need to employ the concept of hybridization, in which atomic orbitals mix to form hybrid orbitals.
- To use hybrid-orbital analysis, we must already know the molecular geometry and bond angles in a molecule. Hybrid orbitals are not used to predict molecular geometries.

## Section 9.5

- Sigma ( $\boldsymbol{\sigma}$ ) bonds form when the region of orbital overlap lies directly between the two atoms. $\operatorname{Pi}(\boldsymbol{\pi})$ bonds form when parallel, unhybridized $p$ orbitals interact. A double bond consists of one sigma bond and one pi bond. A triple bond consists of one sigma bond and two pi bonds.

## Section 9.6

- A paramagnetic species is one that contains unpaired electrons. A diamagnetic species is one in which there are no unpaired electrons. Paramagnetic species are weakly attracted by a magnetic field, whereas diamagnetic species are weakly repelled by a magnetic field.
- According to molecular orbital theory, atomic orbitals combine to form new molecular orbitals that are associated with the molecule, rather than with individual atoms. Molecular orbitals may be sigma, if the orbital lies directly along the internuclear axis, or pi, if the orbital does not lie directly along the internuclear axis.
- Molecular orbitals may be bonding or antibonding. A bonding molecular orbital is lower in energy than the isolated atomic orbitals that combined to form it. The corresponding antibonding molecular orbital is higher in energy than the isolated atomic orbitals. Bond order is a measure of the strength of a bond and can be determined using a molecular orbital diagram.

## Section 9.7

- It is generally best to use the bonding theory that most easily describes the bonding in a particular molecule or polyatomic ion. In species that can be represented by two or more resonance structures, the pi bonds are delocalized, meaning that they are spread out over the molecule and not constrained to just two atoms. Localized bonds are those constrained to two atoms. Many species are best described using a combination of valence bond theory and molecular orbital theory.

## Questions and Problems

## Section 9.1: Molecular Geometry

## Review Questions

9.1 How is the geometry of a molecule defined, and why is the study of molecular geometry important?
9.2 Sketch the shape of a linear triatomic molecule, a trigonal planar molecule containing four atoms, a tetrahedral molecule, a trigonal bipyramidal molecule, and an octahedral molecule. Give the bond angles in each case.

E9.3 How many atoms are directly bonded to the central atom in a tetrahedral molecule, a trigonal bipyramidal molecule, and an octahedral molecule?
9.4 Discuss the basic features of the VSEPR model. Explain why the magnitude of repulsion decreases in the following order: lone pair-lone pair $>$ lone pair-bonding pair $>$ bonding pair-bonding pair.
9.5 In the trigonal bipyramidal arrangement, why does a lone pair occupy an equatorial position rather than an axial position?
9.6 Explain why the $\mathrm{CH}_{4}$ molecule is not square planar, although its Lewis structure makes it look as though it could be.

## Problems

E 9.7 Predict the geometries of the following species using the VSEPR method: (a) $\mathrm{PCl}_{3}$, (b) $\mathrm{CHCl}_{3}$, (c) $\mathrm{SiH}_{4}$, (d) $\mathrm{TeCl}_{4}$.

E9.8 Predict the geometries of the following species: (a) $\mathrm{AlCl}_{3}$, (b) $\mathrm{ZnCl}_{2}$, (c) $\mathrm{HgBr}_{2}$, (d) $\mathrm{N}_{2} \mathrm{O}$ (arrangement of atoms is NNO ).

E9.9 Predict the geometry of the following molecules and ion using the VSEPR model: (a) $\mathrm{CBr}_{4}$, (b) $\mathrm{BCl}_{3}$, (c) $\mathrm{NF}_{3}$, (d) $\mathrm{H}_{2} \mathrm{Se}$, (e) $\mathrm{NO}_{2}^{-}$.
9.10 Predict the geometry of the following molecules and ion using the VSEPR model: (a) $\mathrm{CH}_{3} \mathrm{I}$, (b) $\mathrm{ClF}_{3}$, (c) $\mathrm{H}_{2} \mathrm{~S}$, (d) $\mathrm{SO}_{3}$, (e) $\mathrm{SO}_{4}^{2-}$.
9.11 Predict the geometry of the following ions using the VSEPR method: (a) $\mathrm{SCN}^{-}$(arrangement of atoms is SCN ), (b) $\mathrm{AlH}_{4}^{-}$, (c) $\mathrm{SnCl}_{5}^{-}$, (d) $\mathrm{H}_{3} \mathrm{O}^{+}$, (e) $\mathrm{BeF}_{4}^{2-}$.

E9.12 Predict the geometries of the following ions: (a) $\mathrm{NH}_{4}^{+}$, (b) $\mathrm{NH}_{2}^{-}$, (c) $\mathrm{CO}_{3}^{2-}$, (d) $\mathrm{ICl}_{2}^{-}$, (e) $\mathrm{ICl}_{4}^{-}$.

E9.13 Describe the geometry around each of the three central atoms in the $\mathrm{CH}_{3} \mathrm{COOH}$ molecule.

S9.14 Which of the following species are tetrahedral: $\mathrm{SiCl}_{4}, \mathrm{SeF}_{4}, \mathrm{XeF}_{4}$, $\mathrm{CI}_{4}, \mathrm{CdCl}_{4}^{2-}$ ?

## Section 9.2: Molecular Geometry and Polarity

## Review Questions

9.15 Explain why an atom cannot have a permanent dipole moment.
9.16 The bonds in beryllium hydride $\left(\mathrm{BeH}_{2}\right)$ molecules are polar, and yet the dipole moment of the molecule is zero. Explain.

## Problems

§9.17 Determine whether (a) $\mathrm{BrF}_{5}$ and (b) $\mathrm{BCl}_{3}$ are polar.
E9.18 Determine whether (a) OCS and (b) $\mathrm{XeF}_{4}$ are polar.

Ef 9.19 Which of the molecules shown is polar?

(a)

(b)

(c)

(d)

- 9.20 Which of the molecules shown is polar?

(a)

(b)

(c)

(d)

## Section 9.3: Valence Bond Theory

## Review Questions

9.21 What is valence bond theory? How does it differ from the Lewis concept of chemical bonding?
9.22 Use valence bond theory to explain the bonding in $\mathrm{Cl}_{2}$ and HCl . Show how the atomic orbitals overlap when a bond is formed.
9.23 According to valence bond theory, how many bonds would you expect each of the following atoms (in the ground state) to form: $\mathrm{Be}, \mathrm{C}$ ?
9.24 According to valence bond theory, how many bonds would you expect each of the following atoms (in the ground state) to form: $\mathrm{P}, \mathrm{S}$ ?

## Section 9.4: Hybridization of Atomic Orbitals

## Review Questions

9.25 What is the hybridization of atomic orbitals? Why is it impossible for an isolated atom to exist in the hybridized state?
9.26 How does a hybrid orbital differ from a pure atomic orbital? Can two $2 p$ orbitals of an atom hybridize to give two hybridized orbitals?

E9.27 What is the angle between the following two hybrid orbitals on the same atom: (a) $s p$ and $s p$ hybrid orbitals, (b) $s p^{2}$ and $s p^{2}$ hybrid orbitals, (c) $s p^{3}$ and $s p^{3}$ hybrid orbitals?

## Problems

9.28 Describe the bonding scheme of the $\mathrm{AsH}_{3}$ molecule in terms of hybridization.
9.29 What is the hybridization state of Si (a) in $\mathrm{SiH}_{4}$ and (b) in $\mathrm{H}_{3} \mathrm{Si}-\mathrm{SiH}_{3}$ ?

E 9.30 Describe the change in hybridization (if any) of the Al atom in the following reaction:

$$
\mathrm{AlCl}_{3}+\mathrm{Cl}^{-} \longrightarrow \mathrm{AlCl}_{4}^{-}
$$

9.31 Consider the reaction

$$
\mathrm{BF}_{3}+\mathrm{NH}_{3} \longrightarrow \mathrm{~F}_{3} \mathrm{~B}-\mathrm{NH}_{3}
$$

Describe the changes in hybridization (if any) of the B and N atoms as a result of this reaction.

E9.32 What hybrid orbitals are used by nitrogen atoms in the following species: (a) $\mathrm{NH}_{3}$, (b) $\mathrm{H}_{2} \mathrm{~N}-\mathrm{NH}_{2}$, (c) $\mathrm{NO}_{3}^{-}$?
9.33 Describe the hybridization of phosphorus in $\mathrm{PF}_{5}$.

## Section 9.5: Hybridization in Molecules Containing Multiple Bonds

## Visualizing Chemistry

Figure 9.10
VC 9.1 How is a sigma bond different from a pi bond?
a) A sigma bond is a bonding molecular orbital; a pi bond is an antibonding molecular orbital.
b) A sigma bond is a single bond, whereas a pi bond is a double bond.
c) The electron density in a sigma bond lies along the internuclear axis; that of a pi bond does not.

VC 9.2 Pi bonds form when $\qquad$ atomic orbitals on
$\qquad$ atom(s) overlap.
a) perpendicular, adjacent
b) parallel, adjacent
c) parallel, the same

VC 9.3 Formation of two pi bonds requires the combination of $\qquad$ atomic orbitals.
a) two
b) four
c) $\operatorname{six}$

VC 9.4 Why are there no pi bonds in ethane $\left(\mathrm{C}_{2} \mathrm{H}_{6}\right)$ ?
a) The remaining unhybridized $p$ orbitals do not contain any electrons.
b) There are no unhybridized $p$ orbitals remaining on either C atom.
c) The remaining unhybridized $p$ orbitals are not parallel to each other.

## Review Questions

9.34 How would you distinguish between a sigma bond and a pi bond?
9.35 Which of the following pairs of atomic orbitals of adjacent nuclei can overlap to form a sigma bond? Which overlap to form a pi bond? Which cannot overlap (no bond)? Consider the $x$ axis to be the internuclear axis, that is, the line joining the nuclei of the two atoms. (a) $1 s$ and $1 s$, (b) $1 s$ and $2 p_{x}$, (c) $2 p_{x}$ and $2 p_{y}$, (d) $3 p_{y}$ and $3 p_{y}$, (e) $2 p_{x}$ and $2 p_{x}$, (f) $1 s$ and $2 s$.

## Problems

E9.36 What are the hybrid orbitals of the carbon atoms in the following molecules?
(a) $\mathrm{H}_{3} \mathrm{C}-\mathrm{CH}_{3}$
(b) $\mathrm{H}_{3} \mathrm{C}-\mathrm{CH}=\mathrm{CH}_{2}$
(c) $\mathrm{CH}_{3}-\mathrm{C}=\mathrm{C}-\mathrm{CH}_{2} \mathrm{OH}$
(d) $\mathrm{CH}_{3} \mathrm{CH}=\mathrm{O}$
(e) $\mathrm{CH}_{3} \mathrm{COOH}$

E 9.37 Specify which hybrid orbitals are used by carbon atoms in the following species: (a) CO , (b) $\mathrm{CO}_{2}$, (c) $\mathrm{CN}^{-}$.
9.38 The allene molecule $\left(\mathrm{H}_{2} \mathrm{C}=\mathrm{C}=\mathrm{CH}_{2}\right)$ is linear (the three C atoms lie on a straight line). What are the hybridization states of the carbon atoms? Draw diagrams to show the formation of sigma bonds and pi bonds in allene.

E9.39 What is the hybridization of the central N atom in the azide ion $\left(\mathrm{N}_{3}^{-}\right)$? (The arrangement of atoms is NNN.)

E9.40 How many sigma bonds and pi bonds are there in each of the following molecules?

(a)

(b)

(c)

G9.41 How many pi bonds and sigma bonds are there in the tetracyanoethylene molecule?

E9.42 Tryptophan is one of the 20 amino acids in the human body. Describe the hybridization state of the C and N atoms, and determine the number of sigma and pi bonds in the molecule.

9.43 Benzo(a)pyrene is a potent carcinogen found in coal and cigarette smoke. Determine the number of sigma and pi bonds in the molecule.

## Section 9.6: Molecular Orbital Theory

## Review Questions

9.44 What is molecular orbital theory? How does it differ from valence bond theory?
9.45 Define the following terms: bonding molecular orbital, antibonding molecular orbital, pi molecular orbital, sigma molecular orbital.
9.46 Sketch the shapes of the following molecular orbitals: $\sigma_{1 s}, \sigma_{1 s}^{*}$, $\pi_{2 p}, \pi_{2 p}^{*}$. How do their energies compare?
9.47 Explain the significance of bond order. Can bond order be used for quantitative comparisons of the strengths of chemical bonds?

## Problems

9.48 Explain in molecular orbital terms the changes in $\mathrm{H}-\mathrm{H}$ internuclear distance that occur as the molecular $\mathrm{H}_{2}$ is ionized first to $\mathrm{H}_{2}^{+}$and then to $\mathrm{H}_{2}^{2+}$.
9.49 The formation of $\mathrm{H}_{2}$ from two H atoms is an energetically favorable process. Yet statistically there is less than a 100 percent chance that any two H atoms will undergo the reaction. Apart from energy considerations, how would you account for this observation based on the electron spins in the two H atoms?

H9.50 Draw a molecular orbital energy level diagram for each of the following species: $\mathrm{He}_{2}, \mathrm{HHe}, \mathrm{He}_{2}^{+}$. Compare their relative stabilities in terms of bond orders. (Treat HHe as a diatomic molecule with three electrons.)

Arrange the following species in order of increasing stability: $\mathrm{Li}_{2}$, $\mathrm{Li}_{2}^{+}, \mathrm{Li}_{2}^{-}$. Justify your choice with a molecular orbital energy level diagram.
9.52 Use molecular orbital theory to explain why the $\mathrm{Be}_{2}$ molecule does not exist.

E9.53 Which of these species has a longer bond, $\mathrm{B}_{2}$ or $\mathrm{B}_{2}^{+}$? Explain in terms of molecular orbital theory.
-49.54 Acetylene $\left(\mathrm{C}_{2} \mathrm{H}_{2}\right)$ has a tendency to lose two protons $\left(\mathrm{H}^{+}\right)$and form the carbide ion $\left(\mathrm{C}_{2}^{2-}\right)$, which is present in a number of ionic compounds, such as $\mathrm{CaC}_{2}$ and $\mathrm{MgC}_{2}$. Describe the bonding scheme in the $\mathrm{C}_{2}^{2-}$ ion in terms of molecular orbital theory. Compare the bond order in $\mathrm{C}_{2}^{2-}$ with that in $\mathrm{C}_{2}$.
\&9.55 Compare the Lewis and molecular orbital treatments of the oxygen molecule.
9.56 Explain why the bond order of $\mathrm{N}_{2}$ is greater than that of $\mathrm{N}_{2}^{+}$, but the bond order of $\mathrm{O}_{2}$ is less than that of $\mathrm{O}_{2}^{+}$.
\& 9.57 Compare the relative bond orders of the following species and indicate their magnetic properties (that is, diamagnetic or paramagnetic): $\mathrm{O}_{2}, \mathrm{O}_{2}^{+}, \mathrm{O}_{2}^{-}$(superoxide ion), $\mathrm{O}_{2}^{2-}$ (peroxide ion).
9.58 Use molecular orbital theory to compare the relative stabilities of $\mathrm{F}_{2}$ and $\mathrm{F}_{2}^{+}$.
\$9.59 A single bond is almost always a sigma bond, and a double bond is almost always made up of a sigma bond and a pi bond. There are very few exceptions to this rule. Show that the $B_{2}$ and $C_{2}$ molecules are examples of the exceptions.

## Section 9.7: Bonding Theories and Descriptions of Molecules with Delocalized Bonding

## Review Questions

9.60 How does a delocalized molecular orbital differ from a molecular orbital such as that found in $\mathrm{H}_{2}$ or $\mathrm{C}_{2} \mathrm{H}_{4}$ ? What do you think are the minimum conditions (for example, number of atoms and types of orbitals) for forming a delocalized molecular orbital?
9.61 In Chapter 8 we saw that the resonance concept is useful for dealing with species such as the benzene molecule and the carbonate ion. How does molecular orbital theory deal with these species?

## Problems

9.62 Both ethylene $\left(\mathrm{C}_{2} \mathrm{H}_{4}\right)$ and benzene $\left(\mathrm{C}_{6} \mathrm{H}_{6}\right)$ contain the $\mathrm{C}=\mathrm{C}$ bond. The reactivity of ethylene is greater than that of benzene. For example, ethylene readily reacts with molecular bromine, whereas benzene is normally quite inert toward molecular bromine and many other compounds. Explain this difference in reactivity.
9.63 Explain why the symbol on the left is a better representation of benzene molecules than that on the right.

9.64 Determine which of these molecules has a more delocalized orbital, and justify your choice. (Hint: Both molecules contain two benzene rings. In naphthalene, the two rings are fused together. In biphenyl, the two rings are joined by a single bond, around which the two rings can rotate.)

Biphenyl

Naphthalene
9.65 Nitryl fluoride $\left(\mathrm{FNO}_{2}\right)$ is very reactive chemically. The fluorine and oxygen atoms are bonded to the nitrogen atom. (a) Write a Lewis structure for $\mathrm{FNO}_{2}$. (b) Indicate the hybridization of the nitrogen atom. (c) Describe the bonding in terms of molecular orbital theory. Where would you expect delocalized molecular orbitals to form?
9.66 Describe the bonding in the nitrate ion $\mathrm{NO}_{3}^{-}$in terms of delocalized molecular orbitals.
9.67 What is the state of hybridization of the central O atom in $\mathrm{O}_{3}$ ? Describe the bonding in $\mathrm{O}_{3}$ in terms of delocalized molecular orbitals.

## Additional Problems

\& 9.68 Which of the following species is not likely to have a tetrahedral shape: (a) $\mathrm{SiBr}_{4}$, (b) $\mathrm{NF}_{4}^{+}$, (c) $\mathrm{SF}_{4}$, (d) $\mathrm{BeCl}_{4}^{2-}$, (e) $\mathrm{BF}_{4}^{-}$, (f) $\mathrm{AlCl}_{4}^{-}$?
§9.69 Draw the Lewis structure of mercury(II) bromide. Is this molecule linear or bent? How would you establish its geometry?
9.70 Although both carbon and silicon are in Group 4A, very few $\mathrm{Si}=\mathrm{Si}$ bonds are known. Account for the instability of silicon-tosilicon double bonds in general. (Hint: Compare the atomic radii of C and Si in Figure 7.6. What effect would the larger size have on pi bond formation?)
\& 9.71 Predict the geometry of sulfur dichloride $\left(\mathrm{SCl}_{2}\right)$ and the hybridization of the sulfur atom.
\& 9.72 Antimony pentafluoride $\left(\mathrm{SbF}_{5}\right)$ reacts with $\mathrm{XeF}_{4}$ and $\mathrm{XeF}_{6}$ to form ionic compounds, $\mathrm{XeF}_{3}^{+} \mathrm{SbF}_{6}^{-}$and $\mathrm{XeF}_{5}^{+} \mathrm{SbF}_{6}^{-}$. Describe the geometries of the cations and anions in these two compounds.
9.73 The molecular model of vitamin C is shown here. (a) Write the molecular formula of the compound. (b) What is the hybridization of each C and O atom? (c) Describe the geometry about each C and O atom.

Y 9.74 The molecular model of nicotine (a stimulant) is shown here. (a) Write the molecular formula of the compound. (b) What is the hybridization of each C and N atom? (c) Describe the geometry about each C and N atom.

H9.75 Predict the bond angles for the following molecules: (a) $\mathrm{BeCl}_{2}$, (b) $\mathrm{BCl}_{3}$, (c) $\mathrm{CCl}_{4}$, (d) $\mathrm{CH}_{3} \mathrm{Cl}$, (e) $\mathrm{Hg}_{2} \mathrm{Cl}_{2}$ (arrangement of atoms: ClHgHgCl ), (f) $\mathrm{SnCl}_{2}$, (g) $\mathrm{H}_{2} \mathrm{O}_{2}$, (h) $\mathrm{SnH}_{4}$.
9.76 Briefly compare the VSEPR and hybridization approaches to the study of molecular geometry.

G 9.77 Draw Lewis structures and give the other information requested for the following molecules: (a) $\mathrm{BF}_{3}$. Shape: planar or nonplanar? (b) $\mathrm{ClO}_{3}^{-}$. Shape: planar or nonplanar? (c) HCN . Polar or nonpolar? (d) $\mathrm{OF}_{2}$. Polar or nonpolar? (e) $\mathrm{NO}_{2}$. Estimate the ONO bond angle.

H9.78 Describe the hybridization state of arsenic in arsenic pentafluoride $\left(\mathrm{AsF}_{5}\right)$.
9.79 The disulfide bond, $-S-S-$, plays an important role in determining the three-dimensional structure of proteins. Describe the nature of the bond and the hybridization state of the $S$ atoms.

E9.80 Draw Lewis structures and give the other information requested for the following: (a) $\mathrm{SO}_{3}$. Polar or nonpolar molecule? (b) $\mathrm{PF}_{3}$. Polar or nonpolar? (c) $\mathrm{F}_{3} \mathrm{SiH}$. Polar or nonpolar? (d) $\mathrm{SiH}_{3}^{-}$. Shape: planar or pyramidal? (e) $\mathrm{Br}_{2} \mathrm{CH}_{2}$. Polar or nonpolar molecule?

CI9.81 Which of the following molecules are linear: $\mathrm{ICl}_{2}^{-}, \mathrm{IF}_{2}^{+}, \mathrm{OF}_{2}, \mathrm{SnI}_{2}$, $\mathrm{CdBr}_{2}$ ?

G9.82 Draw the Lewis structure for the $\mathrm{BeCl}_{4}^{2-}$ ion. Predict its geometry, and describe the hybridization state of the Be atom.

- 9.83 The $\mathrm{N}_{2} \mathrm{~F}_{2}$ molecule can exist in either of the following two forms:

(a) What is the hybridization of N in the molecule? (b) Which structure is polar?
9.84 Cyclopropane $\left(\mathrm{C}_{3} \mathrm{H}_{6}\right)$ has the shape of a triangle in which a C atom is bonded to two H atoms and two other C atoms at each corner. Cubane $\left(\mathrm{C}_{8} \mathrm{H}_{8}\right)$ has the shape of a cube in which a C atom is bonded to one H atom and three other C atoms at each corner. (a) Draw Lewis structures of these molecules. (b) Compare the CCC angles in these molecules with those predicted for an $s p^{3}$ hybridized C atom. (c) Would you expect these molecules to be easy to make?
9.85 The compound 1,2-dichloroethane $\left(\mathrm{C}_{2} \mathrm{H}_{4} \mathrm{Cl}_{2}\right)$ is nonpolar, while cis-dichloroethylene $\left(\mathrm{C}_{2} \mathrm{H}_{2} \mathrm{Cl}_{2}\right)$ has a dipole moment: The reason for the difference is that groups connected by a single bond can rotate with respect to each other, but no rotation occurs when a double bond connects the groups. On the basis of bonding considerations, explain why rotation occurs in 1,2-dichloroethane but not in cis-dichloroethylene.

1,2-dichloroethane

cis-dichloroethylene

G9.86 Does the following molecule have a dipole moment? Explain.

9.87 So-called greenhouse gases, which contribute to global warming, have a dipole moment or can be bent or distorted during molecular vibration into shapes that have a temporary dipole moment. Which of the following gases are greenhouse gases: $\mathrm{N}_{2}, \mathrm{O}_{2}, \mathrm{O}_{3}$, $\mathrm{CO}, \mathrm{CO}_{2}, \mathrm{NO}_{2}, \mathrm{~N}_{2} \mathrm{O}, \mathrm{CH}_{4}, \mathrm{CFCl}_{3}$ ?
9.88 (a) From what group must the terminal atoms come in an $\mathrm{AB}_{x}$ molecule where the central atom is from Group 5A, for both the electron-domain geometry and the molecular geometry to be trigonal bipyramidal? (b) From what group must the terminal atoms come in an $\mathrm{AB}_{x}$ molecule where the central atom is from Group 6A, for the electron-domain geometry to be tetrahedral and the molecular geometry to be bent?
9.89 The compound $3^{\prime}$-azido- $3^{\prime}$ deoxythymidine, commonly known as AZT, is one of the drugs used to treat AIDS. What are the hybridization states of the C and N atoms in this molecule?

E9.90 The following molecules $\left(\mathrm{AX}_{4} \mathrm{Y}_{2}\right)$ all have an octahedral geometry. Group the molecules that are equivalent to each other.

9.91 The compounds carbon tetrachloride $\left(\mathrm{CCl}_{4}\right)$ and silicon tetrachloride $\left(\mathrm{SiCl}_{4}\right)$ are similar in geometry and hybridization. However, $\mathrm{CCl}_{4}$ does not react with water but $\mathrm{SiCl}_{4}$ does. Explain the difference in their chemical reactivities. (Hint: The first step of the reaction is believed to be the addition of a water molecule to the Si atom in $\mathrm{SiCl}_{4}$.)
9.92 Write the ground-state electron configuration for $B_{2}$. Is the molecule diamagnetic or paramagnetic?
9.93 What is the hybridization of C and of N in this molecule?

9.94 The stable allotropic form of phosphorus is $\mathrm{P}_{4}$, in which each P atom is bonded to three other P atoms. Draw a Lewis structure of this molecule and describe its geometry. At high temperatures, $\mathrm{P}_{4}$ dissociates to form $\mathrm{P}_{2}$ molecules containing a $\mathrm{P}=\mathrm{P}$ bond. Explain why $P_{4}$ is more stable than $P_{2}$.
9.95 Use molecular orbital theory to explain the difference between the bond enthalpies of $\mathrm{F}_{2}$ and $\mathrm{F}_{2}^{-}$. (See Problem 8.121.)
9.96 Use molecular orbital theory to explain the bonding in the azide ion $\left(\mathrm{N}_{3}^{-}\right)$. (The arrangement of atoms is NNN .)

E9.97 The ionic character of the bond in a diatomic molecule can be estimated by the formula

$$
\frac{\mu}{e d} \times 100 \%
$$

where $\mu$ is the experimentally measured dipole moment (in $\mathrm{C} \cdot \mathrm{m}$ ), $e$ is the electronic charge, and $d$ is the bond length (in meters). (The quantity $e d$ is the hypothetical dipole moment for the case in which the transfer of an electron from the less electronegative to the more electronegative atom is complete.) Given that the dipole moment and bond length of HF are 1.92 D and 91.7 pm , respectively, calculate the percent ionic character of the molecule. $\left(1 \mathrm{D}=3.336 \times 10^{-30} \mathrm{Cm}\right)$
9.98 Draw three Lewis structures for compounds with the formula $\mathrm{C}_{2} \mathrm{H}_{2} \mathrm{~F}_{2}$. Indicate which of the compounds are polar.
9.99 Greenhouse gases absorb (and trap) outgoing infrared radiation (heat) from Earth and contribute to global warming. A molecule of a greenhouse gas either possesses a permanent dipole moment or has a changing dipole moment during its vibrational motions. Consider three of the vibrational modes of carbon dioxide

$$
\leftarrow \mathrm{O}=\mathrm{C}=\overrightarrow{\mathrm{O}} \quad \overrightarrow{\mathrm{O}}=\stackrel{\leftarrow}{\mathrm{C}}=\overrightarrow{\mathrm{O}} \quad \stackrel{\uparrow}{\mathrm{O}}=\underset{\downarrow}{\mathrm{C}}=\stackrel{\uparrow}{\mathrm{O}}
$$

where the arrows indicate the movement of the atoms. (During a complete cycle of vibration, the atoms move toward one extreme position and then reverse their direction to the other extreme position.) Which of the preceding vibrations are responsible for $\mathrm{CO}_{2}$ behaving as a greenhouse gas?
§9.100 Aluminum trichloride $\left(\mathrm{AlCl}_{3}\right)$ is an electron-deficient molecule. It has a tendency to form a dimer (a molecule made up of two $\mathrm{AlCl}_{3}$ units):

$$
\mathrm{AlCl}_{3}+\mathrm{AlCl}_{3} \longrightarrow \mathrm{Al}_{2} \mathrm{Cl}_{6}
$$

(a) Draw a Lewis structure for the dimer. (b) Describe the hybridization state of Al in $\mathrm{AlCl}_{3}$ and $\mathrm{Al}_{2} \mathrm{Cl}_{6}$. (c) Sketch the geometry of the dimer. (d) Do these molecules possess a dipole moment?
9.101 Progesterone is a hormone responsible for female sex characteristics. In the usual shorthand structure, each point where lines meet represents a C atom, and most H atoms are not shown. Draw the complete structure of the molecule, showing all C and H atoms. Indicate which
 C atoms are $s p^{2}$ - and $s p^{3}$-hybridized.
9.102 The molecule benzyne $\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)$ is a very reactive species. It resembles benzene in that it has a six-membered ring of carbon atoms. Draw a Lewis structure of the molecule and account for the molecule's high reactivity.
9.103 Assume that the third-period element phosphorus forms a diatomic molecule, $\mathrm{P}_{2}$, in an analogous way as nitrogen does to form $\mathrm{N}_{2}$. (a) Write the electronic configuration for $\mathrm{P}_{2}$. Use $\left[\mathrm{Ne}_{2}\right]$ to represent the electron configuration for the first two periods.
(b) Calculate its bond order. (c) What are its magnetic properties (diamagnetic or paramagnetic)?
9.104 Consider an $\mathrm{N}_{2}$ molecule in its first excited electronic state, that is, when an electron in the highest occupied molecular orbital is promoted to the lowest empty molecular orbital. (a) Identify the molecular orbitals involved, and sketch a diagram to show the transition. (b) Compare the bond order and bond length of $\mathrm{N}_{2}^{*}$ with $\mathrm{N}_{2}$, where the asterisk denotes the excited molecule. (c) Is $\mathrm{N}_{2}^{*}$ diamagnetic or paramagnetic? (d) When $\mathrm{N}_{2}^{*}$ loses its excess energy and converts to the ground state $\mathrm{N}_{2}$, it emits a photon of wavelength 470 nm , which makes up part of the auroras' lights. Calculate the energy difference between these levels.
9.105 The Lewis structure for $\mathrm{O}_{2}$ is

$$
\because \dot{O}=\dot{\mathrm{O}}
$$

Use molecular orbital theory to show that the structure actually corresponds to an excited state of the oxygen molecule.
G9.106 Draw the Lewis structure of ketene $\left(\mathrm{C}_{2} \mathrm{H}_{2} \mathrm{O}\right)$ and describe the hybridization states of the C atoms. The molecule does not contain $\mathrm{O}-\mathrm{H}$ bonds. On separate diagrams, sketch the formation of the sigma and pi bonds.
9.107 The compound TCDD, or 2,3,7,8-tetrachlorodibenzo-p-dioxin, is highly toxic:

It gained considerable notoriety in 2004 when it was implicated in the attempted murder of a Ukrainian politician. (a) Describe its geometry, and state whether the molecule has a dipole moment. (b) How many pi bonds and sigma bonds are there in the molecule?
9.108 Write the electron configuration of the cyanide ion $\left(\mathrm{CN}^{-}\right)$. Name a stable molecule that is isoelectronic with the ion.
9.109 Carbon monoxide ( CO ) is a poisonous compound due to its ability to bind strongly to $\mathrm{Fe}^{2+}$ in the hemoglobin molecule. The molecular orbitals of CO have the same energy order as those of the $\mathrm{N}_{2}$ molecule. (a) Draw a Lewis structure of CO and assign formal charges. Explain why CO has a rather small dipole moment of 0.12 D . (b) Compare the bond order of CO with that from molecular orbital theory. (c) Which of the atoms ( C or O ) is more likely to form bonds with the $\mathrm{Fe}^{2+}$ ion in hemoglobin?
9.110 Which of the following ions possess a dipole moment: (a) $\mathrm{ClF}_{2}^{+}$, (b) $\mathrm{ClF}_{2}^{-}$, (c) $\mathrm{IF}_{4}^{+}$, (d) $\mathrm{IF}_{4}^{-}$?
9.111 Which of the following geometries has a greater stability for tin(IV) hydride $\left(\mathrm{SnH}_{4}\right)$ ?

9.112 Carbon dioxide has a linear geometry and is nonpolar. Yet we know that the molecule exhibits bending and stretching motions that create a dipole moment. How would you reconcile these seemingly conflicting descriptions of $\mathrm{CO}_{2}$ ?
9.113 Carbon suboxide $\left(\mathrm{C}_{3} \mathrm{O}_{2}\right)$ is a colorless pungent-smelling gas. Does this molecule possess a dipole moment? Explain.

## Pre-Professional Practice Exam Questions: Physical Sciences

These questions are not based on a descriptive passage.

1. What is the shape of the $\mathrm{ICl}_{3}$ molecule?
a) Trigonal planar
c) T-shaped
b) Trigonal pyramidal
d) Tetrahedral
2. Which of the following molecules is nonpolar?
a) $\mathrm{NCl}_{3}$
b) $\mathrm{BCl}_{3}$
c) $\mathrm{PCl}_{3}$
d) $\mathrm{BrCl}_{3}$
3. Which of the following has a bond order of 2 ?

| $\mathrm{N}_{2}^{2-}$ | $\mathrm{N}_{2}$ | $\mathrm{~N}_{2}^{2+}$ |
| :---: | :---: | :---: |
| I | II | III |

a) I only
c) III only
b) II only
d) I and III
4. Which of the following are paramagnetic?

| $\mathrm{O}_{2}^{2-}$ | $\mathrm{O}_{2}^{-}$ | $\mathrm{O}_{2}^{+}$ | $\mathrm{O}_{2}^{2+}$ |
| :---: | :---: | :---: | :---: |
| I | II | III | IV |

a) I and II
c) III and IV
b) II and III
d) I and III

## Answers to In-Chapter Materials

## Answers to Practice Problems

9.1A (a) linear, (b) bent. 9.1B (a) Group 6A, (b) Group 7A. 9.2A Bent about O , tetrahedral about each C , trigonal pyramidal about N . All bond angles are $\sim 109.5^{\circ}$. Angles labeled in blue are $<109.5^{\circ}$.

9.2B $\mathrm{SO}_{2}$ contains double bonds, which are not pushed together by the central atom's lone pair as easily as the single bonds in $\mathrm{NH}_{3} .9 .3 \mathrm{~A}$ (a) polar, (b) nonpolar. 9.3B (a) Trigonal bipyramidal, square planar, octahedral. (b) Octahedral. 9.4A Singly occupied $3 p$ orbitals from the P atom overlap with $s$ orbitals from H atoms. 9.4B We cannot use valence bond theory to explain the bonding in $\mathrm{SO}_{2}$ or $\mathrm{CH}_{4}$. In the case of $\mathrm{SO}_{2}$, although the central atom has two unpaired electrons and can form two bonds, the unpaired electrons on S are in $3 p$ orbitals. Formation of two bonds by the overlap of two $3 p$ orbitals on S would be expected to result in a bond angle of approximately $90^{\circ}$. In the case of $\mathrm{CH}_{4}$, the central atom does not have enough unpaired electrons to form four bonds. 9.5A Two of the $4 p$ electrons in Br are promoted to empty $d$ orbitals. The $s$ orbital, all three $p$ orbitals, and two of the $d$ orbitals hybridize to form six $s p^{3} d^{2}$ hybrid orbitals. One of the hybrid orbitals contains the lone pair. Each of the remaining hybrid orbitals contains one electron and overlaps with a singly occupied $2 p$ orbital on an F atom. The arrangement of hybrid orbitals is octahedral and the bond angles are $\sim 90^{\circ}$.9.5B One of the $2 s$ electrons in Be is promoted to an empty $p$ orbital. The $s$ orbital and one $p$ orbital hydridize to form two $s p$ hybrid orbitals. Each hybrid orbital contains one electron and overlaps with a singly occupied $2 p$ orbital on an F atom. The arrangement is linear with a bond angle of $\sim 180^{\circ}$. 9.6A $16 \sigma$ bonds and $4 \pi$ bonds. 9.6B $17 \sigma$ bonds and $5 \pi$ bonds. 9.7A C and N atoms are $s p$-hybridized. The triple bond between C and N is composed of one sigma bond (from overlap of hybrid orbitals) and two pi bonds (from interaction of remaining $p$ orbitals). The single bond between H and C is the result of an $s p$ orbital from C overlapping with an $s$ orbital from H. 9.7B Each N atom is $s p$-hybridized. One $s p$ orbital on each is singly occupied and one contains a lone pair. The singly occupied $s p$
orbitals overlap to form a sigma bond between the N atoms. The remaining unhybridized $p$ orbitals interact to form two pi bonds. 9.8A paramagnetic; bond order $=2.9 .8 \mathrm{~B}$ paramagnetic; bond order $=2$. 9.9A Two different resonance structures are possible; therefore we consider all three atoms to be $s p^{2}$-hybridized. One of the hybrid orbitals on the central O atom contains the lone pair, the other two form sigma bonds to the terminal O atoms. Each atom has one remaining unhybridized $p$ orbital. The $p$ orbitals combine to form $\pi$ molecular orbitals. 9.9B Two different resonance structures are possible; therefore we consider all three atoms to be $s p^{2}$-hybridized. One of the hybrid orbitals on the central N atom contains the lone pair, the other two form sigma bonds to the terminal O atoms. Each atom has one remaining unhybridized $p$ orbital. The $p$ orbitals combine to form $\pi$ molecular orbitals.

## Answers to Checkpoints

9.1.1 d. 9.1.2 b. 9.1.3 e. 9.1.4 c. 9.1.5 d. 9.2.1 a. 9.2.2 c. 9.3.1 b, e. 9.3.2 b. 9.4.1 b. 9.4.2 d. 9.5 .1 a, c. 9.5 .2 c. 9.5 .3 a, b, e. 9.5 .4 c. 9.6 .1 b. 9.6 .2 c, e. 9.6.3 b. 9.6.4 a, c, e. 9.7.1 c. 9.7.2 b. 9.7.3 a, b. 9.7.4 e.

## Answers to Applying What You've Learned

a) There are 14 carbon-carbon sigma bonds in musk ketone and four pi bonds. b) Each of the top two indicated C atoms has three electron domains around it and is therefore $s p^{2}$-hybridized. The bottom indicated C atom has four electron domains around it and is therefore $s p^{3}$-hybridized. The geometry about the $s p^{2}$-hybridized C atoms is trigonal planar, whereas the geometry about the $s p^{3}$-hybridized C atom is tetrahedral. c) Of the pi bonds, only the carbon-carbon and nitrogen-oxygen pi bonds are delocalized. Only the six-membered ring and the nitro groups can be represented with two different resonance structures. d) The bonding in the ring can be described as follows: each of the C atoms is $s p^{2}$-hybridized. The sigma bonds between the C atoms result from the overlap of $s p^{2}$ hybrid orbitals. Each C atom has one leftover, singly occupied $p$ orbital. As in the case for benzene, the unhybridized $p$ orbitals on all six C atoms combine to form six pi molecular orbitals (three bonding and three antibonding) that lie above and below the plane of the molecule. All six electrons in these pi orbitals reside in the bonding molecular orbitals.

This baby, born in 1958, is one of the millions of healthy babies born in the United States during the late 1950s and early 1960s. During this period, thousands of babies in other countries suffered terrible birth defects as the result of the drug thalidomide.

## The Importance of Organic Chemistry to the Development of New Drugs

Beginning in 1957, the drug thalidomide was marketed in 48 countries around the world as a sleeping pill and as an antinausea medicine for pregnant women suffering from morning sickness. By 1962, the drug was shown to have caused horrific birth defects and an untold number of fetal deaths. Thalidomide interferes with spinal cord and limb development, and more than 10,000 babies had been born with severe spinal cord abnormalities and malformed or absent limbs. Many of the victims were born to mothers who reportedly had taken just one thalidomide pill early in their pregnancies. At the time, thalidomide was not approved for use in the United States, but the otherwise worldwide tragedy did prompt the U.S. Congress to enact a new law to give the FDA more control over the testing and approval of new drugs.

In August of 1998, the FDA approved thalidomide for the treatment of erythema nodosum leprosum (ENL), a painful inflammatory skin condition associated with leprosy. This approval is controversial because of the drug's infamous history, but thalidomide has shown tremendous promise in the treatment of a wide variety of painful and debilitating conditions, including complications from certain cancers, AIDS, and some autoimmune disorders such as lupus and rheumatoid arthritis. Because of the dangers known to be associated with thalidomide, researchers are working on developing ana-logues-drugs that are chemically similar enough to have the same therapeutic benefits but chemically different enough not to have the undesirable and/or dangerous properties. Two such analogues that are currently being investigated are lenalidomide and CC-4047, shown here:

Student Annotation: Thalidomide was not approved for use in the United States thanks in large part to the vigilance of one doctor at the FDA. She was troubled by inadequate research into the safety of the drug and steadfastly refused to approve the drugmaker's application.

Scientists who develop new drugs such as lenalidomide and CC-4047 must understand the principles and concepts of organic chemistry.

At the end of this chapter, you will be able to answer several questions about the drugs thalidomide, lenalidomide, and CC-4047 [ $\|$ Page 427].

## In This Chapter, You Will Learn:

Some of the basic concepts of organic chemistry and how the principles of chemical bonding contribute to the understanding of organic compounds and reactions.

## Before you begin, you should review

- Lewis structures and formal charge [ 144 Sections 8.5 and 8.6]
- Resonance [ 14 Section 8.7]
- Molecular geometry and polarity [ KA Sections 9.1 and 9.2]

Student Annotation: Carbon-containing compounds that are considered inorganic are generally those that are obtained from minerals.

Student Annotation: By contrast, there are only about 100,000 known inorganic compounds.

Student Annotation: To form an ion that is isoelectronic with a noble gas, a C atom would have to either gain or lose four electrons [ 14 Section 7.5]-something that is energetically impossible under ordinary conditions. This is not to say that carbon cannot form ions. But in the vast majority of its compounds, carbon acquires a complete octet by sharing electrons-rather than by gaining or losing them.

### 10.1 Why Carbon Is Different

Organic chemistry is usually defined as the study of compounds that contain carbon. This definition is not entirely satisfactory, though, because it would include such things as cyanide and cyanate complexes and metal carbonates, which are considered to be inorganic. A somewhat more useful definition of organic chemistry is the study of compounds that contain carbon and hydrogen, although many organic compounds also contain other elements, such as oxygen, sulfur, nitrogen, phosphorus, or the halogens, and many do not contain hydrogen. Examples of organic compounds include the following:

| $\mathrm{CH}_{4}$ | $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$ | $\mathrm{C}_{5} \mathrm{H}_{7} \mathrm{O}_{4} \mathrm{COOH}$ | $\mathrm{CH}_{3} \mathrm{NH}_{2}$ | $\mathrm{CCl}_{4}$ |
| :---: | :---: | :---: | :---: | :---: |
| Methane | Ethanol | Ascorbic acid | Methylamine | Carbon tetrachloride |

Early in the study of organic chemistry there was thought to be some fundamental difference between compounds that came from living things, such as plants and animals, and those that came from nonliving things, such as rocks. Compounds obtained from plants or animals were called organic, whereas compounds obtained from nonliving sources were called inorganic. In fact, until early in the nineteenth century, scientists believed that only nature could produce organic compounds. In 1829, however, Friedrich Wöhler prepared urea, a well-known organic compound, by combining the inorganic substances lead cyanate and aqueous ammonia:

$$
\mathrm{Pb}(\mathrm{OCN})_{2}+2 \mathrm{NH}_{3}+2 \mathrm{H}_{2} \mathrm{O} \xrightarrow{\Delta} \underset{\text { Urea }}{2 \mathrm{NH}_{2} \mathrm{CONH}_{2}}+\mathrm{Pb}(\mathrm{OH})_{2}
$$

Wöhler's synthesis of urea dispelled the notion that organic compounds were fundamentally different from inorganic compounds-and that they could only be produced by nature. We now know that it is possible to synthesize a wide variety of organic compounds in the laboratory; in fact, many thousands of new organic compounds are produced in research laboratories each year. In this chapter, we will consider several types of organic compounds that are important biologically.

Because of its unique nature, carbon is capable of forming millions of different compounds. Carbon's position in the periodic table (Group 4A, Period 2) gives it the following set of unique characteristics:

- The electron configuration of carbon ( $[\mathrm{He}] 2 s^{2} 2 p^{2}$ ) effectively prohibits ion formation. This and carbon's electronegativity, which is intermediate between those of metals and nonmetals, cause carbon to complete its octet by sharing electrons. In nearly all its compounds, carbon forms four covalent bonds, which can be oriented in as many as four different directions:

Boron and nitrogen, carbon's neighbors in Groups 3A and 5A, respectively, usually form covalent compounds, too, but B and N form ions more readily than C .

- Carbon's small atomic radius allows the atoms to approach one another closely, giving rise to short, strong, carbon-carbon bonds and stable carbon compounds. In addition, carbon atoms that are $s p$ - or $s p^{2}$-hybridized approach one another closely enough for their singly occupied, unhybridized $p$ orbitals to overlap effectively—giving rise to relatively strong $\pi$ bonds [14 Section 9.5]. Recall that elements in the same group generally exhibit similar chemical behavior [ 14 Section 2.4]. Silicon atoms, however, are bigger than carbon atoms, so silicon atoms generally cannot approach one another closely enough for their unhybridized $p$ orbitals to overlap significantly. As a result, very few compounds exhibit significant $\pi$ bonding between Si atoms:

- Carbon's valence electrons are in the second shell $(n=2)$, where there are no $d$ orbitals. The valence electrons of silicon, on the other hand, are in the third shell $(n=3)$ where there are $d$ orbitals, which can be occupied or attacked by lone pairs on another substance-resulting in a reaction. This reactivity makes silicon compounds far less stable than the analogous carbon compounds. Ethane $\left(\mathrm{CH}_{3}-\mathrm{CH}_{3}\right)$, for example, is stable in both water and air, whereas disilane $\left(\mathrm{SiH}_{3}-\mathrm{SiH}_{3}\right)$ is unstable-breaking down in water and combusting spontaneously in air.

These attributes enable carbon to form chains (straight, branched, and cyclic) containing single, double, and triple carbon-carbon bonds, This, in turn, results in an endless array of organic compounds containing any number and arrangement of carbon atoms. Each carbon atom in a compound can be classified by the number of other carbon atoms to which it is bonded. A carbon atom that is bonded to just one other carbon atom is called a primary carbon; one that is bonded to two other carbon atoms is called a secondary carbon; one that is bonded to three other carbon atoms is called a tertiary carbon; and one that is bonded to four other carbon atoms is called a quaternary carbon. These four types of carbon atoms are identified with the labels $1^{\circ}, 2^{\circ}, 3^{\circ}$, and $4^{\circ}$, respectively. Each of the four carbon types is labeled in the following structure.

One of the important organic molecules that we encountered in Chapter 9 is benzene $\left(\mathrm{C}_{6} \mathrm{H}_{6}\right)$. Organic compounds that are related to benzene, or that contain one or more benzene rings, are called aromatic compounds. Organic molecules that do not contain the benzene ring are called aliphatic compounds.

Benzene

Phenol

Cinnamic aldehyde

Aromatic compounds

Ethanol

Butyric acid

Acetone

Aliphatic compounds

Ethane

Disilane

Student Annotation: Carbon's formation of chains is called catenation.

Student Annotation: A functional group is a group of atoms that determines many of a molecule's properties [ 144 Section 2.6].

Student Annotation: Recall that isomers are different compounds with the same chemical formula [14 Section 9.2].

Acetone

Methylamine

H

Toluene

The functional groups in the types of compounds shown in Table 10.2 are the hydroxy group (in alcohols), the carboxy group (in carboxylic acids), the -COOR group (in esters), the carbonyl group (in aldehydes and ketones), the amino group (in amines), and the amide group (in amides). Functional groups determine many of the properties of a compound, including what types of reactions it is likely to undergo. Figure 10.1 shows ball-and-stick models and electrostatic potential maps of the hydroxy, carboxy, carbonyl, amino, and amide functional groups.

A compound consisting of an alkyl group and the functional group -OH is an alcohol. The identity of an individual alcohol depends on the identity of R , the alkyl group. For example, when R is the methyl group, we have $\mathrm{CH}_{3} \mathrm{OH}$. This is methyl alcohol or methanol, also known as wood alcohol. It is highly toxic and can cause blindness or even death in relatively small doses. When R is the ethyl group, we have $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}$. This is ethyl alcohol or ethanol. Ethanol is the
alcohol in alcoholic beverages. When R is the isopropyl group, we have $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CHOH}$. This is isopropyl alcohol. Isopropyl alcohol, what we commonly call "rubbing alcohol," is widely used as a disinfectant.

TABLE 10.1
Alkyl Groups

| Name | Formula | Model |
| :---: | :---: | :---: |
| Methyl | $-\mathrm{CH}_{3}$ | $9$ |
| Ethyl | $-\mathrm{CH}_{2} \mathrm{CH}_{3}$ |  |
| Propyl | $-\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3}$ |  |
| Isopropyl | $-\mathrm{CH}\left(\mathrm{CH}_{3}\right)_{2}$ |  |
| Butyl | $-\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3}$ |  |
| tert-butyl | $-\mathrm{C}\left(\mathrm{CH}_{3}\right)_{3}$ |  |
| Pentyl | $-\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3}$ |  |
| Isopentyl | $-\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}\left(\mathrm{CH}_{3}\right)_{2}$ |  |
| Hexyl | $-\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3}$ |  |
| Heptyl | $-\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3}$ |  |
| Octyl | $-\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3}$ |  |

## How Are Organic Compounds Named?

Organic compounds are named systematically using International Union of Pure and Applied Chemistry (IUPAC) rules.

Root Names for Alkanes and Alkyl Groups

| Number of Carbons | Name | Number of Carbons | Name |
| :---: | :--- | :---: | :--- |
| 1 | Meth- | 6 | Hex- |
| 2 | Eth- | 7 | Hept- |
| 3 | Prop- | 8 | Oct- |
| 4 | But- | 9 | Non- |
| 5 | Pent- | 10 | Dec- |

## Prefixes for Halogen Substituents

| -F | Fluoro |
| :--- | :--- |
| -Cl | Chloro |
| -Br | Bromo |
| -I | Iodo |

## Alkanes

In Chapter 2, we encountered the names of some simple, straightchain alkanes such as pentane:

To name substituted alkanes (i.e., those that have substituents, which are groups other than -H bonded to the carbons of the chain), we follow a series of steps:

1. Identify the longest continuous carbon chain to get the parent name.
2. Number the carbons in the continuous chain, beginning at the end closest to the substituent. Commonly encountered substituents include alkyl groups and halogens.
3. Identify the substituent and use a number followed by a dash and a prefix to specify its location and identity, respectively.

Step 1: The longest continuous carbon chain contains five C atoms.

(We could also identify the carbon chain as

but the number of C atoms in the chain is the same either way.) The parent name of a five-carbon chain is pentane. (See root names.)
Step 2: We number the carbon atoms beginning at the end nearest the substituent (shaded in green):

Step 3: The substituent is a methyl group, $-\mathrm{CH}_{3}$. It is attached to carbon 2 . Therefore, the name is 2-methylpentane.

Sample Problem 10.1 lets you practice naming some simple organic compounds.

## Sample Problem 10.1

Give names for the following compounds:

(a)

(b)

(c)

Strategy Use the three-step procedure for naming substituted alkanes: (1) name the parent alkane, (2) number the carbons, and (3) name and number the substituent. (Consult Table 2.4 for parent alkane names.)

Setup (a) This is a five-carbon chain. We can number the carbons starting at either end because the Cl substituent will be located on carbon 3 either way:

(b) This may look like a substituted pentane, too, but the longest carbon chain in this molecule is seven carbons long.

Although Lewis structures appear to be flat and to contain $90^{\circ}$ angles, the C atoms in this molecule are all $s p^{3}$-hybridized (four electron domains around each) and there is free rotation about the $\mathrm{C}-\mathrm{C}$ bonds [ 144 Section 9.5]. Thus, the molecule can also be drawn as

The substituent is a methyl group on carbon 4.
(c) This is a substituted hexane.

Solution (a) 3-chloropentane, (b) 4-methylheptane, (c) 2-methylhexane

Think About lt A common error is to misidentify the parent alkane. Double-check to be sure you have identified the longest continuous carbon chain in the molecule. Also be sure to number the carbon atoms so as to give the substituent the lowest possible number.

Practice Problem A Give the systematic IUPAC name for each of the following:
(a)

(b)

(c)

GPractice Problem B Draw structures for (a) 4-ethyloctane, (b) 2-fluoropentane, and (c) 3-methyldecane.

| Student Annotation: Some functional groups have special names and some do not. | TABLE 10.2 | eneral Formulas for Select Classes of Organic Compounds |  |  |
| :---: | :---: | :---: | :---: | :---: |
|  | Class | General Formula | Structure | Functional Group |
|  | Alcohol | ROH | -ÖO-H | Hydroxy group |
|  | Carboxylic acid | RCOOH |  | Carboxy group |
|  | Ester | RCOOR ${ }^{\prime}$ |  | Ester group |
|  | Aldehyde | RCHO |  | Carbonyl group |
|  | Ketone* | RCOR' |  | Carbonyl group |
|  | Amine ${ }^{\dagger}$ | $\mathrm{RNH}_{2}$ |  | Amino group (primary, $1^{\circ}$ ) |
|  | Amine | RNR'H |  | Amino group (secondary, $2^{\circ}$ ) |
|  | Amine | RNR ${ }^{\prime \prime}{ }^{\prime \prime}$ |  | Amino group (tertiary, $3^{\circ}$ ) |
|  | Amide | $\mathrm{RCONH}_{2}$ |  | Amide group (primary, $1^{\circ}$ ) |
|  | Amide | RCONR'H |  | Amide group (secondary, $2^{\circ}$ ) |
|  | Amide | RCONR ${ }^{\prime \prime}{ }^{\prime \prime}$ |  | Amide group (tertiary, $3^{\circ}$ ) |

${ }^{*} \mathrm{R}^{\prime}$ represents a second alkyl group that may or may not be identical to the first alkyl group R . Likewise, $\mathrm{R}^{\prime \prime}$ represents a third alkyl group that may or may not be identical to $R$ or $R^{\prime}$.
$\dagger$ The designations $1^{\circ}, 2^{\circ}$, and $3^{\circ}$ refer to how many R groups are bonded to the N atom.

Figure 10.1 Models and electrostatic potential maps of the hydroxy, carboxy, carbonyl, amino, and amide functional groups.

Many compounds contain more than one functional group. An amino acid, for example, contains both the amine group and the carboxy group.

Alanine
Sample Problem 10.2 lets you practice identifying functional groups in molecules.

## Sample Problem 10.2

Many familiar substances are organic compounds. Some examples include aspartame, the artificial sweetener in the sugar substitute Equal and in many diet sodas; salicylic acid, found in some acne medicines and wart-removal treatments; and amphetamine, a stimulant used to treat narcolepsy, attention-deficit hyperactivity disorder (ADHD), and obesity. Identify the functional group(s) in each molecule:

Aspartame
(a)

Salicylic acid
(b)

Amphetamine
(c)

Strategy Look for and identify the combinations of atoms shown in Table 10.2.
Setup (a) From right to left, aspartame contains a -COOH group, an $-\mathrm{NH}_{2}$ group, a -CONHR group, and a - COOR group:

(b) Salicylic acid contains an -OH group and $\mathrm{a}-\mathrm{COOH}$ group:

(c) Amphetamine contains an $-\mathrm{NH}_{2}$ group:

Solution (a) From right to left, aspartame contains a carboxy group, an amino group, an amide group, and a -COOR (ester) group.
(b) Salicylic acid contains a hydroxy group and a carboxy group.
(c) Amphetamine contains an amino group.

Think About It In part (b), the salicylic acid molecule contains a benzene ring and is therefore aromatic. When the hydroxy group is attached to a benzene ring, the resulting aromatic compound is a phenol, not an alcohol. Amphetamine has several legitimate medicinal uses, but it is also one of the most commonly misused drugs in the United States. Because it frequently is prescribed to adolescents for ADHD, much of it finds its way into high schools, where its misuse is a serious problem. A closely related compound that frequently makes headlines is methamphetamine:

In August of 2005, an issue of Newsweek magazine devoted a cover story to methamphetamine and its abuse.

Practice Problem A Identify the functional groups in each of the following molecules:

(a)
Ethyl butyrate
(c)

(b) Aspirin

HPractice Problem B Identify the functional groups in each of the following cyclic compounds:

## Checkpoint 10.2 Classes of Organic Compounds

10.2.1 Identify the name of the following compound:

a) 2-Ethylpropane
b) 2-Ethylbutane
c) 2-Methylbutane
d) 2-Methylpentane
e) 3-Methylbutane
10.2.2 Identify the name of the following compound:

a) 1-Chloroethane
b) 2-Chloropropane
c) 2-Chloromethane
d) 1-Chloropropane
e) 3-Chloroethane
10.2.3 Identify the name of the following compound:

a) 4-Pentanone
b) 2-Pentanone
c) Ethylpentanal
d) Propylpentanal
e) Propylethanal
10.2.4 Identify the name of the following compound:

a) 3-Methyl-1-ethanamine
b) 2-Methyl-1-ethanamine
c) 1-Pentanamine
d) 2-Methyl-1-butanamine
e) 3-Methyl-1-butanamine

## FAQ You May Be Wondering...

## How Do We Name Molecules with More Than One Substituent?

A systematic name must identify a compound unambiguously. Therefore, a special system of rules must be followed to name molecules that contain more than one substituent.

In molecules that contain two or more identical substituents, the prefixes di, tri, tetra, penta, and so forth, are used to denote the number of substituents. Numbers are then used to denote their positions. (Note that two substituents may be bonded to the same carbon atom. In this case, the carbon's number is repeated with a comma between the numbers.)

2,3-Dimethylpentane

2,2-Dichlorohexanoic acid

In the case where two or more different substituents are present, the substituent names are alphabetized in the systematic name of the compound. Numbers are used to indicate the positions of the alphabetized substituents. If a prefix is used to denote two or more identical substituents, the prefix is not used to determine the alphabetization-only the substituent name is used.

4-Ethyl-2-methylhexane

4-Ethyl-2,2-dimethylhexane
10.2.5 Identify the functional group( $s$ ) in the following molecule:

(Select all that apply.)
a) Hydroxy
b) Carboxy
c) Carbonyl
d) Amino
e) Amide
10.2.6 Identify the functional group(s) in the following molecule:

(Select all that apply.)
a) Hydroxy
b) Carboxy
c) Carbonyl
d) Amino
e) Amide

Student Annotation: The carbonyl carbon is the one that is doubly bonded to oxygen.

Ethanoic acid (acetic acid)

## Alcohols

Identify the longest continuous carbon chain that includes the carbon to which the -OH group is attached. This is the parent alkyl group. Name it according to the number of carbons it contains, and change the $-e$ ending to $-o l$. Number the C atoms such that the -OH group has the lowest possible number, and, when necessary, use a number to indicate the position of the -OH group:

Ethanol

1-Propanol

When the chain that bears the -OH group also bears an alkyl substituent, the chain is numbered in the direction that gives the lowest possible number to the carbon attached to -OH .

## Carboxylic Acids

Identify the longest continuous carbon chain that includes the carboxy group. Name it according to the number of carbons it contains, and change the $-e$ ending to -oic acid. Number the C atoms starting with the carbonyl carbon. Use numbers and prefixes to indicate the position and the identity of any substituents.

Many organic compounds have common names in addition to their systematic names. Common names for some of the carboxylic acids shown here are given in parentheses:

Propanoic acid (propionic acid)

Butanoic acid (butyric acid)

5-Methylhexanoic acid

## Esters

Name esters as derivatives of carboxylic acids by replacing the -ic acid ending with -ate:

Ethyl acetate
Based on acetic acid

Methyl propionate Based on propionic acid
(The first part of an ester's name specifies the substituent that replaces the ionizable hydrogen of the corresponding carboxylic acid.)

## Aldehydes

Identify the longest continuous carbon chain that includes the carbonyl group. Name it according to the number of carbons it contains, and change the $-e$ ending to $-a l$. Number the C atoms starting with the carbonyl carbon. Use numbers and prefixes to indicate the position and the identity of any substituents:

Student Annotation: With carboxylic acids and aldehydes, because we always begin numbering the carbons at the carbonyl, it is not necessary to include the number of the carbonyl carbon (1) in the name.

Ethanal
(acetaldehyde)

Propanal (propionaldehyde)

Butanal

## Ketones

Identify the longest continuous carbon chain that includes the carbonyl group. Name it according to the number of carbons it contains, and change the $-e$ ending to -one. If necessary, number the C atoms to give the carbonyl carbon the lowest possible number. Use numbers and prefixes to indicate the position and the identity of any substituents:

Propanone (acetone)

2-Butanone
(ethyl methyl ketone)

5-Methyl-3-hexanone

Student Annotation: Note that there is only one possible location for the carbonyl carbon in propanone (the middle carbon), making a number in the name unnecessary. If the carbonyl occurred on either of the other carbons, the compound would be an aldehyde, not a ketone.

## Primary Amines

Identify the longest continuous carbon chain that includes the carbon to which the $-\mathrm{NH}_{2}$ group is bonded. Name it according to the number of carbons it contains, and change the $-e$ ending to -amine. Number the C atoms starting with the carbon to which the $-\mathrm{NH}_{2}$ group is bonded. Use numbers and prefixes to indicate the position and the identity of any substituents:

Ethanamine (ethylamine)

1-Propanamine (propylamine)

1-Butanamine (butylamine)

(5-methylhexylamine)

## Primary Amides

Primary amides are named as derivatives of carboxylic acids, but they can also be named by replacing the $-e$ ending of the corresponding alkane with -amide.

Propanamide (propionamide)

Butanamide
(butyramide)

Student Annotation: We will not introduce the nomenclature for secondary and tertiary amines and amides in this text.

Student Annotation: The "necessary" number of H atoms is the number necessary to complete the octet of each C and O atom [ 14 Section 8.3].

### 10.3 Representing Organic Molecules

You've learned previously how to represent molecules using molecular and structural formulas [ 144 Section 2.6], as well as using Lewis structures [ 14 Section 8.3]. In this section, we will learn several additional ways to represent molecules-ways that are particularly useful in the study of organic chemistry.

The representation of organic molecules is especially important because the atoms in an organic molecule, unlike those in inorganic compounds, may be arranged in an enormous variety of different ways. For example, there are literally dozens of different ways that a compound containing five carbon atoms, one oxygen atom, and the necessary number of hydrogen atoms can be arranged, with each arrangement representing a unique organic compound. Here are ten possibilities:

## Condensed Structural Formulas

A condensed structural formula, or simply a condensed structure, shows the same information as a structural formula, but in a condensed form. For instance, the molecular formula, structural formula, and condensed structural formula of octane are as follows:

In the condensed structural formula, the identical adjacent groups of atoms (in this case $-\mathrm{CH}_{2}-$ groups) are enclosed in parentheses and subscripted to denote their number.

In molecules where the carbon atoms do not form a single, unbranched chain, branches are indicated using additional parentheses in the condensed structural formula. For example, 2-methylheptane has the same molecular formula $\left(\mathrm{C}_{8} \mathrm{H}_{18}\right)$ as octane. In effect, the chain is one C atom shorter than in octane and one of the hydrogen atoms on the second C atom has been replaced by a methyl group. The molecular formula, structural formula, and condensed structural formula of 2-methylheptane are as follows:

## Kekulé Structures

Kekulé structures are similar to Lewis structures except that they do not show lone pairs. For molecules that contain no lone pairs, such as octane, the Lewis and Kekulé structures are identical:

(Many of the structures already shown in this chapter are Kekulé structures.) The Kekulé structures for several familiar organic molecules are as follows:

Ethanol

Formaldehyde

Acetic acid

## Skeletal Structures

Skeletal structures are especially useful for representing complex organic molecules. A skeletal structure consists of straight lines that represent carbon-carbon bonds. The carbon atoms themselves (and the attached hydrogen atoms) are not shown, but you need to know that they are there. The structural formulas and skeletal structures for several hydrocarbons [ 14 Section 2.6] are as follows:

| Name | Structural Formula | Skeletal Structure |
| :---: | :---: | :---: |
| Pentane | $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3}$ | $\bigcirc$ |
| Isopentane |  |  |
| Neopentane |  |  |

The end of each straight line in a skeletal structure corresponds to a carbon atom (unless another atom of a different type is explicitly shown at the end of the line). Additionally, there are as many hydrogen atoms attached to each carbon atom as are necessary to give each carbon atom a total of four bonds.

Student Annotation: Study these structural formulas and skeletal structures, and those shown earlier, and make sure you understand how to interpret the skeletal structures.

Think About It Make sure that each C atom is surrounded by four electron pairs: four single bonds, two single bonds and a double bond, or two double bonds. Remember that the single bonds to H typically are not shown in a skeletal structureyou have to remember that they are there and account for the H atoms when you deduce the formula.

When a molecule contains an element other than carbon or hydrogen, those atoms, called heteroatoms, are shown explicitly in the skeletal structure. Furthermore, while the hydrogens attached to carbon atoms typically are not shown, hydrogens attached to heteroatoms are shown, as illustrated by the molecule ethylamine in the following:

Although carbon and hydrogen atoms need not be shown in a skeletal structure, some of the C and H atoms can be shown for the purpose of emphasizing a particular part of a molecule. Often when we show a molecule, we choose to emphasize the functional group(s), which are largely responsible for the properties and reactivity of the compound [ 1 ks Section 2.6].

Sample Problem 10.3 shows how to interpret skeletal structures.

## Sample Problem 10.3

Write a molecular formula and a structural formula (or condensed structural formula) for the following:
(a)

(b)

Strategy Count the C atoms represented and the heteroatoms shown. Determine how many H atoms are present using the octet rule.

Setup Each line represents a bond. (Double lines represent double bonds.) Count one C atom at the end of each line unless another atom is shown there. Count the number of H atoms necessary to complete the octet of each C atom.

Solution (a) Molecular formula: $\mathrm{C}_{4} \mathrm{H}_{8}$; structural formula: $\mathrm{CH}_{3}(\mathrm{CH})_{2} \mathrm{CH}_{3}$.
(b) Molecular formula: $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{NO}$; structural formula: $\mathrm{CH}_{3} \mathrm{CONH}_{2}$.

Practice Problem A Write a structural formula for the compound represented by the following skeletal structure:

$\boldsymbol{\Psi}$ Practice Problem B Draw the skeletal structure for $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{C}=\mathrm{CHNH}_{2}$.

## Resonance

Recall from Chapter 8 that many molecules and ions can be represented by more than one Lewis structure [ 14 Section 8.7]. Furthermore, two or more equally valid Lewis structures that differ only in the position of their electrons are called resonance structures. For example, $\mathrm{SO}_{3}$ can be represented by three different Lewis structures [ 14 Sample Problem 8.10].

None of these Lewis structures represents the $\mathrm{SO}_{3}$ molecule accurately. The bonds in $\mathrm{SO}_{3}$ are actually equivalent-equal in length and strength, which we would not expect if two were single bonds and one were a double bond. Each individual resonance structure implies that electron pairs are localized in specific bonds or on specific atoms. The concept of resonance allows us to envision certain electron pairs as delocalized over several atoms [ 14 Section 9.7]. Delocalization of electron pairs imparts additional stability to a molecule (or polyatomic ion), and a species that can be represented by two or more resonance structures is said to be resonance stabilized.

Chemists sometimes use curved arrows to specify the differences in positions of electrons in resonance structures. In $\mathrm{SO}_{3}$, for example, the "repositioning" of electrons in the resonance structures can be indicated as follows:

Resonance stabilization is observed in many organic species as well and affects chemical properties such as in the acidic behavior of ethanol $\left(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}\right)$ and ethanoic acid $\left(\mathrm{CH}_{3} \mathrm{COOH}\right)$, also commonly known as acetic acid. Each of these molecules has one ionizable hydrogen atom [144 Section 2.6], enabling it to behave as a Brønsted acid [ 14 Section 4.3]. However, the concentration of hydronium ions in a solution of ethanoic acid is hundreds of thousands of times higher than that in a comparable solution of ethanol. The reason for this large discrepancy is that the hydrogen atom on ethanoic acid is far more easily ionized than the one on ethanol. Resonance helps us explain why.

When a species loses its ionizable hydrogen atom, what remains is an anion. In the case of ethanoic acid and ethanol, the anions are

and

We can draw a second resonance structure for the anion produced by the ionization of ethanoic acid by repositioning the electron pairs as follows:

The negative charge on the anion resides on an oxygen atom. Which oxygen atom bears the charge depends on which resonance structure we look at. In essence, the greater the number of possible locations for the negative charge, the more stable the anion. And the more stable the anion, the more easily the ionizable hydrogen atom is lost, resulting in the production of more hydronium ions in solution.

It is not possible to draw additional resonance structures for the anion produced by the ionization of ethanol because there is nowhere else to put the lone pairs that reside on the O atom. They cannot be moved in between the O and C atoms because C can only have four electron pairs around it. (We were able to do this with $\mathrm{CH}_{3} \mathrm{COO}^{-}$because we could also move one of the pairs already around C to the other O atom. See the curved arrows in the preceding resonance structure.)

Sample Problems 10.4 and 10.5 illustrate the use of curved arrow notation and the determination of resonance structures.

Student Annotation: Remember that the real structure of the molecule is neither the first structure nor the second, but rather something in between that cannot be represented by a single structure [ 14 Section 8.7].

Student Annotation: We determine where a charge resides in a polyatomic anion by calculating the formal charge on each atom [1/4 Section 8.6].

Student Annotation: Recall that formal charge is equal to valence electrons - associated electrons [14 Section 8.6].

Think About It Count the number of electron pairs around each atom. Remember that the C and N atoms can have no more than four electron pairs. The H atom can have no more than one electron pair.

## Sample Problem 10.4

Following the curved arrows, draw a resonance structure for the $\mathrm{HCONH}^{-}$ion.

Strategy Move electron pairs as indicated by the curved arrows, and calculate formal charges to reposition the negative charge.

Setup To determine the formal charge, we must first calculate the number of valence electrons on the atoms in question. The O and N atoms have six and five valence electrons, respectively.

Solution Repositioning electron pairs as directed by the curved arrows gives

The formal charge on N , which had been -1 , is now $[5-(3+2)]=0$. The formal charge on O , which had been 0 , is now $[6-(1+6)]=-1$. Thus, the negative charge now resides on the oxygen atom.

Practice Problem A Follow the curved arrows to draw a second resonance structure for the $\mathrm{HCOO}^{-}$ion.

EPractice Problem B Given the following two resonance structures, draw the curved arrows on the first structure that will give rise to the second structure.

## Sample Problem 10.5

Adenosine triphosphate (ATP) is sometimes called the "universal energy carrier" or "molecular energy currency." It contains two high-energy bonds (shown in red) that, when hydrolyzed (broken by the addition of water), release the energy necessary for cell function. Resonance stabilization of the hydrogen phosphate ion is one of the reasons the breakdown of ATP releases energy.

Student Annotation: The hydrogen phosphate ion that results from the breakdown of ATP is commonly referred to in biology textbooks as phosphate or as inorganic phosphate.

Draw all the possible resonance structures for the hydrogen phosphate ion $\left(\mathrm{HPO}_{4}^{2-}\right)$. Use curved arrows to indicate how electrons are repositioned, and determine the position(s) of the negative charges.

Strategy Draw a valid Lewis structure for $\mathrm{HPO}_{4}^{2-}$, and determine whether and where electrons can be repositioned to produce one or more additional structures. Indicate the movement of electrons with curved arrows, and draw all possible resonance structures. Calculate the formal charge on each atom to determine the placement of charges.

Setup A valid Lewis structure for the hydrogen phosphate ion is

For the purpose of determining formal charges, P and O have five and six valence electrons, respectively.

Solution A lone pair can be moved from one of the oxygen atoms to create a double bond to the phosphorus, and a pair of electrons from the original double bond can be moved onto that oxygen atom. The net result is simply a repositioning of the double bond by moving two electron pairs. This can be done once more, giving a total of three resonance structures for $\mathrm{HPO}_{4}^{2-}$. In each of the resonance structures, the formal charge on phosphorus is $[5-(5)]=0$. The formal charge on each singly bonded oxygen is $[6-(1+6)]=-1$, and the formal charge on the doubly bonded oxygen is $[6-(2+4)]=0$.

Practice Problem A Draw a valid Lewis structure for the carbonate ion $\left(\mathrm{CO}_{3}^{2-}\right)$, and use curved arrows to generate all possible resonance structures.

EPPractice Problem B In which of the following examples do the curved arrows not correspond correctly to the repositioning of electrons needed to arrive at the resonance structure shown?

## Checkpoint 10.3 Representing Organic Molecules

10.3.1 Give the molecular formula of the compound represented by

a) $\mathrm{C}_{5} \mathrm{H}_{12} \mathrm{O}$
b) $\mathrm{C}_{6} \mathrm{H}_{8} \mathrm{O}$
c) $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}$
d) $\mathrm{C}_{5} \mathrm{H}_{6} \mathrm{O}$
e) $\mathrm{C}_{6} \mathrm{H}_{13} \mathrm{O}$
10.3.2 Give the molecular formula of the compound represented by

a) $\mathrm{C}_{5} \mathrm{H}_{12} \mathrm{O}$
b) $\mathrm{C}_{6} \mathrm{H}_{13} \mathrm{O}$
c) $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}$
d) $\mathrm{C}_{6} \mathrm{H}_{14} \mathrm{O}$
e) $\mathrm{C}_{4} \mathrm{H}_{13} \mathrm{O}$

## Checkpoint 10.3 Representing Organic Molecules (continued)

10.3.3 Which of the following pairs of species are resonance structures? (Select all that apply.)

10.3.4 Which of the following structural formulas represents a species that has two or more resonance structures? (Select all that apply.)
a) HCOOH
b) $\mathrm{HCOO}^{-}$
c) $\mathrm{CH}_{2} \mathrm{CH}_{2}$
d) $\mathrm{O}_{3}$
e) $\mathrm{CO}_{2}$

### 10.4 Isomerism

We first encountered the term isomer in the context of molecular geometry and molecular polarity [ 144 Section 9.2]. Isomers are different compounds that have the same chemical formula. In this section, we will discuss the different types of isomerism (namely, constitutional isomerism and stereoisomerism) and their importance to organic chemistry.

## Constitutional Isomerism

Also known as structural isomerism, constitutional isomerism occurs when the same atoms can be connected in two or more different ways. For example, there are three different ways to arrange the atoms in a compound with the chemical formula $\mathrm{C}_{5} \mathrm{H}_{12}$. Constitutional isomers have distinct names and generally have different physical and chemical properties. Table 10.3 lists the three constitutional isomers of $\mathrm{C}_{5} \mathrm{H}_{12}$ along with their boiling points for comparison.

Organic and Biochemistry-structural isomers of hexane.

## Stereoisomerism

Stereoisomers are those that contain identical bonds but differ in the orientation of those bonds in space. Two types of stereoisomers exist: geometrical isomers and optical isomers. Geometrical isomers occur in compounds that have restricted rotation around a bond. For instance, compounds that contain carbon-carbon double bonds can form geometrical isomers. Individual geometrical isomers have the same names but are distinguished by a prefix such as cis or trans. Dichloroethylene, ethylene in which two of the H atoms (one on each C atom) have been replaced by Cl atoms, exists as two geometrical isomers. The isomer in which the Cl atoms both lie on the same side (above or below, in this example) of the double bond is called the cis isomer. The isomer in which the Cl atoms lie on opposite sides of the double bond is called the trans isomer. (The compound in which both Cl atoms are attached to the same C atom is a constitutional isomer rather than a stereoisomer.) Figure 10.2 depicts the isomers of $\mathrm{C}_{2} \mathrm{H}_{2} \mathrm{Cl}_{2}$.

## TABLE 10.3 <br> Constitutional Isomers of $\mathrm{C}_{5} \mathrm{H}_{12}$

| Name | Structural Formula | Skeletal Structure | Ball-and-Stick Model | BP ( ${ }^{\circ} \mathrm{C}$ ) |
| :---: | :---: | :---: | :---: | :---: |
| Pentane ( $n$-pentane) |  |  |  | 36.1 |
| Methylbutane (isopentane) |  |  |  | 27.8 |
| 2,2-Dimethylpropane (neopentane) |  |  |  | 9.5 |

Geometrical isomers usually have different physical and chemical properties. Trans isomers tend to be more stable and are generally easier to synthesize than their cis counterparts. The existence of cis isomers in living systems is a testament to how much better nature is at chemical synthesis than we are. As the information in the box on page 410 demonstrates, geometrical isomerism is sometimes of tremendous biological significance.

Stereoisomers that are mirror images of each other, but are not superimposable, are called optical isomers. Consider the hypothetical organic molecule shown in Figure 10.3. It consists of an $s p^{3}$-hybridized carbon atom that is bonded to four different groups. Its mirror image appears identical to it, just as your right and left hands appear identical to each other. But, if you have ever

(a)

(b)

Student Annotation: The word chiral comes from the Greek word cheir for "hand." Chiral molecules may be right-handed or left-handed.
tried to put a right-handed glove on your left hand, or vice versa, you know that your hands are not identical. Imagine rotating the molecule on the right so that its green and red spheres coincide with those of the molecule on the left. Doing so results in the yellow sphere of one molecule coinciding with the blue sphere on the other. These two molecules are mirror images of each other, but they are not identical.

Molecules with nonsuperimposable mirror images are called chiral; and a pair of such mirrorimage molecules are called enantiomers. Most of the chemical properties of enantiomers and all their physical properties are identical. Their chemical properties differ only in reactions that involve another chiral species, such as a chiral molecule or a receptor site that is shaped to fit only one enantiomer. Most biochemical processes consist of a series of chemically specific reactions that use chiral receptor sites to facilitate reaction by allowing only the specific reactants to fit (and thus react).

In organic chemistry, it often is necessary to represent tetrahedral molecules (threedimensional objects) on paper (a two-dimensional surface). By convention, this is done using solid lines to represent bonds that lie in the plane of the page, dashes to represent bonds that point behind the page, and wedges to represent bonds that point in front of the page:

Methane

1, 2-Dichloroethane

One property of chiral molecules is that the two enantiomers rotate the plane of planepolarized light in opposite directions; that is, they are optically active. Unlike ordinary light, which oscillates in all directions, plane-polarized light oscillates only in a single plane. We use a polarimeter, shown schematically in Figure 10.4, to measure the rotation of polarized light by optical isomers. A beam of unpolarized light first passes through a Polaroid sheet, called the polarizer, and then through a sample tube containing a solution of an optically active, chiral species. As the polarized light passes through the sample tube, its plane of polarization is rotated either to the right or to the left. The amount of rotation can be measured by turning the analyzer in the appropriate direction until minimal light transmission is achieved.

Figure 10.4 Schematic of a polarimeter.

(a)

(b)

Minimal transmission occurs when the plane of polarization of the light is perpendicular to that of the analyzer through which it is viewed. This effect can be demonstrated using two pairs of polarized sunglasses as shown in Figure 10.5. If the plane of polarization is rotated to the right, the isomer is said to be dextrorotatory and is labeled $d$; if it is rotated to the left, the isomer is called levorotatory and labeled $l$. Enantiomers always rotate the light by the same amount, but in opposite directions. Thus, in an equimolar mixture of both enantiomers, called a racemic mixture, the net rotation is zero.

## Bringing Chemistry to Life

## Plane-Polarized Light and 3-D Movies

We see in three dimensions because our eyes view the world from slightly different positions. Our brains synthesize a three-dimensional (3-D) picture based on the two different pictures sent to it by our eyes. Modern 3-D movies make use of this phenomenon to make it seem as though objects on the screen are actually moving toward the viewer.

Three-dimensional movies are filmed using two different cameras at slightly different angles to the action. Thus, there are actually two movies that must be shown to us simultaneously. To make sure that our two eyes receive two different perspectives, each movie is projected through a polarizer, which polarizes the two projections in directions perpendicular to each other (Figure 10.6).

Figure 10.6 Two different versions of the same movie are projected onto the screen. Polarized lenses make it so that each eye sees only one version. The result is the perception of three-dimensional action.

Figure 10.5 Two pairs of polarized sunglasses. (a) When two polarized lenses overlap with their planes of polarization parallel to each other, light is transmitted. (b) When one pair is rotated so that its plane of polarization is perpendicular to the other, no light is transmitted through the overlapped lenses.

Student Annotation: There are several conventions used to designate specific enantiomers. Dextro- and levo- prefixes refer to the direction of rotation of polarized light. $R$ and $S$, the most commonly used designations, are assigned based on the "priority" assigned to each of the four groups attached to the chiral carbon-something that is beyond the scope of this text.

Student Annotation: In some cases, the other enantiomer has no biological activity; in other cases, the other enantiomer has a different type of activity, making it detrimental or even deadly-as in the case of thalidomide.

Figure 10.7 The partial positive charge on H in HCl is attracted to the region of electron density in ethylene's double bond.

If we were to watch the movie without the special glasses provided by the movie house, we would see the blurry combination of the two movies. However, the 3-D glasses consist of polarized lenses, with planes of polarization that are mutually perpendicular. The left lens, polarized in one direction, blocks the image that is polarized perpendicular to it. The right lens, polarized in the other direction, blocks the other image. Our eyes are "tricked" into seeing two different movies, which our brain combines to form one 3-D image. The results of this process can be quite impressive!

## Bringing Chemistry to Life

## Biological Activity of Enantiomers

The importance of enantiomers in living systems cannot be overstated. Numerous processes important to biological function involve one enantiomer of a chiral compound. Many drugs, including thalidomide, are chiral with only one enantiomer having the desired properties. Some such drugs have been manufactured and marketed as racemic mixtures. It has become common, though, for drug companies to invest in chiral switching, the preparation of single-isomer versions of drugs originally marketed as racemic mixtures, in an effort to improve on existing therapies and to combat the revenue losses caused by generic drugs. A fairly high-profile example of this is the single-isomer drug Nexium, the so-called purple pill. AstraZeneca, makers of Nexium, held a patent for the drug Prilosec, originally a prescription heartburn medication that is now available over the counter. Prilosec is a racemic mixture of the chiral compound omeprazole. Prior to the 2002 expiration of its patent on Prilosec, AstraZeneca began producing and marketing Nexium, which contains only the therapeutically effective enantiomer (S)-omeprazole or esomeprazole.

Another example of chiral switching is that of the selective serotonin reuptake inhibitor (SSRI) antidepressant Celexa, which was introduced to the market in 1998 by Forest Laboratories. Celexa is a racemic mixture of $(R)$-citalopram oxalate and $(S)$-citalopram oxalate. While only the $(S)$ enantiomer has therapeutic antidepressant properties, both enantiomers contribute to the side effects of the drug and therefore limit effectiveness and patient tolerance. In 2002, the FDA approved Lexapro, a new antidepressant derived from Celexa but from which the therapeutically ineffective ( $R$ ) enantiomer has been removed. The benefits of isolating the active isomer include smaller required dosages, reduced side effects, and a faster and better patient response to the drug.

Although the intellectual property laws regarding single-isomer drug patents are somewhat ambiguous, chiral switching has enabled some pharmaceutical companies to extend the time that they are able to market their popular prescriptions exclusively. Strictly speaking, the FDA does not consider a single enantiomer of an already approved chiral drug to be a "new chemical entity," which is a requirement for obtaining a patent on a compound. Early in the history of chiral switching, however, there was some disagreement among patent examiners regarding what constituted a new chemical entity, and patents were granted on single-isomer drugs that might not be granted today.

### 10.5 Organic Reactions

Coulomb's law, which we first encountered in the box in Section 7.3, measures the force of the attraction between opposite charges. The attraction between regions of opposite charge on neighboring species and the resulting movement of electrons are the basis for our understanding of many organic reactions. We begin by defining what electrophiles and nucleophiles are, two terms used frequently in organic chemistry.

An electrophile is a species with a positive or partial positive charge. Literally, an electrophile "loves electrons." Thus, an electrophile is attracted to a region of negative or partial negative charge. An electrophile may be a cation, such as $\mathrm{H}^{+}$, or the positive portion of a polar molecule, such as the H atom in HCl . Electrophiles are electron-poor.

A nucleophile is a species with a negative or partial negative charge. Literally, a nucleophile "loves a nucleus." A nucleophile is attracted to a region of positive or partial positive charge (i.e., an electrophile). A nucleophile may be an anion, such as $\mathrm{Cl}^{-}$, or the negative portion of a polar molecule, such as the Cl atom in HCl . Nucleophiles are electron-rich. Electron-rich sites and electron-poor sites are attracted to one another.

## Addition Reactions

The electrostatic potential maps of HCl and $\mathrm{C}_{2} \mathrm{H}_{4}$ shown in Figure 10.7 demonstrate that both molecules have regions of partial positive charge and partial negative charge. For example, HCl is a polar molecule, with H bearing a partial positive charge, due to the large difference in electronegativity between hydrogen and chlorine. Moreover, the carbon-carbon double bond in $\mathrm{C}_{2} \mathrm{H}_{4}$ consists of two pairs of shared electrons, one pair in a sigma bond and one pair in a pi bond [ 14 Section 9.5], making the double bond a region of partial negative charge. The partial positive charge on the H in the HCl molecule is an electrophile. The double bond in ethylene, a region of relatively high electron density, is a nucleophile.

A reaction takes place when the positive end of the HCl molecule approaches the double bond in ethylene. The pi bond breaks, and the electrons it contained move as indicated by the curved arrows shown in the following equation, forming a sigma bond between the H atom of the HCl molecule and one of the C atoms. As this new bond forms, two things happen:

1. Because there cannot be more than one bond to the H atom, the original bond between H and Cl breaks. Both of the electrons originally shared by H and Cl go with the Cl atom. The resulting intermediate species are shown in square brackets in the following equation (dashed lines represent bonds that are being formed):

The C atom on the right bears a positive charge after the valence electron it originally shared (in the pi bond with the other C atom) is removed from it completely. A species such as this, in which one of the carbons is surrounded by only six electrons, is called a carbocation. Although carbon must obey the octet in any stable compound, some reactions involve transient, intermediate species in which a carbon atom may be electron deficient-having only three electron pairs around it.
2. The C atom forming the new sigma bond to the H atom changes from $s p^{2}$-hybridized to $s p^{3}$-hybridized:

Student Annotation: Although it ionizes completely in aqueous solution [ 1 ks Section 4.1]. HCl exists as molecules in the gas phase.

Student Annotation: When an electrophile approaches another species and accepts electrons from it to form a bond, this is called electrophilic attack.

Student Annotation: Curved arrows are used to illustrate the mechanism by which an organic reaction occurs. Unlike their use in resonance structures, curved arrows in a reaction mechanism correspond to the actual movement of electrons.

Student Annotation: Nucleophilic attack in which only one electron is donated by the attacking species can also occur. These are called radical reactions.

The formation of a new sigma bond between the Cl and C atoms causes the hybridization of the second C to change from $s p^{2}$ to $s p^{3}$ :

The overall reaction is called an addition reaction. Specifically, this is an electrophilic addition reaction because it begins with the electrophilic attack by HCl on the region of electron density in the double bond.

Addition reactions can also begin with nucleophilic attack, in which case the reaction is called a nucleophilic addition. In a nucleophilic addition reaction, a bond forms when a nucleophile donates a pair of electrons to an electron-deficient atom. Water, for example, reacts with carbon dioxide to produce carbonic acid. Although the addition reaction happens essentially all at once, it is helpful to think of the movement of electrons as the following stepwise process:

One of the lone pairs on the O atom in water attacks the C atom, which is electron deficient because of the highly electronegative O atoms bonded to it. As the new bond forms, one of the original $\mathrm{C}-\mathrm{O}$ pi bonds breaks. The electron pair from the broken pi bond is repositioned on the corresponding O atom, leaving the atom with a negative charge.
2.

One of the $\mathrm{O}-\mathrm{H}$ bonds in water breaks, with both electrons remaining with the O atom. The H atom separates from the water molecule as a proton.
3.

Finally, the negatively charged O atom acquires the proton lost by the water molecule that served as the nucleophile.

A summary of the mechanisms of electrophilic and nucleophilic addition reactions is given in Figure 10.8.

(b)

## Substitution Reactions

Electrophilic and nucleophilic attack can also lead to substitution reactions in which one group is replaced by another group. Electrophilic substitution occurs when an electrophile attacks an aromatic molecule and replaces a hydrogen atom. Nucleophilic substitution occurs when a nucleophile replaces another group on a carbon atom. Figure 10.9 shows the general mechanisms for substitution reactions.

The nitration of benzene is an example of an electrophilic substitution reaction:

Nitric acid and sulfuric acid react to produce the nitronium ion $\left({ }^{+} \mathrm{NO}_{2}\right)$, which acts as the electrophile:

The positively charged nitronium ion is attracted to the electron-rich pi bonds of the benzene ring. A bond forms between one of the carbon atoms and the nitronium ion, breaking one of benzene's pi bonds:

The resulting carbocation is stabilized by resonance:

Figure 10.9 (a) Electrophilic substitution. Benzene is attacked by an electrophile ( $\mathrm{E}^{+}$). (b) Nucleophilic substitution reaction.

Figure 10.10 Reaction of glucose and ATP to produce glucose-6-phosphate and ADP.

Student Annotation: The C atom in methyl bromide bears a partial positive charge because it is bonded to the somewhat more electronegative bromine atom [144 Section 8.4].

Student Annotation: Digestion of proteins also begins with a nucleophilic substitution reaction.

Finally, the electrons in the $\mathrm{C}-\mathrm{H}$ bond move to the ring, restoring the original pi bond, and the hydrogen atom leaves as a proton, $\mathrm{H}^{+}$:

When necessary, one additional step can convert the $-\mathrm{NO}_{2}$ group into the $-\mathrm{NH}_{2}$ group:

A simple example of nucleophilic substitution is the reaction of an alkyl halide such as methyl bromide with a nucleophile such as the chloride ion. The chloride ion is attracted to the partial positive charge on the C atom in methyl bromide. A lone pair on the chloride ion moves to form a sigma bond between the Cl atom and the C atom. And, because there can be no more than four electron pairs around the C atom, the original $\mathrm{C}-\mathrm{Br}$ bond breaks, with both of the electrons originally shared by C and Br going to the Br atom. The result is a methyl chloride molecule and a bromide ion:

Nucleophilic substitutions are particularly important in living systems. The hydrolysis of ATP (adenosine triphosphate), which was described in Section 10.3, is an example of nucleophilic substitution. In hydrolysis, the oxygen atom in water acts as the nucleophile, attacking the electron-deficient phosphorus atom. A similar reaction happens between glucose and ATP, as shown in Figure 10.10. The P atom that is attacked is electron deficient because of the four highly electronegative O atoms bonded to it. As a bond forms between the attacking O and the P , one of the original $\mathrm{P}-\mathrm{O}$ bonds breaks. The net result is the replacement of the original -H group on glucose with a $-\mathrm{PO}_{4}^{3-}$ group to give glucose-6-phosphate and ADP (adenosine diphosphate).

## Bringing Chemistry to Life

## $S_{N} 1$ Reactions

Thalidomide is a chiral drug, but only one of its enantiomers has the desired therapeutic properties. The other enantiomer causes severe birth defects. Thalidomide was originally dispensed as a racemic mixture, giving patients equal amounts of both enantiomers. Unlike some chiral drugs, thalidomide cannot be administered as a single isomer to avoid the undesirable enantiomer. Within hours of administering one enantiomer of thalidomide, both enantiomers are found in roughly equal amounts in the blood. Although the mechanism by which one enantiomer of thalidomide is
converted to the other is the subject of some debate, one way that enantiomers can be interconverted is via a nucleophilic substitution reaction.

Nucleophilic substitution reactions fall into two categories, called $S_{N} 1$ reactions and $S_{N} 2$ reactions. (The numbers 1 and 2 refer to a specific aspect of the kinetics of the reactions [ $M$ Chapter 14].) The nucleophilic substitution that converts one enantiomer to a mixture of both is an $S_{N} 1$ reaction. An $\mathrm{S}_{\mathrm{N}} 1$ reaction begins when one of the groups bonded to a carbon "leaves," leaving behind a carbocation [Figure 10.9(b)]. The hybridization of the carbon atom changes from $s p^{3}$ to $s p^{2}$ when the carbocation forms.

Commonly encountered "leaving groups" include $\mathrm{Cl}^{-}, \mathrm{Br}^{-}$, and $\mathrm{I}^{-}$. A carbocation is an unstable species and, being positively charged, is prone to nucleophilic attack. Because the carbocation is planar about the carbon that bears the positive charge, it is equally likely that a nucleophile will attack from either side.

In the reaction of $\left(\mathrm{CH}_{3}\right)_{3} \mathrm{CBr}$ with $\mathrm{H}_{2} \mathrm{O}$, the product is the same regardless of whether the nucleophile (water) attacks from the front or from the back. When a molecule loses a leaving group from a chiral carbon, however, as would be the case with the thalidomide molecule, attack from one side of the carbocation will yield one enantiomer whereas attack from the other side will yield the other enantiomer. The result is a racemic mixture. The conversion of a single enantiomer to a racemic mixture of both enantiomers is called racemization.

Nucleophilic attack on opposite sides of the carbocation leads to two different products, which are mirror images of each other.

Sample Problems 10.6 and 10.7 show how to draw mechanisms for addition and substitution reactions.

Student Annotation: Recall that $s p^{2}$-hybrid orbitals form a trigonal plane [ 14 Table 9.2].

## Sample Problem 10.6

The electrophilic addition of water to a molecule containing a double bond, known as hydration, is a reaction that is important biologically. One example is the enzyme-catalyzed hydration of fumarate to form malate, one of the steps in the citric acid cycle (also known as the Krebs cycle).

Step 7
Fumarate
The
Krebs
Cycle

Think About lt This time the product is the same regardless of which C atom forms the $\mathrm{C}-\mathrm{O}$ bond and which forms the $\mathrm{C}-\mathrm{H}$ bond, but this is not always the case. If $\mathrm{CH}_{2} \mathrm{CHCH}_{3}$ undergoes hydration, for instance, there are two possible products:

In this case, for reasons beyond the scope of this book, the product that forms is 2-propanol. If you take organic chemistry, you will learn what factors determine which C atom gets the -OH group and which gets the -H .

Using curved arrows to indicate the movement of electrons, draw the mechanism for the electrophilic addition of water to fumarate to yield malate.

Strategy For electrophilic addition, draw Lewis structures with the electrophile close to the region of electron density where attack will occur.

Setup (a) The electrophile is one of the H atoms in $\mathrm{H}_{2} \mathrm{O}$. The site of attack is the pi bond between the C atoms in fumarate:

## Solution

Practice Problem A Using curved arrows to indicate the movement of electrons, draw the mechanism for the electrophilic addition of HI to $\mathrm{C}_{2} \mathrm{H}_{4}$.

EPractice Problem B In which of the following examples do the curved arrows correspond correctly to the proper movement of electrons in the mechanism of electrophilic addition?
(a)

(b)

## Sample Problem 10.7

Using curved arrows to indicate the movement of electrons, draw the mechanism for each of the following reactions: (a) nucleophilic addition of $\mathrm{CN}^{-}$to $\mathrm{CH}_{3} \mathrm{CHO}$ and (b) electrophilic substitution of benzene with ${ }^{+} \mathrm{SO}_{3} \mathrm{H}$. (Draw all resonance structures for the carbocation intermediate.)

Strategy For nucleophilic addition, draw Lewis structures with the nucleophile close to the electron-poor atom where attack will occur (in this case, the carbonyl carbon). For electrophilic substitution, draw Lewis structures with the electrophile close to the site of attack on the benzene ring. Remember that nucleophiles are attracted to and react with electron-poor atoms whereas electrophiles are attracted to and react with electron-rich areas of the molecule. Using this information, and the octet rule, determine which electrons are likely to be involved in the reaction and indicate their repositioning with curved arrows.

Setup (a) The nucleophile is $\mathrm{CN}^{-}$. The site of attack is the carbonyl C in $\mathrm{CH}_{3} \mathrm{CHO}$, which is electron-poor because it is bonded to the more electronegative O atom.
(b) The electrophile is ${ }^{+} \mathrm{SO}_{3} \mathrm{H}$. The site of attack is the electron-rich, delocalized pi bonds of the benzene ring.

(b)
(Continued)

Think About It Additions such as the one in part (a) are carried out in acidic solution. The availability of protons in solution makes the final step the protonation of the negatively charged O atom:

Also, the C atoms in benzene are all equivalent, so the choice of which C will bear the substituent in part (b) is arbitrary. All the following represent the same product:

Practice Problem A Draw mechanisms for (a) nucleophilic addition of $\mathrm{H}^{-}$to $\mathrm{CH}_{3} \mathrm{COCH}_{3}$ and (b) electrophilic substitution of benzene with $\mathrm{Cl}^{+}$.

EfPractice Problem B Draw all the possible products that could result from the following electrophilic substitution reaction:

## Other Types of Organic Reactions

Other important organic reaction types are elimination, oxidation-reduction, and isomerization. An elimination reaction is one in which a double bond forms and a molecule such as water is removed. The dehydration of 2-phosphoglycerate to form phosphoenolpyruvate (Figure 10.11), one of the steps in carbohydrate metabolism, is an example of an elimination reaction.

Oxidation-reduction reactions, as we learned previously [ 141 Section 4.4], involve the loss and gain of electrons, respectively. Determining which species have lost or gained electrons may seem less straightforward with organic reactions than with the inorganic reactions we have encountered, but the following guidelines can help you decide when an organic molecule has been oxidized or reduced:

1. When a molecule gains O or loses H , it is oxidized.
2. When a molecule loses O or gains H , it is reduced.

An important biological example of oxidation is the enzyme-catalyzed reaction by which ethanol is converted to acetaldehyde in the liver:

The ethanol molecule loses two H atoms in this reaction, so it is oxidized.

Figure 10.11 The highlighted atoms are those that constitute the eliminated water molecule.

Isomerization reactions are those in which one isomer is converted to another. The interconversion between the sugars aldose and ketose is an example:

## Bringing Chemistry to Life

## The Chemistry of Vision

Vision, our ability to perceive light, is the result of an isomerization reaction. Our eyes contain millions of cells called rods that are packed with rhodopsin, an 11-cis-retinal molecule

bonded to a large protein. When visible light strikes rhodopsin, the retinal molecule isomerizes to the all-trans isomer:

This isomerization causes such a significant change in the structure of retinal that it separates from the protein. These events trigger the electrical impulses that stimulate the optic nerve and result in the brain receiving the signals that we know as vision. The all-trans-retinal diffuses away from the protein and is converted back to 11-cis-retinal. The regenerated 11-cis-retinal can then rebind with the protein. Interestingly, the conversion of the all-trans isomer back to the 11-cis isomer, which is necessary for us to perceive light, is much slower than the light-induced conversion from cis to trans. This is why after looking at a bright light, you have a "blind spot" for a period of time.

Student Annotation: Many of the organic reactions in living systems require enzymes, natural catalysts, in order to occur rapidly enough to be useful [ Chapter 14].

Student Annotation: Polymers typically have very high molar masses-sometimes thousands or even millions of grams.

Student Annotation: Some of the other properties that suggested a high-molar-mass solute were low osmotic pressure and negligible freezing-point depression. These are known as colligative properties [ 1 Chapter 13].

## Multimedia

Organic and Biochemistry-natural and synthetic polymers.

### 10.6 Organic Polymers

Polymers are molecular compounds, either natural or synthetic, that are made up of many repeating units called monomers. The physical properties of these so-called macromolecules differ greatly from those of small, ordinary molecules.

The development of polymer chemistry began in the 1920s with the investigation of the puzzling behavior of some materials including wood, gelatin, cotton, and rubber. For example, when rubber, with the known empirical formula of $\mathrm{C}_{5} \mathrm{H}_{8}$, was dissolved in an organic solvent, the solution displayed several properties, including a higher than expected viscosity, which suggested that the dissolved compound had a very high molar mass. Despite the experimental evidence, though, scientists at the time were not ready to accept the idea that such giant molecules could exist. Instead, they postulated that materials such as rubber consisted of aggregates of small molecular units, like $\mathrm{C}_{5} \mathrm{H}_{8}$ or $\mathrm{C}_{10} \mathrm{H}_{16}$, held together by intermolecular forces. This misconception persisted for a number of years, until Hermann Staudinger ${ }^{1}$ clearly showed that these so-called aggregates were, in fact, enormously large molecules, each of which contained many thousands of atoms held together by covalent bonds.

Once the structures of these macromolecules were understood, the way was open for the synthesis of polymers, which now pervade almost every aspect of our daily lives. About 90 percent of today's chemists, including biochemists, work with polymers. In this section, we will discuss the reactions that result in polymer formation and some of the natural polymers that are important to biology.

## Addition Polymers

Addition polymers form when monomers such as ethylene join end to end to make polyethylene. Reactions of this type can be initiated by a radical-a species that contains an unpaired electron [144 Section 8.8]. The mechanism of addition polymerization is as follows:

1. The radical, which is unstable because of its unpaired electron, attacks a carbon atom on an ethylene molecule. This is the initiation of the reaction.
2. This attack would result in the carbon atom in question having more than eight electrons around it. To keep the carbon atom from having too many electrons around it, the double bond breaks.
3. One of the electrons in the double bond, together with the electron from the radical, becomes a new bond between the ethylene molecule and the radical.

[^24]4. The other electron remains with the other carbon atom, generating a new radical species.
5. The new radical species, also unstable, attacks another ethylene molecule, causing the same sequence of events to happen again. The generation of a new, highly reactive radical species at each step is known as propagation of the reaction.
6. Each step lengthens the chain of carbon atoms and results in the formation of a new radical, continuing the propagation of the reaction. Reactions such as this are known as chain reactions. They continue until the system runs out of ethylene molecules or until the radical species encounters another radical species-resulting in termination of the reaction.

Initiation step

Some familiar and important addition polymers are listed in Table 10.4.

## Condensation Polymers

Reactions in which two or more molecules become connected with the elimination of a small molecule, often water, are called condensation reactions (Figure 10.12). Condensation polymers form when molecules with two different functional groups combine, with the elimination of a small molecule, often water. Many condensation polymers are copolymers, meaning that they are made up of two or more different monomers.

The first synthetic fiber, nylon 66, is a condensation copolymer of two molecules: one with carboxy groups at each end (adipic acid) and one with amine groups at both ends (hexamethylenediamine):

$$
\underset{\text { Hexamethylenediamine }}{\mathrm{H}_{2} \mathrm{~N}-\left(\mathrm{CH}_{2}\right)_{6}-\mathrm{NH}_{2}}+\underset{\mathrm{HOOC}-\left(\mathrm{CH}_{2}\right)_{4}-\mathrm{COOH}}{\text { Adipic acid }}
$$

$\downarrow$ Condensation

$\downarrow$ Further condensation reactions

Student Annotation: The number 66 refers to the fact that there are six $C$ atoms in each monomer. Other nylons, such as nylon 610, are made from various combinations of molecules similar to adipic acid and hexamethylenediamine.

(a)

(b)

Nylon was first made by Wallace Carothers ${ }^{2}$ at DuPont in 1931. The versatility of nylons is so great that the annual production of nylons and related substances now amounts to several billion pounds.

## Biological Polymers

Naturally occurring polymers include proteins, polysaccharides, and nucleic acids.
Proteins, polymers of amino acids, play an important role in nearly all biological processes. The human body contains an estimated 100,000 different kinds of proteins, each of which has a
2. Wallace H. Carothers (1896-1937). American chemist. Besides its enormous commercial success, Carothers's work on nylon is ranked with that of Staudinger in clearly elucidating macromolecular structure and properties. Depressed by the death of his sister and wrongly believing that his life's work had been a failure, Carothers committed suicide at the age of 41 .

specific physiological function. An amino acid has both the carboxylic acid functional group and the amino functional group. Amino acids are joined together into chains when a condensation reaction occurs between a carboxy group on one molecule and an amino group on another molecule (Figure 10.13).

The bonds that form between amino acids are called peptide bonds. Very long chains of amino acids assembled in this way are called proteins, while shorter chains are called polypeptides.

Amino acids consist of a central carbon atom bonded to four different groups: an amino group, a carboxy group, a hydrogen atom, and an additional group (highlighted in Figure 10.14) consisting of carbon, hydrogen, and sometimes other elements such as nitrogen or sulfur. Proteins are made essentially from the 20 different amino acids shown in Figure 10.14. The identity of a protein depends on which of the 20 amino acids it contains and on the order in which the amino acids are assembled.

Polysaccharides are polymers of sugars such as glucose and fructose. Starch and cellulose are two polymers of glucose with slightly different linkages-and very different properties. In starch, glucose molecules are connected by what biochemists call $\alpha$ linkages. This enables animals, including humans, to digest the starch in such foods as corn, wheat, potatoes, and rice.

Starch
In cellulose, the glucose molecules are connected by $\beta$ linkages. Digestion of cellulose requires enzymes that most animals do not have. Species that do digest cellulose, such as termites and ruminants (including cattle, sheep, and llamas), do so with the help of enzyme-producing symbiotic bacteria in the gut.

Nucleic acids, which are polymers of nucleotides, play an important role in protein synthesis. There are two types of nucleic acids: deoxyribonucleic acid (DNA) and ribonucleic acid (RNA). Each nucleotide in a nucleic acid consists of a purine or pyrimidine base, a furanose sugar (deoxyribose for DNA; ribose for RNA), and a phosphate group. Figure 10.15 (p. 426) shows the building blocks of DNA and RNA. The components of a nucleotide are linked together as shown in Figure 10.16 (p. 426). These molecules are among the largest known-they can have molar masses of up to tens of billions of grams. RNA molecules, on the other hand, typically have molar masses on the order of tens of thousands of grams. Despite their sizes, the composition of nucleic acids is relatively simple compared with proteins. Proteins consist of up to 20 different amino acids, whereas DNA and RNA consist of only four different nucleotides each.

Figure 10.13 Formation of a peptide bond with elimination of water.

Student Annotation: Peptide bonds are also called amide bonds or amide linkages because they contain the amide functional group.

Organic and Biochemistry-molecular structure in DNA.

## Applying What You've Learned

Although it was approved by the FDA in 1998, thalidomide is the most regulated prescription drug in history, because it is known to harm developing fetuses. The drug's manufacturer, Celgene Corporation, has developed the System for Thalidomide Education and Prescribing Safety (STEPS) program. In order for physicians to prescribe thalidomide to their patients, they must be registered in the STEPS program. Female patients must have a negative pregnancy test within 24 hours of beginning treatment and must undergo periodic pregnancy testing throughout treatment. Both female and male patients must comply with mandatory contraceptive measures, patient registration, and patient surveys. Moreover, new patients must view an informational video in which a thalidomide victim explains the potential dangers of the drug.

## Problems:

a) From the structures given at the beginning of the chapter, identify the functional groups in thalidomide. [ 14 Sample Problem 10.2]
b) Write molecular formulas for thalidomide, lenalidomide, and CC-4047.
[14 Sample Problem 10.3]
c) Thalidomide is converted to the drug CC-4047 by substitution of an amino group for one of the H atoms on the aromatic portion of the molecule. Using curved arrows, draw the mechanism for this reaction and all the resonance structures for the carbocation intermediate. [14 Sample Problem 10.7]

## Chapter Summary

## Section 10.1

- Organic chemistry is the study of carbon-based substances. Although it was once thought that organic compounds could only be produced by nature, thousands of new organic compounds are now synthesized each year by scientists.
- Carbon's position in the periodic table makes it uniquely able to form long, stable chains-a process called catenation.
- Aromatic compounds contain one or more benzene rings. Aliphatic compounds are organic compounds that do not contain benzene rings.

## Section 10.2

- Alkyl groups consist of just carbon and hydrogen. They are derived from the corresponding alkane by removing one hydrogen atom and are represented generically in the formulas of organic compounds with the letter R.
- Functional groups are specific arrangements of atoms that are responsible for the properties and reactivity of organic compounds. Common functional groups and their formulas include

| Alcohol | ROH |
| :--- | :--- |
| Carboxylic acid | RCOOH |
| Aldehyde | RCHO |
| Ketone | $\mathrm{RCOR}^{\prime}$ |
| Ester | $\mathrm{RCOOR}^{\prime}$ |
| Amine | $\mathrm{RNH}_{2}, \mathrm{RNHR}^{\prime}$, or $\mathrm{RNR}^{\prime} \mathrm{R}^{\prime \prime}$ |
| Amide | $\mathrm{RCONH}_{2}, \mathrm{RCONHR}^{\prime}$, or $\mathrm{RCONR}^{\prime} \mathrm{R}^{\prime \prime}$ |

- Many organic compounds contain more than one functional group. A substituent in an alkane is a group other than hydrogen that is bonded to the carbon chain.
- An amino acid contains both the carboxy group and the amino group.

## Section 10.3

- Condensed structural formulas or condensed structures abbreviate a series of repeating units, such as $-\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2}-$, into a more compact form, such as $-\left(\mathrm{CH}_{2}\right)_{4}-$. Kekulé structures are similar to Lewis structures but do not show the lone pairs on a molecule. Skeletal structures use straight lines to represent C-C bonds. They typically do not show the C atoms explicitly except for the purpose of emphasizing a particular functional group. H atoms are not shown in skeletal structures-again, except to emphasize a functional group. The number of H atoms bonded to a C atom must be inferred from the number of $\mathrm{C}-\mathrm{C}$ bonds in the structure. Heteroatoms, atoms other than C and H , are always shown explicitly in a skeletal structure.

## Section 10.4

- Constitutional isomers are molecules in which the same atoms are connected differently. Stereoisomers are molecules in which the same atoms are connected by the same bonds but the bonds are oriented differently. Geometrical isomers arise due to restricted rotation about a carbon-carbon double bond. Cis and trans isomers are geometrical isomers.
- Molecules that are nonsuperimposable mirror images of each other are optical isomers. They are also referred to as chiral, and each of the mirror images is called an enantiomer. Optical isomers are so called because they rotate the plane of plane-polarized light. The degree of rotation is the same for both enantiomers, but the directions of rotation are opposite each other. An equal mixture of both enantiomers is called a racemic mixture. A racemic mixture does not rotate the plane of plane-polarized light.

## Section 10.5

- An electrophile generally is a positively charged ion that is attracted to electrons. A nucleophile is a negatively charged ion or a partially negatively charged atom in a polar molecule. Nucleophiles and electrophiles are attracted to each other.
- A carbocation is an intermediate species in which one of the carbon atoms is surrounded by only six electrons and bears a positive charge.
- Electrophilic addition reactions and nucleophilic addition reactions involve the addition of a molecule or an ion to another molecule.
- Substitution reactions occur when an electrophile replaces a hydrogen on an aromatic ring or when a nucleophile replaces a leaving group on a carbon atom.
- Carbocations are the intermediate species in racemization, a nucleophilic substitution reaction in which a single enantiomer is converted into a racemic mixture.
- Hydration is the addition of a water molecule across a double bond.
- An elimination reaction is one in which a double bond forms and a small molecule, such as water, is eliminated.
- Isomerization reactions convert one isomer into another.

## Section 10.6

- Polymers are long chains of repeating molecular units called monomers. Polysaccharides are polymers of sugars. Addition polymers form when a radical species attacks a double bond, forming a new, longer radical species that attacks another double bond, and so on.
- An elimination reaction that joins two molecules is a condensation reaction. Condensation polymers form when molecules with two different functional groups undergo a condensation reaction.
- Copolymers are polymers that contain more than one type of monomer.
- Proteins and polypeptides are biological polymers in which the monomers are amino acids. Amino acids are joined by peptide bonds, which result from the condensation reaction between the amino group of one amino acid and the carboxyl group of another amino acid.
- Nucleic acids are polymers of nucleotides. The two types of nucleic acid are deoxyribonucleic acid (DNA) and ribonucleic acid (RNA). Each nucleotide in a nucleic acid consists of a purine or pyrimidine base, a furanose sugar (deoxyribose for DNA; ribose for RNA), and a phosphate group linked together.

## Questions and Problems

## Section 10.1: Why Carbon Is Different

## Review Questions

10.1 Explain why carbon is able to form so many more compounds than any other element.
10.2 Why was Wöhler's synthesis of urea so important for the development of organic chemistry?
10.3 What are aromatic organic compounds? What are aliphatic organic compounds?

## Section 10.2: Classes of Organic Compounds

## Review Questions

10.4 What are functional groups? Why is it logical and useful to classify organic compounds according to their functional groups?
10.5 Draw the Lewis structure for each of the following functional groups: alcohol, aldehyde, ketone, carboxylic acid, amine.
10.6 Name the classes to which the following compounds belong:
(a) $\mathrm{C}_{4} \mathrm{H}_{9} \mathrm{OH}$
(b) $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{CHO}$
(c) $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COOH}$
(d) $\mathrm{CH}_{3} \mathrm{NH}_{2}$

## Problems

10.7 Classify each of the following molecules as alcohol, aldehyde, ketone, carboxylic acid, or amine:
(a) $\mathrm{CH}_{3}-\mathrm{CH}_{2}-\mathrm{NH}_{2}$
(b)

(d)

(e) $\mathrm{CH}_{3}-\mathrm{CH}_{2} \mathrm{CH}_{2}-\mathrm{OH}$
10.8 Draw structures for molecules with the following formulas:
(a) $\mathrm{CH}_{4} \mathrm{O}$
(b) $\mathrm{C}_{2} \mathrm{H}_{6} \mathrm{O}$
(c) $\mathrm{C}_{3} \mathrm{H}_{6} \mathrm{O}_{2}$
(d) $\mathrm{C}_{3} \mathrm{H}_{8} \mathrm{O}$

E10.9 Name each of the following compounds:
(a)

(b)

(c)

I 10.10 Name each of the following compounds:
(a)

(b)

(c)

10.11 Give the name of the alkane represented by the model shown.

EI 10.12 The molecular formula corresponding to the model is $\mathrm{C}_{5} \mathrm{H}_{9} \mathrm{ClO}_{2}$. What is the name of the compound?

E10.13 Write structural formulas for each of the following based on their systematic names. The names quoted in parentheses are so-called common names. Common names are not systematic and are more difficult, sometimes impossible, to connect with a unique structure.
(a) 2,2,4-Trimethylpentane ("isooctane")
(b) 3-Methyl-1-butanol ("isoamyl alcohol")
(c) Hexanamide ("caproamide")
(d) 2,2,2-Trichloroethanal ("chloral")
10.14 Write structural formulas for each of the following:
(a) 3,3-Dimethyl-2-butanone ("pinacolone")
(b) 3-Hydroxybutanal ("acetaldol")
(c) Ethyl pentanoate ("ethyl valerate")
(d) 6-Methyl-2-heptanamine ("isooctylamine")
10.15 Classify the oxygen-containing groups in the plant hormone abscisic acid.

10.16 Identify the functional groups in the antipsychotic drug haloperidol.

10.17 PABA was the active UV-absorbing compound in earlier versions of sunblock creams. What functional groups are present in PABA?

10.18 Lidocaine $\left(\mathrm{C}_{14} \mathrm{H}_{22} \mathrm{~N}_{2} \mathrm{O}\right)$ is a widely used local anesthetic. Classify its nitrogen-containing functional groups.

## Section 10.3: Representing Organic Molecules

## Problems

H10.19 Write structural formulas for the following organic compounds: (a) 3-methylhexane, (b) 2,3-dimethylpentane, (c) 2-bromo-4-phenylpentane, (d) 3,4,5-trimethyloctane.

E10.20 Write structural formulas for the following compounds:
(a) 1,1,3-trichloro-2-propanol, (b) 3-methyl-3-pentanamine,
(c) 3-bromo-1-chloro-2-butanone, (d) propyl-4-bromobutanoate.
10.21 (a) Convert $\mathrm{CH}_{3}\left(\mathrm{CH}_{2}\right)_{4} \mathrm{C}(\mathrm{O}) \mathrm{CH}_{2} \mathrm{CO}_{2} \mathrm{H}$ to a Kekulé structure and to a skeletal (line) structure.
(b) Convert the following to a condensed structure and to a skeletal (line) structure:

(c) Convert the following to a condensed structure and to a Kekulé structure:

10.22 (a) Convert $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{C}=\mathrm{CHCO}_{2} \mathrm{H}$ to a Kekulé structure and to a skeletal (line) structure.
(b) Convert the following to a condensed structure and to a skeletal (line) structure:

$$
\begin{gathered}
\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{NCH}_{2} \mathrm{CH}_{3} \\
\stackrel{\mathrm{CH}_{3}}{ }
\end{gathered}
$$

(c) Convert the skeletal structure of the general anesthetic isoflurane to a condensed structure and to a Kekulé structure:

10.23 Convert each of the molecular models to a condensed structural formula, a Kekulé structure, and a skeletal (line) structure.

(b)

$\mathrm{C}_{6} \mathrm{H}_{8} \mathrm{O}_{7}$ : Citric acid, which contributes to the tart taste of citrus fruits.
(c)

$\mathrm{C}_{6} \mathrm{H}_{8} \mathrm{O}_{6}$ : Commonly known as "isoamyl acetate," this ester is largely responsible for the characteristic odor of bananas.

E 10.24 Convert each of the molecular models to a condensed structural formula, a Kekulé structure, and a skeletal (line) structure.
(a)

$\mathrm{C}_{3} \mathrm{H}_{6} \mathrm{O}_{3}$ : Dihydroxyacetone, an intermediate in glycolysis, the process by which glucose is converted to energy.
(b)

$\mathrm{C}_{4} \mathrm{H}_{5} \mathrm{Cl}$ : Chloroprene, which gives neoprene on polymerization.
(c)

$\mathrm{C}_{6} \mathrm{H}_{13} \mathrm{NO}_{2}$ : Isoleucine, one of the 20 amino acids that occur in proteins.
10.25 Given a structural formula or skeletal (line) structure, rewrite it in the other style.
(a) $\mathrm{CH}_{3} \mathrm{CH}_{2} \underset{\mid}{\mathrm{O}} \mathrm{CHCH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3}$
(b)

(c)

10.26 Given a structural formula or skeletal (line) structure, rewrite it in the other style.
(a) $\mathrm{ClCH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}=\mathrm{CH}_{2}$
(b)

(c)

$G 1$ 10.27 Using the curved arrows as a guide to placing the electrons, write a resonance structure for each of the compounds shown. The resonance structure should include formal charges where appropriate.
(a) $\mathrm{CH}_{3}-\mathrm{C} \xlongequal{=} \mathrm{N}$ :
(b)

(c)

E10.28 Using the curved arrows as a guide to placing the electrons, write a resonance structure for each of the compounds shown. The resonance structure should include formal charges where appropriate.
(a)

(b)

(c)

H10.29 Use curved arrows to show how the resonance structure on the left can be transformed to the one on the right.
(a)

(b)

(c)

10.30 Use curved arrows to show how the resonance structure on the left can be transformed to the one on the right.
(a)

## Section 10.4: Isomerism

## Review Questions

10.31 Alkenes exhibit geometrical isomerism because rotation about the $\mathrm{C}=\mathrm{C}$ bond is restricted. Explain.
10.32 Why is it that alkanes and alkynes, unlike alkenes, have no geometrical isomers?
10.33 Define the term chiral. What are enantiomers?
10.34 What factor determines whether a carbon atom in a compound is chiral?
10.35 Fill in the blanks in the given paragraph with the most appropriate term from the following: chiral, cis, constitutional isomers, enantiomers, resonance structures, stereoisomers, trans.

Isomers are different compounds that have the same molecular formula. Isomers that have their atoms connected in a different order (branched versus unbranched chain, for example) or a different sequence of bond types $(\mathrm{C}=\mathrm{CCC}$ versus $\mathrm{CC}=\mathrm{CC}$, for example) are termed $\qquad$ . Isomers with the same order of connections and sequence of bond types, but which differ in the spatial arrangement of the atoms are called . This is often seen in compounds where substituents may be on the same or opposite sides of a carbon-carbon double bond. Substituents on the same side are described as $\qquad$ ; those on opposite sides are
$\qquad$ A different kind of isomerism characterizes a molecule, that is, a molecule with a structure that allows for two nonsuperimposable mirror-image forms. Two nonsuperimposable mirror images are $\qquad$ of the other.

## Problems

10.36 Write structural formulas for all the $\mathrm{C}_{5} \mathrm{H}_{10}$ alkenes, and identify the relationship (constitutional isomer or stereoisomer) of each one to the others. Are any chiral?
10.37 Draw all possible structural isomers for the following alkane: $\mathrm{C}_{7} \mathrm{H}_{16}$.

E 10.38 Draw all possible isomers for the molecule $\mathrm{C}_{4} \mathrm{H}_{8}$.
10.39 Draw all possible isomers for the molecule $\mathrm{C}_{3} \mathrm{H}_{5} \mathrm{Br}$.

E10.40 Which of the following amino acids are chiral:
(a) $\mathrm{CH}_{3} \mathrm{CH}\left(\mathrm{NH}_{2}\right) \mathrm{COOH}$, (b) $\mathrm{CH}_{2}\left(\mathrm{NH}_{2}\right) \mathrm{COOH}$,
(c) $\mathrm{CH}_{2}(\mathrm{OH}) \mathrm{CH}\left(\mathrm{NH}_{2}\right) \mathrm{COOH}$ ?
10.41 Draw all the possible structural isomers for the molecule having the formula $\mathrm{C}_{7} \mathrm{H}_{7} \mathrm{Cl}$. All isomers contain one benzene ring.
10.42 Draw all the structural isomers of compounds with the formula $\mathrm{C}_{4} \mathrm{H}_{8} \mathrm{Cl}_{2}$. Indicate which isomers are chiral, and give them systematic names.

E10.43 Indicate the asymmetric carbon atoms in the following compounds:
(a)

(b)

10.44 Suppose benzene contained three distinct single bonds and three distinct double bonds. How many different isomers would there be for dichlorobenzene $\left(\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{Cl}_{2}\right)$ ? Draw all your proposed structures.
10.45 Write the structural formula of an aldehyde that is a structural isomer of acetone.

I 10.46 How many asymmetric carbon atoms are present in each of the following compounds?
(a)

(b)

(c)

10.47 Draw structures of each of the compounds shown, using wedges and dashes to show stereochemistry.
(a)

(b)

(c)

(d)

10.48 Write the structural formulas of the alcohols with the formula $\mathrm{C}_{6} \mathrm{H}_{14} \mathrm{O}$ and indicate those that are chiral. Show only the C atoms and the -OH groups.

## Section 10.5: Organic Reactions

## Review Questions

10.49 What property distinguishes an electrophile from a nucleophile? Of the two, which would you expect to be more reactive toward a cation? Toward an anion? Give a specific example of an electrophile and a nucleophile.

E 10.50 Classify each of the following according to whether you think it reacts as an electrophile or a nucleophile.
(a)

(b) $\mathrm{CH}_{3} \mathrm{CH}_{2} \ddot{\mathrm{~N}}_{2}$

(d) $\mathrm{CH}_{3}-\mathrm{C} \equiv{ }^{+}$:
10.51 (a) The compound 2-bromopropane $\left[\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CHBr}\right]$ can undergo both substitution and elimination when treated with $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{O}^{-}$, which is a strong base. Predict the organic product in each case, and write a separate chemical equation for each reaction.
(b) The compound 1,2-dibromoethane $\left(\mathrm{BrCH}_{2} \mathrm{CH}_{2} \mathrm{Br}\right)$ was formerly used in large amounts as an agricultural chemical. Write a chemical equation showing how this compound could be prepared from ethylene by an addition reaction.
(c) Certain reactions of aldehydes and ketones begin with isomerization of the aldehyde or ketone to an enol isomer. Enols contain an -OH group attached to a carbon-carbon double bond. Write a chemical equation for the isomerization of acetone $\left[\left(\mathrm{CH}_{3}\right)_{2} \mathrm{C}=\mathrm{O}\right]$ to its enol isomer.

EI 10.52 Classify the following reactions according to whether they are addition, substitution, elimination, or isomerization.

(c) $\mathrm{CH}_{3} \mathrm{CH}=\mathrm{CH}_{2}+\mathrm{Cl}_{2} \longrightarrow \underset{\substack{ \\\mathrm{Cl}}}{\mathrm{CH}_{3} \mathrm{CHCH}_{2} \mathrm{Cl}}$

(e)

G 10.53 (a) Define carbocation.
(b) Which of the following are carbocations?

(iv)
(v)

## Problems

10.54 Halogenated hydrocarbons are biodegraded in the natural environment by reactions catalyzed by dehalogenase enzymes. The reaction that takes place with 1,2-dichloroethane begins with nucleophilic substitution involving a carboxylate site of the enzyme.

Expand this equation by adding curved arrows to show the movement of electrons.
10.55 A common reaction in carbohydrate biochemistry is the conversion of an aldose to a ketose. The glucose to fructose isomerization is a specific example; the equation illustrates the general case:

The first stage in the reaction is shown in the following equation. Enzymes facilitate the reaction, but for simplicity the overall change can be approximated with water molecules. Use curved arrows to show the flow of electrons in the equation.

10.56 (a) Benzene reacts with tert-butyl cation $\left[\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}^{+}\right]$by a two-step electrophilic aromatic substitution mechanism to yield tertbutylbenzene $\left[\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{C}\left(\mathrm{CH}_{3}\right)_{3}\right]$. Write a chemical equation for each step in the mechanism and use curved arrows to track electron flow.
(b) Electrophilic addition of hydrogen chloride to styrene gives the product shown. Write the mechanism for this reaction including curved arrows.

10.57 (a) Acetylide ion undergoes nucleophilic addition to aldehydes and ketones to give the species shown. Subsequent addition of water yields an acetylenic alcohol. Add curved arrows to the equations to show how the reaction occurs.

(b) A nucleophilic site on a molecule can substitute for a halogen elsewhere in the same molecule to form a ring. Use curved arrows to show how the following cyclization is related to a conventional nucleophilic substitution.

10.58 Complete the following reaction by including essential unshared electron pairs and formal charges. Use curved arrows to show electron flow.

$\boldsymbol{\Psi 1 0 . 5 9}$ The product of the reaction of chlorobenzene with $\mathrm{NaNH}_{2}$ is a very reactive species called benzyne. Add necessary electron pairs and formal charges to the net ionic equation, and use curved arrows to show how benzyne is formed. To what general type of reaction does this belong?

E 10.60 Consider the following reactions of butanal:
(i)

(ii)

In which reaction is butanal oxidized? In which reaction is it reduced?
10.61 Esters can be prepared by the acid-catalyzed condensation of a carboxylic acid and an alcohol:

Is this an oxidation-reduction reaction? If so, identify the species being oxidized and the species being reduced.

EI 10.62 A compound has the empirical formula $\mathrm{C}_{5} \mathrm{H}_{12} \mathrm{O}$. Upon controlled oxidation, it is converted into a compound of empirical formula $\mathrm{C}_{5} \mathrm{H}_{10} \mathrm{O}$, which behaves as a ketone. Draw possible structures for the original compound and the final compound.
10.63 Isopropanol is prepared by reacting propylene $\left(\mathrm{CH}_{3} \mathrm{CHCH}_{2}\right)$ with sulfuric acid, followed by treatment with water. (a) Show the sequence of steps leading to the product. What is the role of sulfuric acid? (b) Draw the structure of an alcohol that is an isomer of isopropanol. (c) Is isopropanol a chiral molecule?

## Section 10.6: Organic Polymers

## Review Questions

E 10.64 Define the following terms: monomer, polymer, copolymer.
10.65 Name 10 objects that contain synthetic organic polymers.

E 10.66 Calculate the molar mass of a particular polyethylene sample, $\left(\mathrm{CH}_{2}-\mathrm{CH}_{2}\right)_{n}$, where $n=4600$.
10.67 Describe the two major mechanisms of organic polymer synthesis.
10.68 What are the steps involved in polymer formation by chain reaction?
10.69 Polysaccharides, proteins, and nucleic acids comprise the three main classes of biopolymers. Compare and contrast them with respect to structure and function. What are the building block units for each? What are the key functional groups involved in linking the units together? In which biopolymer is there the greatest variety of building block structure? In which is there the least?

## Problems

E10.70 Teflon is formed by a radical addition reaction involving the monomer tetrafluoroethylene. Show the mechanism for this reaction.
10.71 Vinyl chloride $\left(\mathrm{H}_{2} \mathrm{C}=\mathrm{CHCl}\right)$, undergoes copolymerization with 1,1-dichloroethylene, $\left(\mathrm{H}_{2} \mathrm{C}=\mathrm{CCl}_{2}\right)$, to form a polymer commercially known as Saran. Draw the structure of the polymer, showing the repeating monomer units.
10.72 Deduce plausible monomers for polymers with the following repeating units:
(a) $+\mathrm{CH}_{2}-\mathrm{CF}_{2}-{ }_{n}$

10.73 Deduce plausible monomers for polymers with the following repeating units:
(a) $-\mathrm{CH}_{2}-\mathrm{CH}=\mathrm{CH}-\mathrm{CH}_{2}-_{n}$
(b) $\left(\mathrm{CO}\left(-\mathrm{CH}_{2}\right)_{6} \mathrm{NH}\right)_{n}$

H10.74 Draw the structures of the dipeptides that can be formed from the reaction between the amino acids glycine and alanine.
10.75 Draw the structures of the dipeptides that can be formed from the reaction between the amino acids glycine and lysine.
10.76 From among the given nucleotides, identify those that occur naturally in RNA and those that occur in DNA. Do any not occur in either RNA or DNA?

(a)

(b)

(c)

(d)

## Additional Problems

10.77 Write structural formulas for all the constitutionally isomeric $\mathrm{C}_{4} \mathrm{H}_{9}$ alkyl groups. Check your answers with Table 10.1, and note the names of these groups.
10.78 Ethers are compounds (excluding esters) that contain the $\mathrm{C}-\mathrm{O}-\mathrm{C}$ functional group. An acceptable way to name them is to list the two groups attached to oxygen in alphabetical order as separate words, followed by the word ether. If the two groups are the same, add the prefix $d i$ to the name of the alkyl group. Thus, $\mathrm{CH}_{3} \mathrm{OCH}_{2} \mathrm{CH}_{3}$ is "ethyl methyl ether" and $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OCH}_{2} \mathrm{CH}_{3}$ is "diethyl ether."

Write structural formulas and provide names for all the constitutionally isomeric ethers in which only the $\mathrm{C}_{4} \mathrm{H}_{9}$ alkyl groups from Problem 10.77 are attached to oxygen. Which of these ethers is potentially chiral?
10.79 The $\alpha$-amino acids found in proteins are based on the structural formula:

From the $\mathrm{C}_{4} \mathrm{H}_{9}$ alkyl groups in Problem 10.77, find the ones that correspond to "R" among the amino acids listed in Figure 10.14. Match the name of the amino acid with the name of the group.
10.80 Alkynes are hydrocarbons that contain a carbon-carbon triple bond.
(a) Write structural formulas for all the isomeric alkynes of molecular formula $\mathrm{C}_{5} \mathrm{H}_{8}$.
(b) Are any of the alkynes chiral?
(c) Are any of the alkynes stereoisomeric?
10.81 Among the many alkenes of molecular formula $\mathrm{C}_{6} \mathrm{H}_{12}$, only one is chiral.
(a) Write a structural formula for this alkene.
(b) Place substituents on the tetrahedral carbons so as to represent the two enantiomers of this alkene.

E 10.82 (a) Use VSEPR to predict the geometry at the carbon shown in bold in the carbocation, radical, and anion derived from the tertbutyl group. Is the arrangement of bonds to this carbon linear, tetrahedral, trigonal planar, or trigonal pyramidal?

$$
\begin{array}{cccc}
\text { tert-Butyl } & { }^{+} \mathbf{C}\left(\mathrm{CH}_{3}\right)_{3} & { }_{\text {Cation }} & \stackrel{\mathrm{C}\left(\mathrm{CH}_{3}\right)_{3}}{\text { Radical }}
\end{array}
$$

(b) Which of these species is the most nucleophilic? Which is the most electrophilic?
(c) Predict which species reacts with water to give $\mathrm{HC}\left(\mathrm{CH}_{3}\right)_{3}$.
(d) Write a chemical equation for the reaction in part (c), and use curved arrows to show the flow of electrons.
10.83 In each of the following pairs, specify whether the two structural formulas represent constitutional isomers, cis,trans-stereoisomers, enantiomers, resonance structures, or are simply a different representation of the same structure.
(a)

and

(b)
 and

 and

(d)
 and

El 10.84 In each of the following pairs, specify whether the two structural formulas represent constitutional isomers, cis,trans-stereoisomers, enantiomers, resonance structures, or are simply a different representation of the same structure.
(a)

and

(b)
 and

(c)

and

(d) H
 and

10.85 The electrophile in the following aromatic substitution is $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CH}^{+}$, and the mechanism involves the intermediate shown. Write two other resonance structures for this intermediate.

E 10.86 Two isomeric alkenes are formed in the dehydration of 2-methyl-2-butanol. What are these two alkenes? Are they constitutional isomers or stereoisomers?
10.87 Electrophilic addition of HCl to cis-2-butene gave 2-chlorobutane, which was determined not to be optically active when examined with a polarimeter.

Which of the following is the better explanation for the lack of optical activity in the 2-chlorobutane formed in this reaction?
(a) 2-Chlorobutane is not chiral.
(b) Two enantiomers of 2-chlorobutane were formed in equal amounts.

E 10.88 Reactions such as the following have been used in carbohydrate synthesis since the nineteenth century.

Classify this procedure according to reaction type.
(a) Electrophilic addition
(b) Electrophilic substitution
(c) Nucleophilic addition
(d) Nucleophilic substitution
10.89 Excluding compounds that have rings, there are three hydrocarbons that have the molecular formula $\mathrm{C}_{4} \mathrm{H}_{6}$. Write their structural formulas, and specify the hybridization of each carbon in these isomers.
10.90 Give the structures of the two tertiary amines that are isomers of $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{NH}_{2}$.
10.91 In which class of compounds, esters or amides, do you think electron donation into the carbonyl group is more pronounced? Explain.

$\$ 10.92$ (a) A plane of symmetry in a molecule is a plane passing through the middle of the molecule that bisects the molecule into two mirror-image halves. If a molecule has a plane of symmetry, it cannot be chiral and cannot be optically active. Which of the following have at least one plane of symmetry? Do any have more than one?

1,1-Dichlorocyclopropane

cis-1,2-Dichlorocyclopropane

trans-1,2-Dichlorocyclopropane
(b) Specify the relationships (constitutionally isomeric or stereoisomeric) among these compounds.
10.93 All alkanes give off heat when burned in air. Such combustion of alkanes is exothermic, and the sign of $\Delta H^{\circ}$ is negative. The general equation for the combustion of the alkanes of molecular formula $\mathrm{C}_{5} \mathrm{H}_{12}$ is

$$
\mathrm{C}_{5} \mathrm{H}_{12}+8 \mathrm{O}_{2} \longrightarrow 5 \mathrm{CO}_{2}+6 \mathrm{H}_{2} \mathrm{O}
$$

The values of $\Delta H^{\circ}$ for the combustion of the three pentane isomers are

$$
\begin{array}{ll}
\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3} & =-3536 \mathrm{~kJ} / \mathrm{mol} \\
\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CHCH}_{2} \mathrm{CH}_{3} & =-3529 \mathrm{~kJ} / \mathrm{mol} \\
\left(\mathrm{CH}_{3}\right)_{4} \mathrm{C} & =-3515 \mathrm{~kJ} / \mathrm{mol}
\end{array}
$$

(a) What do these data tell you about the effect of chain branching on the relative potential energies and stabilities of these isomers?
(b) Assume this effect is general to predict which one of the 18
$\mathrm{C}_{8} \mathrm{H}_{18}$ isomers should be the most stable.

EI 10.94 Carbon dioxide reacts with sodium hydroxide according to the following equation:

$$
\mathrm{CO}_{2}+2 \mathrm{NaOH} \longrightarrow \mathrm{Na}_{2} \mathrm{CO}_{3}+\mathrm{H}_{2} \mathrm{O}
$$

The overall reaction is the result of two separate reactions.

Reaction II:

(a) Use curved arrows to track the flow of electrons in reaction I.
(b) Use curved arrows to track the flow of electrons in reaction II.
(c) Classify reaction I as electrophilic addition, nucleophilic addition, electrophilic substitution, or acid-base.
(d) Classify reaction II according to the choices in part (c).
$\Psi 10.95$ The combustion of 20.63 mg of compound Y , which contains only $\mathrm{C}, \mathrm{H}$, and O , with excess oxygen gave 57.94 mg of $\mathrm{CO}_{2}$ and 11.85 mg of $\mathrm{H}_{2} \mathrm{O}$. (a) Calculate how many milligrams of $\mathrm{C}, \mathrm{H}$, and O were present in the original sample of Y . (b) Derive the empirical formula of Y. (c) Suggest a plausible structure for Y if the empirical formula is the same as the molecular formula.

Ef 10.96 Match each molecular model with the correct line-wedge-dash structure.

(c)

(d)

10.97 Kevlar is a copolymer used in bulletproof vests. It is formed in a condensation reaction between the following two monomers:

Sketch a portion of the polymer chain showing several monomer units. Write the overall equation for the condensation reaction.

Describe the formation of polystyrene.
E110.99 The amino acid glycine can be condensed to form a polymer called polyglycine. Draw the repeating monomer unit.
10.100 Nylon can be destroyed easily by strong acids. Explain the chemical basis for the destruction. (Hint: The products are the starting materials of the polymerization reaction.)
$\boldsymbol{\Psi}$ 10.101 How many different tripeptides can be formed by lysine and alanine?

EH 10.102 Nylon was designed to be a synthetic silk. (a) The average molar mass of a batch of nylon 66 is $12,000 \mathrm{~g} / \mathrm{mol}$. How many monomer units are there in this sample? (b) Which part of nylon's structure is similar to a polypeptide's structure? (c) How many different tripeptides (made up of three amino acids) can be formed from the amino acids alanine (Ala), glycine (Gly), and serine (Ser), which account for most of the amino acids in silk?

## Pre-Professional Practice Exam Questions: Verbal Reasoning

In 1960, Canadian-born doctor and pharmacologist Frances Kelsey was hired by the FDA to review applications for the approval of new drugs. Her first assignment was an application by the William S. Merrell Company of Cincinnati, Ohio, requesting approval of thalidomide as a sedative and antiemetic for pregnant women suffering from morning sickness. Kelsey rejected the application, citing the manufacturer's failure to prove the drug's safety, and requested that further studies be done. Although the company initially complied with her request, Kelsey, still unsatisfied with the data, refused the application a second time. Eventually, Merrell appealed to Kelsey's superiors to pressure her to approve the drug. By early 1961, though, a study in England reported that repeated use of the drug might have serious nervoussystem side effects. In addition, Kelsey's research in pharmacology early in her career made her question the effects of the drug on a developing fetus. She continued to resist the pressure to approve the drug and was vindicated late in 1961 when a German scientist, Dr. Widukind Lenz, reported that use of thalidomide by pregnant women might be the cause of the epidemic of phocomelia, a malformation of limbs in newborn babies, in Germany.
U.S. law at the time allowed drugs that had not yet been approved by the FDA to be distributed to physicians for "experimental use." Nevertheless, only 17 thalidomide babies are known to have been born in the United States. If not for the diligence and dedication of Dr. Frances Kelsey, there would almost certainly have been thousands more. In recognition of her incalculable service to the people of the United States, Dr. Kelsey was given the President's Award for Distinguished Federal Civilian Service, the highest award ever given to a civilian. President John F. Kennedy presented the medal to Kelsey at a ceremony at the White House in August 1962. As a result of the thalidomide tragedy, new laws were enacted placing a greater burden on drug manufacturers to prove the safety and efficacy of their drugs. In addition, the concept of "informed consent" was introduced, preventing the distribution of unapproved drugs to unsuspecting patients.

1. The main point of the passage is that Frances Kelsey
a) was born in Canada.
b) worked for the FDA.
c) prevented the thalidomide tragedy in the United States.
d) was awarded the Distinguished Federal Civilian Service medal.
2. According to the passage, Dr. Kelsey refused to approve thalidomide for distribution in the United States because
a) her superiors pressured her not to approve it.
b) she knew that it had caused thousands of birth defects in Europe.
c) 17 babies had been born with birth defects as a result of the drug.
d) she was not satisfied with the manufacturer's studies on the safety of the drug.
3. Based on the passage, what was likely the reason that 17 thalidomide babies were born in the United States?
a) Physicians in the United States gave the drug to their patients without FDA approval.
b) Pregnant women arrived from Europe and gave birth in the United States.
c) U.S. citizens obtained the drug from overseas sources.
d) Some women in the United States failed to heed the manufacturer's warning about use during pregnancy.
4. Based on the passage, the author most likely considers Kelsey to be a) a celebrity.
b) an activist.
c) a hero.
d) a role model.

## Answers to In-Chapter Materials

## Answers to Practice Problems

10.1A (a) 3-ethylpentane, (b) 2-bromohexane, (c) 2-chlorobutane.

(c) $\mathrm{CH}_{3} \mathrm{CH}_{2}{\underset{\mathrm{CH}}{3}}_{\mathrm{CHCH}}^{2} 2 \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3} .10 .2 \mathrm{~A}$ (a) ester,
(b) carboxy group; ester, (c) 2 hydroxy groups, 2 carboxy groups.
10.2B (a) ketone, (b) $3^{\circ}$ amide, (c) ester.
10.3A CH ${ }_{2} \mathrm{BrCH}_{2} \mathrm{COOH}$. 10.3B

10.6B b. 10.7A (a)

## Answers to Checkpoints

10.2.1 c. 10.2.2 b. 10.2.3 b. 10.2.4 e. 10.2.5 b, c. 10.2 .6 a, b. 10.3 .1 b. 10.3.2 d. 10.3.3 e. 10.3.4 b, d. 10.5.1 d. 10.5.2 a.

## Answers to Applying What You've Learned

a) Thalidomide contains several carbonyl groups, an amino group, and an amide group. Note that the amide group on the right could be defined using either of the carbonyl groups adjacent to it. b) Molecular formulas: thalidomide, $\mathrm{C}_{13} \mathrm{H}_{10} \mathrm{~N}_{2} \mathrm{O}_{4}$; lenalidomide, $\mathrm{C}_{13} \mathrm{H}_{13} \mathrm{~N}_{3} \mathrm{O}_{3}$; and CC-4047, $\mathrm{C}_{13} \mathrm{H}_{11} \mathrm{~N}_{3} \mathrm{O}_{4}$.

Scuba divers breathe a compressed mixture of gases. For shallow recreational diving, compressed air is generally used. For dives to greater depths, various mixtures of helium, nitrogen, and oxygen are used.

## How the Properties of Gases Contribute to the Hazards of Scuba Diving

One of the first lessons taught in scuba certification is that divers must never hold their breath during ascent to the surface. Failure to heed this warning can result in serious injury or death. During underwater ascent, the air in a diver's lungs expands. If the air is not expelled, it causes overexpansion and rupture of alveoli-the tiny sacks that normally fill with air on inhalation. This condition, known as "burst lung," can cause air to escape into the chest cavity, where further expansion can collapse the ruptured lung. The potential for these catastrophic injuries is not limited to deep-sea divers, though, as burst lung can occur during a rapid ascent of as little as 3 meters, a depth common in public swimming pools. Furthermore, spontaneous pneumothorax, the medical term for this injury, can be caused even without the failure to exhale if there is an air-filled cyst in the diver's lung, or if there is a region of lung tissue blocked by phlegm due to a respiratory tract infection. In addition to the risk of spontaneous pneumothorax, burst lung can result in gas bubbles entering the bloodstream. Expansion of these bubbles during rapid underwater ascent can block circulation, a condition known as gas embolism, which can lead to heart attack or stroke.
Because the cause of burst lung in divers is rapid decompression, treatment for the resulting conditions, especially gas embolism, usually includes recompression in a hyperbaric chamber. Hyperbaric chambers are cylindrical enclosures built to withstand pressures significantly above atmospheric pressure. With the victim of a rapid decompression and, in some cases, medical personnel inside the enclosure, the door is sealed and highpressure air is pumped in until the interior pressure is high enough to compress the gas bubbles in the victim's system. The victim usually breathes pure oxygen through a mask to help purge the undesirable gases during treatment. The pressure in a typical medical hyperbaric chamber can be increased to as many as six times atmospheric pressure.
Understanding the risks associated with scuba diving and the efforts to prevent and treat related injuries requires knowledge of the behavior of gases.

Pneumothorax

Monoplace hyperbaric chamber

Student Annotation: "Monoplace" hyperbaric chambers, which are large enough to accommodate only one person, typically are pressurized with pure oxygen, although monoplace chambers are not used to treat decompression injuries.

At the end of this chapter, you will be able to solve a series of problems involving the properties of gases as they relate to the safety of athletes [ $N$ Page 480].

## In This Chapter, You Will Learn:

About the properties and behavior of gases.
Before you begin, you should review

- Tracking units [ I 4 Section 1.6]
- Stoichiometry [ 14 Section 3.3]

Figure 11.1 Solid, liquid, and gaseous states of a substance.

Student Annotation: In general, the term vapor is used to refer to the gaseous state of a substance that is a liquid or solid at room temperature.

Student Annotation: Recall that oxygen also exists as the triatomic molecule ozone $\left(\mathrm{O}_{3}\right)$ [ 14 Section 2.6]. Diatomic $\mathrm{O}_{2}$, however, is the more stable allotrope at room temperature.

### 11.1 Properties of Gases

Recall from Chapter 1 that matter exists in one of three states: solid, liquid, or gas. In fact, most substances that are solid or liquid at room temperature $\left(25^{\circ} \mathrm{C}\right)$ can exist as gases under appropriate conditions. Water, for instance, evaporates under the right conditions. Water vapor is a gas. In this chapter we will explore the nature of gases and how their properties at the molecular level give rise to the macroscopic properties that we observe. Figure 11.1 illustrates the three states of matter at the macroscopic level and at the molecular level.

Relatively few elements exist as gases at room temperature. Those that do are hydrogen, nitrogen, oxygen, fluorine, chlorine, and the noble gases. Of these, the noble gases exist as isolated atoms, whereas the others exist as diatomic molecules [ 141 Section 2.6]. Figure 11.2 shows where the gaseous elements appear in the periodic table.

Many molecular compounds, most often those with low molar masses, exist as gases at room temperature. Table 11.1 lists some gaseous compounds that may be familiar to you.

Figure 11.2 Elements that exist as gases at room temperature.

## TABLE 11.1 Molecular Compounds That Are Gases at Room Temperature

| Molecular Formula | Compound Name |
| :---: | :--- |
| HCl | Hydrogen chloride |
| $\mathrm{NH}_{3}$ | Ammonia |
| $\mathrm{CO}_{2}$ | Carbon dioxide |
| $\mathrm{N}_{2} \mathrm{O}$ | Dinitrogen monoxide or nitrous oxide |
| $\mathrm{CH}_{4}$ | Methane |
| HCN | Hydrogen cyanide |

## Characteristics of Gases

Gases differ from the condensed phases (solids and liquids) in the following important ways:

1. A sample of gas assumes both the shape and volume of its container. Like a liquid, a gas consists of particles (molecules or atoms) that do not have fixed positions in the sample [ 14 Section 1.2]. As a result, both liquids and gases are able to flow. (Recall from Chapter 1 that we refer to liquids and gases collectively as fluids.) While a sample of liquid will assume the shape of the part of its container that it occupies, a sample of gas will expand to fill the entire volume of its container.
2. Gases are compressible. Unlike a solid or a liquid, a gas consists of particles with relatively large distances between them; that is, the distance between any two particles in a gas is much larger than the size of a molecule or atom. Because gas particles are far apart, it is possible to move them closer together by confining them to a smaller volume.
3. The densities of gases are much smaller than those of liquids and solids and are highly variable depending on temperature and pressure. The densities of gases are typically expressed in $\mathrm{g} / \mathrm{L}$, whereas those of liquids and solids are typically expressed in $\mathrm{g} / \mathrm{mL}$ or $\mathrm{g} / \mathrm{cm}^{3}$.

When we compress a sample of gas, we decrease its volume. Because its mass remains the same, the ratio of mass to volume (density) increases. Conversely, if we increase the volume to which a sample of gas is confined, we decrease its density.

If you have ever seen a hot-air balloon aloft, you have seen a demonstration of how the density of a gas varies with temperature. Hot air is less dense than cold air, so hot air "floats" on cold air, much like oil floats on water.
4. Gases form homogeneous mixtures (solutions) with one another in any proportion. Some liquids (e.g., oil and water) do not mix with one another. Gases, on the other hand, because their particles are so far apart, do not interact with one another to any significant degree unless a chemical reaction takes place between them. This allows molecules of different gases to mix uniformly. That is, gases that don't react with each other are mutually miscible.
Each of these four characteristics is the result of the properties of gases at the molecular level.

## Gas Pressure: Definition and Units

A sample of gas confined to a container exerts a pressure on the walls of its container. For example, the air in the tires of your car exerts pressure on the inside walls of the tires. In fact, gases exert pressure on everything they touch. Thus, while you may add enough air to increase the pressure inside your tire to 32 pounds per square inch (psi), there is also a pressure of approximately 14.7 psi, called atmospheric pressure, acting on the outside of the tire-and on everything else, including your body. The reason you don't feel the pressure of the atmosphere pushing on the outside of your body is that an equal pressure exists inside your body so that there is no net pressure on you.

Atmospheric pressure, the pressure exerted by Earth's atmosphere, can be demonstrated using the empty metal container shown in Figure 11.3(a). Because the container is open to the atmosphere, atmospheric pressure acts on both the internal and external walls of the container. When we attach a vacuum pump to the opening of the container and draw air out of it, however, we reduce the pressure inside the container. When the pressure against the interior walls is reduced, atmospheric pressure crushes the container [Figure 11.3(b)].

(a)

(b)

Figure 11.3 (a) An empty metal can. (b) When the air is removed by a vacuum pump, atmospheric pressure crushes the can.

Student Annotation: $1 \mathrm{~mL}=1 \mathrm{~cm}^{3}$ [/IT Section 1.3].

Student Annotation: Common penciltype pressure gauges actually measure the difference between internal and external pressure. Thus, if the tire is completely flat, the reading of 0 psi means that the pressure inside the tire is the same as that outside the tire.

Pencil-type tire gauge

Student Annotation: Force is mass $\times$ acceleration.

Student Annotation: In SI base units, $1 \mathrm{~Pa}=1 \mathrm{~kg} / \mathrm{m} \cdot \mathrm{s}^{2}$.

Figure 11.4 A column of air $1 \mathrm{~cm} \times 1 \mathrm{~cm}$ from Earth's surface to the top of the atmosphere weighs approximately 1 kg .

Student Annotation: Remember that when a unit is raised to a power, any conversion factor you use must also be raised to that power [14 Section 1.6].

## TABLE 11.2 Units of Pressure Commonly Used in Chemistry

| Unit | Origin | Definition |
| :--- | :--- | :--- |
| standard <br> atmosphere <br> $(\mathrm{atm})$ | Pressure at sea level | $1 \mathrm{~atm}=101,325 \mathrm{~Pa}$ |
| mmHg | Barometer measurement | $1 \mathrm{mmHg}=133.322 \mathrm{~Pa}$ |
| torr | Name given to mmHg in honor of Torricelli, <br> the inventor of the barometer | $1 \mathrm{torr}=133.322 \mathrm{~Pa}$ |
| bar | Same order of magnitude as atm, <br> but a decimal multiple of Pa | $1 \mathrm{bar}=1 \times 10^{5} \mathrm{~Pa}$ |

Pressure is defined as the force applied per unit area:

$$
\text { pressure }=\frac{\text { force }}{\text { area }}
$$

The SI unit of force is the newton $(N)$, where

$$
1 \mathrm{~N}=1 \mathrm{~kg} \cdot \mathrm{~m} / \mathrm{s}^{2}
$$

The SI unit of pressure is the pascal $(\mathbf{P a})$, defined as 1 newton per square meter.

$$
1 \mathrm{~Pa}=1 \mathrm{~N} / \mathrm{m}^{2}
$$

Although the pascal is the SI unit of pressure, there are other units of pressure that are more commonly used. Table 11.2 lists the units in which pressure is most commonly expressed in chemistry and their definitions in terms of pascals. Which of these units you encounter most often will depend on your specific field of study. Use of atmospheres (atm) is common in chemistry, although use of the bar is becoming increasingly common. Use of millimeters mercury $(\mathrm{mmHg})$ is common in medicine and meteorology. We will use all these units in this text.

## Calculation of Pressure

The force experienced by an area exposed to Earth's atmosphere is equal to the weight of the column of air above it. For example, the mass of air above a spot on the ground near sea level, with an area of $1 \mathrm{~cm}^{2}$, is approximately 1 kg (Figure 11.4).

The weight of an object that is subject to Earth's gravitational pull is equal to its mass times the gravitational constant, $9.80665 \mathrm{~m} / \mathrm{s}^{2}$. Thus, the force exerted by this column of air is

$$
1 \mathrm{~kg} \times \frac{9.80665 \mathrm{~m}}{\mathrm{~s}^{2}} \approx 10 \mathrm{~kg} \cdot \mathrm{~m} / \mathrm{s}^{2}=10 \mathrm{~N}
$$

Pressure, though, is force per unit area. Specifically, pressure in pascals is equal to force in newtons per square meter. We must first convert area from $\mathrm{cm}^{2}$ to $\mathrm{m}^{2}$,

$$
1 \mathrm{~cm}^{2} \times\left(\frac{1 \mathrm{~m}}{100 \mathrm{~cm}}\right)^{2}=0.0001 \mathrm{~m}^{2}
$$

and then divide force by area,

$$
\frac{10 \mathrm{~N}}{0.0001 \mathrm{~m}^{2}}=1 \times 10^{5} \mathrm{~Pa}
$$

This pressure is roughly equal to $1 \mathrm{~atm}\left(\sim 1 \times 10^{5} \mathrm{~Pa}\right)$, which we would expect at sea level.
We can calculate the pressure exerted by a column of any fluid (gas or liquid) in the same way. In fact, this is how atmospheric pressure is commonly measured-by determining the height of a column of mercury it can support.

## Measurement of Pressure

A simple barometer, an instrument used to measure atmospheric pressure, consists of a long glass tube, closed at one end and filled with mercury. The tube is carefully inverted in a container of mercury so that no air enters the tube. When the tube is inverted, and the open end is submerged in

the mercury in the container, some of the mercury in the tube will flow out into the container, creating an empty space at the top (closed end) of the tube (Figure 11.5). The weight of the mercury remaining in the tube is supported by atmospheric pressure pushing down on the surface of the mercury in the container. In other words, the pressure exerted by the column of mercury is equal to the pressure exerted by the atmosphere. Standard atmospheric pressure ( 1 atm ) was originally defined as the pressure that would support a column of mercury exactly 760 mm high at $0^{\circ} \mathrm{C}$ at sea level. The mmHg unit is also called the torr, after the Italian scientist Evangelista Torricelli, ${ }^{1}$ who invented the barometer. Standard atmospheric pressure is given in all the common units of pressure in the margin.

A manometer is a device used to measure pressures other than atmospheric pressure. The principle of operation of a manometer is similar to that of a barometer. There are two types of manometers, both of which are shown in Figure 11.6. The closed-tube manometer [Figure 11.6(a)] is normally used to measure pressures below atmospheric pressure, whereas the open-tube manometer [Figure 11.6(b)] is generally used to measure pressures equal to or greater than atmospheric pressure.

[^25]Figure 11.5 Barometer.

Figure 11.6 (a) Closed-tube manometer. The space labeled "vacuum" actually contains a small amount of mercury vapor. (b) Opentube manometer.
Student Annotation:
1 atm*
$101,325 \mathrm{~Pa}$
$760 \mathrm{mmHg}^{*}$
760 torr*
1.01325 bar
14.7 psi
*These are exact numbers.

1 atm
$101,325 \mathrm{~Pa}$
760 mmHg *
1.01325 bar
*These are exact numbers.

Think About It Make sure your units cancel properly in this type of problem. Common errors include forgetting to express height in meters and density in $\mathrm{kg} / \mathrm{m}^{3}$. You can avoid these errors by becoming familiar with the value of atmospheric pressure in the various units. A column of mercury slightly less than 760 mm is equivalent to slightly less than $101,325 \mathrm{~Pa}$ and slightly less than 1 atm.

The pressure exerted by a column of fluid, such as that in a barometer (Figure 11.5), is given by Equation 11.1.

$$
\text { Equation } 11.1
$$

$$
P=h d g
$$

where $h$ is the height of the column in meters, $d$ is the density of the fluid in $\mathrm{kg} / \mathrm{m}^{3}$, and $g$ is the gravitational constant equal to $9.80665 \mathrm{~m} / \mathrm{s}^{2}$. This equation explains why barometers historically have been constructed using mercury. The height of a column of fluid supported by a given pressure is inversely proportional to the density of the fluid. (At a given $P$, as $d$ goes up, $h$ must go down-and vice versa.) Mercury's high density made it possible to construct barometers and manometers of manageable size. For example, a barometer filled with mercury that stands 1 m tall would have to be over 13 m tall if it were filled with water.

Sample Problem 11.1 shows how to calculate the pressure exerted by a column of fluid.

## Sample Problem 11.1

Calculate the pressure exerted by a column of mercury 70.0 cm high. Express the pressure in pascals and in atmospheres. The density of mercury is $13.5951 \mathrm{~g} / \mathrm{cm}^{3}$.

Strategy Use Equation 1.1 to calculate pressure. Remember that height must be expressed in meters and density must be expressed in $\mathrm{kg} / \mathrm{m}^{3}$.

## Setup

$$
\begin{aligned}
& h=70.0 \mathrm{~cm} \times \frac{1 \mathrm{~m}}{100 \mathrm{~cm}}=0.700 \mathrm{~m} \\
& d=\frac{13.5951 \mathrm{~g}}{\mathrm{~cm}^{3}} \times \frac{1 \mathrm{~kg}}{1000 \mathrm{~g}} \times\left(\frac{100 \mathrm{~cm}}{1 \mathrm{~m}}\right)^{3}=1.35951 \times 10^{4} \mathrm{~kg} / \mathrm{m}^{3} \\
& g=9.80665 \mathrm{~m} / \mathrm{s}^{2}
\end{aligned}
$$

## Solution

$$
\begin{gathered}
\text { pressure }=0.700 \mathrm{~m} \times \frac{1.35951 \times 10^{4} \mathrm{~kg}}{\mathrm{~m}^{3}} \times \frac{9.80665 \mathrm{~m}}{\mathrm{~s}^{2}}=9.33 \times 10^{4} \mathrm{~kg} / \mathrm{m} \cdot \mathrm{~s}^{2}=9.33 \times 10^{4} \mathrm{~Pa} \\
9.33 \times 10^{4} \mathrm{~Pa} \times \frac{1 \mathrm{~atm}}{101,325 \mathrm{~Pa}}=0.921 \mathrm{~atm}
\end{gathered}
$$

Practice Problem A What pressure (in atm) is exerted by a column of mercury exactly 1 m high?
FPractice Problem B What would be the height of a column of water supported by the pressure you calculated in Sample Problem 11.1? Assume that the density of the water is $1.00 \mathrm{~g} / \mathrm{cm}^{3}$.

## Checkpoint 11.1 Properties of Gases

11.1.1 Express a pressure of 1.15 atm in units of bar.
a) 1.17 bar
b) 1.13 bar
c) 0.881 bar
d) 874 bar
e) $1.51 \times 10^{-3}$ bar
11.1.2 Which of the following is true? (Select all that apply.)
a) $0.80 \mathrm{~atm}=0.80 \mathrm{torr}$
b) $4180 \mathrm{mmHg}=5.573 \times 10^{5} \mathrm{~Pa}$
c) 433 torr $=433 \mathrm{mmHg}$
d) $2.300 \mathrm{~atm}=1748$ torr
e) $5.5 \mathrm{~atm}=1.0 \times 10^{5} \mathrm{~Pa}$
11.1.3 Calculate the height of a column of ethanol that would be supported by atmospheric pressure ( 1 atm ). The density of ethanol is $0.789 \mathrm{~g} / \mathrm{cm}^{3}$.
a) $1.31 \times 10^{4} \mathrm{~m}$
b) 0.789 m
c) 600 mm
d) 13.1 m
e) 780 mm
11.1.4 What pressure is exerted by a column of water 50.0 m high? Assume the density of the water is $1.00 \mathrm{~g} / \mathrm{cm}^{3}$.
a) 490 atm
b) 4.84 atm
c) 0.087 atm
d) 50 atm
e) 1.62 atm
11.1.5 How do the pressures exerted by the following columns of water compare?

a) i $=$ ii $<$ iii
b) i $<$ iii $<$ ii
c) iii $<$ i $<$ ii
d) ii $<$ i $=$ iii
e) iii $<$ i $=$ ii

### 11.2 The Gas Laws

In contrast to the condensed phases, all gases, even those with vastly different chemical compositions, exhibit remarkably similar physical behavior. Numerous experiments carried out in the seventeenth and eighteenth centuries showed that the physical state of a sample of gas can be described completely with just four parameters: temperature $(T)$, pressure $(P)$, volume $(V)$, and number of moles ( $n$ ). Knowing any three of these parameters enables us to calculate the fourth. The relationships between these parameters are known as the gas laws.

## Boyle's Law: The Pressure-Volume Relationship

Imagine that you have a plastic syringe filled with air. If you hold your finger tightly against the tip of the syringe and push the plunger with your other hand, decreasing the volume of the air, you will increase the pressure in the syringe. During the seventeenth century Robert Boyle ${ }^{2}$ conducted systematic studies of the relationship between gas volume and pressure using a simple apparatus like the one shown in Figure 11.7. The J-shaped tube contains a sample of gas confined by a column of mercury. The apparatus functions as an open-end manometer. When the mercury levels on both sides are equal [Figure 11.7(a)], the pressure of the confined gas is equal to atmospheric pressure. When more mercury is added through the open end, the pressure of the confined gas is increased by an amount proportional to the height of the added mercury-and the volume of the gas decreases. If, for example, as shown in Figure 11.7(b), we double the pressure on the confined gas by adding enough mercury to make the difference in mercury levels on the left and right 760 mm (the height of a mercury column that exerts a pressure equal to 1 atm ), the volume of the gas is reduced by half. If we triple the original pressure on the confined gas by adding more mercury, the volume of the gas is reduced to one-third of its original volume [Figure 11.7(c)].

Table 11.3 gives a set of data typical of Boyle's experiments. Figure 11.8(a) and (b) shows some of the volume data plotted as a function of pressure and as a function of the inverse of pressure, respectively. These data illustrate Boyle's law, which states that the pressure of a fixed amount of gas at a constant temperature is inversely proportional to the volume of the gas. This inverse relationship between pressure and volume can be expressed mathematically as follows:

$$
V \propto \frac{1}{P}
$$

[^26]Figure 11.7 Demonstration of Boyle's law. The volume of a sample of gas is inversely proportional to its pressure. (a) $P=760 \mathrm{mmHg}$, $V=100 \mathrm{~mL}$. (b) $P=1520 \mathrm{mmHg}$, $V=50 \mathrm{~mL}$. (c) $P=2280 \mathrm{mmHg}$, $V=33 \mathrm{~mL}$. Note that the total pressure exerted on the gas is the sum of atmospheric pressure $(760 \mathrm{mmHg})$ and the difference in height of the mercury.

TABLE 11.3 $\quad$ Typical Data from Experiments with the Apparatus of Figure 11.7

| $P(\mathrm{mmHg})$ | 760 | 855 | 950 | 1045 | 1140 | 1235 | 1330 | 1425 | 1520 |
| :--- | :---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| $V(\mathrm{~mL})$ | 100 | 89 | 78 | 72 | 66 | 59 | 55 | 54 | 50 |
|  | Shown in <br> Figure <br> $11.7(\mathrm{a})$ |  |  |  |  |  |  | Shown in <br> Figure | Shown in <br> Figure |
| $11.7(\mathrm{~b})$ | $11.7(\mathrm{c})$ |  |  |  |  |  |  |  |  |

(a)

(b)

Figure 11.8 Plots of volume (a) as a function of pressure and (b) as a function of $1 /$ pressure.

$$
V=k_{1} \frac{1}{P} \quad(\text { at constant temperature }) \quad \text { Equation } 11.2(\mathrm{a})
$$

where $k_{1}$ is a proportionality constant. We can rearrange Equation 11.2(a) to get

$$
\begin{equation*}
P V=k_{1} \quad(\text { at constant temperature }) \tag{b}
\end{equation*}
$$

According to this form of Boyle's law, the product of the pressure and the volume of a given sample of gas (at constant temperature) is a constant.

Although the individual values of pressure and volume can vary greatly for a given sample of gas, the product of $P$ and $V$ is always equal to the same constant as long as the temperature is held constant and the amount of gas does not change. Therefore, for a given sample of gas under two different sets of conditions at constant temperature, we can write

$$
P_{1} V_{1}=k_{1}=P_{2} V_{2}
$$

or

$$
P_{1} V_{1}=P_{2} V_{2} \quad(\text { at constant temperature }) \quad \text { Equation } 11.3
$$

where $V_{1}$ is the volume at pressure $P_{1}$ and $V_{2}$ is the volume at pressure $P_{2}$.
Sample Problem 11.2 illustrates the use of Boyle's law.

## Sample Problem 11.2

If a skin diver takes a breath at the surface, filling his lungs with 5.82 L of air, what volume will the air in his lungs occupy when he dives to a depth where the pressure is 1.92 atm ? (Assume constant temperature and that the pressure at the surface is exactly 1 atm .)

Strategy Use Equation 11.3 to solve for $V_{2}$.
Setup $P_{1}=1.00 \mathrm{~atm}, V_{1}=5.82 \mathrm{~L}$, and $P_{2}=1.92 \mathrm{~atm}$.

$$
\text { Solution } \quad V_{2}=\frac{P_{1} \times V_{1}}{P_{2}}=\frac{1.00 \mathrm{~atm} \times 5.82 \mathrm{~L}}{1.92 \mathrm{~atm}}=3.03 \mathrm{~L}
$$

Practice Problem A Calculate the volume of a sample of gas at 5.75 atm if it occupies 5.14 L at 2.49 atm . (Assume constant temperature.)

EPractice Problem B At what pressure would a sample of gas occupy 7.86 L if it occupies 3.44 L at 4.11 atm ? (Assume constant temperature.)

## Charles's and Gay-Lussac's Law: The Temperature-Volume Relationship

If you took a helium-filled Mylar balloon outdoors on a cold day, the balloon would shrink somewhat when it came into contact with the cold air. This would occur because the volume of a sample of gas depends on the temperature. A more dramatic illustration is shown in Figure 11.9, where liquid nitrogen is being poured over an air-filled balloon. The large drop in temperature of the air in the balloon (the boiling liquid nitrogen has a temperature of $-196^{\circ} \mathrm{C}$ ) results in a significant decrease in its volume, causing the balloon to shrink. Note that the pressure inside the balloon is roughly equal to the external pressure.

The first to study the relationship between gas volume and temperature were French scientists Jacques Charles ${ }^{3}$ and Joseph Gay-Lussac. ${ }^{4}$ Their studies showed that, at constant pressure,

[^27]Think About It At higher pressure, the volume should be smaller. Therefore, the answer makes sense. Gas Laws-Charles's law.

Figure 11.9 (a) Air-filled balloon. (b) Lowering the temperature with liquid nitrogen causes a volume decrease. The pressure inside the balloon, which is roughly equal to the external pressure, remains constant in this process.

Figure 11.10 (a) Plot of the volume of a sample of gas as a function of temperature. (b) Plot of the volume of a sample of gas as a function of temperature at three different pressures.
the volume of a gas sample increases when heated and decreases when cooled. Figure 11.10(a) shows a plot of data typical of Charles's and Gay-Lussac's experiments. Note that with pressure held constant, the volume of a sample of gas plotted as a function of temperature yields a straight line. These experiments were carried out at several different pressures [Figure 11.10(b)], each yielding a different straight line. Interestingly, if the lines are extrapolated to zero volume, they all meet at the $x$ axis at the temperature $-273.15^{\circ} \mathrm{C}$. The implication is that a gas sample occupies zero volume at $-273.15^{\circ} \mathrm{C}$. This is not observed in practice, however, because all gases condense to form liquids or solids before $-273.15^{\circ} \mathrm{C}$ is reached.

In 1848, Lord Kelvin ${ }^{5}$ realized the significance of the extrapolated lines all meeting at $-273.15^{\circ} \mathrm{C}$. He identified $-273.15^{\circ} \mathrm{C}$ as absolute zero, theoretically the lowest attainable temperature. Then he set up an absolute temperature scale, now called the Kelvin temperature scale, with

[^28]absolute zero as the lowest point [ 144 Section 1.3]. On the Kelvin scale, 1 kelvin (K) is equal in magnitude to 1 degree Celsius. The difference is simply an offset of 273.15. We obtain the absolute temperature by adding 273.15 to the temperature expressed in Celsius, although we often use simply 273 instead of 273.15 . Several important points on the two scales match up as follows:

|  | Kelvin Scale (K) | Celsius Scale $\left({ }^{\circ} \mathbf{C}\right)$ |
| :--- | :---: | :---: |
| Absolute zero | 0 K | $-273.15^{\circ} \mathrm{C}$ |
| Freezing point of water | 273.15 K | $00^{\circ} \mathrm{C}$ |
| Boiling point of water | 373.15 K | $100^{\circ} \mathrm{C}$ |

The dependence of the volume of a sample of gas on temperature is given by

$$
V \propto T
$$

or

$$
\begin{equation*}
V=k_{2} T \quad \text { (at constant pressure) } \tag{a}
\end{equation*}
$$

where $k_{2}$ is the proportionality constant. We can rearrange Equation 11.4(a) to get

$$
\begin{equation*}
\frac{V}{T}=k_{2} \quad(\text { at constant pressure }) \tag{b}
\end{equation*}
$$

Equations 11.4(a) and (b) are expressions of Charles's and Gay-Lussac's law, often referred to simply as Charles's law, which states that the volume of a fixed amount of gas maintained at constant pressure is directly proportional to the absolute temperature of the gas.

Just as we did with the pressure-volume relationship at constant temperature, we can compare two sets of volume-temperature conditions for a given sample of gas at constant pressure. From Equation 11.4 we can write

$$
\frac{V_{1}}{T_{1}}=k_{2}=\frac{V_{2}}{T_{2}}
$$

or

$$
\frac{V_{1}}{T_{1}}=\frac{V_{2}}{T_{2}} \quad \text { (at constant pressure) }
$$

Equation 11.5
where $V_{1}$ is the volume of the gas at $T_{1}$ and $V_{2}$ is the volume of the gas at $T_{2}$.
Sample Problem 11.3 shows how to use Charles's law.

## Sample Problem 11.3

A sample of argon gas that originally occupied 14.6 L at $25.0^{\circ} \mathrm{C}$ was heated to $50.0^{\circ} \mathrm{C}$ at constant pressure. What is its new volume?

Strategy Use Equation 11.5 to solve for $V_{2}$. Remember that temperatures must be expressed in kelvin.

Setup $T_{1}=298.15 \mathrm{~K}, V_{1}=14.6 \mathrm{~L}$, and $T_{2}=323.15 \mathrm{~K}$.
Solution

$$
V_{2}=\frac{V_{1} \times T_{2}}{T_{1}}=\frac{14.6 \mathrm{~L} \times 323.15 \mathrm{~K}}{298.15 \mathrm{~K}}=15.8 \mathrm{~L}
$$

Practice Problem A A sample of gas originally occupies 29.1 L at $0.0^{\circ} \mathrm{C}$. What is its new volume when it is heated to $15.0^{\circ} \mathrm{C}$ ? (Assume constant pressure.)

EPractice Problem B At what temperature (in ${ }^{\circ} \mathrm{C}$ ) will a sample of gas occupy 82.3 L if it occupies 50.0 L at $75.0^{\circ} \mathrm{C}$ ? (Assume constant pressure.)
.

Student Annotation: Remember that a kelvin and a degree Celsius have the same magnitude. Thus, while we add 273.15 to the temperature in ${ }^{\circ} \mathrm{C}$ to get the temperature in K , a change in temperature in Celsius is equal to the change in temperature in K . A temperature of $20^{\circ} \mathrm{C}$ is the same as 293.15 K . A change in temperature of $20^{\circ} \mathrm{C}$, however, is the same as a change in temperature of 20 K .

Student Annotation: Don't forget that volume is proportional to absolute temperature. The volume of a sample of gas at constant pressure doubles if the temperature increases from 100 K to 200 K -but not if the temperature increases from $100^{\circ} \mathrm{C}$ to $200^{\circ} \mathrm{C}$ !

## Avogadro's Law: The Amount-Volume Relationship

In 1811, the Italian scientist Amedeo Avogadro proposed that equal volumes of different gases contain the same number of particles (molecules or atoms) at the same temperature and pressure. This hypothesis gave rise to Avogadro's law, which states that the volume of a sample of gas is directly proportional to the number of moles in the sample at constant temperature and pressure:

$$
V \propto n
$$

or

Equation 11.6(a) $\quad V=k_{3} n \quad$ (at constant temperature and pressure)

Rearranging Equation 11.6(a) gives

$$
\begin{equation*}
\frac{V}{n}=k_{3} \tag{~b}
\end{equation*}
$$

Equations 11.6(a) and (b) are expressions of Avogadro's law.
As with the other gas laws, we can compare two sets of conditions using Avogadro's law where $n$ and $V$ both change at constant pressure and temperature and write

$$
\frac{V_{1}}{n_{1}}=k_{3}=\frac{V_{2}}{n_{2}}
$$

or

Equation 11.7

$$
\frac{V_{1}}{n_{1}}=\frac{V_{2}}{n_{2}}
$$

where $V_{1}$ is the volume of a sample of gas consisting of $n_{1}$ moles and $V_{2}$ is the volume of a sample consisting of $n_{2}$ moles-under conditions of constant temperature and pressure. Coupled with a balanced chemical equation, Avogadro's law enables us to predict the volumes of gaseous reactants and products. Consider the reaction of $\mathrm{H}_{2}$ and $\mathrm{N}_{2}$ to form $\mathrm{NH}_{3}$ :

$$
3 \mathrm{H}_{2}(g)+\mathrm{N}_{2}(g) \longrightarrow 2 \mathrm{NH}_{3}(g)
$$

The balanced equation reveals the ratio of combination of reactants in terms of moles [ 14 Section 3.4]. However, because the volume of a gas (at a given temperature and pressure) is directly proportional to the number of moles, the balanced equation also reveals the ratio of combination in terms of volume. Thus, if we were to combine three volumes (liters, milliliters, etc.) of hydrogen gas with one volume of nitrogen gas, assuming they react completely according to the balanced equation, we would expect two volumes of ammonia gas to be produced (Figure 11.11). The ratio of combination of $\mathrm{H}_{2}$ and $\mathrm{N}_{2}$ (and production of $\mathrm{NH}_{3}$ ), whether expressed in moles or units of volume, is $3: 1: 2$.

Sample Problem 11.4 shows how to apply Avogadro's law.

Figure 11.11 Illustration of Avogadro's law. The volume of a sample of gas is directly proportional to the number of moles.

## Sample Problem 11.4

If we combine 3.0 L of NO and 1.5 L of $\mathrm{O}_{2}$, and they react according to the balanced equation $2 \mathrm{NO}(\mathrm{g})+\mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{NO}_{2}(\mathrm{~g})$, what volume of $\mathrm{NO}_{2}$ will be produced? (Assume that the reactants and product are all at the same temperature and pressure.)

Strategy Apply Avogadro's law to determine the volume of a gaseous product.
Setup Because volume is proportional to the number of moles, the balanced equation determines in what volume ratio the reactants combine and the ratio of product volume to reactant volume. The amounts of reactants given are stoichiometric amounts [ 141 Section 3.6].

Solution According to the balanced equation, the volume of $\mathrm{NO}_{2}$ formed will be equal to the volume of NO that reacts. Therefore, 3.0 L of $\mathrm{NO}_{2}$ will form.

Practice Problem A What volume (in liters) of water vapor will be produced when 34 L of $\mathrm{H}_{2}$ and 17 L of $\mathrm{O}_{2}$ react according to the equation $2 \mathrm{H}_{2}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(\mathrm{g})$ ?
\& Practice Problem B What volumes (in liters) of carbon monoxide and oxygen gas must react according to the equation $2 \mathrm{CO}(\mathrm{g})+\mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{CO}_{2}(\mathrm{~g})$ to form 3.16 L of carbon dioxide?

## The Combined Gas Law:

## The Pressure-Temperature-Amount-Volume Relationship

Although the gas laws we have discussed so far are useful, each requires that two of the system's parameters be held constant.

| Problem Type | Relates | Requires Constant |
| :--- | :--- | :---: |
| Boyle's law | $P$ and $V$ | $n$ and $T$ |
| Charles's law | $T$ and $V$ | $n$ and $P$ |
| Avogadro's law | $n$ and $V$ | $P$ and $T$ |

Many of the problems we will encounter involve changes to $P, T$, and $V$, and, in some cases, also to $n$. To solve such problems, we need a gas law that relates all the variables. By combining Equations 11.3, 11.5, and 11.7, we obtain the combined gas law:

$$
\begin{equation*}
\frac{P_{1} V_{1}}{n_{1} T_{1}}=\frac{P_{2} V_{2}}{n_{2} T_{2}} \tag{a}
\end{equation*}
$$

The combined gas law can be used to solve problems where any or all of the variables change. Note that when a problem involves a fixed quantity of gas, Equation 11.8(a) reduces to the more common form of the combined gas law:

$$
\begin{equation*}
\frac{P_{1} V_{1}}{T_{1}}=\frac{P_{2} V_{2}}{T_{2}} \tag{b}
\end{equation*}
$$

Sample Problem 11.5 illustrates the use of the combined gas law.

## Sample Problem 11.5

If a child releases a 6.25 -L helium balloon in the parking lot of an amusement park where the temperature is $28.50^{\circ} \mathrm{C}$ and the air pressure is 757.2 mmHg , what will the volume of the balloon be when it has risen to an altitude where the temperature is $-34.35^{\circ} \mathrm{C}$ and the air pressure is 366.4 mmHg ?

Strategy In this case, because there is a fixed amount of gas, we use Equation 11.8(b). The only value we don't know is $V_{2}$. Temperatures must be expressed in kelvins. We can use any units of pressure, as long as we are consistent.

Student Annotation: It is important to recognize that coefficients indicate ratios in liters only in balanced equations in which all the reactants and products are gases. We cannot apply the same approach to reactions in which there are solid, liquid, or aqueous species.

Think About It Note that the solution is essentially multiplying the original volume by the ratio of $P_{1}$ to $P_{2}$, and by the ratio of $T_{2}$ to $T_{1}$. The effect of decreasing external pressure is to increase the balloon volume. The effect of decreasing temperature is to decrease the volume. In this case, the effect of decreasing pressure predominates and the balloon volume increases significantly.

Setup $T_{1}=301.65 \mathrm{~K}, T_{2}=238.80 \mathrm{~K}$. Solving Equation $11.8(\mathrm{~b})$ for $V_{2}$ gives

$$
V_{2}=\frac{P_{1} T_{2} V_{1}}{P_{2} T_{1}}
$$

## Solution

$$
V_{2}=\frac{757.2 \mathrm{mmHg} \times 238.80 \mathrm{~K} \times 6.25 \mathrm{~L}}{366.4 \mathrm{mmHg} \times 301.65 \mathrm{~K}}=10.2 \mathrm{~L}
$$

Practice Problem A What would be the volume of the balloon in Sample Problem 11.5 if, instead of being released to rise in the atmosphere, it were submerged in a swimming pool to a depth where the pressure is 922.3 mmHg and the temperature is $26.35^{\circ} \mathrm{C}$ ?

EIPractice Problem B The volume of a bubble that starts at the bottom of a lake at $4.55^{\circ} \mathrm{C}$ increases by a factor of 10 as it rises to the surface where the temperature is $18.45^{\circ} \mathrm{C}$ and the air pressure is 0.965 atm . Assuming that the density of the lake water is $1.00 \mathrm{~g} / \mathrm{cm}^{3}$, determine the depth of the lake. (Hint: You will need to use Equation 11.1.)

## Checkpoint 11.2 The Gas Laws

11.2.1 Given $P_{1}=1.50 \mathrm{~atm}, V_{1}=37.3 \mathrm{~mL}$, and $P_{2}=1.18 \mathrm{~atm}$, calculate $V_{2}$. Assume that $n$ and $T$ are constant.
a) 0.0211 mL
b) 0.0341 mL
c) 29.3 mL
d) 12.7 mL
e) 47.4 mL
11.2.2 Given $T_{1}=21.5^{\circ} \mathrm{C}, V_{1}=50.0 \mathrm{~mL}$, and $T_{2}=316^{\circ} \mathrm{C}$, calculate $V_{2}$. Assume that $n$ and $P$ are constant.
a) 100 mL
b) 73.5 mL
c) 25.0 mL
d) 3.40 mL
e) 26.5 mL
11.2.3 At what temperature will a gas sample occupy 100.0 L if it originally occupies 76.1 L at $89.5^{\circ} \mathrm{C}$ ? Assume constant $P$.
a) $276^{\circ} \mathrm{C}$
b) $118^{\circ} \mathrm{C}$
c) $203{ }^{\circ} \mathrm{C}$
d) $68.1^{\circ} \mathrm{C}$
e) $99.6^{\circ} \mathrm{C}$
11.2.4 What volume of $\mathrm{NH}_{3}$ will be produced when 180 mL of $\mathrm{H}_{2}$ reacts with 60.0 mL of $\mathrm{N}_{2}$ according to the following equation:

$$
3 \mathrm{H}_{2}(g)+\mathrm{N}_{2}(g) \longrightarrow 2 \mathrm{NH}_{3}(g)
$$

Assume constant $T$ and $P$ for reactants and products.
a) 120 mL
b) 60 mL
c) 180 mL
d) 240 mL
e) 220 mL
11.2.5 Which diagram could represent the result of increasing the temperature and decreasing the external pressure on a fixed amount of gas in a balloon?

a) i only
b) ii only
c) i and ii
d) i, ii, and iii
e) iii only
11.2.6 Which diagram in question 11.2 .5 could represent the result of decreasing both the temperature and the pressure?
a) i only
b) ii only
c) i and ii
d) i, ii, and iii
e) iii only

### 11.3 The Ideal Gas Equation

Recall that the state of a sample of gas is described completely using the four variables $T, P, V$, and $n$. Each of the gas laws introduced in Section 11.2 relates one variable of a sample of gas to another while the other two variables are held constant. In experiments with gases, however, there are usually changes in more than just two of the variables. Therefore, it is useful for us to combine the equations representing the gas laws into a single equation that will enable us to account for changes in any or all of the four variables.

## Deriving the Ideal Gas Equation from the Empirical Gas Laws

Summarizing the gas law equations from Section 11.2:

$$
\begin{array}{lc}
\text { Boyle's law: } & V \propto \frac{1}{P} \\
\text { Charles's law: } & V \propto T \\
\text { Avogadro's law: } & V \propto n
\end{array}
$$

We can combine these equations into the following general equation that describes the physical behavior of all gases:

$$
V \propto \frac{n T}{P}
$$

or

$$
V=R \frac{n T}{P}
$$

where $R$ is the proportionality constant. This equation can be rearranged to give:

$$
P V=n R T
$$

Equation 11.9
Equation 11.9 is the most commonly used form of the ideal gas equation, which describes the relationship among the four variables $P, V, n$, and $T$. An ideal gas is a hypothetical sample of gas whose pressure-volume-temperature behavior is predicted accurately by the ideal gas equation. Although the behavior of real gases generally differs slightly from that predicted by Equation 11.9 , in most of the cases we will encounter, the differences are usually small enough for us to use the ideal gas equation to make reasonably good predictions about the behavior of gases.

The proportionality constant, $R$, in Equation 11.9 is called the gas constant. Its value and units depend on the units in which $P$ and $V$ are expressed. (The variables $n$ and $T$ are always expressed in mol and K, respectively.) Recall from Section 11.1 that pressure is commonly expressed in atmospheres, mmHg (torr), pascals, or bar. Volume is typically expressed in liters or milliliters, but can also be expressed in other units, such as $\mathrm{m}^{3}$. Table 11.4 lists several different expressions of the gas constant, $R$.

## TABLE 11.4

Various Equivalent Expressions of the Gas Constant, $R$

## Numerical Value

0.08206
62.36
0.08314
8.314
8.314
1.987

## Unit

$\mathrm{L} \cdot \mathrm{atm} / \mathrm{K} \cdot \mathrm{mol}$
$\mathrm{L} \cdot \mathrm{torr} / \mathrm{K} \cdot \mathrm{mol}$
$\mathrm{L} \cdot \mathrm{bar} / \mathrm{K} \cdot \mathrm{mol}$
$\mathrm{m}^{3} \cdot \mathrm{~Pa} / \mathrm{K} \cdot \mathrm{mol}$
$\mathrm{J} / \mathrm{K} \cdot \mathrm{mol}$
$\mathrm{cal} / \mathrm{K} \cdot \mathrm{mol}$

Note that the product of volume and pressure gives units of energy (i.e., joules and calories).

Student Annotation: We will discuss the conditions that result in deviation from ideal behavior in Section 11.7.

Student Annotation: When you use $R$ in a calculation, use the version that facilitates proper cancellation of units.

Student Annotation: In thermochemistry we often used $25^{\circ} \mathrm{C}$ as the "standard" temperature-although temperature is not actually part of the definition of the standard state [ 144 Section 5.6]. The standard temperature for gases is defined specifically as $0^{\circ} \mathrm{C}$.

Student Annotation: In this problem, because they are specified rather than measured, $0^{\circ} \mathrm{C}$, 1 mole, and 1 atm are exact numbers and do not affect the number of significant figures in the result [ 14 Section 1.5].

Think About It With the pressure held constant, we should expect the volume to increase with increased temperature. Room temperature is higher than the standard temperature for gases $\left(0^{\circ} \mathrm{C}\right)$, so the molar volume at room temperature $\left(25^{\circ} \mathrm{C}\right)$ should be higher than the molar volume at $0^{\circ} \mathrm{C}$-and it is.

Student Annotation: $n \times \mathcal{M}=m$, where $m$ is mass in grams.

Student Annotation: Another way to arrive at Equation 11.10 is to substitute $m / \mathcal{M}$ for $n$ in the ideal gas equation and rearrange to solve for $m / V$ (density):

$$
P V=\frac{m}{M} R T \quad \text { and } \quad \frac{m}{V}=d=\frac{P M}{R T}
$$

Keep in mind that all these expressions of $R$ are equal to one another, just as 1 yard is equal to 3 ft . They are simply expressed in different units.

One of the simplest uses of the ideal gas equation is the calculation of one of the variables when the other three are already known. For example, we can calculate the volume of 1 mole of an ideal gas at $0^{\circ} \mathrm{C}$ and 1 atm , conditions known as standard temperature and pressure (STP). In this case, $n, T$, and $P$ are given. $R$ is a constant, leaving $V$ as the only unknown. We can rearrange Equation 11.9 to solve for $V$,

$$
V=\frac{n R T}{P}
$$

enter the information that is given, and calculate $V$. Remember that in calculations using the ideal gas equation, temperature must always be expressed in kelvins.

$$
V=\frac{(1 \mathrm{~mol})(0.08206 \mathrm{~L} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{~mol})(273.15 \mathrm{~K})}{1 \mathrm{~atm}}=22.41 \mathrm{~L}
$$

Thus, the volume occupied by 1 mole of an ideal gas at STP is 22.41 L , a volume slightly less than 6 gal.

Sample Problem 11.6 shows how to calculate the molar volume of a gas at a temperature other than $0^{\circ} \mathrm{C}$.

## Sample Problem 11.6

Calculate the volume of a mole of ideal gas at room temperature $\left(25^{\circ} \mathrm{C}\right)$ and 1 atm .
Strategy Convert the temperature in ${ }^{\circ} \mathrm{C}$ to temperature in kelvins, and use the ideal gas equation to solve for the unknown volume.

Setup The data given are $n=1 \mathrm{~mol}, T=298.15 \mathrm{~K}$, and $P=1.00 \mathrm{~atm}$. Because the pressure is expressed in atmospheres, we use $R=0.08206 \mathrm{~L} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{mol}$ to solve for volume in liters.

## Solution

$$
V=\frac{(1 \mathrm{~mol})(0.08206 \mathrm{~L} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{~mol})(298.15 \mathrm{~K})}{1 \mathrm{~atm}}=24.5 \mathrm{~L}
$$

Practice Problem A What is the volume of 5.12 moles of an ideal gas at $32^{\circ} \mathrm{C}$ and 1.00 atm ?
GPractice Problem B At what temperature (in ${ }^{\circ} \mathrm{C}$ ) would 1 mole of ideal gas occupy 50.0 L ( $P=1.00 \mathrm{~atm}$ )?

## Applications of the Ideal Gas Equation

Using some simple algebraic manipulation, we can solve for variables other than those that appear explicitly in the ideal gas equation. For example, if we know the molar mass of a gas ( $\mathrm{g} / \mathrm{mol}$ ), we can determine its density at a given temperature and pressure. Recall from Section 11.1 that the density of a gas is generally expressed in units of $\mathrm{g} / \mathrm{L}$. We can rearrange the ideal gas equation to solve for $\mathrm{mol} / \mathrm{L}$ :

$$
\frac{n}{V}=\frac{P}{R T}
$$

If we then multiply both sides by the molar mass, $\mathcal{M}$, we get

$$
\mathcal{M} \times \frac{n}{V}=\frac{P}{R T} \times \mathcal{M}
$$

where $\mathcal{M} \times n / V$ gives $\mathrm{g} / \mathrm{L}$ or density, $d$. Therefore,

$$
d=\frac{P \mathcal{M}}{R T}
$$

Conversely, if we know the density of a gas, we can determine its molar mass:

$$
\mathcal{M}=\frac{d R T}{P}
$$

Equation 11.11

In a typical experiment, in which the molar mass of a gas is determined, a flask of known volume is evacuated and weighed [Figure 11.12(a)]. It is then filled (to a known pressure) with the gas of unknown molar mass and reweighed [Figure 11.12(b)]. The difference in mass is the mass of the gas sample. Dividing by the known volume of the flask gives the density of the gas, and the molar mass can then be determined using Equation 11.11.

Similarly, the molar mass of a volatile liquid can be determined by placing a small volume of it in the bottom of a flask, the mass and volume of which are known. The flask is then immersed in a hot-water bath, causing the volatile liquid to completely evaporate and its vapor to fill the flask. Because the flask is open, some of the excess vapor escapes. When no more vapor escapes, the flask is capped and removed from the water bath. The flask is then weighed to determine the mass of the vapor. (At this point, some or all of the vapor has condensed but the mass remains the same.) The density of the vapor is determined by dividing the mass of the vapor by the volume of the flask. Equation 11.11 is then used to calculate the molar mass of the volatile liquid.

Sample Problems 11.7 and 11.8 illustrate the use of Equations 11.10 and 11.11.

## Sample Problem 11.7

Carbon dioxide is effective in fire extinguishers partly because its density is greater than that of air, so $\mathrm{CO}_{2}$ can smother the flames by depriving them of oxygen. (Air has a density of approximately $1.2 \mathrm{~g} / \mathrm{L}$ at room temperature and 1 atm .) Calculate the density of $\mathrm{CO}_{2}$ at room temperature $\left(25^{\circ} \mathrm{C}\right)$ and 1.0 atm .

Strategy Use Equation 11.10 to solve for density. Because the pressure is expressed in atm, we should use $R=0.08206 \mathrm{~L} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{mol}$. Remember to express temperature in kelvins.

Setup The molar mass of $\mathrm{CO}_{2}$ is $44.01 \mathrm{~g} / \mathrm{mol}$.

## Solution

$$
d=\frac{P \mathcal{M}}{R T}=\frac{(1 \mathrm{~atm})\left(\frac{44.01 \mathrm{~g}}{\mathrm{~mol}}\right)}{\left(\frac{0.08206 \mathrm{~L} \cdot \mathrm{~atm}}{\mathrm{~K} \cdot \mathrm{~mol}}\right)(298.15 \mathrm{~K})}=1.8 \mathrm{~g} / \mathrm{L}
$$

Practice Problem A Calculate the density of air at $0^{\circ} \mathrm{C}$ and 1 atm . (Assume that air is 80 percent $\mathrm{N}_{2}$ and 20 percent $\mathrm{O}_{2}$.)
$\mathbb{H}$ Practice Problem B What pressure would be required for helium at $25^{\circ} \mathrm{C}$ to have the same density as carbon dioxide at $25^{\circ} \mathrm{C}$ and 1 atm ?

Figure 11.12 (a) Evacuated flask. (b) Flask filled with gas. The mass of the gas is the difference between the two masses. The density of the gas is determined by dividing mass by volume.

Student Annotation: Because the flask is open to the atmosphere while the volatile liquid vaporizes, we can use atmospheric pressure as $P$. Also, because the flask is capped at the water bath temperature, we can use the water bath temperature as $T$.

Think About lt The calculated density of $\mathrm{CO}_{2}$ is greater than that of air under the same conditions (as expected). Although it may seem tedious, it is a good idea to write units for each and every entry in a problem such as this. Unit cancellation is very useful for detecting errors in your reasoning or your solution setup.

Think About It Because more than one compound can have a particular molar mass, this method is not definitive for identification. However, in this circumstance, further testing of the proprietary formula certainly would be warranted.

## Sample Problem 11.8

A company has just patented a new synthetic alcohol for alcoholic beverages. The new product is said to have all the pleasant properties associated with ethanol but none of the undesirable effects such as hangover, impairment of motor skills, and risk of addiction. The chemical formula is proprietary. You analyze a sample of the new product by placing a small volume of it in a roundbottomed flask with a volume of 511.0 mL and an evacuated mass of 131.918 g . You submerge the flask in a water bath at $100.0^{\circ} \mathrm{C}$ and allow the volatile liquid to vaporize. You then cap the flask and remove it from the water bath. You weigh it and determine the mass of the vapor in the flask to be 0.768 g . What is the molar mass of the volatile liquid, and what does it mean with regard to the new product? (Assume the pressure in the laboratory is 1 atm .)

Strategy Use the measured mass of the vapor and the given volume of the flask to determine the density of the vapor at 1 atm and $100.0^{\circ} \mathrm{C}$, and then use Equation 11.8 to determine molar mass.

Setup $P=1 \mathrm{~atm}, V=0.5110 \mathrm{~L}, R=0.8206 \mathrm{~L} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{mol}$, and $T=373.15 \mathrm{~K}$.
Solution

$$
\begin{aligned}
& d=\frac{0.768 \mathrm{~g}}{0.5110 \mathrm{~L}}=1.5029 \mathrm{~g} / \mathrm{L} \\
& \mathcal{M}=\frac{\left(\frac{1.5029 \mathrm{~g}}{\mathscr{L}}\right)\left(\frac{0.08206 \mathrm{~L} \cdot \mathrm{~atm}}{K \cdot \mathrm{~mol}}\right)(373.15 \mathrm{~K})}{1 \mathrm{~atm}}=46.02 \mathrm{~g} / \mathrm{mol}
\end{aligned}
$$

The result is a molar mass suspiciously close to that of ethanol!

Practice Problem A Determine the molar mass of a gas with a density of $1.905 \mathrm{~g} / \mathrm{L}$ at $80.0^{\circ} \mathrm{C}$ and 1.00 atm .

EPractice Problem B A sample of the volatile liquid propyl acetate $\left(\mathrm{C}_{5} \mathrm{H}_{10} \mathrm{O}_{2}\right)$ is analyzed using the procedure and equipment described in Sample Problem 11.8. What will the mass of the $511.0-\mathrm{mL}$ flask be after evaporation of the propyl acetate?

## Checkpoint 11.3 The Ideal Gas Equation

11.3.1 Calculate the volume occupied by 8.75 moles of an ideal gas at STP.
a) 196 L
b) 268 L
c) 0.718 L
d) 18.0 L
e) 2.56 L
11.3.2 Calculate the pressure exerted by 10.2 moles of an ideal gas in a 7.5-L vessel at $150^{\circ} \mathrm{C}$.
a) 17 atm
b) 31 atm
c) 0.72 atm
d) 1.3 atm
e) 47 atm
11.3.3 Determine the density of a gas with $\mathcal{M}=$ $146.07 \mathrm{~g} / \mathrm{mol}$ at 1.00 atm and $100.0^{\circ} \mathrm{C}$.
a) $6.85 \times 10^{-3} \mathrm{~g} / \mathrm{L}$
b) $4.77 \mathrm{~g} / \mathrm{L}$
c) $146 \mathrm{~g} / \mathrm{L}$
d) $30.6 \mathrm{~g} / \mathrm{L}$
e) $17.8 \mathrm{~g} / \mathrm{L}$
11.3.4 Determine the molar mass of a gas with $d=1.963 \mathrm{~g} / \mathrm{L}$ at 1.00 atm and $100.0^{\circ} \mathrm{C}$.
a) $0.0166 \mathrm{~g} / \mathrm{mol}$
b) $60.1 \mathrm{~g} / \mathrm{mol}$
c) $16.1 \mathrm{~g} / \mathrm{mol}$
d) $6.09 \times 10^{3} \mathrm{~g} / \mathrm{mol}$
e) $1.63 \times 10^{3} \mathrm{~g} / \mathrm{mol}$

### 11.4 Reactions with Gaseous Reactants and Products

In Chapter 3 we used balanced chemical equations to calculate amounts of reactants and/or products in chemical reactions-expressing those amounts in mass (usually grams). However, in the case of reactants and products that are gases, it is more practical to measure and express amounts
in volume (liters or milliliters). This makes the ideal gas equation useful in the stoichiometric analysis of chemical reactions that involve gases.

## Calculating the Required Volume of a Gaseous Reactant

According to Avogadro's law, the volume of a gas at a given temperature and pressure is proportional to the number of moles. Moreover, balanced chemical equations give the ratio of combination of gaseous reactants in both moles and volume (Figure 11.11). Therefore, if we know the volume of one reactant in a gaseous reaction, we can determine the required amount of another reactant (at the same temperature and pressure). For example, consider the reaction of carbon monoxide and oxygen to yield carbon dioxide:

$$
2 \mathrm{CO}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{CO}_{2}(g)
$$

The ratio of combination of CO and $\mathrm{O}_{2}$ is 2:1, whether we are talking about moles or units of volume. Thus, if we want to determine the stoichiometric amount [ 144 Section 3.6] of $\mathrm{O}_{2}$ required to combine with a particular volume of CO, we simply use the conversion factor provided by the balanced equation, which can be expressed as any of the following:

$$
\frac{1 \mathrm{~mol} \mathrm{O}_{2}}{2 \mathrm{~mol} \mathrm{CO}} \text { or } \frac{1 \mathrm{~L} \mathrm{O}_{2}}{2 \mathrm{~L} \mathrm{CO}} \text { or } \frac{1 \mathrm{~mL} \mathrm{O}_{2}}{2 \mathrm{~mL} \mathrm{CO}}
$$

Let's say we want to determine what volume of $\mathrm{O}_{2}$ is required to react completely with 65.8 mL of CO at STP. We could use the ideal gas equation to convert the volume of CO to moles, use the stoichiometric conversion factor to convert to moles $\mathrm{O}_{2}$, and then use the ideal gas equation again to convert moles $\mathrm{O}_{2}$ to volume. But this method involves several unnecessary steps. We get the same result simply by using the conversion factor expressed in milliliters:

$$
65.8 \mathrm{~mL} \mathrm{CO} \times=\frac{1 \mathrm{~mL} \mathrm{O}_{2}}{2 \mathrm{~mL} \mathrm{CO}}=32.9 \mathrm{~mL} \mathrm{O}_{2}
$$

In cases where only one of the reactants is a gas, we do need to use the ideal gas equation in our analysis. Recall, for example, the reaction of sodium metal and chlorine gas used to illustrate the Born-Haber cycle [14 Section 8.2]:

$$
2 \mathrm{Na}(s)+\mathrm{Cl}_{2}(g) \longrightarrow 2 \mathrm{NaCl}(s)
$$

Given moles (or more commonly the mass) of Na , and information regarding temperature and pressure, we can determine the volume of $\mathrm{Cl}_{2}$ required to react completely:

Sample Problem 11.9 shows how to use the ideal gas equation in a stoichiometric analysis.

## Sample Problem 11.9

Sodium peroxide $\left(\mathrm{Na}_{2} \mathrm{O}_{2}\right)$ is used to remove carbon dioxide from (and add oxygen to) the air supply in spacecrafts. It works by reacting with $\mathrm{CO}_{2}$ in the air to produce sodium carbonate $\left(\mathrm{Na}_{2} \mathrm{CO}_{3}\right)$ and $\mathrm{O}_{2}$.

$$
2 \mathrm{Na}_{2} \mathrm{O}_{2}(s)+2 \mathrm{CO}_{2}(g) \longrightarrow 2 \mathrm{Na}_{2} \mathrm{CO}_{3}(s)+\mathrm{O}_{2}(g)
$$

What volume (in liters) of $\mathrm{CO}_{2}$ (at STP ) will react with a kilogram of $\mathrm{Na}_{2} \mathrm{O}_{2}$ ?
Strategy Convert the given mass of $\mathrm{Na}_{2} \mathrm{O}_{2}$ to moles, use the balanced equation to determine the stoichiometric amount of $\mathrm{CO}_{2}$, and then use the ideal gas equation to convert moles of $\mathrm{CO}_{2}$ to liters.

Setup The molar mass of $\mathrm{Na}_{2} \mathrm{O}_{2}$ is $77.98 \mathrm{~g} / \mathrm{mol}(1 \mathrm{~kg}=1000 \mathrm{~g})$. (Treat the specified mass of $\mathrm{Na}_{2} \mathrm{O}_{2}$ as an exact number.)

Think About It The answer may seems like an enormous volume of $\mathrm{CO}_{2}$. If you check the cancellation of units carefully in ideal gas equation problems, however, with practice you will develop a sense of whether such a calculated volume is reasonable.

## Solution

$$
\begin{aligned}
& 1000 \mathrm{~g} \mathrm{Na}_{2} \mathrm{O}_{2} \times \frac{1 \mathrm{~mol} \mathrm{Na}_{2} \mathrm{O}_{2}}{77.98 \mathrm{~g} \mathrm{Na}_{2} \mathrm{O}_{2}}=12.82 \mathrm{~mol} \mathrm{Na}_{2} \mathrm{O}_{2} \\
& 12.82 \mathrm{molNa}_{2} \mathrm{O}_{2} \times \frac{2 \mathrm{~mol} \mathrm{CO}_{2}}{2 \mathrm{~mol} \mathrm{Na}_{2} \mathrm{O}_{2}}=12.82 \mathrm{~mol} \mathrm{CO}_{2} \\
&\left.V_{\mathrm{CO}_{2}}=\frac{(12.82 \mathrm{~mol} \mathrm{CO}}{2}\right)(0.08206 \mathrm{~L} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{~mol})(273.15 \mathrm{~K}) \\
& 1 \mathrm{~atm}=287.4 \mathrm{~L} \mathrm{CO}_{2}
\end{aligned}
$$

Practice Problem A What volume (in liters) of $\mathrm{CO}_{2}$ can be consumed at STP by $525 \mathrm{~g} \mathrm{Na}_{2} \mathrm{O}_{2}$ ?
EPractice Problem B What mass (in grams) of $\mathrm{Na}_{2} \mathrm{O}_{2}$ is necessary to consume $1.00 \mathrm{~L} \mathrm{CO}_{2}$ at STP?

## Determining the Amount of Reactant Consumed Using Change in Pressure

Although none of the empirical gas laws focuses on the relationship between $n$ and $P$ explicitly, we can rearrange the ideal gas equation to show that $n$ is directly proportional to $P$ at constant $V$ and $T$ :

$$
\text { Equation 11.12(a) } \quad n=P \times\left(\frac{V}{R T}\right) \quad \text { (at constant } V \text { and } T \text { ) }
$$

Therefore, we can use the change in pressure in a reaction vessel to determine how many moles of a gaseous reactant are consumed in a chemical reaction:

Equation 11.12(b)

$$
\Delta n=\Delta P \times\left(\frac{V}{R T}\right) \quad(\text { at constant } V \text { and } T)
$$

where $\Delta n$ is the number of moles of gas consumed and $\Delta P$ is the change in pressure in the reaction vessel. Sample Problem 11.10 shows how to use Equation 11.12(b).

## Sample Problem 11.10

Another air-purification method for enclosed spaces involves the use of "scrubbers" containing aqueous lithium hydroxide, which reacts with carbon dioxide to produce lithium carbonate and water:

$$
2 \mathrm{LiOH}(a q)+\mathrm{CO}_{2}(g) \longrightarrow \mathrm{Li}_{2} \mathrm{CO}_{3}(s)+\mathrm{H}_{2} \mathrm{O}(l)
$$

Consider the air supply in a submarine with a total volume of $2.5 \times 10^{5} \mathrm{~L}$. The pressure is 0.9970 atm , and the temperature is $25^{\circ} \mathrm{C}$. If the pressure in the submarine drops to 0.9891 atm as the result of carbon dioxide being consumed by an aqueous lithium hydroxide scrubber, how many moles of $\mathrm{CO}_{2}$ are consumed?

Strategy Use Equation $11.12(\mathrm{~b})$ to determine $\Delta n$, the number of moles of $\mathrm{CO}_{2}$ consumed.
Setup $\Delta P=0.9970 \mathrm{~atm}-0.9891 \mathrm{~atm}=7.9 \times 10^{-3} \mathrm{~atm}$. According to the problem statement, $V=2.5 \times 10^{5} \mathrm{~L}$ and $T=298.15 \mathrm{~K}$. For problems in which $P$ is expressed in atmospheres and $V$ in liters, use $R=0.08206 \mathrm{~L} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{mol}$.

## Solution

$$
\Delta n_{\mathrm{CO}_{2}}=7.9 \times 10^{-3} \mathrm{~atm} \times \frac{2.5 \times 10^{5} \mathrm{~L}}{(0.08206 \mathrm{~L} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{~mol}) \times(298.15 \mathrm{~K})}=81 \text { moles } \mathrm{CO}_{2} \text { consumed }
$$

Practice Problem A Using all the same conditions as those described in Sample Problem 11.10, calculate the number of moles of $\mathrm{CO}_{2}$ consumed if the pressure drops by 0.010 atm .

EPractice Problem B By how much would the pressure in the submarine drop if 2.55 kg of LiOH were completely consumed by reaction with $\mathrm{CO}_{2}$ ? (Assume the same starting $P, V$, and $T$ as in Sample Problem 11.10.)

## Predicting the Volume of a Gaseous Product

Using a combination of stoichiometry and the ideal gas equation, we can calculate the volume of gas that we expect to be produced in a chemical reaction. We first use stoichiometry to determine the number of moles produced, and then apply the ideal gas equation to determine what volume will be occupied by that number of moles under the specified conditions.

Sample Problem 11.11 shows how to predict the volume of a gaseous product.

## Sample Problem 11.11

The air bags in cars are inflated when a collision triggers the explosive, highly exothermic decomposition of sodium azide $\left(\mathrm{NaN}_{3}\right)$ :

$$
2 \mathrm{NaN}_{3}(s) \longrightarrow 2 \mathrm{Na}(s)+3 \mathrm{~N}_{2}(g)
$$

A typical driver-side air bag contains about 50 g of $\mathrm{NaN}_{3}$. Determine the volume of $\mathrm{N}_{2}$ gas that would be generated by the decomposition of 50.0 g of sodium azide at $85.0^{\circ} \mathrm{C}$ and 1.00 atm .

Strategy Convert the given mass of $\mathrm{NaN}_{3}$ to moles, use the ratio of the coefficients from the balanced chemical equation to determine the corresponding number of moles of $\mathrm{N}_{2}$ produced, and then use the ideal gas equation to determine the volume of that number of moles at the specified temperature and pressure.

Setup The molar mass of $\mathrm{NaN}_{3}$ is $65.02 \mathrm{~g} / \mathrm{mol}$.
Solution

$$
\begin{gathered}
\mathrm{mol} \mathrm{NaN}_{3}=\frac{50.0 \mathrm{~g} \mathrm{NaN}_{3}}{65.02 \mathrm{~g} / \mathrm{mol}}=0.769 \mathrm{~mol} \mathrm{NaN}_{3} \\
0.769 \mathrm{~mol} \mathrm{NaN}_{3} \times\left(\frac{3 \mathrm{~mol} \mathrm{~N}_{2}}{2 \mathrm{~mol} \mathrm{NaN}_{3}}\right)=1.15 \mathrm{~mol} \mathrm{~N}_{2} \\
V_{\mathrm{N}_{2}}=\frac{\left(1.15 \mathrm{~mol} \mathrm{~N}_{2}\right)(0.08206 \mathrm{~L} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{~mol})(358.15 \mathrm{~K})}{1 \mathrm{~atm}}=33.9 \mathrm{~L} \mathrm{~N}_{2}
\end{gathered}
$$

Practice Problem A The chemical equation for the metabolic breakdown of glucose $\left(\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}\right)$ is the same as that for the combustion of glucose [ 14 Section 3.3-Bringing Chemistry to Life box]:

$$
\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}(a q)+6 \mathrm{O}_{2}(g) \longrightarrow 6 \mathrm{CO}_{2}(g)+6 \mathrm{H}_{2} \mathrm{O}(l)
$$

Calculate the volume of $\mathrm{CO}_{2}$ produced at normal human body temperature $\left(37^{\circ} \mathrm{C}\right)$ and 1.00 atm when 10.0 g of glucose is consumed in the reaction.

GIPractice Problem B The passenger-side air bag in a typical car must fill a space approximately four times as large as the driver-side air bag to be effective. Calculate the mass of sodium azide required to fill a $125-\mathrm{L}$ air bag at $85.0^{\circ} \mathrm{C}$ and 1.00 atm .

## Checkpoint 11.4 Reactions with Gaseous Reactants and Products

11.4.1 Determine the volume of $\mathrm{Cl}_{2}$ gas at STP that will react with 1.00 mole of Na solid to produce NaCl according to the equation,

$$
2 \mathrm{Na}(s)+\mathrm{Cl}_{2}(g) \longrightarrow 2 \mathrm{NaCl}(s)
$$

a) 22.4 L
b) 44.8 L
c) 15.3 L
d) 11.2 L
e) 30.6 L
d) 664 g
e) 442 g

Think About It The calculated volume represents the space between the driver and the steering wheel and dashboard that must be filled by the air bag to prevent injury. Air bags also contain an oxidant that consumes the sodium metal produced in the reaction.

### 11.5 Gas Mixtures

So far our discussion of the physical properties of gases has focused on the behavior of pure gaseous substances, even though the gas laws were all developed based on observations of samples of air, which is a mixture of gases. In this section, we will consider gas mixtures and their physical behavior. We will restrict our discussion in this section to gases that behave ideally and that do not react with one another.

## Dalton's Law of Partial Pressures

When two or more gaseous substances are placed in a container, each gas behaves as though it occupies the container alone. For example, if we place 1.00 mole of $\mathrm{N}_{2}$ gas in a $5.00-\mathrm{L}$ container at $0^{\circ} \mathrm{C}$, it exerts a pressure of

$$
P=\frac{(1.00 \mathrm{~mol})(0.08206 \mathrm{~L} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{~mol})(273.15 \mathrm{~K})}{5.00 \mathrm{~L}}=4.48 \mathrm{~atm}
$$

If we then add a mole of another gas, such as $\mathrm{O}_{2}$, the pressure exerted by $\mathrm{N}_{2}$ does not change. It remains at 4.48 atm . The $\mathrm{O}_{2}$ gas exerts its own pressure, also 4.48 atm . Neither gas is affected by the presence of the other. In a mixture of gases, the pressure exerted by each gas is known as the partial pressure $\left(\boldsymbol{P}_{\mathrm{i}}\right)$ of the gas. We use subscripts to denote partial pressures:

$$
\begin{aligned}
& P_{\mathrm{N}_{2}}=\frac{(1.00 \mathrm{~mol})(0.08206 \mathrm{~L} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{~mol})(273.15 \mathrm{~K})}{5.00 \mathrm{~L}}=4.48 \mathrm{~atm} \\
& P_{\mathrm{O}_{2}}=\frac{(1.00 \mathrm{~mol})(0.08206 \mathrm{~L} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{~mol})(273.15 \mathrm{~K})}{5.00 \mathrm{~L}}=4.48 \mathrm{~atm}
\end{aligned}
$$

and we can solve the ideal gas equation for each component of any gas mixture:

$$
P_{\mathrm{i}}=\frac{n_{\mathrm{i}} R T}{V}
$$

Dalton's law of partial pressures states that the total pressure exerted by a gas mixture is the sum of the partial pressures exerted by each component of the mixture:

$$
P_{\text {total }}=\Sigma P_{\mathrm{i}}
$$

Thus, the total pressure exerted by a mixture of $1.00 \mathrm{~mol} \mathrm{~N}_{2}$ and $1.00 \mathrm{~mol} \mathrm{O}_{2}$ in a $5.00-\mathrm{L}$ vessel at $0^{\circ} \mathrm{C}$ is

$$
P_{\text {total }}=P_{\mathrm{N}_{2}}+P_{\mathrm{O}_{2}}=4.48 \mathrm{~atm}+4.48 \mathrm{~atm}=8.96 \mathrm{~atm}
$$

Figure 11.13 illustrates Dalton's law of partial pressures.

Figure 11.13 Schematic illustration of Dalton's law of partial pressures. Total pressure is equal to the sum of partial pressures.

Sample Problem 11.12 shows how to apply Dalton's law of partial pressures.

## Sample Problem 11.12

A 1.00-L vessel contains 0.215 mole of $\mathrm{N}_{2}$ gas and 0.0118 mole of $\mathrm{H}_{2}$ gas at $25.5^{\circ} \mathrm{C}$. Determine the partial pressure of each component and the total pressure in the vessel.

Strategy Use the ideal gas equation to find the partial pressure of each component of the mixture, and sum the two partial pressures to find the total pressure.

Setup $T=298.65 \mathrm{~K}$.
Solution

$$
\begin{aligned}
& P_{\mathrm{N}_{2}}=\frac{(0.215 \mathrm{~mol})\left(\frac{0.08206 \mathrm{~L} \cdot \mathrm{~atm}}{\mathrm{~K} \cdot \mathrm{~mol}}\right)(298.65 \mathrm{~K})}{1.00 \mathrm{~L}}=5.27 \mathrm{~atm} \\
& P_{\mathrm{H}_{2}}=\frac{(0.0118 \mathrm{~mol})\left(\frac{0.08206 \mathrm{~L} \cdot \mathrm{~atm}}{\mathrm{~K} \cdot \mathrm{~mol}}\right)(298.65 \mathrm{~K})}{1.00 \mathrm{~L}}=0.289 \mathrm{~atm} \\
& P_{\text {total }}=P_{\mathrm{N}_{2}}+P_{\mathrm{H}_{2}}=5.27 \mathrm{~atm}+0.289 \mathrm{~atm}=5.56 \mathrm{~atm}
\end{aligned}
$$

Practice Problem A Determine the partial pressures and the total pressure in a 2.50-L vessel containing the following mixture of gases at $15.8^{\circ} \mathrm{C}: 0.0194 \mathrm{~mol}$ $\mathrm{He}, 0.0411 \mathrm{~mol} \mathrm{H}_{2}$, and 0.169 mol Ne .

HPractice Problem B Determine the number of moles of each gas present in a mixture of $\mathrm{CH}_{4}$ and $\mathrm{C}_{2} \mathrm{H}_{6}$ in a $2.00-\mathrm{L}$ vessel at $25.0^{\circ} \mathrm{C}$ and 1.50 atm , given that

Think About It The total pressure in the vessel can also be determined by summing the number of moles of mixture components $(0.215+0.0118=0.227 \mathrm{~mol})$ and solving the ideal gas equation for $P_{\text {total }}$ :

$$
P_{\text {total }}=\frac{(0.227 \mathrm{~mol})\left(\frac{0.08206 \mathrm{~L} \cdot \mathrm{~atm}}{\mathrm{~K} \cdot \mathrm{~mol}}\right)(298.65 \mathrm{~K})}{1.00 \mathrm{~L}}=5.56 \mathrm{~atm}
$$

## Mole Fractions

The relative amounts of the components of a gas mixture can be specified using mole fractions. The mole fraction ( $\boldsymbol{\chi}_{\boldsymbol{i}}$ ) of a component of a mixture is the number of moles of the component divided by the total number of moles in the mixture:

$$
\begin{equation*}
\chi_{\mathrm{i}}=\frac{n_{\mathrm{i}}}{n_{\text {total }}} \tag{Equation 11.13}
\end{equation*}
$$

Student Annotation: Mole fractions do not refer only to gas mixtures. They can be used to specify the concentrations of components of mixtures in any phase. Mole fractions are used extensively in Chapter 12.

There are three things to remember about mole fractions:

1. The mole fraction of a mixture component is always less than 1 .
2. The sum of mole fractions for all components of a mixture is always 1 .
3. Mole fraction is dimensionless.

In addition, $n$ and $P$ are proportional [Equation 11.12(a)] at a specified $T$ and $V$, so we can determine mole fraction by dividing the partial pressure of a component by the total pressure:

$$
\begin{equation*}
\chi_{\mathrm{i}}=\frac{P_{\mathrm{i}}}{P_{\text {total }}} \tag{Equation 11.14}
\end{equation*}
$$

Rearranging Equations 11.13 and 11.14 gives

$$
\begin{equation*}
\chi_{\mathrm{i}} \times n_{\text {total }}=n_{\mathrm{i}} \tag{Equation 11.15}
\end{equation*}
$$

and

$$
\begin{equation*}
\chi_{\mathrm{i}} \times P_{\text {total }}=P_{\mathrm{i}} \tag{Equation 11.16}
\end{equation*}
$$

Think About It To check your work, determine $\chi_{N_{2}}$ by subtracting $\chi_{\text {No }}$ from 1. Using each mole fraction and the total pressure, calculate the partial pressure of each component using Equation 11.16 and verify that they sum to the total pressure.

Sample Problem 11.13 lets you practice calculations involving mole fractions, partial pressures, and total pressure.

## Sample Problem 11.13

In 1999, the FDA approved the use of nitric oxide (NO) to treat and prevent lung disease, which occurs commonly in premature infants. The nitric oxide used in this therapy is supplied to hospitals in the form of a $\mathrm{N}_{2} / \mathrm{NO}$ mixture. Calculate the mole fraction of NO in a 10.00-L gas cylinder at room temperature $\left(25^{\circ} \mathrm{C}\right)$ that contains $6.022 \mathrm{~mol} \mathrm{~N}_{2}$ and in which the total pressure is 14.75 atm .

Strategy Use the ideal gas equation to calculate the total number of moles in the cylinder. Subtract moles of $\mathrm{N}_{2}$ from the total to determine moles of NO. Divide moles NO by total moles to get mole fraction (Equation 11.14).

Setup The temperature is 298.15 K .

## Solution

$$
\begin{aligned}
\text { total moles } & =\frac{P V}{R T}=\frac{(14.75 \mathrm{~atm})(10.00 \mathrm{~L})}{\left(\frac{0.08206 \mathrm{~L} \cdot \mathrm{~atm}}{\mathrm{~K} \cdot \mathrm{~mol}}\right)(298.15 \mathrm{~K})}=6.029 \mathrm{~mol} \\
\mathrm{~mol} \mathrm{NO} & =\text { total moles }-\mathrm{mol} \mathrm{~N}_{2}=6.029-6.022=0.007 \mathrm{~mol} \mathrm{NO} \\
\chi_{\mathrm{NO}} & =\frac{n_{\mathrm{NO}}}{n_{\text {total }}}=\frac{0.007 \mathrm{~mol} \mathrm{NO}}{6.029 \mathrm{~mol}}=0.001
\end{aligned}
$$

Practice Problem A Determine the mole fractions and partial pressures of $\mathrm{CO}_{2}, \mathrm{CH}_{4}$, and He in a sample of gas that contains 0.250 mole of $\mathrm{CO}_{2}, 1.29$ moles of $\mathrm{CH}_{4}$, and 3.51 moles of He , and in which the total pressure is 5.78 atm .
\$Practice Problem B Determine the partial pressure and number of moles of each gas in a $15.75-\mathrm{L}$ vessel at $30.0^{\circ} \mathrm{C}$ containing a mixture of xenon and neon gases only. The total pressure in the vessel is 6.50 atm , and the mole fraction of xenon is 0.761 .

## Using Partial Pressures to Solve Problems

The volume of gas produced by a chemical reaction can be measured using an apparatus like the one shown in Figure 11.14. Dalton's law of partial pressures is useful in the analysis of these kinds of experimental results. For example, the decomposition of potassium chlorate $\left(\mathrm{KClO}_{3}\right)$, the reaction used to generate emergency oxygen supplies on airplanes, produces potassium chloride and oxygen:

$$
2 \mathrm{KClO}_{3}(s) \longrightarrow 2 \mathrm{KCl}(s)+3 \mathrm{O}_{2}(g)
$$

The oxygen gas is collected over water, as shown in Figure 11.14(a). The volume of water displaced by the gas is equal to the volume of gas produced. (Prior to reading the volume of the gas, the level of the graduated cylinder must be adjusted such that the water levels inside and outside the cylinder are the same. This ensures that the pressure inside the graduated cylinder is the same as atmospheric pressure [Figure 11.14(b)].) However, because the measured volume contains both the oxygen produced by the reaction and water vapor, the pressure exerted inside the graduated cylinder is the sum of the two partial pressures:

$$
P_{\text {total }}=P_{\mathrm{O}_{2}}+P_{\mathrm{H}_{2} \mathrm{O}}
$$

By subtracting the partial pressure of water from the total pressure, which is equal to atmospheric pressure, we can determine the partial pressure of oxygen-and thereby determine how many moles are produced by the reaction. We get the partial pressure of water, which depends on temperature, from a table of values. Table 11.5 lists the partial pressure (also known as the vapor pressure) of water at various temperatures.

Sample Problem 11.14 shows how to use Dalton's law of partial pressures to determine the amount of gas produced in a chemical reaction and collected over water.

Figure 11.14 (a) Apparatus for measuring the amount of gas produced in a chemical reaction. (b) When the water levels inside and outside the collection vessel are the same, the pressure inside the vessel is equal to atmospheric pressure.

## TABLE 11.5 Vapor Pressure of Water $\left(P_{\mathrm{H}_{2} \mathrm{O}}\right)$ as a Function of Temperature

| $\boldsymbol{T}\left({ }^{\circ} \mathbf{C}\right)$ | $\boldsymbol{P}$ (torr) | $\boldsymbol{T}\left({ }^{\circ} \mathbf{C}\right)$ | $\boldsymbol{P}$ (torr) | $\boldsymbol{T}\left({ }^{\circ} \mathrm{C}\right)$ | $\boldsymbol{P}$ (torr) |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 0 | 4.6 | 35 | 42.2 | 70 | 233.7 |
| 5 | 6.5 | 40 | 55.3 | 75 | 289.1 |
| 10 | 9.2 | 45 | 71.9 | 80 | 355.1 |
| 15 | 12.8 | 50 | 92.5 | 85 | 433.6 |
| 20 | 17.5 | 55 | 118.0 | 90 | 525.8 |
| 25 | 23.8 | 60 | 149.4 | 95 | 633.9 |
| 30 | 31.8 | 65 | 187.5 | 100 | 760.0 |

## Sample Problem 11.14

Calcium metal reacts with water to produce hydrogen gas [144 Section 7.7]:

$$
\mathrm{Ca}(s)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{Ca}(\mathrm{OH})_{2}(a q)+\mathrm{H}_{2}(g)
$$

Determine the mass of $\mathrm{H}_{2}$ produced at $25^{\circ} \mathrm{C}$ and 0.967 atm when 525 mL of the gas is collected over water as shown in Figure 11.14.

Strategy Use Dalton's law of partial pressures to determine the partial pressure of $\mathrm{H}_{2}$, use the ideal gas equation to determine moles of $\mathrm{H}_{2}$, and then use the molar mass of $\mathrm{H}_{2}$ to convert to mass. (Pay careful attention to units. Atmospheric pressure is given in atmospheres, whereas the vapor pressure of water is tabulated in torr.)

Setup $V=0.525 \mathrm{~L}$ and $T=298.15 \mathrm{~K}$. The partial pressure of water at $25^{\circ} \mathrm{C}$ is 23.8 torr (Table 11.5) or 23.8 torr $(1 \mathrm{~atm} / 760 \mathrm{torr})=0.0313 \mathrm{~atm}$. The molar mass of $\mathrm{H}_{2}$ is $2.016 \mathrm{~g} / \mathrm{mol}$.

## Solution

$$
\begin{aligned}
P_{\mathrm{H}_{2}} & =P_{\text {total }}-P_{\mathrm{H}_{2} \mathrm{O}}=0.967 \mathrm{~atm}-0.0313 \mathrm{~atm}=0.936 \mathrm{~atm} \\
\text { moles of } \mathrm{H}_{2} & =\frac{(0.9357 \mathrm{~atm})(0.525 \mathrm{~L})}{\left(\frac{0.08206 \mathrm{~L} \cdot \mathrm{~atm}}{\mathrm{~K} \cdot \mathrm{~mol}}\right)(298.15 \mathrm{~K})}=2.01 \times 10^{-2} \mathrm{~mol} \\
\text { mass of } \mathrm{H}_{2} & =\left(2.008 \times 10^{-2} \mathrm{~mol}\right)(2.016 \mathrm{~g} / \mathrm{mol})=0.0405 \mathrm{~g} \mathrm{H}_{2}
\end{aligned}
$$

Think About It Check unit cancellation carefully, and remember that the densities of gases are relatively low. The mass of approximately half a liter of hydrogen at or near room temperature and 1 atm should be a very small number.

Media Player/MPEG Animation: Figure 11.15, Molar Volume of a Gas, pp. 468-469.

Student Annotation: One unfortunate group of patients was undergoing treatment when the power to the chamber was shut off accidentally. All the patients died. At the time, their deaths were attributed to influenza, but they almost certainly died as the result of the unintended rapid decompression.

Catalina hyperbaric chamber

## Think About It Monoplace

 hyperbaric chambers, which are large enough to accommodate only one person, commonly are pressurized to 2.8 atm with pure $\mathrm{O}_{2}$.Practice Problem A Calculate the mass of $\mathrm{O}_{2}$ produced by the decomposition of $\mathrm{KClO}_{3}$ when 821 mL of $\mathrm{O}_{2}$ is collected over water at $30.0^{\circ} \mathrm{C}$ and 1.015 atm .

EPractice Problem B Determine the volume of gas collected over water when $0.501 \mathrm{~g} \mathrm{O}_{2}$ is produced by the decomposition of $\mathrm{KClO}_{3}$ at $35.0^{\circ} \mathrm{C}$ and 1.08 atm .

Collection over water can also be used to determine the molar volume of a gas generated in a chemical reaction as shown in Figure 11.15.

## Bringing Chemistry to Life

## Hyperbaric Oxygen Therapy

In 1918, during the Spanish flu epidemic that claimed tens of millions of lives worldwide, physician Orville Cunningham noted that people living at lower elevations appeared to have a greater chance of surviving the flu than those living at higher elevations. Believing this to be the result of increased air pressure, he developed a hyperbaric chamber to treat flu victims. One of Cunningham's earliest and most notable successes was the recovery of a flu-stricken colleague who had been near death. Cunningham subsequently built a hyperbaric chamber large enough to accommodate dozens of patients and treated numerous flu victims, most with success.

In the decades following the Spanish flu epidemic, hyperbaric therapy fell out of favor with the medical community and was largely discontinued. Interest in it was revived when the U.S. military ramped up its underwater activities in the 1940s and hyperbaric chambers were constructed to treat military divers suffering from decompression sickness (DCS), also known as "the bends." Significant advancement in hyperbaric methods began in the 1970s when the Undersea Medical Society (renamed the Undersea and Hyperbaric Medical Society in 1976) became involved in the clinical use of hyperbaric chambers. Today, hyperbaric oxygen therapy (HBOT) is used to treat a wide variety of conditions, including carbon monoxide poisoning, anemia caused by critical blood loss, severe burns, and life-threatening bacterial infections. Once considered an "alternative" therapy and viewed with skepticism, HBOT is now covered by most insurance plans.

Sample Problem 11.15 illustrates the importance of mole fractions and partial pressures in hyperbaric oxygen therapy.

## Sample Problem 11.15

The Catalina hyperbaric chamber at the University of Southern California's Wrigley Marine Science Center treats mostly victims of diving accidents. In one treatment protocol, the chamber is pressurized to 6.0 atm with compressed air and the patient breathes a mixture of gases that is 47 percent $\mathrm{O}_{2}$ by volume. In another protocol, the chamber is pressurized with compressed air to 2.8 atm and the patient breathes pure $\mathrm{O}_{2}$. Determine the partial pressure of $\mathrm{O}_{2}$ in each treatment protocol and compare the results.

Strategy Because the gas the patient breathes is inside the hyperbaric chamber, its total pressure is the same as the chamber pressure. To obtain the partial pressure of $\mathrm{O}_{2}$, multiply the mole fraction of $\mathrm{O}_{2}$ in the breathing gas in each protocol by the total pressure (Equation 11.16).

Setup In the first protocol, the breathing gas is 47 percent $\mathrm{O}_{2}$, so the mole fraction of $\mathrm{O}_{2}$ is 0.47 . In the second protocol, where pure $\mathrm{O}_{2}$ is used, the mole fraction of $\mathrm{O}_{2}$ is 1 . Use Equation 11.16 to calculate the partial pressure of $\mathrm{O}_{2}$ in each protocol.

$$
\chi_{\mathrm{i}} \times P_{\text {total }}=P_{\mathrm{i}}
$$

Solution In the first protocol, the pressure of $\mathrm{O}_{2}$ is

$$
0.47 \times 6.0 \mathrm{~atm}=2.8 \mathrm{~atm}
$$

In the second protocol, the pressure of $\mathrm{O}_{2}$ is

$$
1 \times 2.8 \mathrm{~atm}=2.8 \mathrm{~atm}
$$

Both protocols produce the same pressure of $\mathrm{O}_{2}$.

Practice Problem A What mole fraction of $\mathrm{O}_{2}$ is necessary for the partial pressure of $\mathrm{O}_{2}$ to be 2.8 atm when the total pressure is 4.6 atm ?

EPractice Problem B What chamber pressure would be required for a patient to receive the therapeutic partial pressure of $\mathrm{O}_{2}(2.8 \mathrm{~atm})$ without breathing a special mixture of gases through a mask? Assume that the air used to pressurize the chamber is 21 percent $\mathrm{O}_{2}$ by volume.

## Checkpoint 11.5 Gas Mixtures

11.5.1 What is the partial pressure of He in a $5.00-\mathrm{L}$ vessel at $25^{\circ} \mathrm{C}$ that contains 0.0410 mole of $\mathrm{He}, 0.121$ mole of Ne , and 0.0922 mole of Ar?
a) 1.24 atm
b) 0.248 atm
c) 0.117 atm
d) 2.87 atm
e) 0.201 atm
11.5.2 What is the mole fraction of $\mathrm{CO}_{2}$ in a mixture of 0.756 mole of $\mathrm{N}_{2}, 0.189$ mole of $\mathrm{O}_{2}$, and 0.0132 mole of $\mathrm{CO}_{2}$ ?
a) 0.789
b) 0.0138
c) 0.0140
d) 1.003
e) 0.798
11.5.3 What is the partial pressure of oxygen in a gas mixture that contains 4.10 moles of oxygen, 2.38 moles of nitrogen, and 0.917 mole of carbon dioxide and that has a total pressure of 2.89 atm ?
a) 1.60 atm
b) 3.59 atm
c) 0.391 atm
d) 0.705 atm
e) 0.624 atm
11.5.4 What mass of acetylene $\left(\mathrm{C}_{2} \mathrm{H}_{2}\right)$ is produced by the reaction of calcium carbide $\left(\mathrm{CaC}_{2}\right)$ and water,

$$
\mathrm{CaC}_{2}(s)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{C}_{2} \mathrm{H}_{2}(g)+\mathrm{Ca}(\mathrm{OH})_{2}(a q)
$$

if 425 mL of the gas is collected over water at $30^{\circ} \mathrm{C}$ and a pressure of 0.996 atm ?
a) 0.016 g
b) 16.3 g
c) 0.019 g
d) 0.424 g
e) 0.443 g
11.5.5 In the diagram, each color represents a different gas molecule. Calculate the mole fraction of each gas.

a) $\chi_{\text {red }}=0.5, \chi_{\text {blue }}=0.4, \chi_{\text {green }}=0.7$
b) $\chi_{\text {red }}=0.05, \chi_{\text {blue }}=0.07, \chi_{\text {green }}=0.07$
c) $\chi_{\text {red }}=0.3125, \chi_{\text {blue }}=0.25, \chi_{\text {green }}=0.4375$
d) $\chi_{\text {red }}=0.4167, \chi_{\text {blue }}=0.333, \chi_{\text {green }}=0.5833$
e) $\chi_{\text {red }}=0.333, \chi_{\text {blue }}=0.333, \chi_{\text {green }}=0.333$
11.5.6 Calculate the partial pressure of each gas in the diagram in question 11.5 .5 if the total pressure is 8.21 atm .
a) $P_{\text {red }}=0.5 \mathrm{~atm}, P_{\text {blue }}=0.25 \mathrm{~atm}, P_{\text {green }}=4.5 \mathrm{~atm}$
b) $P_{\text {red }}=2.57 \mathrm{~atm}, P_{\text {blue }}=2.05 \mathrm{~atm}, P_{\text {green }}=3.59 \mathrm{~atm}$
c) $P_{\text {red }}=3.13 \mathrm{~atm}, P_{\text {blue }}=2.50 \mathrm{~atm}, P_{\text {green }}=2.58 \mathrm{~atm}$
d) $P_{\text {red }}=2.74 \mathrm{~atm}, P_{\text {blue }}=2.74 \mathrm{~atm}, P_{\text {green }}=2.74 \mathrm{~atm}$
e) $P_{\text {red }}=3.125 \mathrm{~atm}, P_{\text {blue }}=2.500 \mathrm{~atm}, P_{\text {green }}=4.375 \mathrm{~atm}$

Figure 11.15

## Molar Volume of a Gas

The reaction between zinc and hydrochloric acid produces hydrogen gas. The net ionic equation for the reaction is

$$
\mathrm{Zn}(s)+2 \mathrm{H}^{+}(a q) \longrightarrow \mathrm{Zn}^{2+}(a q)+\mathrm{H}_{2}(g)
$$

The $\mathrm{H}_{2}$ gas evolved in the reaction is collected in the inverted graduated cylinder. Using the balanced equation, we determine how much $\mathrm{H}_{2}$ will be produced.

$$
\begin{aligned}
& 0.072 \mathrm{gZn} \times \frac{1 \mathrm{~mol} \mathrm{Zn}}{65.41 \mathrm{gZn}}=0.0011 \mathrm{~mol} \mathrm{Zn} \\
& 0.0011 \mathrm{molZn} \times \frac{1 \mathrm{~mol} \mathrm{H}_{2}}{1 \mathrm{motZn}}=0.0011 \mathrm{~mol} \mathrm{H}_{2}
\end{aligned}
$$

The reservoir is inverted and the zinc drops into the 1.0 MHCl .

A $0.072-\mathrm{g}$ sample of zinc is placed in the reservoir. The vessel contains approximately 5 mL of 1.0 M HCl . A graduated cylinder is filled with water and inverted over the tubing to collect the gas produced by the reaction of zinc and acid. The temperature of the water is $25.0^{\circ} \mathrm{C}$ and the pressure in the room is 748.0 torr.

Zn is the limiting reactant. When all of the zinc has been consumed, the reaction is complete and no more gas is evolved.

We adjust the level of the graduated cylinder to make the water level the same inside and outside of the cylinder. This lets us know that the pressure inside the cylinder is the same as the pressure in the room. When the water levels are the same, we can read the volume of gas collected, which is 26.5 mL .

The pressure inside the cylinder is the sum of two partial pressures: that of the collected $\mathrm{H}_{2}$, and that of water vapor. To determine the partial pressure of $\mathrm{H}_{2}$, which is what we want, we must subtract the vapor pressure of water from the total pressure. Table 11.5 gives the vapor pressure of water at $25.0^{\circ} \mathrm{C}$ as 23.8 torr. Therefore, the pressure of $\mathrm{H}_{2}$ is $748.0-23.8=724.2$ torr. Using Equation 11.8(b),

$$
\frac{P_{1} V_{1}}{T_{1}}=\frac{P_{2} V_{2}}{T_{2}}
$$

we calculate the volume the $\mathrm{H}_{2}$ gas would occupy at STP.

$$
\begin{gathered}
\frac{(724.2 \text { torr })(26.5 \mathrm{~mL})}{298.15 \mathrm{~K}}=\frac{(760 \text { torr }) V_{2}}{273.15 \mathrm{~K}} \\
V_{2}=\frac{(724.2 \text { torा })(26.5 \mathrm{~mL})(273.15 \mathrm{~K})}{(760 \mathrm{trf})(298.15 \mathrm{~K})}=23.13 \mathrm{~mL}
\end{gathered}
$$

This is the volume of $0.0011 \mathrm{~mol} \mathrm{H}_{2}$. The molar volume is

$$
\frac{23.13 \mathrm{~mL}}{0.0011 \mathrm{~mol}}=2.1 \times 10^{4} \mathrm{~mL} / \mathrm{mol} \text { or } 21 \mathrm{~L} / \mathrm{mol}
$$

## What's the point?

The gas collected in the graduated cylinder is a mixture of the gas produced by the reaction and water vapor. We determine the pressure of the gas produced by the reaction by subtracting the tabulated partial pressure of water from the total pressure.
Knowing the volume, pressure, and temperature of a sample of gas, in this case $\mathrm{H}_{2}$, we can determine what volume the same sample of gas would occupy at STP. This enables us to determine experimentally the molar volume of $\mathrm{H}_{2}$ at STP , which turns out to be fairly close to the accepted value of 22.4 L . Several sources of error, including uncertainty in the volume of the collected gas, contribute to the result not being exactly 22.4 L .

### 11.6 The Kinetic Molecular Theory of Gases

The gas laws were derived empirically, and they enable us to predict the macroscopic behavior of gases. They do not explain, however, why gases behave as they do. The kinetic molecular theory, which was put forth in the nineteenth century by a number of physicists, notably Ludwig Boltzmann ${ }^{6}$ and James Maxwell, ${ }^{7}$ explains how the molecular nature of gases gives rise to their macroscopic properties. The basic assumptions of the kinetic molecular theory are as follows:

1. A gas is composed of particles that are separated by relatively large distances. The volume occupied by individual molecules is negligible.
2. Gas molecules are constantly in random motion, moving in straight paths, colliding with the walls of their container and with one another in perfectly elastic collisions. (Energy is transferred but not lost in the collisions.)
3. Gas molecules do not exert attractive or repulsive forces on one another.
4. The average kinetic energy, $\overline{E_{\mathrm{k}}}$, of gas molecules in a sample is proportional to the absolute temperature:

$$
\overline{E_{\mathrm{k}}} \propto T
$$

Recall that kinetic energy is the energy associated with motion [14 Section 5.1]:

$$
E_{\mathrm{k}}=\frac{1}{2} m u^{2}
$$

Thus, the kinetic energy of an individual gas molecule is proportional to its mass and its velocity squared. When we talk about a group of gas molecules, we determine the average kinetic energy using the mean square speed, $\overline{u^{2}}$, which is the average of the speed squared for all the molecules in the sample:

$$
\overline{u^{2}}=\frac{u_{1}^{2}+u_{2}^{2}+u_{3}^{2}+\cdots+u_{N}^{2}}{N}
$$

where $N$ is the number of molecules in the sample.

## Application to the Gas Laws

Kinetic molecular theory enables us to understand some of the properties and behavior of gases in the following ways.

## Compressibility

Gases are compressible because molecules in the gas phase are separated by large distances (assumption 1) and can be moved closer together by decreasing the volume occupied by a sample of gas (Figure 11.16).

## Boyle's Law ( $V \propto 1 / P$ )

The pressure exerted by a gas is the result of the collisions of gas molecules with the walls of their container (assumption 2). The magnitude of the pressure depends on both the frequency of collision and the speed of molecules when they collide with the walls. Decreasing the volume occupied by a sample of gas increases the frequency of these collisions, thus increasing the pressure (Figure 11.16).

## Charles's Law $(V \propto T)$

Heating a sample of gas increases its average kinetic energy (assumption 4). Because the masses of the molecules do not change, an increase in average kinetic energy must be accompanied by an increase in the mean square speed of the molecules. In other words, heating a sample of gas makes the gas molecules move faster. Faster-moving molecules collide more frequently and with greater

[^29]
speed at impact, thus increasing the pressure. If the container can expand (as is the case with a balloon or a cylinder with a movable piston), the volume of the gas sample will increase, thereby decreasing the frequency of collisions until the pressure inside the container and the pressure outside are again equal (Figure 11.17).

## Avogadro's Law $(V \propto n)$

Because the magnitude of the pressure exerted by a sample of gas depends on the frequency of the collisions with the container wall, the presence of more molecules would cause an increase in pressure. Again, the container will expand if it can. Expansion of the container will decrease the frequency of collisions until the pressures inside and outside the container are once again equal (Figure 11.18).

## Dalton's Law of Partial Pressures ( $\boldsymbol{P}_{\text {total }}=\Sigma \boldsymbol{P}_{\mathrm{i}}$ )

Gas molecules do not attract or repel one another (assumption 3), so the pressure exerted by one gas is unaffected by the presence of another gas. Consequently, the total pressure exerted by a mixture of gases is simply the sum of the partial pressures of the individual components in the mixture (Figure 11.19).

## Molecular Speed

One of the important outcomes of the kinetic molecular theory is that the total kinetic energy of a mole of gas (any gas) is equal to $\frac{3}{2} R T$. With assumption 4 we saw that the average kinetic energy of one molecule is $\frac{1}{2} m u^{2}$. For 1 mole of the gas we write

$$
N_{\mathrm{A}}\left(\frac{1}{2} m \overline{u^{2}}\right)=\frac{3}{2} R T
$$

where $N_{\mathrm{A}}$ is Avogadro's number and $R$ is the gas constant expressed as $8.314 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$. Because $m \times N_{\mathrm{A}}=\mathcal{M}$, we can rearrange the preceding equation as follows:

$$
\overline{u^{2}}=\sqrt{\frac{3 R T}{M}}
$$

Taking the square root of both sides gives

$$
\sqrt{\overline{u^{2}}}=\sqrt{\frac{3 R T}{M}}
$$

Figure 11.16 Gases can be compressed by decreasing their volume. (a) Before volume decrease. (b) After volume decrease, the increased frequency of collisions between molecules and the walls of their container constitutes higher pressure.

(a)
—Charles's Law
Heating or cooling a gas
ETA

$$
P=\left(\frac{n R}{V}\right) T \quad \frac{n R}{V} \text { is constant }
$$

(b)

Figure 11.17 Charles's law. (a) The volume of a sample of gas at constant pressure is proportional to its absolute temperature. (b) The pressure of a sample of gas at constant volume is proportional to its absolute temperature.

Figure 11.18 Avogadro's law. The volume of a gas at constant temperature and pressure is proportional to the number of moles.

Figure 11.19 Each component of a gas mixture exerts a pressure independent of the other components. The total pressure is the sum of the individual components' partial pressures.
where $\sqrt{\overline{u^{2}}}$ is the root-mean-square (rms) speed ( $\boldsymbol{u}_{r m s}$ ). The result,

$$
u_{\mathrm{rms}}=\sqrt{\frac{3 R T}{M}}
$$

Equation 11.17
gives us the root-mean-square speed, which is the speed of a molecule with the average kinetic energy in a gas sample. Equation 11.17 indicates two important things: (1) The root-mean-square speed is directly proportional to the square root of the absolute temperature, and (2) the root-mean-square speed is inversely proportional to the square root of $\mathcal{M}$. Thus, for any two samples of gas at the same temperature, the gas with the larger molar mass will have the lower root-meansquare speed, $u_{\text {rms }}$.

Keep in mind that most molecules will have speeds either higher or lower than $u_{\mathrm{rms}}$-and that $u_{\mathrm{rms}}$ is temperature dependent. James Maxwell studied extensively the behavior of gas molecules at various temperatures. Figure 11.20(a) shows typical Maxwell speed distribution curves for nitrogen gas at three different temperatures. At a given temperature, the distribution curve tells us the number of molecules moving at a certain speed. The maximum of each curve represents the most probable speed-that is, the speed of the largest number of molecules. Note that the most probable speed increases as temperature increases [the maximum shifts toward the right in Figure 11.20(a)]. Furthermore, the curve also begins to flatten out with increasing temperature, indicating that larger numbers of molecules are moving faster.

Figure 11.20(b) shows the speed distributions of three different gases $\left(\mathrm{Cl}_{2}, \mathrm{~N}_{2}\right.$, and He$)$ at the same temperature ( 300 K ). The difference in these curves can be explained by noting that lighter molecules, on average, move faster than heavier ones.

Although we can use Equation 11.17 to calculate $u_{\mathrm{rms}}$ of a molecule in a particular sample, we will generally find it more useful to compare the $u_{\mathrm{rms}}$ values of molecules in different gas samples. For example, we can write Equation 11.17 for two different gases:

$$
u_{\mathrm{rms}}(1)=\sqrt{\frac{3 R T}{\mathcal{M}_{1}}} \quad \text { and } \quad u_{\mathrm{rms}}(2)=\sqrt{\frac{3 R T}{\mathcal{M}_{2}}}
$$

We can then determine the $u_{\mathrm{rms}}$ of a molecule in one gas relative to that in the other gas:

$$
\frac{u_{\mathrm{rms}}(1)}{u_{\mathrm{rms}}(2)}=\frac{\sqrt{\frac{3 R T}{\mathcal{M}_{1}}}}{\sqrt{\frac{3 R T}{\mathcal{M}_{2}}}}
$$

Student Annotation: In Equation 11.17, $R$ must be expressed as $8.314 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$ and $\mathcal{M}$ must be expressed in $\mathrm{kg} / \mathrm{mol}$.

Student Annotation: Remember that the average kinetic energy of a gas depends on its absolute temperature. Therefore, any two gas samples at the same temperature have the same average kinetic energy.

Figure 11.20 (a) The distribution of speeds for nitrogen gas at three different temperatures. At higher temperatures more molecules are moving faster. (b) The distribution of speeds for three different gases at the same temperature. On average, lighter molecules move faster than heavier molecules.

Student Annotation: Note that because Equation 11.18 contains the ratio of two molar masses, we can express the molar masses as $\mathrm{g} / \mathrm{mol}$ or $\mathrm{kg} / \mathrm{mol}$. (In Equation 11.17, we had to express molar mass as $\mathrm{kg} / \mathrm{mol}$ for the units to cancel properly.)

Think About It Remember that the relationship between molar mass and molecular speed (Equation 11.18) is reciprocal. A $\mathrm{CO}_{2}$ molecule has approximately 10 times the mass of an He atom. Therefore, we should expect an He atom, on average, to be moving approximately $\sqrt{10}$ times ( $\sim 3.2$ times) as fast as a $\mathrm{CO}_{2}$ molecule.

Canceling identical terms, when both gases are at the same temperature, we can write

Equation 11.18

$$
\frac{u_{\mathrm{rms}}(1)}{u_{\mathrm{rms}}(2)} \sqrt{\frac{\mathcal{M}_{1}}{\mathcal{M}_{2}}}
$$

Using Equation 11.18 we can compare $u_{\mathrm{rms}}$ values of molecules with different molar masses (at a given temperature). Sample Problem 11.16 shows how this is done.

## Sample Problem 11.16

Determine how much faster a helium atom moves, on average, than a carbon dioxide molecule at the same temperature.

Strategy Use Equation 11.18 and the molar masses of He and $\mathrm{CO}_{2}$ to determine the ratio of their root-mean-square speeds. When solving a problem such as this, it is generally best to label the lighter of the two molecules as molecule 1 and the heavier molecule as molecule 2. This ensures that the result will be greater than 1 , which is relatively easy to interpret.

Setup The molar masses of He and $\mathrm{CO}_{2}$ are 4.003 and $44.01 \mathrm{~g} / \mathrm{mol}$, respectively.

## Solution

$$
\frac{u_{\mathrm{rms}}(\mathrm{He})}{u_{\mathrm{rms}}\left(\mathrm{CO}_{2}\right)}=\frac{\sqrt{\frac{44.01 \mathrm{~g}}{\mathrm{~mol}}}}{\sqrt{\frac{4.003 \mathrm{~g}}{\mathrm{~mol}}}}=3.316
$$

On average, He atoms move 3.316 times faster than $\mathrm{CO}_{2}$ molecules at the same temperature.

Practice Problem A Determine the relative root-mean-square speeds of $\mathrm{O}_{2}$ and $\mathrm{SF}_{6}$ at a given temperature.
flPractice Problem B Determine the molar mass and identity of a gas that moves 4.67 times as fast as $\mathrm{CO}_{2}$.

## Diffusion and Effusion

The random motion of gas molecules gives rise to two readily observable phenomena: diffusion and effusion. Diffusion is the mixing of gases as the result of random motion and frequent collisions (Figure 11.21), while effusion is the escape of gas molecules from a container to a region of vacuum (Figure 11.22). One of the earliest successes of the kinetic molecular theory was its ability to explain diffusion and effusion.

Graham's law states that the rate of diffusion or effusion of a gas is inversely proportional to the square root of its molar mass:

$$
\text { Rate } \propto \frac{1}{\sqrt{M}}
$$

This is essentially a restatement of Equation 11.17. Thus, lighter gases diffuse and effuse more rapidly than heavier gases.

## Checkpoint 11.6 The Kinetic Molecular Theory of Gases

11.6.1 Methane $\left(\mathrm{CH}_{4}\right)$ diffuses approximately 2.4 times as fast as a certain unknown gas. Which of the following could be the unknown gas?
a) $\mathrm{O}_{2}$
b) $\mathrm{C}_{2} \mathrm{H}_{6}$
c) $\mathrm{CH}_{3} \mathrm{Br}$
d) $\mathrm{CH}_{3} \mathrm{I}$
e) $F_{2}$
11.6.2 Which gas effuses faster, He or Ar, and how much faster does it effuse?
a) He effuses 9.98 times as fast as Ar.
b) He effuses 3.16 times as fast as Ar.
c) Ar effuses 9.98 times as fast as He .
d) Ar effuses 3.16 times as fast as He .
e) He and Ar effuse at the same rate.

Figure 11.21 Diffusion is the mixing of gases. (a) Two different gases in separate containers. (b) When the stopcock is opened, the gases mix by diffusion.

Figure 11.22 Effusion is the escape of a gas into a vacuum.

Figure 11.23 Molar volumes of some common gases at STP.

### 11.7 Deviation from Ideal Behavior

The gas laws and the kinetic molecular theory assume that molecules in the gas phase occupy negligible volume (assumption 1) and that they do not exert any force on one another, either attractive or repulsive (assumption 3). Gases that behave as though these assumptions were strictly true are said to exhibit ideal behavior. Many gases do exhibit ideal or nearly ideal behavior under ordinary conditions. Figure 11.23 shows the molar volumes of some common gases at STP. All are remarkably close to the ideal value of 22.41 L . Although we generally assume that real gases behave ideally, there are conditions, namely, high pressure and low temperature, under which the behavior of a real gas deviates from ideal.

## Factors That Cause Deviation from Ideal Behavior

At high pressures, gas molecules are relatively close together. We can assume that gas molecules occupy no volume only when the distances between molecules are large. When the distances between molecules are reduced, the volume occupied by each individual molecule becomes more significant.

At low temperatures, gas molecules are moving more slowly. We can assume that there are no intermolecular forces between gas molecules, either attractive or repulsive, when the gas molecules are moving very fast and the magnitude of their kinetic energies is much larger than the magnitude of any intermolecular forces. When molecules move more slowly, they have lower kinetic energies and the magnitude of the forces between them becomes more significant.

## The van der Waals Equation

Because there are conditions under which use of the ideal gas equation would result in large errors (i.e., high pressure and/or low temperature), we must use a slightly different approach when gases

Figure 11.24 The effect of intermolecular attractions on the pressure exerted by a gas. do not behave ideally. Analyses of real gases that took into account nonzero molecular volumes and intermolecular forces were first carried out by J. D. van der Waals ${ }^{8}$ in 1873. Van der Waals's treatment provides us with an interpretation of the behavior of real gases at the molecular level.

Consider the approach of a particular molecule toward the wall of its container (Figure 11.24). The intermolecular attractions exerted by neighboring molecules prevent the molecule from hitting the wall as hard as it otherwise would. This results in the pressure exerted by a real gas being lower than that predicted by the ideal gas equation. Van der Waals suggested that the pressure exerted by an ideal gas, $P_{\text {ideal }}$, is related to the experimentally measured pressure, $P_{\text {real }}$, by the equation

$$
P_{\text {ideal }}=P_{\text {real }}+\frac{a n^{2}}{V^{2}}
$$

where $a$ is a constant and $n$ and $V$ are the number of moles and volume of the gas, respectively. The correction term for pressure $\left(a n^{2} / V^{2}\right)$ can be understood as follows. The intermolecular interaction that gives rise to nonideal behavior depends on how frequently any two molecules encounter each other. The number of such encounters increases with the square of the number of molecules per

[^30]
## TABLE 11.6 Van der Waals Constants of Some Common Gases

| Gas | $\boldsymbol{a}\left(\frac{\mathrm{atm} \cdot \mathrm{L}^{2}}{\mathrm{~mol}^{2}}\right)$ | $\boldsymbol{b}\left(\frac{\mathrm{L}}{\mathrm{mol}}\right)$ | Gas | $\boldsymbol{a}\left(\frac{\mathrm{atm} \cdot \mathrm{L}^{2}}{\mathrm{~mol}^{2}}\right)$ | $\boldsymbol{b}\left(\frac{\mathrm{L}}{\mathrm{mol}}\right)$ |
| :--- | :---: | :---: | :---: | :---: | :---: |
| He | 0.034 | 0.0237 | $\mathrm{O}_{2}$ | 1.36 | 0.0318 |
| Ne | 0.211 | 0.0171 | $\mathrm{Cl}_{2}$ | 6.49 | 0.0562 |
| Ar | 1.34 | 0.0322 | $\mathrm{CO}_{2}$ | 3.59 | 0.0427 |
| Kr | 2.32 | 0.0398 | $\mathrm{CH}_{4}$ | 2.25 | 0.0428 |
| Xe | 4.19 | 0.0510 | $\mathrm{CCl}_{4}$ | 20.4 | 0.138 |
| $\mathrm{H}_{2}$ | 0.244 | 0.0266 | $\mathrm{NH}_{3}$ | 4.17 | 0.0371 |
| $\mathrm{~N}_{2}$ | 1.39 | 0.0391 | $\mathrm{H}_{2} \mathrm{O}$ | 5.46 | 0.0305 |

unit volume $(n / V)$, and $a$ is a proportionality constant. The quantity $P_{\text {ideal }}$ is the pressure we would measure if there were no intermolecular attractions.

The other correction concerns the volume occupied by the gas molecules. In the ideal gas equation, $V$ represents the volume of the container. However, each molecule actually occupies a very small but nonzero volume. We can correct for the volume occupied by the gas molecules by subtracting a term, $n b$, from the volume of the container:

$$
V_{\text {real }}=V_{\text {ideal }}-n b
$$

where $n$ and $b$ are the number of moles and the proportionality constant, respectively.
Incorporating both corrections into the ideal gas equation gives us the van der Waals equation, with which we can analyze gases under conditions where ideal behavior is not expected.

The van der Waals constants $a$ and $b$ for a number of gases are listed in Table 11.6. The magnitude of $a$ indicates how strongly molecules of a particular type of gas attract one another. The magnitude of $b$ is related to molecular (or atomic) size, although the relationship is not a simple one.

Sample Problem 11.17 shows how to use the van der Waals equation.

## Sample Problem 11.17

A sample of 3.50 moles of $\mathrm{NH}_{3}$ gas occupies 5.20 L at $47^{\circ} \mathrm{C}$. Calculate the pressure of the gas (in atm) using (a) the ideal gas equation and (b) the van der Waals equation.

Strategy (a) Use the ideal gas equation, $P V=n R T$.
(b) Use Equation 11.19 and $a$ and $b$ values for $\mathrm{NH}_{3}$ from Table 11.6.

Setup $T=320.15 \mathrm{~K}, a=4.17 \mathrm{~atm} \cdot \mathrm{~L} / \mathrm{mol}^{2}$, and $b=0.0371 \mathrm{~L} / \mathrm{mol}$.
Solution (a) $P=\frac{n R T}{V}=\frac{(3.50 \mathrm{~mol})\left(\frac{0.08206 \mathrm{~L} \cdot \mathrm{~atm}}{\mathrm{~K} \cdot \mathrm{~mol}}\right)(320.15 \mathrm{~K})}{5.20 \mathrm{~L}}=17.7 \mathrm{~atm}$
(b) Evaluating the correction terms in the van der Waals equation, we get

$$
\begin{aligned}
\frac{a n^{2}}{V^{2}} & =\frac{\left(\frac{4.17 \mathrm{~atm} \cdot \mathrm{~L}^{2}}{\mathrm{~mol}^{2}}\right)(3.50 \mathrm{~mol})^{2}}{(5.20 \mathrm{~L})^{2}}=1.89 \mathrm{~atm} \\
n b & =(3.50 \mathrm{~mol})\left(\frac{0.0371 \mathrm{~L}}{\mathrm{~mol}}\right)=0.130 \mathrm{~L}
\end{aligned}
$$

## Think About It As is often

 the case, the pressure exerted by the real gas sample is lower than predicted by the ideal gas equation.Finally, substituting these results into Equation 11.19, we have

$$
\begin{aligned}
(P+1.89 \mathrm{~atm})(5.20 \mathrm{~L}-0.130 \mathrm{~L}) & =(3.50 \mathrm{~mol})\left(\frac{0.08206 \mathrm{~L} \cdot \mathrm{~atm}}{\mathrm{~K} \cdot \mathrm{~mol}}\right)(320.15 \mathrm{~K}) \\
P & =16.2 \mathrm{~atm}
\end{aligned}
$$

Practice Problem A Using data from Table 11.6, calculate the pressure exerted by 11.9 moles of neon gas in a volume of 5.75 L at $25^{\circ} \mathrm{C}$ using (a) the ideal gas equation and (b) the van der Waals equation (Equation 11.19). Compare your results.
\&Practice Problem B Calculate the pressure exerted by 0.35 mole of oxygen gas in a volume of 6.50 L at $32^{\circ} \mathrm{C}$ using (a) the ideal gas equation and (b) the van der Waals equation.

(a)

(b)

Figure 11.25 (a) Compressibility factor $(Z)$ as a function of pressure for several gases at $0^{\circ} \mathrm{C}$. (b) Compressibility factor as a function of pressure for $\mathrm{N}_{2}$ gas at several different temperatures.

One way to measure a gas's deviation from ideal behavior is to determine its compressibility factor, $Z$, where $Z=P V / R T$. For one mole of an ideal gas, $Z$ is equal to 1 at all pressures and temperatures. For real gases, the factors that contribute to nonideal behavior cause the value of $Z$ to deviate from 1. Intermolecular forces help to account for the plots in Figure 11.25(a). Molecules exert both attraction and repulsion on one another. At large separations (low pressures), attraction predominates. In this region, the gas is more compressible than an ideal gas and the curve dips below the horizontal line $(Z<1)$. As molecules are brought closer together under pressure, repulsion begins to play an important role. If the pressure continues to increase, a point is reached when the gas becomes less compressible than an ideal gas because the molecules repel one another and the curve rises above the horizontal line $(Z>1)$. Figure $11.25(\mathrm{~b})$ shows the plots of $Z$ versus pressure at different temperatures. We see that as the temperature increases, the gas behaves more like an ideal gas (the curves become closer to the horizontal line). The increase in the molecules' kinetic energy makes molecular attraction less important.

## Checkpoint 11.7 Deviation from Ideal Behavior

11.7.1 Which of the following conditions cause deviation from ideal behavior? (Select all that apply.)
a) High pressure
b) Low pressure
c) High temperature
d) Low temperature
e) High volume
11.7.2 Using the van der Waals equation, calculate the pressure exerted by 1.5 moles of carbon dioxide in a 3.75 -L vessel at $10^{\circ} \mathrm{C}$.
a) 9.3 atm
b) 8.9 atm
c) 10 atm
d) 8.6 atm
e) -2.4 atm

## ҒA@ You May Be Wondering...

## What's Really the Difference Between Real Gases and Ideal Gases?

As illustrated by the molar volumes in Figure 11.23, the ideal gas equation is remarkably accurate for common gases at or near STP. However, at low temperatures and high pressures, the assumptions that enable us to treat gases as ideal are no longer valid. In these cases, we must consider the effects of attractive forces between the molecules and the nonzero volume that the molecules occupy.

When a gas is cooled and/or compressed, it condenses to a liquid-indicating that there are attractive forces between the molecules [ $\boldsymbol{\omega}$ Chapter 12]. Even in the gas phase, the attractive forces between molecules can impact the observed behavior of a substance. As illustrated in Figure 11.24, a molecule that is attracted to other molecules in a sample of gas will not strike the wall of the container with as high a velocity as it would if there were no such intermolecular attractions. The pressure term in the van der Waals equation, $P+a(n / V)^{2}$, is the experimentally determined pressure, $P$, plus a correction for the pressure that we do not observe because of attractive forces between the gas molecules. Note that the correction factor depends on the moles-per-unit-volume $(n / V)$ squared. The value of the constant $a$ is specific to a particular gas.

When two gas molecules (assumed to be spherical) approach each other, the distance of closest approach is the sum of their radii ( $2 r$ ). The volume around each molecule into which the center of another molecule cannot penetrate is called the excluded volume. The effect of the excluded volume is to limit the fraction of the container volume actually available for molecules to move about in a gas sample. Thus, the volume term in the van der Waals equation, $V-n b$, is the container volume $V$ minus the correction for the excluded volume, $n b$, where $n$ is the number of moles of the gas and $b$ is the excluded volume per mole of the gas.

Sample Problem 11.18 shows how to calculate excluded volume.

## Sample Problem 11.18

Consider a gas sample consisting of molecules with radius $r$. (a) Determine the excluded volume defined by two molecules and (b) calculate the excluded volume per mole (b) for the gas. Compare the excluded volume per mole with the volume actually occupied by a mole of the molecules.

Strategy (a) Use the formula for volume of a sphere to calculate the volume of a sphere of radius $2 r$. This is the excluded volume defined by two molecules. (b) Multiply the excluded volume per molecule by Avogadro's number to determine excluded volume per mole.

Setup The equation for volume of a sphere is $\frac{4}{3} \pi r^{3} ; N_{\mathrm{A}}=6.022 \times 10^{23}$.
Solution (a) Excluded volume defined by two molecules $=\frac{4}{3} \pi(2 r)^{3}=8\left(\frac{4}{3} \pi r^{3}\right)$
(b) Excluded volume per mole $=\frac{8\left(\frac{4}{3} \pi r^{3}\right)}{2 \text { molecules }} \times \frac{N_{\mathrm{A}} \text { molecules }}{1 \text { mole }}=\frac{4 N_{\mathrm{A}}\left(\frac{4}{3} \pi r^{3}\right)}{1 \text { mole }}$

The volume actually occupied by a mole of molecules with radius $r$ is $N_{\mathrm{A}}\left(\frac{4}{3} \pi r^{3}\right)$.

Practice Problem A Determine the excluded volume per mole and the total volume of the molecules in a mole for a gas consisting of molecules with radius 165 pm . [Note: To obtain the volume in liters, we must express the radius in decimeters (dm).]
$\boldsymbol{\$}$ Practice Problem B Because the van der Waals constant $b$ is the excluded volume per mole of a gas, we can use the value of $b$ to estimate the radius of a molecule or atom. Consider a gas that consists of molecules, for which the van der Waals constant $b$ is $0.0315 \mathrm{~L} / \mathrm{mol}$. Estimate the molecular radius in picometers ( pm ). Assume that the molecules are spherical.

Think About It The excluded volume per mole is four times the volume actually occupied by a mole of molecules.

## Applying What You've Learned

Student Annotation: The Gamow Bag earned the praises even of Sir Edmund Hillary, leader of the first expedition to the summit of Mount Everest.

Gamow Bag

Scuba divers are not the only athletes who can suffer the detrimental effects of sudden changes in pressure. Mountain climbers, too, are susceptible to the dangers of rapid ascent. At high elevation, air pressure is significantly lower than at sea level. A lower total pressure means a lower partial pressure of oxygen, and insufficient oxygen or hypoxia can cause altitude sickness. Early symptoms of altitude sickness include headache, dizziness, and nausea. In severe cases, climbers may suffer hallucinations, seizure, coma, and even death.

In 1990, Igor Gamow, a professor of microbiology at the University of Colorado, patented a portable device for high-altitude treatment of altitude sickness. The Gamow Bag is an inflatable cylinder large enough to accommodate an adult mountain climber. The bag is inflated and pressurized with a foot pump, and the afflicted climber remains sealed inside the pressurized bag until symptoms subside enough to begin descent. Although the bag is pressurized to only about 0.14 atm above atmospheric pressure, at very high altitudes this corresponds to a simulated descent on the order of $10,000 \mathrm{ft}$ !

## Problems:

a) If a Gamow Bag is pressurized to 0.14 atm above atmospheric pressure at an altitude of $25,000 \mathrm{ft}$, where atmospheric pressure is 0.37 atm , what height column of mercury would be supported by the pressure inside the pressurized bag?
[ 14 Sample Problem 11.1]
b) The Gamow Bag inflates to a volume of $4.80 \times 10^{2} \mathrm{~L}$. What volume would be occupied by the air in the pressurized bag in part (a) at standard atmospheric pressure? (Assume no change in temperature.) [ 14 Sample Problem 11.2]
c) Calculate the density of the air in the pressurized bag in part (a) at $0^{\circ} \mathrm{C}$. (Assume that air is 80 percent $\mathrm{N}_{2}$ and 20 percent $\mathrm{O}_{2}$ by volume.) [ 144 Sample Problem 11.7]
d) LiOH scrubbers are sometimes used to prevent the buildup of $\mathrm{CO}_{2}$ during use of the bag. What volume of $\mathrm{CO}_{2}$ (at $0^{\circ} \mathrm{C}$ ) can be removed from the pressurized bag in part (a) by 0.50 kg LiOH ? [ 14 Sample Problem 11.9]
e) Calculate the number of moles of each gas in the pressurized bag in part (a) at $0^{\circ} \mathrm{C}$. [ 144 Sample Problem 11.13]

## Chapter Summary

## Section 11.1

- A gas assumes the volume and shape of its container and is compressible. Gases generally have low densities (expressed in g/L) and will mix in any proportions to give homogeneous solutions.
- Gases exert pressure, which is the force per unit area. The SI units of force and pressure are the newton $(N)$ and the pascal (Pa), respectively. Other commonly used units of pressure are atmosphere (atm), mmHg, torr, and bar.
- Pressure can be measured using a barometer or a manometer.
- Standard atmospheric pressure (1 atm) is the pressure exerted by the atmosphere at sea level.

## Section 11.2

- The physical state of a sample of gas can be described using four parameters: temperature $(T)$, pressure $(P)$, volume $(V)$, and number of moles (n). Equations relating these parameters are called the gas laws.
- Boyle's law states that the volume of a sample of gas at constant temperature is inversely proportional to pressure.
- Experiments done by Charles and Gay-Lussac showed that the volume of a gas at constant pressure is directly proportional to temperature. Lord Kelvin used Charles's and Gay-Lussac's data to propose that absolute zero is the lowest theoretically attainable temperature. The absolute temperature scale, also known as the Kelvin temperature scale, is used for all calculations involving gases.
- Charles's and Gay-Lussac's law, commonly known as Charles's law, states that the volume of a sample of gas at constant pressure is directly proportional to its absolute temperature.
- Avogadro's law states that the volume of a sample of gas at constant temperature and pressure is directly proportional to the number of moles.
- The combined gas law combines the laws of Boyle, Charles, and Avogadro and relates pressure, volume, temperature, and number of moles without assuming that any of the parameters is constant.

## Section 11.3

- The ideal gas equation, $P V=n R T$, makes it possible to predict the behavior of gases. An ideal gas is one that behaves in a way predicted by the ideal gas equation. $R$ is the gas constant, which may be expressed in a variety of units. The units used to express $R$ depend on the units used to express $P$ and $V$.
- Standard temperature and pressure (STP) is defined as $0^{\circ} \mathrm{C}$ and 1 atm.
- The ideal gas equation can be used to calculate the density of a gas and to interconvert between density and molar mass.

## Section 11.4

- For a reaction occurring at constant temperature and pressure, and involving only gases, the coefficients in the balanced chemical equation apply to units of volume, as well as to numbers of molecules or moles.
- A balanced chemical equation and the ideal gas equation can be used to determine volumes of gaseous reactants and/or products in a reaction.

## Section 11.5

- Each component in a mixture of gases exerts a partial pressure $\left(\boldsymbol{P}_{i}\right)$ independent of the other mixture components. Dalton's law of partial pressures states that the total pressure exerted by a gas mixture is the sum of the partial pressures of the components.
- Mole fraction $\left(\boldsymbol{\chi}_{i}\right)$ is the unitless quotient of the number of moles of a mixture component and the total number of moles in the mixture, $n_{\mathrm{i}} / n_{\text {total }}$.

## Section 11.6

- According to the kinetic molecular theory, gases are composed of particles with negligible volume that are separated by large distances; the particles are in constant, random motion, and collisions between the particles and between the particles and their container walls are perfectly elastic; there are no attractive or repulsive forces between the particles; and the average kinetic energy of particles in a sample is proportional to the absolute temperature of the sample.
- Kinetic molecular theory can be used to explain the compressibility of gases and the empirical gas laws.
- The root-mean-square (rms) speed ( $\boldsymbol{u}_{\text {rms }}$ ) of gas molecules in a sample at a given temperature is inversely proportional to the molecular mass.
- According to Graham's law, the rates of diffusion (mixing of gases) and effusion (escape of a gas from a container into a vacuum) are inversely proportional to the square root of the molar mass of the gas.

## Section 11.7

- Deviation from ideal behavior is observed at high pressure and/or low temperature. The van der Waals equation makes corrections for the nonzero volume of gas molecules and the attractive forces between molecules.

$11.19 \quad\left(P+\frac{a n^{2}}{V^{2}}\right)(V-n b)=n R T$

## Questions and Problems

## Section 11.1: Properties of Gases

## Review Questions

11.1 Name five elements and five compounds that exist as gases at room temperature.
11.2 List the physical characteristics of gases.
11.3 Define pressure and give the common units for pressure.
11.4 Describe how a barometer and a manometer are used to measure gas pressure.
11.5 Why is mercury a more suitable substance to use in a barometer than water?
11.6 Explain why the height of mercury in a barometer is independent of the cross-sectional area of the tube.
11.7 Would it be easier to drink water with a straw on top of Mt. Everest or at the foot? Explain.
11.8 Is the atmospheric pressure in a mine that is 500 m below sea level greater or less than 1 atm ?
11.9 What is the difference between the terms gas and vapor? At $25^{\circ} \mathrm{C}$, which of the following substances in the gas phase should be properly called a gas and which should be called a vapor: molecular chlorine $\left(\mathrm{Cl}_{2}\right)$, molecular iodine $\left(\mathrm{I}_{2}\right)$ ?
11.10 If the maximum distance that water may be brought up a well by a suction pump is $34 \mathrm{ft}(10.3 \mathrm{~m})$, how is it possible to obtain water and oil from hundreds of feet below the surface of Earth?
11.11 Why is it that if the barometer reading falls in one part of the world, it must rise somewhere else?
11.12 Why do astronauts have to wear protective suits when they are on the surface of the moon?

## Problems

11.13 Convert 375 mmHg to atmospheres, bar, torr, and pascals.

E 11.14 The atmospheric pressure at the summit of Mt. McKinley is 581 mmHg on a certain day. What is the pressure in atmospheres and in kilopascals?

GI11.15 Calculate the height of a column of methanol $\left(\mathrm{CH}_{3} \mathrm{OH}\right)$ that would be supported by atmospheric pressure. The density of methanol is $0.787 \mathrm{~g} / \mathrm{cm}^{3}$.
11.16 Calculate the height of a column of ethylene glycol $\left[\mathrm{CH}_{2}(\mathrm{OH}) \mathrm{CH}_{2}(\mathrm{OH})\right]$ that would be supported by atmospheric pressure ( 1 atm ). The density of ethylene glycol is $1.12 \mathrm{~g} / \mathrm{cm}^{3}$.
11.17 What pressure (in atm) is exerted by a column of toluene $\left(\mathrm{C}_{7} \mathrm{H}_{8}\right)$ 87 m high? The density of toluene is $0.867 \mathrm{~g} / \mathrm{cm}^{3}$.

E 11.18 What pressure (in atm) is exerted by a column of isopropanol $\left(\mathrm{C}_{3} \mathrm{H}_{7} \mathrm{OH}\right) 264 \mathrm{~m}$ high? The density of isopropanol is $0.785 \mathrm{~g} / \mathrm{cm}^{3}$.

## Section 11.2: The Gas Laws

## Review Questions

11.19 State the following gas laws in words and also in the form of an equation: Boyle's law, Charles's law, Avogadro's law. In each case, indicate the conditions under which the law is applicable, and give the units for each quantity in the equation.
11.20 Explain why a helium weather balloon expands as it rises in the air. Assume that the temperature remains constant.

## Problems

H11.21 A gaseous sample of a substance is cooled at constant pressure. Which of the following diagrams best represents the situation if the final temperature is (a) above the boiling point of the substance and (b) below the boiling point but above the freezing point of the substance?

(a)

(b)

(c)

(d)

EI 11.22 Consider the following gaseous sample in a cylinder fitted with a movable piston. Initially there are $n$ moles of the gas at temperature $T$, pressure $P$, and volume $V$.

Choose the cylinder that correctly represents the gas after each of the following changes. (1) The pressure on the piston is tripled at constant $n$ and $T$. (2) The absolute temperature is doubled at constant $n$ and $P$. (3) $n$ more moles of the gas are added at constant $T$ and $P$. (4) Absolute temperature is halved at constant $P$.

E11.23 A gas sample occupying a volume of 25.6 mL at a pressure of 0.970 atm is allowed to expand at constant temperature until its pressure reaches 0.541 atm . What is its final volume?
11.24 At $46^{\circ} \mathrm{C}$ a sample of ammonia gas exerts a pressure of 5.3 atm . What is the pressure when the volume of the gas is reduced to one-fourth of the original value at the same temperature?
11.25 The volume of a gas is 7.15 L , measured at 1.00 atm . What is the pressure of the gas in mmHg if the volume is changed to 9.25 L ? (The temperature remains constant.)

E 11.26 A sample of air occupies 3.8 L when the pressure is 1.2 atm . (a) What volume does it occupy at 6.6 atm ? (b) What pressure is required to compress it to 0.075 L ? (The temperature is kept constant.)
$\boldsymbol{H} 11.27$ A 28.4-L volume of methane gas is heated from $35^{\circ} \mathrm{C}$ to $72^{\circ} \mathrm{C}$ at constant pressure. What is the final volume of the gas?
11.28 Under constant-pressure conditions a sample of hydrogen gas initially at $88^{\circ} \mathrm{C}$ and 9.6 L is cooled until its final volume is 3.4 L. What is its final temperature?
11.29 Ammonia burns in oxygen gas to form nitric oxide (NO) and water vapor. How many volumes of NO are obtained from one volume of ammonia at the same temperature and pressure?

El 11.30 Molecular chlorine and molecular fluorine combine to form a gaseous product. Under the same conditions of temperature and pressure it is found that one volume of $\mathrm{Cl}_{2}$ reacts with three volumes of $\mathrm{F}_{2}$ to yield two volumes of the product. What is the formula of the product?

## Section 11.3: The Ideal Gas Equation

## Review Questions

11.31 List the characteristics of an ideal gas.
11.32 What are standard temperature and pressure (STP)? What is the significance of STP in relation to the volume of 1 mole of an ideal gas?
11.33 Why is the density of a gas much lower than that of a liquid or solid under atmospheric conditions? What units are normally used to express the density of gases?

## Problems

11.34 A sample of nitrogen gas in a 4.5-L container at a temperature of $27^{\circ} \mathrm{C}$ exerts a pressure of 4.1 atm . Calculate the number of moles of gas in the sample.

E11.35 Given that 6.9 moles of carbon monoxide gas are present in a container of volume 30.4 L , what is the pressure of the gas (in atm) if the temperature is $82^{\circ} \mathrm{C}$ ?

E11.36 What volume will 9.8 moles of sulfur hexafluoride $\left(\mathrm{SF}_{6}\right)$ gas occupy if the temperature and pressure of the gas are $105^{\circ} \mathrm{C}$ and 9.4 atm , respectively?
11.37 A certain amount of gas at $25^{\circ} \mathrm{C}$ and at a pressure of 0.800 atm is contained in a vessel. Suppose that the vessel can withstand a pressure no higher than 5.00 atm . How high can you raise the temperature of the gas without bursting the vessel?

E11.38 A gas-filled balloon having a volume of 2.50 L at 1.2 atm and $20^{\circ} \mathrm{C}$ is allowed to rise to the stratosphere (about 30 km above the surface of Earth), where the temperature and pressure are $-23^{\circ} \mathrm{C}$ and $3.00 \times 10^{-3} \mathrm{~atm}$, respectively. Calculate the final volume of the balloon.
11.39 The temperature of 2.5 L of a gas initially at STP is raised to $210^{\circ} \mathrm{C}$ at constant volume. Calculate the final pressure of the gas in atmospheres.
11.40 The pressure of 6.0 L of an ideal gas in a flexible container is decreased to one-third of its original pressure, and its absolute temperature is decreased by one-half. What is the final volume of the gas?
11.41 A gas evolved during the fermentation of glucose (wine making) has a volume of 0.67 L at $22.5^{\circ} \mathrm{C}$ and 1.00 atm . What was the volume of this gas at the fermentation temperature of $36.5^{\circ} \mathrm{C}$ and 1.00 atm pressure?

E11.42 An ideal gas originally at 0.85 atm and $66^{\circ} \mathrm{C}$ was allowed to expand until its final volume, pressure, and temperature were $94 \mathrm{~mL}, 0.60 \mathrm{~atm}$, and $45^{\circ} \mathrm{C}$, respectively. What was its initial volume?
11.43 Calculate the volume (in liters) of 124.3 g of $\mathrm{CO}_{2}$ at STP.
$\leftrightarrows 11.44$ A gas at 572 mmHg and $35.0^{\circ} \mathrm{C}$ occupies a volume of 6.15 L . Calculate its volume at STP.
11.45 Dry ice is solid carbon dioxide. A $0.050-\mathrm{g}$ sample of dry ice is placed in an evacuated $4.6-\mathrm{L}$ vessel at $30^{\circ} \mathrm{C}$. Calculate the pressure inside the vessel after all the dry ice has been converted to $\mathrm{CO}_{2}$ gas.

E11.46 At STP, 0.280 L of a gas weighs 0.400 g . Calculate the molar mass of the gas.
11.47 At 741 torr and $44^{\circ} \mathrm{C}, 7.10 \mathrm{~g}$ of a gas occupies a volume of 5.40 L. What is the molar mass of the gas?

I 11.48 Ozone molecules in the stratosphere absorb much of the harmful radiation from the sun. Typically, the temperature and pressure of ozone in the stratosphere are 250 K and $1.0 \times 10^{-3} \mathrm{~atm}$, respectively. How many ozone molecules are present in 1.0 L of air under these conditions?
11.49 Assuming that air contains 78 percent $\mathrm{N}_{2}, 21$ percent $\mathrm{O}_{2}$, and 1.0 percent Ar , all by volume, how many molecules of each type of gas are present in 1.0 L of air at STP?

G11.50 A $2.10-\mathrm{L}$ vessel contains 4.65 g of a gas at 1.00 atm and $27.0^{\circ} \mathrm{C}$. (a) Calculate the density of the gas in $g / L$. (b) What is the molar mass of the gas?
11.51 Calculate the density of hydrogen bromide ( HBr ) gas in $\mathrm{g} / \mathrm{L}$ at 733 mmHg and $46^{\circ} \mathrm{C}$.

G11.52 A certain anesthetic contains 64.9 percent $C, 13.5$ percent $H$, and 21.6 percent O by mass. At $120^{\circ} \mathrm{C}$ and $750 \mathrm{mmHg}, 1.00 \mathrm{~L}$ of the gaseous compound weighs 2.30 g . What is the molecular formula of the compound?
11.53 A compound has the empirical formula $\mathrm{SF}_{4}$. At $20^{\circ} \mathrm{C}, 0.100 \mathrm{~g}$ of the gaseous compound occupies a volume of 22.1 mL and exerts a pressure of 1.02 atm . What is the molecular formula of the gas?

## Section 11.4: Reactions with Gaseous Reactants and Products

## Problems

G11.54 Consider the formation of nitrogen dioxide from nitric oxide and oxygen:

$$
2 \mathrm{NO}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{NO}_{2}(g)
$$

If 9.0 L of NO is combined with excess $\mathrm{O}_{2}$ at STP, what is the volume in liters of the $\mathrm{NO}_{2}$ produced?
11.55 Methane, the principal component of natural gas, is used for heating and cooking. The combustion process is

$$
\mathrm{CH}_{4}(g)+2 \mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(l)
$$

If 15.0 moles of $\mathrm{CH}_{4}$ react with oxygen, what is the volume of $\mathrm{CO}_{2}$ (in liters) produced at $23.0^{\circ} \mathrm{C}$ and 0.985 atm ?
11.56 When coal is burned, the sulfur present in coal is converted to sulfur dioxide $\left(\mathrm{SO}_{2}\right)$, which is responsible for the acid rain phenomenon:

$$
\mathrm{S}(s)+\mathrm{O}_{2}(g) \longrightarrow \mathrm{SO}_{2}(g)
$$

If 3.15 kg of S reacts with oxygen, calculate the volume of $\mathrm{SO}_{2}$ gas (in mL ) formed at $30.5^{\circ} \mathrm{C}$ and 1.04 atm .
$\$ 11.57$ In alcohol fermentation, yeast converts glucose to ethanol and carbon dioxide:

$$
\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}(s) \longrightarrow 2 \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(l)+2 \mathrm{CO}_{2}(g)
$$

If 5.97 g of glucose reacts and 1.44 L of $\mathrm{CO}_{2}$ gas is collected at 293 K and 0.984 atm , what is the percent yield of the reaction?
11.58 A compound of P and F was analyzed as follows: Heating 0.2324 g of the compound in a $378-\mathrm{cm}^{3}$ container turned all of it to gas, which had a pressure of 97.3 mmHg at $77^{\circ} \mathrm{C}$. Then the gas was mixed with calcium chloride solution, which converted all the F to 0.2631 g of $\mathrm{CaF}_{2}$. Determine the molecular formula of the compound.
11.59 A quantity of 0.225 g of a metal M (molar mass $=27.0 \mathrm{~g} / \mathrm{mol}$ ) liberated 0.303 L of molecular hydrogen (measured at $17^{\circ} \mathrm{C}$ and 741 mmHg ) from an excess of hydrochloric acid. Deduce from these data the corresponding equation, and write formulas for the oxide and sulfate of M .

H11.60 What is the mass of the solid $\mathrm{NH}_{4} \mathrm{Cl}$ formed when 73.0 g of $\mathrm{NH}_{3}$ is mixed with an equal mass of HCl ? What is the volume of the gas remaining, measured at $14.0^{\circ} \mathrm{C}$ and 752 mmHg ? What gas is it?
$\$ 11.61$ Dissolving 3.00 g of an impure sample of calcium carbonate in hydrochloric acid produced 0.656 L of carbon dioxide (measured at $20.0^{\circ} \mathrm{C}$ and 792 mmHg ). Calculate the percent by mass of calcium carbonate in the sample. State any assumptions.

EI 11.62 Calculate the mass in grams of hydrogen chloride produced when 5.6 L of molecular hydrogen measured at STP react with an excess of molecular chlorine gas.
11.63 Ethanol $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right)$ burns in air:

$$
\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(l)+\mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l)
$$

Balance the equation and determine the volume of air in liters at $45.0^{\circ} \mathrm{C}$ and 793 mmHg required to burn 185 g of ethanol. Assume that air is 21.0 percent $\mathrm{O}_{2}$ by volume.

## Section 11.5: Gas Mixtures

## Visualizing Chemistry

Figure 11.15
VC 11.1 The molar volume of hydrogen can be determined using the reaction of zinc metal and acid,

$$
\mathrm{Zn}(s)+2 \mathrm{H}^{+}(a q) \longrightarrow \mathrm{Zn}^{2+}(a q)+\mathrm{H}_{2}(g)
$$

as shown in Figure 11.15. When the reaction is complete, what does the space above the water in the graduated cylinder contain?
a) $\mathrm{H}_{2}(g), \mathrm{Zn}^{2+}(a q)$, and $\mathrm{H}_{2} \mathrm{O}(g)$
b) $\mathrm{H}_{2}(g)$ and $\mathrm{H}_{2} \mathrm{O}(g)$
a) $\mathrm{H}_{2}(g), \mathrm{H}_{2} \mathrm{O}(g)$, and air

VC 11.2 How would the calculated molar volume be affected if we neglected to subtract the partial pressure of water vapor from the total pressure?
a) It would be greater.
b) It would be smaller.
c) It would not change.

VC 11.3 How would the calculated molar volume be affected if we neglected to adjust the level of the graduated cylinder prior to reading the volume of gas collected? Assume that the level of water inside the graduated cylinder is higher than the level outside.
a) It would be greater.
b) It would be smaller.
c) It would not change.

VC 11.4 How would the calculated molar volume be affected if some of the zinc metal failed to drop into the aqueous acid?
a) It would be greater.
b) It would be smaller.
c) It would not change.

## Review Questions

11.64 State Dalton's law of partial pressures and explain what mole fraction is. Does mole fraction have units?
11.65 What are the approximate partial pressures of $\mathrm{N}_{2}$ and $\mathrm{O}_{2}$ in air at the top of a mountain where atmospheric pressure is 0.8 atm ? (See Problem 11.49.)

## Problems

11.66 A mixture of gases contains $0.31 \mathrm{~mol} \mathrm{CH}_{4}, 0.25 \mathrm{~mol} \mathrm{C}_{2} \mathrm{H}_{6}$, and $0.29 \mathrm{~mol} \mathrm{C}_{3} \mathrm{H}_{8}$. The total pressure is 1.50 atm . Calculate the partial pressures of the gases.
11.67 A 2.5-L flask at $15^{\circ} \mathrm{C}$ contains a mixture of $\mathrm{N}_{2}, \mathrm{He}$, and Ne at partial pressures of 0.32 atm for $\mathrm{N}_{2}, 0.15 \mathrm{~atm}$ for He , and 0.42 atm for Ne . (a) Calculate the total pressure of the mixture.
(b) Calculate the volume in liters at STP occupied by He and Ne if the $\mathrm{N}_{2}$ is removed selectively.
11.68 Dry air near sea level has the following composition by volume: $\mathrm{N}_{2}, 78.08$ percent; $\mathrm{O}_{2}$, 20.94 percent; Ar, 0.93 percent; $\mathrm{CO}_{2}$, 0.05 percent. The atmospheric pressure is 1.00 atm . Calculate (a) the partial pressure of each gas in atmospheres and (b) the concentration of each gas in $\mathrm{mol} / \mathrm{L}$ at $0^{\circ} \mathrm{C}$. (Hint: Because volume is proportional to the number of moles present, mole fractions of gases can be expressed as ratios of volumes at the same temperature and pressure.)
11.69 A mixture of helium and neon gases is collected over water at $28.0^{\circ} \mathrm{C}$ and 745 mmHg . If the partial pressure of helium is 368 mmHg , what is the partial pressure of neon? (Vapor pressure of water at $28^{\circ} \mathrm{C}=28.3 \mathrm{mmHg}$.)

E11.70 A piece of sodium metal reacts completely with water as follows:

$$
2 \mathrm{Na}(s)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{NaOH}(a q)+\mathrm{H}_{2}(g)
$$

The hydrogen gas generated is collected over water at $25.0^{\circ} \mathrm{C}$. The volume of the gas is 246 mL measured at 1.00 atm . Calculate the number of grams of sodium used in the reaction. (Vapor pressure of water at $25^{\circ} \mathrm{C}=0.0313 \mathrm{~atm}$.)
11.71 A sample of zinc metal reacts completely with an excess of hydrochloric acid:

$$
\mathrm{Zn}(s)+2 \mathrm{HCl}(a q) \longrightarrow \mathrm{ZnCl}_{2}(a q)+\mathrm{H}_{2}(g)
$$

The hydrogen gas produced is collected over water at $25.0^{\circ} \mathrm{C}$ using an arrangement similar to that shown in Figure 11.14(a). The volume of the gas is 7.80 L , and the pressure is 0.980 atm . Calculate the amount of zinc metal in grams consumed in the reaction. (Vapor pressure of water at $25^{\circ} \mathrm{C}=23.8 \mathrm{mmHg}$.)
11.72 Helium is mixed with oxygen gas for deep-sea divers. Calculate the percent by volume of oxygen gas in the mixture if the diver has to submerge to a depth where the total pressure is 5.2 atm . The partial pressure of oxygen is maintained at 0.20 atm at this depth.
11.73 A sample of ammonia $\left(\mathrm{NH}_{3}\right)$ gas is completely decomposed to nitrogen and hydrogen gases over heated iron wool. If the total pressure is 866 mmHg after the reaction, calculate the partial pressures of $\mathrm{N}_{2}$ and $\mathrm{H}_{2}$.

E11.74 Consider the three containers shown, all of which have the same volume and are at the same temperature. (a) Which container has the smallest mole fraction of gas A (red)? (b) Which container has the highest partial pressure of gas B (green)? (c) Which container has the highest total pressure?

11.75 The volume of the box on the right is twice that of the box on the left. The boxes contain helium atoms (red) and hydrogen molecules (green) at the same temperature. (a) Which box has a higher total pressure? (b) Which box has a higher partial pressure of helium?

## Section 11.6: The Kinetic Molecular Theory of Gases

## Review Questions

11.76 What are the basic assumptions of the kinetic molecular theory of gases?
11.77 How does the kinetic molecular theory explain Boyle's law, Charles's law, Avogadro's law, and Dalton's law of partial pressures?
11.78 What does the Maxwell speed distribution curve tell us? Does Maxwell's theory work for a sample of 200 molecules? Explain.
11.79 Which of the following statements is correct? (a) Heat is produced by the collision of gas molecules against one another. (b) When a gas is heated at constant volume, the molecules collide with one another more often.
11.80 Uranium hexafluoride $\left(\mathrm{UF}_{6}\right)$ is a much heavier gas than helium, yet at a given temperature, the average kinetic energies of the samples of the two gases are the same. Explain.
11.81 What is the difference between gas diffusion and effusion?

## Problems

$\Psi 11.82$ Compare the root-mean-square speeds of $\mathrm{O}_{2}$ and $\mathrm{UF}_{6}$ at $65^{\circ} \mathrm{C}$.
H11.83 The temperature in the stratosphere is $-23^{\circ} \mathrm{C}$. Calculate the root-mean-square speeds of $\mathrm{N}_{2}, \mathrm{O}_{2}$, and $\mathrm{O}_{3}$ molecules in this region.
11.84 The average distance traveled by a molecule between successive collisions is called mean free path. For a given amount of a gas, how does the mean free path of a gas depend on (a) density, (b) temperature at constant volume, (c) pressure at constant temperature, (d) volume at constant temperature, and (e) size of the atoms?
11.85 At a certain temperature the speeds of six gaseous molecules in a container are $2.0,2.2,2.6,2.7,3.3$, and $3.5 \mathrm{~m} / \mathrm{s}$. Calculate the root-mean-square speed and the average speed of the molecules. These two average values are close to each other, but the root-mean-square value is always the larger of the two. Why?

E 11.86 The ${ }^{235} \mathrm{U}$ isotope undergoes fission when bombarded with neutrons. However, its natural abundance is only 0.72 percent. To separate it from the more abundant ${ }^{238} \mathrm{U}$ isotope, uranium is first converted to $\mathrm{UF}_{6}$, which is easily vaporized above room temperature. The mixture of the ${ }^{235} \mathrm{UF}_{6}$ and ${ }^{238} \mathrm{UF}_{6}$ gases is then subjected to many stages of effusion. Calculate how much faster ${ }^{235} \mathrm{UF}_{6}$ effuses than ${ }^{238} \mathrm{UF}_{6}$.
11.87 An unknown gas evolved from the fermentation of glucose is found to effuse through a porous barrier in 15.0 min . Under the same conditions of temperature and pressure, it takes an equal volume of $\mathrm{N}_{2} 12.0 \mathrm{~min}$ to effuse through the same barrier. Calculate the molar mass of the unknown gas, and suggest what the gas might be.
11.88 Nickel forms a gaseous compound of the formula $\mathrm{Ni}(\mathrm{CO})_{x}$. What is the value of $x$ given the fact that under the same conditions of temperature and pressure, methane $\left(\mathrm{CH}_{4}\right)$ effuses 3.3 times faster than the compound?

## Section 11.7: Deviation from Ideal Behavior

## Review Questions

11.89 Cite two pieces of evidence to show that gases do not behave ideally under all conditions. Under what set of conditions would a gas be expected to behave most ideally: (a) high temperature and low pressure, (b) high temperature and high pressure, (c) low temperature and high pressure, or (d) low temperature and low pressure?
11.90 Figure 11.25 (a) shows that at $0^{\circ} \mathrm{C}$, with the exception of $\mathrm{H}_{2}$, each of the gases has a pressure at which its compressibility factor is equal to 1 -the point at which the curve crosses the ideal gas line. What is the significance of this point? Does each of these gases have a pressure at which the assumptions of ideal behavior (negligible molecular volume and no intermolecular attractions) are valid? Explain.
11.91 Write the van der Waals equation for a real gas. Explain the corrective terms for pressure and volume.
11.92 (a) A real gas is introduced into a flask of volume $V$. Is the corrected volume of the gas greater or less than $V$ ? (b) Ammonia has a larger $a$ value than neon does (see Table 11.6). What can you conclude about the relative strength of the attractive forces between molecules of ammonia and between atoms of neon?

## Problems

11.93 Using the data shown in Table 11.6, calculate the pressure exerted by 2.50 moles of $\mathrm{CO}_{2}$ confined in a volume of 5.00 L at 450 K . Compare the pressure with that predicted by the ideal gas equation.
11.94 At $27^{\circ} \mathrm{C}, 10.0$ moles of a gas in a $1.50-\mathrm{L}$ container exert a pressure of 130 atm . Is this an ideal gas?

## Additional Problems

11.95 Discuss the following phenomena in terms of the gas laws: (a) the pressure increase in an automobile tire on a hot day, (b) the "popping" of a paper bag, (c) the expansion of a weather balloon as it rises in the air, (d) the loud noise heard when a lightbulb shatters.
11.96 Under the same conditions of temperature and pressure, which of the following gases would behave most ideally: $\mathrm{Ne}, \mathrm{N}_{2}$, or $\mathrm{CH}_{4}$ ? Explain.
11.97 Nitroglycerin, an explosive compound, decomposes according to the equation

$$
4 \mathrm{C}_{3} \mathrm{H}_{5}\left(\mathrm{NO}_{3}\right)_{3}(s) \longrightarrow 12 \mathrm{CO}_{2}(g)+10 \mathrm{H}_{2} \mathrm{O}(g)+6 \mathrm{~N}_{2}(g)+\mathrm{O}_{2}(g)
$$

Calculate the total volume of gases when collected at 1.2 atm and $25^{\circ} \mathrm{C}$ from $2.6 \times 10^{2} \mathrm{~g}$ of nitroglycerin. What are the partial pressures of the gases under these conditions?
11.98 The empirical formula of a compound is CH . At $200^{\circ} \mathrm{C}, 0.145 \mathrm{~g}$ of this compound occupies 97.2 mL at a pressure of 0.74 atm . What is the molecular formula of the compound?
$\$ 11.99$ When ammonium nitrite $\left(\mathrm{NH}_{4} \mathrm{NO}_{2}\right)$ is heated, it decomposes to give nitrogen gas. This property is used to inflate some tennis balls. (a) Write a balanced equation for the reaction. (b) Calculate the quantity (in grams) of $\mathrm{NH}_{4} \mathrm{NO}_{2}$ needed to inflate a tennis ball to a volume of 86.2 mL at 1.20 atm and $22^{\circ} \mathrm{C}$.

G11.100 The percent by mass of bicarbonate $\left(\mathrm{HCO}_{3}^{-}\right)$in a certain Alka-Seltzer product is 32.5 percent. Calculate the volume of $\mathrm{CO}_{2}$ generated (in mL) at $37^{\circ} \mathrm{C}$ and 1.00 atm when a person ingests a $3.29-\mathrm{g}$ tablet. (Hint: The reaction is between $\mathrm{HCO}_{3}^{-}$ and HCl acid in the stomach.)
11.101 Three flasks containing gases $A$ (red) and $B$ (blue) are shown here. (a) If the total pressure in (i) is 2.0 atm , what are the pressures in (ii) and (iii)? (b) Calculate the total pressure and the partial pressure of each gas after the valves are opened. The volumes of (i) and (iii) are 2.0 L each, and the volume of (ii) is 1.0 L . The temperature is the same throughout.

11.102 The boiling point of liquid nitrogen is $-196^{\circ} \mathrm{C}$. On the basis of this information alone, do you think nitrogen is an ideal gas at STP?
11.103 In the metallurgical process of refining nickel, the metal is first combined with carbon monoxide to form tetracarbonylnickel, which is a gas at $43^{\circ} \mathrm{C}$ :

$$
\mathrm{Ni}(s)+4 \mathrm{CO}(g) \longrightarrow \mathrm{Ni}(\mathrm{CO})_{4}(g)
$$

This reaction separates nickel from other solid impurities. (a) Starting with 86.4 g of Ni , calculate the pressure of $\mathrm{Ni}(\mathrm{CO})_{4}$ in a container of volume 4.00 L . (Assume the preceding reaction goes to completion.) (b) At temperatures above $43^{\circ} \mathrm{C}$, the pressure of the gas is observed to increase much more rapidly than predicted by the ideal gas equation. Explain.
11.104 The partial pressure of carbon dioxide varies with seasons. Would you expect the partial pressure in the Northern Hemisphere to be higher in the summer or winter? Explain.
11.105 A healthy adult exhales about $5.0 \times 10^{2} \mathrm{~mL}$ of a gaseous mixture with each breath. Calculate the number of molecules present in this volume at $37^{\circ} \mathrm{C}$ and 1.1 atm . List the major components of this gaseous mixture.

E11.106 Sodium bicarbonate $\left(\mathrm{NaHCO}_{3}\right)$ is called baking soda because, when heated, it releases carbon dioxide gas, which is responsible for the rising of cookies, some doughnuts, and cakes. (a) Calculate the volume (in liters) of $\mathrm{CO}_{2}$ produced by heating 5.0 g of $\mathrm{NaHCO}_{3}$ at $180^{\circ} \mathrm{C}$ and 1.3 atm . (b) Ammonium bicarbonate $\left(\mathrm{NH}_{4} \mathrm{HCO}_{3}\right)$ has also been used for the same purpose. Suggest one advantage and one disadvantage of using $\mathrm{NH}_{4} \mathrm{HCO}_{3}$ instead of $\mathrm{NaHCO}_{3}$ for baking.
11.107 On heating, potassium chlorate $\left(\mathrm{KClO}_{3}\right)$ decomposes to yield potassium chloride and oxygen gas. In one experiment, a student heated 20.4 g of $\mathrm{KClO}_{3}$ until the decomposition was complete. (a) Write a balanced equation for the reaction. (b) Calculate the volume of oxygen (in liters) if it was collected at 0.962 atm and $18.3^{\circ} \mathrm{C}$.

E- 11.108 Some commercial drain cleaners contain a mixture of sodium hydroxide and aluminum powder. When the mixture is poured down a clogged drain, the following reaction occurs:
$2 \mathrm{NaOH}(a q)+2 \mathrm{Al}(s)+6 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{NaAl}(\mathrm{OH})_{4}(a q)+3 \mathrm{H}_{2}(g)$ The heat generated in this reaction helps melt away obstructions such as grease, and the hydrogen gas released stirs up the solids clogging the drain. Calculate the volume of $\mathrm{H}_{2}$ formed at $23^{\circ} \mathrm{C}$ and 1.00 atm if 3.12 g of Al are treated with an excess of NaOH .

- 11.109 The volume of a sample of pure HCl gas was 189 mL at $25^{\circ} \mathrm{C}$ and 108 mmHg . It was completely dissolved in about 60 mL of water and titrated with an NaOH solution; 15.7 mL of the NaOH solution was required to neutralize the HCl . Calculate the molarity of the NaOH solution.

E 11.110 Propane $\left(\mathrm{C}_{3} \mathrm{H}_{8}\right)$ burns in oxygen to produce carbon dioxide gas and water vapor. (a) Write a balanced equation for this reaction. (b) Calculate the number of liters of carbon dioxide measured at STP that could be produced from 7.45 g of propane.
11.111 Consider the following apparatus. Calculate the partial pressures of helium and neon after the stopcock is opened. The temperature remains constant at $16^{\circ} \mathrm{C}$.

11.112 Nitric oxide (NO) reacts with molecular oxygen as follows:

$$
2 \mathrm{NO}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{NO}_{2}(g)
$$

Initially NO and $\mathrm{O}_{2}$ are separated as shown here. When the valve is opened, the reaction quickly goes to completion. Determine what gases remain at the end and calculate their partial pressures. Assume that the temperature remains constant at $25^{\circ} \mathrm{C}$.

11.113 Consider the apparatus shown here. When a small amount of water is introduced into the flask by squeezing the bulb of the medicine dropper, water is squirted upward out of the long glass tubing. Explain this observation. (Hint: Hydrogen chloride gas is soluble in water.)

11.114 Describe how you would measure, by either chemical or physical means, the partial pressures of a mixture of gases of the following composition: (a) $\mathrm{CO}_{2}$ and $\mathrm{H}_{2}$, (b) He and $\mathrm{N}_{2}$.
$\boldsymbol{\Psi 1 1 . 1 1 5}$ A certain hydrate has the formula $\mathrm{MgSO}_{4} \cdot x \mathrm{H}_{2} \mathrm{O}$. A quantity of 54.2 g of the compound is heated in an oven to drive off the water. If the steam generated exerts a pressure of 24.8 atm in a 2.00-L container at $120^{\circ} \mathrm{C}$, calculate $x$.
11.116 A mixture of $\mathrm{Na}_{2} \mathrm{CO}_{3}$ and $\mathrm{MgCO}_{3}$ of mass 7.63 g is combined with an excess of hydrochloric acid. The $\mathrm{CO}_{2}$ gas generated occupies a volume of 1.67 L at 1.24 atm and $26^{\circ} \mathrm{C}$. From these data, calculate the percent composition by mass of $\mathrm{Na}_{2} \mathrm{CO}_{3}$ in the mixture.
11.117 The apparatus shown here can be used to measure atomic and molecular speeds. Suppose that a beam of metal atoms is directed at a rotating cylinder in a vacuum. A small opening in the cylinder allows the atoms to strike a target area. Because the cylinder is rotating, atoms traveling at different speeds will strike the target at different positions. In time, a layer of the metal will deposit on the target area, and the variation in its thickness is found to correspond to Maxwell's speed distribution. In one experiment it is found that at $850^{\circ} \mathrm{C}$ some bismuth ( Bi ) atoms struck the target at a point 2.80 cm from the spot directly opposite the slit. The diameter of the cylinder is 15.0 cm , and it is rotating at 130 revolutions per second. (a) Calculate the speed (in $\mathrm{m} / \mathrm{s}$ ) at which the target is moving. (Hint: The circumference of a circle is given by $2 \pi r$, where $r$ is the radius.) (b) Calculate the time (in seconds) it takes for the target to travel 2.80 cm . (c) Determine the speed of the Bi atoms. Compare your result in part (c) with the $u_{\mathrm{rms}}$ of Bi at $850^{\circ} \mathrm{C}$. Comment on the difference.

E 11.118 If 10.00 g of water is introduced into an evacuated flask of volume 2.500 L at $65^{\circ} \mathrm{C}$, calculate the mass of water vaporized. (Hint: Assume that the volume of the remaining liquid water is negligible; the vapor pressure of water at $65^{\circ} \mathrm{C}$ is 187.5 mmHg .)

E11.119 Commercially, compressed oxygen is sold in metal cylinders. If a 120-L cylinder is filled with oxygen to a pressure of 132 atm at $22^{\circ} \mathrm{C}$, what is the mass of $\mathrm{O}_{2}$ present? How many liters of $\mathrm{O}_{2}$ gas at 1.00 atm and $22^{\circ} \mathrm{C}$ could the cylinder produce? (Assume ideal behavior.)

E11.120 The shells of hard-boiled eggs sometimes crack due to the rapid thermal expansion of the shells at high temperatures. Suggest another reason why the shells may crack.
11.121 Ethylene gas $\left(\mathrm{C}_{2} \mathrm{H}_{4}\right)$ is emitted by fruits and is known to be responsible for their ripening. Based on this information, explain why a bunch of bananas ripens faster in a closed paper bag than in an open bowl.

G11.122 About $8.0 \times 10^{6}$ tons of urea $\left[\left(\mathrm{NH}_{2}\right)_{2} \mathrm{CO}\right]$ is used annually as a fertilizer. The urea is prepared at $200^{\circ} \mathrm{C}$ and under high-pressure conditions from carbon dioxide and ammonia (the products are urea and steam). Calculate the volume of ammonia (in liters) measured at 150 atm needed to prepare 1.0 ton of urea.
11.123 Some ballpoint pens have a small hole in the main body of the pen. What is the purpose of this hole?
11.124 The gas laws are vitally important to scuba divers. The pressure exerted by 33 ft of seawater is equivalent to 1 atm pressure. (a) A diver ascends quickly to the surface of the water from a depth of 36 ft without exhaling gas from his lungs. By what factor will the volume of his lungs increase by the time he reaches the surface? Assume that the temperature is constant. (b) The partial pressure of oxygen in air is about 0.20 atm . (Air is 20 percent oxygen by volume.) In deep-sea diving, the composition of air the diver breathes must be changed to maintain this partial pressure. What must the oxygen content (in percent by volume) be when the total pressure exerted on the diver is 4.0 atm ? (At constant temperature and pressure, the volume of a gas is directly proportional to the number of moles of gases.)
11.125 Nitrous oxide $\left(\mathrm{N}_{2} \mathrm{O}\right)$ can be obtained by the thermal decomposition of ammonium nitrate $\left(\mathrm{NH}_{4} \mathrm{NO}_{3}\right)$. (a) Write a balanced equation for the reaction. (b) In a certain experiment, a student obtains 0.340 L of the gas at 718 mmHg and $24^{\circ} \mathrm{C}$. If the gas weighs 0.580 g , calculate the value of the gas constant.

E 11.126 Two vessels are labeled $A$ and $B$. Vessel A contains $\mathrm{NH}_{3}$ gas at $70^{\circ} \mathrm{C}$, and vessel B contains Ne gas at the same temperature. If the average kinetic energy of $\mathrm{NH}_{3}$ is $7.1 \times 10^{-21} \mathrm{~J} /$ molecule, calculate the root-mean-square speed of Ne atoms in $\mathrm{m}^{2} / \mathrm{s}^{2}$.
11.127 Which of the following molecules has the largest $a$ value: $\mathrm{CH}_{4}$, $\mathrm{F}_{2}, \mathrm{C}_{6} \mathrm{H}_{6}, \mathrm{Ne}$ ?
11.128 The following procedure is a simple though somewhat crude way to measure the molar mass of a gas. A liquid of mass 0.0184 g is introduced into a syringe like the one shown here by injection through the rubber tip using a hypodermic needle. The syringe is then transferred to a temperature bath heated to $45^{\circ} \mathrm{C}$, and the liquid vaporizes. The final volume of the vapor (measured by the outward movement of the plunger) is 5.58 mL , and the atmospheric pressure is 760 mmHg . Given that the compound's empirical formula is $\mathrm{CH}_{2}$, determine the molar mass of the compound.

11.129 In 1995 a man suffocated as he walked by an abandoned mine in England. At that moment there was a sharp drop in atmospheric pressure due to a change in the weather. Suggest what might have caused the man's death.

E11.130 Acidic oxides such as carbon dioxide react with basic oxides like calcium oxide $(\mathrm{CaO})$ and barium oxide $(\mathrm{BaO})$ to form salts (metal carbonates). (a) Write equations representing these two reactions. (b) A student placed a mixture of BaO and CaO of combined mass 4.88 g in a 1.46-L flask containing carbon dioxide gas at $35^{\circ} \mathrm{C}$ and 746 mmHg . After the reactions were complete, she found that the $\mathrm{CO}_{2}$ pressure had dropped to 252 mmHg . Calculate the percent composition by mass of the mixture. Assume that the volumes of the solids are negligible.
11.131 (a) What volume of air at 1.0 atm and $22^{\circ} \mathrm{C}$ is needed to fill a 0.98 -L bicycle tire to a pressure of 5.0 atm at the same temperature? (Note that the 5.0 atm is the gauge pressure, which is the difference between the pressure in the tire and atmospheric pressure. Before filling, the pressure in the tire was 1.0 atm .) (b) What is the total pressure in the tire when the gauge pressure reads 5.0 atm ? (c) The tire is pumped by filling the cylinder of a hand pump with air at 1.0 atm and then, by compressing the gas in the cylinder, adding all the air in the pump to the air in the tire. If the volume of the pump is 33 percent of the tire's volume, what is the gauge pressure in the tire after three full strokes of the pump? Assume constant temperature.

G11.132 The running engine of an automobile produces carbon monoxide (CO), a toxic gas, at the rate of about 188 g CO per hour. A car is left idling in a poorly ventilated garage that is 6.0 m long, 4.0 m wide, and 2.2 m high at $20^{\circ} \mathrm{C}$. (a) Calculate the rate of CO production in $\mathrm{mol} / \mathrm{min}$. (b) How long would it take to build up a lethal concentration of CO of 1000 ppmv (parts per million by volume)?
11.133 Interstellar space contains mostly hydrogen atoms at a concentration of about 1 atom $/ \mathrm{cm}^{3}$. (a) Calculate the pressure of the H atoms. (b) Calculate the volume (in liters) that contains 1.0 g of H atoms. The temperature is 3 K .
11.134 Atop Mt. Everest, the atmospheric pressure is 210 mmHg and the air density is $0.426 \mathrm{~kg} / \mathrm{m}^{3}$. (a) Calculate the air temperature, given that the molar mass of air is $29.0 \mathrm{~g} / \mathrm{mol}$. (b) Assuming no change in air composition, calculate the percent decrease in oxygen gas from sea level to the top of Mt. Everest.
11.135 Relative humidity is defined as the ratio (expressed as a percentage) of the partial pressure of water vapor in the air to the equilibrium vapor pressure (see Table 11.5) at a given temperature. On a certain summer day in North Carolina the partial pressure of water vapor in the air is $3.9 \times 10^{3} \mathrm{~Pa}$ at $30^{\circ} \mathrm{C}$. Calculate the relative humidity.
11.136 Under the same conditions of temperature and pressure, why does 1 L of moist air weigh less than 1 L of dry air? In weather forecasts, an oncoming low-pressure front usually means imminent rainfall. Explain.

E11.137 Air entering the lungs ends up in tiny sacs called alveoli. It is from the alveoli that oxygen diffuses into the blood. The average radius of the alveoli is 0.0050 cm , and the air inside contains 14 percent oxygen. Assuming that the pressure in the alveoli is 1.0 atm and the temperature is $37^{\circ} \mathrm{C}$, calculate the number of oxygen molecules in one of the alveoli. (Hint: The volume of a sphere of radius $r$ is $\frac{4}{3} \pi r^{3}$.)
11.138 A student breaks a thermometer and spills most of the mercury $(\mathrm{Hg})$ onto the floor of a laboratory that measures 15.2 m long, 6.6 m wide, and 2.4 m high. (a) Calculate the mass of mercury vapor (in grams) in the room at $20^{\circ} \mathrm{C}$. The vapor pressure of mercury at $20^{\circ} \mathrm{C}$ is $1.7 \times 10^{-6} \mathrm{~atm}$. (b) Does the concentration of mercury vapor exceed the air quality regulation of 0.050 mg $\mathrm{Hg} / \mathrm{m}^{3}$ of air? (c) One way to deal with small quantities of spilled mercury is to spray sulfur powder over the metal. Suggest a physical and a chemical reason for this action.
11.139 Nitrogen forms several gaseous oxides. One of them has a density of $1.33 \mathrm{~g} / \mathrm{L}$ measured at 764 mmHg and $150^{\circ} \mathrm{C}$. Write the formula of the compound.
$\mathbb{Y}$ 11.140 Nitrogen dioxide $\left(\mathrm{NO}_{2}\right)$ cannot be obtained in a pure form in the gas phase because it exists as a mixture of $\mathrm{NO}_{2}$ and $\mathrm{N}_{2} \mathrm{O}_{4}$. At $25^{\circ} \mathrm{C}$ and 0.98 atm , the density of this gas mixture is $2.7 \mathrm{~g} / \mathrm{L}$. What is the partial pressure of each gas?
G11.141 Lithium hydride reacts with water as follows:

$$
\mathrm{LiH}(s)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{LiOH}(a q)+\mathrm{H}_{2}(g)
$$

During World War II, U.S. pilots carried LiH tablets. In the event of a crash landing at sea, the LiH would react with the seawater and fill their life jackets and lifeboats with hydrogen gas. How many grams of LiH are needed to fill a 4.1-L life jacket at 0.97 atm and $12^{\circ} \mathrm{C}$ ?

Y 11.142 The atmosphere on Mars is composed mainly of carbon dioxide. The surface temperature is 220 K , and the atmospheric pressure is about 6.0 mmHg . Taking these values as Martian "STP," calculate the molar volume in liters of an ideal gas on Mars.
11.143 Venus's atmosphere is composed of 96.5 percent $\mathrm{CO}_{2}, 3.5$ percent $\mathrm{N}_{2}$, and 0.015 percent $\mathrm{SO}_{2}$ by volume. Its standard atmospheric pressure is $9.0 \times 10^{6} \mathrm{~Pa}$. Calculate the partial pressures of the gases in pascals.
11.144 A student tries to determine the volume of a bulb like the one shown in Figure 11.12. These are her results: mass of the bulb filled with dry air at $23^{\circ} \mathrm{C}$ and $744 \mathrm{mmHg}=91.6843 \mathrm{~g}$; mass of evacuated bulb $=91.4715 \mathrm{~g}$. Assume the composition of air
is 78 percent $\mathrm{N}_{2}$, 21 percent $\mathrm{O}_{2}$, and 1 percent argon by volume. What is the volume (in mL ) of the bulb? (Hint: First calculate the average molar mass of air, as shown in Problem 3.153.)
11.145 Apply your knowledge of the kinetic theory of gases to the following situations. (a) Two flasks of volumes $V_{1}$ and $V_{2}$ $\left(V_{2}>V_{1}\right)$ contain the same number of helium atoms at the same temperature. (i) Compare the root-mean-square (rms) speeds and average kinetic energies of the helium ( He ) atoms in the flasks. (ii) Compare the frequency and the force with which the He atoms collide with the walls of their containers. (b) Equal numbers of He atoms are placed in two flasks of the same volume at temperatures $T_{1}$ and $T_{2}\left(T_{2}>T_{1}\right)$. (i) Compare the rms speeds of the atoms in the two flasks. (ii) Compare the frequency and the force with which the He atoms collide with the walls of their containers. (c) Equal numbers of He and neon $(\mathrm{Ne})$ atoms are placed in two flasks of the same volume, and the temperature of both gases is $74^{\circ} \mathrm{C}$. Comment on the validity of the following statements: (i) The rms speed of He is equal to that of Ne . (ii) The average kinetic energies of the two gases are equal. (iii) The rms speed of each He atom is $1.47 \times 10^{3} \mathrm{~m} / \mathrm{s}$.
11.146 At what temperature will He atoms have the same $u_{\mathrm{rms}}$ value as $\mathrm{N}_{2}$ molecules at $25^{\circ} \mathrm{C}$ ?
11.147 Estimate the distance (in nm ) between molecules of water vapor at $100^{\circ} \mathrm{C}$ and 1.0 atm . Assume ideal behavior. Repeat the calculation for liquid water at $100^{\circ} \mathrm{C}$, given that the density of water is $0.96 \mathrm{~g} / \mathrm{cm}^{3}$ at that temperature. Comment on your results. (Assume each water molecule to be a sphere with a diameter of 0.3 nm .) (Hint: First calculate the number density of water molecules. Next, convert the number density to linear density, that is, the number of molecules in one direction.)
11.148 Which of the noble gases would not behave ideally under any circumstance? Why?
$\leftrightarrows 11.149$ A 5.72-g sample of graphite was heated with 68.4 g of $\mathrm{O}_{2}$ in a $8.00-\mathrm{L}$ flask. The reaction that took place was

$$
\mathrm{C} \text { (graphite) }+\mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g)
$$

After the reaction was complete, the temperature in the flask was $182^{\circ} \mathrm{C}$. What was the total pressure inside the flask?

E 11.150 A 6.11-g sample of a $\mathrm{Cu}-\mathrm{Zn}$ alloy reacts with HCl acid to produce hydrogen gas. If the hydrogen gas has a volume of 1.26 L at $22^{\circ} \mathrm{C}$ and 728 mmHg , what is the percent of Zn in the alloy? (Hint: Cu does not react with HCl .)

E11.151 A stockroom supervisor measured the contents of a 25.0-gal drum partially filled with acetone on a day when the temperature was $18.0^{\circ} \mathrm{C}$ and atmospheric pressure was 750 mmHg , and found that 15.4 gal of the solvent remained. After tightly sealing the drum, an assistant dropped the drum while carrying it upstairs to the organic laboratory. The drum was dented, and its internal volume was decreased to 20.4 gal. What is the total pressure inside the drum after the accident? The vapor pressure of acetone at $18.0^{\circ} \mathrm{C}$ is 400 mmHg . (Hint: At the time the drum was sealed, the pressure inside the drum, which is equal to the sum of the pressures of air and acetone, was equal to the atmospheric pressure.)
$\$ 11.152$ In $2.00 \mathrm{~min}, 29.7 \mathrm{~mL}$ of He effuses through a small hole. Under the same conditions of pressure and temperature, 10.0 mL of a mixture of CO and $\mathrm{CO}_{2}$ effuses through the hole in the same amount of time. Calculate the percent composition by volume of the mixture.

Y11.153 A mixture of methane $\left(\mathrm{CH}_{4}\right)$ and ethane $\left(\mathrm{C}_{2} \mathrm{H}_{6}\right)$ is stored in a container at 294 mmHg . The gases are burned in air to form $\mathrm{CO}_{2}$ and $\mathrm{H}_{2} \mathrm{O}$. If the pressure of $\mathrm{CO}_{2}$ is 356 mmHg , measured at the same temperature and volume as the original mixture, calculate the mole fractions of the gases.
11.154 Use the kinetic theory of gases to explain why hot air rises.
11.155 Given that the van der Waals constant $b$ is the excluded volume and that the excluded volume is four times the volume actually occupied by the gas molecules in a sample (see Sample Problem 11.18), determine what percentage of the container volume is actually occupied by $\mathrm{CCl}_{4}(g)$ molecules at (a) STP, (b) 10.0 atm and 273 K , and (c) 50.0 atm and 273 K .
11.156 A 5.00-mole sample of $\mathrm{NH}_{3}$ gas is kept in a 1.92-L container at 300 K . If the van der Waals equation is assumed to give the correct answer for the pressure of the gas, calculate the percent error made in using the ideal gas equation to calculate the pressure.
11.157 The root-mean-square speed of a certain gaseous oxide is $493 \mathrm{~m} / \mathrm{s}$ at $20^{\circ} \mathrm{C}$. What is the molecular formula of the compound?
11.158 Referring to Figure 11.20, we see that the maximum of each speed distribution plot is called the most probable speed $\left(u_{\mathrm{mp}}\right)$ because it is the speed possessed by the largest number of molecules. It is given by $u_{\mathrm{mp}}=\sqrt{2 R T} / \mathcal{M}$. (a) Compare $u_{\mathrm{mp}}$ with $u_{\mathrm{rms}}$ for nitrogen at $25^{\circ} \mathrm{C}$. (b) The following diagram shows the Maxwell speed distribution curves for an ideal gas at two different temperatures $T_{1}$ and $T_{2}$. Calculate the value of $T_{2}$.

11.159 A gaseous reaction takes place at constant volume and constant pressure in a cylinder as shown here. Which of the following equations best describes the reaction? The initial temperature $\left(T_{1}\right)$ is twice that of the final temperature $\left(T_{2}\right)$.
(a) $\mathrm{A}+\mathrm{B} \longrightarrow \mathrm{C}$
(b) $\mathrm{AB} \longrightarrow \mathrm{C}+\mathrm{D}$
(c) $\mathrm{A}+\mathrm{B} \longrightarrow \mathrm{C}+\mathrm{D}$
(d) $\mathrm{A}+\mathrm{B} \longrightarrow 2 \mathrm{C}+\mathrm{D}$

11.160 Assuming ideal behavior, which of the following gases will have the greatest volume at STP? (a) 0.82 mole of He , (b) 24 g of $\mathrm{N}_{2}$, or (c) $5.0 \times 10^{23}$ molecules of $\mathrm{Cl}_{2}$.
11.161 Calculate the density of helium in a helium balloon at $25.0^{\circ} \mathrm{C}$. (Assume that the pressure inside the balloon is 1.10 atm .)
11.162 Helium atoms in a closed container at room temperature are constantly colliding with one another and with the walls of their container. Does this "perpetual motion" violate the law of conservation of energy? Explain.
11.163 Uranium hexafluoride $\left(\mathrm{UF}_{6}\right)$ is a much heavier gas than hydrogen, yet at a given temperature, the average kinetic energies of these two gases are the same. Explain.
11.164 Consider the molar volumes shown in Figure 11.23. (a) Explain why $\mathrm{Cl}_{2}$ and $\mathrm{NH}_{3}$ have molar volumes significantly smaller from that of an ideal gas. (b) Explain why $\mathrm{H}_{2}$, He , and Ne have molar
volumes greater than that of an ideal gas. (Hint: Look up the boiling points of the gases shown in the figure.)
11.165 The plot of $Z$ versus $P$ for a gas at $0^{\circ} \mathrm{C}$ is shown. Explain the causes of the negative deviation from ideal behavior at lower pressures and the positive deviation from ideal behavior at higher pressures.

## Pre-Professional Practice Exam Problems: Physical and Biological Sciences

It has been said that every breath we take, on average, contains molecules that were once exhaled by Wolfgang Amadeus Mozart (1756-1791).

1. Calculate the total number of molecules in the atmosphere. (Assume that the total mass of the atmosphere is $6 \times 10^{18} \mathrm{~kg}$ and the average molar mass of air is $29.0 \mathrm{~g} / \mathrm{mol}$.)
a) $1 \times 10^{23}$
b) $1 \times 10^{26}$
c) $1 \times 10^{29}$
d) $1 \times 10^{18}$
2. Assuming the volume of every breath (inhale or exhale) is 0.5 L , calculate the number of molecules exhaled in each breath at body temperature $\left(37^{\circ} \mathrm{C}\right)$ and 1 atm .
a) $1 \times 10^{22}$
b) $1 \times 10^{21}$
c) $1 \times 10^{23}$
d) $6 \times 10^{23}$
3. Calculate the mass of air exhaled with each breath.
a) 0.02 g
b) 0.6 g
c) 0.2 g
d) 6 g
4. If Mozart's life span was exactly 35 years, what is the number of molecules he exhaled in that period (given that an average person breathes 12 times per minute)?
a) $2 \times 10^{8}$
b) $2 \times 10^{29}$
c) $1 \times 10^{29}$
d) $3 \times 10^{30}$

Late in 2007, reports began to surface that infants in China were falling ill after being fed formula contaminated with melamine.
The contamination was the result of criminal activity.

## How Intermolecular Forces Contributed to the Contaminated Infant Formula Tragedy in China

Life as we know it depends heavily on intermolecular forces-the attractions that keep molecules together. Without them, water-perhaps the most essential ingredient in lifewould not be a liquid. On this occasion, though, intermolecular forces caused two contaminants in infant formula, each relatively innocuous by itself, to form a highly toxic complex that caused many thousands of babies in China to develop acute kidney failure.

The contamination turned out to have been the result of foul play. Unscrupulous vendors of dairy products sought to increase their profits by diluting the milk they sold. However, because its protein content would have appeared too low, diluted milk would not have passed the industry quality control tests. To boost the apparent protein content, the vendors added melamine $\left(\mathrm{C}_{3} \mathrm{H}_{6} \mathrm{~N}_{6}\right)$ to the diluted milk. Although melamine is not a protein, its high nitrogen content ( 66.6 percent by mass) made the milk appear to contain adequate protein. The industry test for protein does not measure protein specifically but rather nitrogen content, which in unadulterated milk would give a measure of the protein content. In addition to being added to the milk illegally, the melamine was itself contaminated with another compound, cyanuric acid $\left(\mathrm{C}_{3} \mathrm{H}_{3} \mathrm{~N}_{3} \mathrm{O}_{3}\right)$. At sufficiently high concentrations, these two contaminants form an insoluble complex that precipitates as an unusual type of stone, causing severe kidney damage. The molecules in the insoluble complex are held together by powerful attractive forces known as hydrogen bonds (shown as dashed red lines).

Secrecy surrounding the scandal has made it impossible to know for certain how many babies were poisoned-and how many died. The formation of the toxic melaminecyanuric acid complex is the result of particularly strong attractive forces between the melamine and cyanuric acid molecules. Attractive forces between molecules (intermolecular forces) and within molecules (intramolecular forces) determine many of the physical properties of liquids and solids.

At the end of this chapter, you will be able to answer questions about the physical properties of substances used in the treatment and prevention of kidney stones [ $M$ Page 527].

## In This Chapter, You Will Learn:

About the types of forces that hold the molecules (or atoms or ions) in substances together and about the properties that arise because of these forces.

Before you begin, you should review

- Molecular geometry and polarity [K4 Section 9.2]
- Basic trigonometry [ $\boldsymbol{\|}$ Appendix 1]

### 12.1 Intermolecular Forces

In Chapter 11, we learned that gases consist of rapidly moving particles (molecules or atoms), separated by relatively large distances. Liquids and solids, the condensed phases [ K 4 margin note on page 6], consist of particles (molecules, atoms, or ions) that are touching one another. The attractive forces that hold particles together in the condensed phases are called intermolecular forces. The magnitude of intermolecular forces is what determines whether the particles that make up a substance are a gas, liquid, or solid.

Student Annotation: The term intermolecular is used to refer to attractive forces between molecules, atoms, or ions.

Student Annotation: Hydrogen bonding constitutes a special type of dipole-dipole interaction and is discussed separately.

HCl

We have already encountered an example of "intermolecular" forces in the form of ionic bonding [ 14 Section 8.2], where the magnitude of attraction between oppositely charged particles is governed by Coulomb's law [ 14 Section 7.3]. Because the particles that make up an ionic compound have discrete (full) charges, the attractive forces that hold them together are especially powerful. In fact, that's the reason that they're solids at room temperature. The intermolecular forces that we will encounter in this chapter are also the result of Coulombic attractions, but the attractions involve only partial charges [14 Section 8.4] rather than discrete charges and are therefore weaker than the forces involved in ionic bonding.

We will begin our discussion of intermolecular forces with the attractive forces that act between atoms or molecules in a pure substance. These forces are known collectively as van der Waals forces, and they include dipole-dipole interactions, including hydrogen bonding and dispersion forces.

## Dipole-Dipole Interactions

Dipole-dipole interactions are attractive forces that act between polar molecules. Recall that a diatomic molecule containing elements of significantly different electronegativities, such as HCl , has an unequal distribution of electron density and therefore has partial charges, positive $(\delta+)$ at one end and negative $(\delta-)$ at the other. The partial positive charge on one molecule is attracted to the partial negative charge on a neighboring molecule. Figure 12.1 shows the orientation of polar molecules in a solid and in a liquid. The arrangement is somewhat less orderly in the liquid than it is in the solid.

Because this attractive force between polar molecules is Coulombic, the magnitude of the attractive forces depends on the magnitude of the dipole. In general, the larger the dipole, the larger the attractive force. Certain physical properties such as boiling point reflect the magnitude of intermolecular forces. A substance in which the particles are held together by larger intermolecular attractions will require more energy to separate the particles and will therefore boil at a higher temperature. Table 12.1 lists several compounds with similar molar masses along with their dipole moments and boiling points.

Figure 12.1 Arrangement of polar molecules in a liquid (left) and in a solid (right).

## TABLE 12.1 Dipole Moments and Boiling Points of Compounds with Similar Molecular Masses

| Compound | Structural Formula | Dipole Moment (D) | Boiling Point $\left({ }^{\circ} \mathrm{C}\right)$ |
| :--- | :---: | :---: | :---: |
| Propane | $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{3}$ | 0.1 | -42 |
| Dimethyl ether | $\mathrm{CH}_{3} \mathrm{OCH}_{3}$ | 1.3 | -25 |
| Methyl chloride | $\mathrm{CH}_{3} \mathrm{Cl}$ | 1.9 | -24 |
| Acetaldehyde | $\mathrm{CH}_{3} \mathrm{CHO}$ | 2.7 | 21 |
| Acetonitrile | $\mathrm{CH}_{3} \mathrm{CN}$ | 2.9 | 82 |

## Hydrogen Bonding

Hydrogen bonding is a special type of dipole-dipole interaction. But, whereas dipole-dipole interactions act between any polar molecules, hydrogen bonding occurs only in molecules that contain H bonded to a small, highly electronegative atom, such as $\mathrm{N}, \mathrm{O}$, or F . In a molecule such as HF , which is shown in Figure 12.2, the F atom to which H is bonded draws electron density toward itself. Being small and very electronegative, the F atom draws electron density away from H very effectively. Because H has only one electron, this leaves the hydrogen nucleus practically unshielded-giving H a very large partial positive charge. This large partial positive charge is powerfully attracted to the large partial negative charge (lone pairs) on the small, highly electronegative F atom of a neighboring HF molecule. The result is an especially strong dipole-dipole attraction.

In Sample Problem 8.5 we calculated the partial charges on H and F as +0.41 and -0.41 , respectively. The partial charges on H and Cl , by contrast, are only +0.18 and -0.18 , respectively. They are smaller in HCl because Cl is larger and less electronegative than F . Because of the very high electronegativity of F , and the high partial positive charges that result, HF exhibits significant hydrogen bonding, whereas HCl does not.

Figure 12.3 (page 496) shows the boiling points of the binary hydrogen compounds of Groups 4A through 7A. Within the series of hydrogen compounds of Group 4A, the boiling point increases with increasing molar mass. For Groups 5A through 7A, the same trend is observed for all but the smallest member of each series, which has what appears to be an unexpectedly high boiling point. This departure from the trend in boiling points illustrates how powerful hydrogen bonding can be. $\mathrm{NH}_{3}$ (Group 5A), HF (Group 7A), and $\mathrm{H}_{2} \mathrm{O}$ (Group 6A) have anomalously high boiling points because they exhibit strong hydrogen bonding. $\mathrm{CH}_{4}$ (the smallest member of the Group 4A series) does not exhibit hydrogen bonding because it does not contain an $\mathrm{N}-\mathrm{H}, \mathrm{O}-\mathrm{H}$, or $\mathrm{F}-\mathrm{H}$ bond; hence, it has the lowest boiling point of that group.

Student Annotation: It is a common error to assume that hydrogen bonding occurs in any molecule that contains hydrogen. It only occurs to a significant degree in molecules with $\mathrm{N}-\mathrm{H}, \mathrm{O}-\mathrm{H}$, or $\mathrm{F}-\mathrm{H}$ bonds.

Student Annotation: Strictly speaking, HCl does exhibit hydrogen bonding to a very small degree. But only molecules containing an $\mathrm{N}-\mathrm{H}, \mathrm{O}-\mathrm{H}$, or $\mathrm{F}-\mathrm{H}$ bond exhibit significant hydrogen bonding.

Student Annotation: Hydrogen bonding also occurs in mixtures, between solute and solvent molecules that contain $\mathrm{N}-\mathrm{H}, \mathrm{F}-\mathrm{H}$, or $\mathrm{O}-\mathrm{H}$ bonds.

Figure 12.2 Hydrogen bonds between HF molecules.

Figure 12.3 Boiling points of the hydrogen compounds of elements from Groups 4A through 7A. Although normally the boiling point increases with increasing mass within a group, the lightest compound has the highest boiling point in Groups 5A through 7A. This departure from the observed trend is due to hydrogen bonding.

## Bringing Chemistry to Life

## Sickle Cell Disease

Amino acids are the building blocks of proteins. Each amino acid has both amino $\left(-\mathrm{NH}_{2}\right)$ and carboxy $(-\mathrm{COOH})$ functional groups, in addition to a side group that may be polar or nonpolar. Valine (Val), histidine (His), leucine (Leu), threonine (Thr), proline (Pro), and glutamic acid (Glu) are 6 of the 20 amino acids [ 14 Section 10.6] that make up human proteins. The characteristic side group of each amino acid is shaded to identify it:

Proteins form when amino acids are joined together with peptide bonds, also known as amide linkages, in which the carboxy group on one amino acid connects to the amino group of the next. The carboxy group of the second amino acid connects to the amino group of another, and so on. A water molecule is eliminated with the formation of each peptide bond. What remains of each amino acid after the formation of peptide bonds (and the corresponding loss of water molecules) is referred to as an amino acid residue, or simply a residue. (Peptide bonds are shown in blue.)

The primary structure of a protein refers to the sequence of amino acids that make up the protein chain.

| Val | His | Leu | Thr | Pro | Glu |
| :--- | :--- | :--- | :--- | :--- | :--- |

Secondary structure refers to the shape the protein chain adopts as the result of hydrogen bonding between nearby residues. One of the possible secondary structures is a helix.

Tertiary structure refers to the folding of the protein into a characteristic shape, which is stabilized by attractive forces between more distant residues.

Quaternary structure refers to the shape resulting from the assembly of two or more proteins, called subunits, to form a larger protein complex. In the case of hemoglobin, four subunits [two $\alpha$ subunits (purple), each consisting of 141 amino acids; and two $\beta$ subunits (pink), each consisting of 146 amino acids] make up the larger complex.

Hemoglobin is a globular protein, meaning that it assembles into a roughly spherical shape with polar residues covering most of the sphere's surface and nonpolar residues largely confined to the interior of the complex. Distribution of polar residues on the outside of the sphere enhances a globular protein's aqueous solubility.

In normal hemoglobin, the sixth amino acid residue (of 146) in each $\beta$ subunit is a glutamic acid residue, which is polar. In hemoglobin $S$, the type associated with sickle cell disease, the glutamic acid residue in the sixth position of each $\beta$ subunit is replaced by a valine residue, which is nonpolar. This results in a nonpolar group on the surface of the protein complex, where there should be a polar group.

Although most of the surface of the spherical hemoglobin complex is polar, when it is not oxygenated, one of hemoglobin's $\beta$ subunits has a small nonpolar region on the exterior of the complex. Ordinarily, this is of no consequence.

In hemoglobin $S$, however, the nonpolar valine residue on the surface of one complex is attracted to the nonpolar region on a nearby complex.

This results in hemoglobin forming long chains that precipitate from solution, causing the deformation of red blood cells that is characteristic of sickle cell disease.

These deformed blood cells clog narrow capillaries, restricting blood flow to the body's organs. The reduced blood flow gives rise to anemia, episodes of debilitating pain, susceptibility to infections, stroke, and eventually premature death.

## Dispersion Forces

Nonpolar gases, such as $\mathrm{N}_{2}$ and $\mathrm{O}_{2}$, can be liquefied under the right conditions of pressure and temperature, so nonpolar molecules must also exhibit attractive intermolecular forces. These intermolecular forces are Coulombic in nature (as are all intermolecular forces), but they differ from other intermolecular forces because they arise from the movement of electrons in nonpolar molecules.

On average, the distribution of electron density in a nonpolar molecule is uniform and symmetrical (which is why a nonpolar molecule has no dipole moment). However, because electrons in a molecule have some freedom to move about, at any given point in time the molecule may have a nonuniform distribution of electron density, giving it a fleeting, temporary dipole-called an instantaneous dipole. An instantaneous dipole in one molecule can induce dipoles in neighboring molecules. For example, the temporary partial negative charge on a molecule repels the electrons in a molecule next to it. This repulsion polarizes the second molecule, which then acquires a temporary dipole. It in turn polarizes the next molecule and so on, leaving a collection of ordinarily nonpolar molecules with partial positive and negative charges and Coulombic attractions between them as shown in Figure 12.4. The resulting attractive forces are called London ${ }^{1}$ dispersion forces or simply dispersion forces.

Nonpolar molecule $\longrightarrow$

Figure 12.4 Instantaneous dipoles in ordinarily nonpolar molecules can induce temporary dipoles in neighboring molecules, causing the molecules to be attracted to one another. This type of interaction is responsible for the condensation of nonpolar gases.

[^31]| TABLE 12.2 | Molar Masses, Boiling Points, and States of the Halogens <br> at Room Temperature |  |  |
| :---: | :---: | :---: | :---: |
| Molecule | Molar Mass <br> $(\mathbf{g} / \mathrm{mol})$ | Boiling Point <br> $\left({ }^{\circ} \mathrm{C}\right)$ | State <br> (Room Temp.) |
| $\mathrm{F}_{2}$ | 38.0 | -188 | Gas |
| $\mathrm{Cl}_{2}$ | 70.9 | -34 | Gas |
| $\mathrm{Br}_{2}$ | 159.8 | 59 | Liquid |
| $\mathrm{I}_{2}$ | 253.8 | 184 | Solid |

The magnitude of dispersion forces depends on how mobile the electrons in the molecule are. In small molecules, such as $\mathrm{F}_{2}$, the electrons are relatively close to the nuclei and cannot move about very freely; thus, the electron distribution in $\mathrm{F}_{2}$ is not easily polarized. In larger molecules, such as $\mathrm{Cl}_{2}$, the electrons are somewhat farther away from the nuclei and therefore move about more freely. The electron density in $\mathrm{Cl}_{2}$ is more easily polarized than that in $\mathrm{F}_{2}$, resulting in larger instantaneous dipoles, larger induced dipoles, and larger intermolecular attractions overall. The trend in magnitude of dispersion forces with increasing molecular size is illustrated by the data in Table 12.2. (It is also illustrated by the correlation between molar mass and boiling point in Figure 12.3.) Dispersion forces act not only between nonpolar molecules, but between all molecules.

Sample Problem 12.1 lets you practice determining what kinds of forces exist between particles in liquids and solids.

## Sample Problem 12.1

What kind(s) of intermolecular forces exist in (a) $\mathrm{CCl}_{4}(l)$, (b) $\mathrm{CH}_{3} \mathrm{COOH}(l)$, (c) $\mathrm{CH}_{3} \mathrm{COCH}_{3}(l)$, and (d) $\mathrm{H}_{2} \mathrm{~S}(l)$ ?

Strategy Draw Lewis dot structures and apply VSEPR theory [ 14 Section 9.2] to determine whether each molecule is polar or nonpolar. Nonpolar molecules exhibit dispersion forces only. Polar molecules exhibit both dipole-dipole interactions and dispersion forces. Polar molecules with $\mathrm{N}-\mathrm{H}$, $\mathrm{F}-\mathrm{H}$, or $\mathrm{O}-\mathrm{H}$ bonds exhibit dipole-dipole interactions (including hydrogen bonding) and dispersion forces.

Setup The Lewis dot structures for molecules (a) to (d) are:

(a)

(b)

(c)
$\mathrm{H}-\ddot{\mathrm{S}}-\mathrm{H}$
(d)

## Solution

(a) $\mathrm{CCl}_{4}$ is nonpolar, so the only intermolecular forces are dispersion forces.
(b) $\mathrm{CH}_{3} \mathrm{COOH}$ is polar and contains an $\mathrm{O}-\mathrm{H}$ bond, so it exhibits dipole-dipole interactions (including hydrogen bonding) and dispersion forces.
(c) $\mathrm{CH}_{3} \mathrm{COCH}_{3}$ is polar but does not contain $\mathrm{N}-\mathrm{H}, \mathrm{O}-\mathrm{H}$, or $\mathrm{F}-\mathrm{H}$ bonds, so it exhibits dipoledipole interactions and dispersion forces.
(d) $\mathrm{H}_{2} \mathrm{~S}$ is polar but does not contain $\mathrm{N}-\mathrm{H}, \mathrm{O}-\mathrm{H}$, or $\mathrm{F}-\mathrm{H}$ bonds, so it exhibits dipole-dipole interactions and dispersion forces.

Practice Problem A What kind(s) of intermolecular forces exist in (a) $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3}($ l), (b) $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}(l)$, (c) $\mathrm{H}_{2} \mathrm{CO}(l)$, and (d) $\mathrm{O}_{2}(l)$ ?
$\oiint$ Practice Problem B What kind(s) of intermolecular forces exist in (a) $\mathrm{CH}_{2} \mathrm{Cl}_{2}(l)$, (b) $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{OH}(l)$, (c) $\mathrm{H}_{2} \mathrm{O}_{2}(l)$, and (d) $\mathrm{N}_{2}(l)$ ?

Student Annotation: Molecules that more readily acquire an instantaneous dipole are said to be polarizable. In general, larger molecules have greater polarizability than small ones.

Think About It Being able to draw correct Lewis structures is, once again, vitally important. Review, if you need to, the procedure for drawing them [ 144 Section 8.5].

Student Annotation: Hydration
[14 Section 4.2] is one example of an ion-dipole interaction.

Figure 12.5 Ion-dipole interactions between ions and water molecules. In each case the positive charge on the ion is attracted to the partial negative charge on the oxygen atom in the water molecule. The attraction is stronger when the distance between the two species is smaller.

Figure 12.6 Intermolecular forces acting on a molecule in the surface layer of a liquid and in the interior region of the liquid.

## Ion-Dipole Interactions

Ion-dipole interactions are Coulombic attractions between ions (either positive or negative) and polar molecules. These interactions occur in mixtures of ionic and polar species such as an aqueous solution of sodium chloride. The magnitude of ion-dipole interactions depends on the charge and the size of the ion, and on the dipole moment and size of the polar molecule. Cations generally interact more strongly with dipoles than anions (of the same magnitude charge) because they tend to be smaller.

Figure 12.5 shows the ion-dipole interaction between the $\mathrm{Na}^{+}$and $\mathrm{Mg}^{2+}$ ions with a water molecule, which has a large dipole moment $(1.87 \mathrm{D})$. Because the $\mathrm{Mg}^{2+}$ ion has a higher charge and a smaller size [ 144 Section 7.6] than the $\mathrm{Na}^{+}$ion (the ionic radii of $\mathrm{Mg}^{2+}$ and $\mathrm{Na}^{+}$are 78 and 98 pm , respectively), $\mathrm{Mg}^{2+}$ interacts more strongly with water molecules. The properties of solutions are discussed in Chapter 13.

Although the intermolecular forces discussed so far are all attractive forces, molecules also exert repulsive forces on one another (when like charges approach one another). When two molecules approach each other closely, the repulsions between electrons and between nuclei in the molecules become significant. The magnitude of these repulsive forces rises very steeply as the distance separating the molecules in a condensed phase decreases. This is the reason that liquids and solids are so hard to compress. In these phases, the molecules are already in close contact with one another, and so they greatly resist being compressed further.

## Checkpoint 12.1 Intermolecular Forces

12.1.1 What kind(s) of intermolecular forces exist between benzene molecules $\left(\mathrm{C}_{6} \mathrm{H}_{6}\right)$ ? (Select all that apply.)
a) Dispersion forces
b) Dipole-dipole interactions
c) Hydrogen bonding
d) Ion-dipole interactions
e) Ionic bonding
12.1.2 Which of the following exhibits significant hydrogen bonding? (Select all that apply.)
a) HBr
b) $\mathrm{H}_{2} \mathrm{CF}_{2}$
c) $\mathrm{H}_{2}$
d) $\mathrm{H}_{2} \mathrm{O}_{2}$
e) $\mathrm{CH}_{3} \mathrm{CN}$

### 12.2 Properties of Liquids

Several of the physical properties of a liquid depend on the magnitude of its intermolecular forces. In this section we consider three such properties: surface tension, viscosity, and vapor pressure.

## Surface Tension

A molecule within a liquid is pulled in all directions by the intermolecular forces between it and the other molecules that surround it. There is no net pull in any one direction. A molecule at the surface of the liquid is similarly pulled down and to the sides by neighboring molecules, but Figure 12.6 shows there is no upward pull to balance the downward or inward pull (into the bulk of the liquid). This results in a net pull inward on molecules at the surface, causing the surface of a liquid to tighten like an elastic film, thus minimizing its surface area. The "beading" of water on the surface of a freshly waxed car, shown in Figure 12.7, is an illustration of this phenomenon.

A quantitative measure of the elastic force in the surface of a liquid is the surface tension, the amount of energy required to stretch or increase the surface of a liquid by a unit area (for example, by $1 \mathrm{~cm}^{2}$ ). A liquid with strong intermolecular forces has a high surface tension. Water, for instance, with its strong hydrogen bonds, has a very high surface tension.

Another illustration of surface tension is the meniscus, the curved surface of a liquid contained in a narrow tube. Figure 12.8(a) shows the concave surface of water in a graduated cylinder. (You probably know from your laboratory class that you are to read the volume level with the bottom of the meniscus.) This is caused by a thin film of water adhering to the wall of the glass cylinder. The surface tension of water causes this film to contract, and as it does, it pulls the water up the cylinder. This effect, known as capillary action, is more pronounced in a cylinder with a very small diameter, such as a capillary tube used to draw a small amount of blood. Two types of forces bring about capil-

lary action. One is cohesion, the attractions between like molecules (in this case, between water molecules). The other is adhesion, the attractions between unlike molecules (in this case, between water molecules and the molecules that make up the interior surface of the graduated cylinder). If adhesion is stronger than cohesion, as it is in Figure 12.8(a), the contents of the tube will be pulled upward. The upward movement is limited by the weight of the liquid in the tube. In the case of mercury, shown in Figure $12.8(\mathrm{~b})$, the cohesive forces are stronger than the adhesive forces, resulting in a convex meniscus in which the liquid level at the glass wall is lower than that in the middle.

## Viscosity

Another property determined by the magnitude of intermolecular forces in a liquid is viscosity. Viscosity, with units of $\mathrm{N} \cdot \mathrm{s} / \mathrm{m}^{2}$, is a measure of a fluid's resistance to flow. The higher the viscosity, the more slowly a liquid flows. The viscosity of a liquid typically decreases with increasing temperature. The phrase "slow as molasses in winter" refers to the fact that molasses pours more slowly (has a higher viscosity) in cold weather. You may also have noticed that honey and maple syrup seem thinner when they are heated.

Liquids that have strong intermolecular forces have higher viscosities than those that have weaker intermolecular forces. Table 12.3 lists the viscosities of some liquids that may be familiar to you. Water's high viscosity, like its high surface tension, is the result of hydrogen bonding. Note how large the viscosity of glycerol is compared to the other liquids listed in Table 12.3. The structure of glycerol, which is a sweet tasting, syrupy liquid used for a wide variety of things including the manufacture of candy and antibiotics, is

Glycerol

Figure 12.7 Surface tension causes water to bead up on a just-washed car.

Figure 12.8 (a) When water is measured in a glass graduated cylinder, the adhesive forces are greater than the cohesive forces and the meniscus is concave. (b) When mercury is measured in a glass graduated cylinder, cohesive forces are greater than adhesive forces and the meniscus is convex.

Blood being drawn from a finger into a capillary tube.

Student Annotation: Cohesion and adhesion are also called cohesive forces and adhesive forces.

Student Annotation: Substances that have high vapor pressures at room temperature are said to be volatile. Note that this does not mean that a substance is explosive - only that it has a high vapor pressure.

Student Annotation: The processes of vaporization and condensation are examples of phase changes. These and other phase changes are discussed in detail in Section 12.6.

Student Annotation: We often use the simpler term vapor pressure to mean equilibrium vapor pressure.

Like water, glycerol can form hydrogen bonds. Each glycerol molecule has three - OH groups that can participate in hydrogen bonding with other glycerol molecules. Furthermore, because of their shape, the molecules have a great tendency to become entangled rather than to slip past one another as the molecules of less viscous liquids do. These interactions contribute to its high viscosity.

## Vapor Pressure

In Chapter 11 we encountered the term vapor pressure, referring to the temperature-dependent partial pressure of water [i4 Section 11.5$]$. In fact, vapor pressure is another property of liquids that depends on the magnitude of intermolecular forces. The molecules in a liquid are in constant motion, and, like the molecules in a gas, they have a distribution of kinetic energies. The most probable kinetic energy for molecules in a sample of liquid increases with increasing temperature, as shown in Figure 12.9. If a molecule at the surface of a liquid has sufficient kinetic energy, it can escape from the liquid phase into the gas phase. This phenomenon is known as evaporation or vaporization. Consider the apparatus shown in Figure 12.10. As a liquid begins to evaporate, molecules leave the liquid phase and become part of the gas phase in the space above the liquid. Molecules in the gas phase can return to the liquid phase if they strike the liquid surface and again become trapped by intermolecular forces, a process known as condensation. Initially, evaporation occurs more rapidly than condensation. As the number of molecules in the gas phase increases, however, so does the rate of condensation. The vapor pressure over the liquid increases until the rate of condensation is equal to the rate of evaporation, which is constant at any given temperature (Figure 12.11). This (or any other) situation, wherein a forward process and reverse process are occurring at the same rate, is called a dynamic equilibrium. Although both processes are ongoing (dynamic), the number of molecules in the gas phase at any given point in time does not change (equilibrium). The pressure exerted by the molecules that have escaped to the gas phase, once the pressure has stopped increasing, is the equilibrium vapor pressure.

Figure 12.9 Kinetic energy distribution curves for molecules in a liquid (a) at temperature $T_{1}$ and (b) at a higher temperature $T_{2}$. Note that at the higher temperature, the curve flattens out. The shaded areas represent the number of molecules possessing kinetic energy equal to or greater than a certain kinetic energy $E_{1}$. The higher the temperature, the greater the number of molecules with high kinetic energy.

Figure 12.10 Establishment of equilibrium vapor pressure. (a) Initially, there are no molecules in the gas phase. (b) Molecules enter the gas phase, increasing the total pressure above the liquid. (c) The partial pressure of the liquid continues to increase until the rates of vaporization and condensation are equal. (d) Vaporization and condensation continue to occur at the same rate, and there is no further net change in pressure.

The average kinetic energy of molecules in a liquid increases with increasing temperature (see Figure 12.9). At a higher temperature, therefore, a greater percentage of molecules at the liquid surface will possess sufficient kinetic energy to escape into the gas phase. Consequently, as we have already seen with water in Table 11.5, vapor pressure increases with increasing temperature. Figure 12.12 shows the plots of vapor pressure versus temperature for three different liquids.

The plots in Figure 12.12 of vapor pressure as a function of temperature are not linear. However, a linear relationship does exist between the natural $\log$ of vapor pressure and the reciprocal of absolute temperature. This relationship is called the Clausius ${ }^{2}$-Clapeyron ${ }^{3}$ equation:

$$
\ln P=-\frac{\Delta H_{\text {vap }}}{R T}+C
$$

Equation 12.1
where $\ln P$ is the natural logarithm of the vapor pressure, $\Delta H_{\text {vap }}$ is the molar heat of vaporization $(\mathrm{kJ} / \mathrm{mol}), R$ is the gas constant $(8.314 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol})$, and $C$ is a constant that must be determined experimentally for each different compound. The Clausius-Clapeyron equation has the form of the general linear equation $y=m x+b$ :

$$
\begin{aligned}
\ln P & =\left(-\frac{\Delta H_{\text {vap }}}{R}\right)\left(\frac{1}{T}\right)+C \\
y & =m x+b
\end{aligned}
$$

By measuring the vapor pressure of a liquid at several different temperatures and plotting $\ln P$ versus $1 / T$, we can determine the slope of the line, which is equal to $-\Delta H_{\text {vap }} / R$. ( $\Delta H_{\text {vap }}$ is assumed to be independent of temperature.)

[^32]Figure 12.11 Comparison of the rates of vaporization and condensation at constant temperature.

Figure 12.12 The increase in vapor pressure with temperature for three liquids. The normal boiling points of the liquids (at 1 atm ) are shown on the horizontal axis. The strong metallic bonding in mercury results in its having a very low vapor pressure at room temperature.

Student Annotation: The units of $R$ are those that enable us to cancel the units of $\mathrm{J} / \mathrm{mol}($ or $\mathrm{kJ} / \mathrm{mol})$ associated with $\Delta H_{\text {vap }}$ [/44 Section 11.3, Table 11.4].

If we know the value of $\Delta H_{\text {vap }}$ and the vapor pressure of a liquid at one temperature, we can use the Clausius-Clapeyron equation to calculate the vapor pressure of the liquid at a different temperature. At temperatures $T_{1}$ and $T_{2}$, the vapor pressures are $P_{1}$ and $P_{2}$. From Equation 12.1 we can write

Equation 12.2

$$
\ln P_{1}=-\frac{\Delta H_{\text {vap }}}{R T_{1}}+C
$$

Equation 12.3

$$
\ln P_{2}=-\frac{\Delta H_{\text {vap }}}{R T_{2}}+C
$$

Subtracting Equation 12.3 from Equation 12.2 we get

$$
\begin{aligned}
\ln P_{1}-\ln P_{2} & =-\frac{\Delta H_{\text {vap }}}{R T_{1}}-\left(-\frac{\Delta H_{\text {vap }}}{R T_{2}}\right) \\
& =\frac{\Delta H_{\text {vap }}}{R}\left(\frac{1}{T_{2}}-\frac{1}{T_{1}}\right)
\end{aligned}
$$

and finally

## Equation 12.4

$$
\ln \frac{P_{1}}{P_{2}}=\frac{\Delta H_{\text {vap }}}{R}\left(\frac{1}{T_{2}}-\frac{1}{T_{1}}\right)
$$

Sample Problem 12.2 shows how to use Equation 12.4.

## Sample Problem 12.2

Diethyl ether is a volatile, highly flammable organic liquid that today is used mainly as a solvent. (It was used as an anesthetic during the nineteenth century and as a recreational intoxicant early in the twentieth century during prohibition, when ethanol was difficult to obtain.) The vapor pressure of diethyl ether is 401 mmHg at $18^{\circ} \mathrm{C}$, and its molar heat of vaporization is $26 \mathrm{~kJ} / \mathrm{mol}$. Calculate its vapor pressure at $32^{\circ} \mathrm{C}$.

Strategy Given the vapor pressure at one temperature, $P_{1}$, use Equation 12.4 to calculate the vapor pressure at a second temperature, $P_{2}$.

$$
\ln \frac{P_{1}}{P_{2}}=\frac{\Delta H_{\text {vap }}}{R}\left(\frac{1}{T_{2}}-\frac{1}{T_{1}}\right)
$$

Setup Temperature must be expressed in kelvins, so $T_{1}=291.15 \mathrm{~K}$ and $T_{2}=305.15 \mathrm{~K}$. Because the molar heat of vaporization is given in $\mathrm{kJ} / \mathrm{mol}$, we will have to convert it to $\mathrm{J} / \mathrm{mol}$ for the units of $R$ to cancel properly: $\Delta H_{\text {vap }}=2.6 \times 10^{4} \mathrm{~J} / \mathrm{mol}$. The inverse function of $\ln x$ is $e^{x}$.

## Solution

$$
\begin{aligned}
\ln \frac{P_{1}}{P_{2}} & =\frac{2.6 \times 10^{4} \mathrm{~J} / \mathrm{mol}}{8.314 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol}}\left(\frac{1}{305.15 \mathrm{~K}}-\frac{1}{291.15 \mathrm{~K}}\right) \\
& =-0.4928 \\
\frac{P_{1}}{P_{2}} & =e^{-0.4928}=0.6109 \\
\frac{P_{1}}{0.6109} & =P_{2} \\
P_{2} & =\frac{401 \mathrm{mmHg}}{0.6109}=6.6 \times 10^{2} \mathrm{mmHg}
\end{aligned}
$$

Practice Problem A The vapor pressure of ethanol is $1.00 \times 10^{2} \mathrm{mmHg}$ at $34.9^{\circ} \mathrm{C}$. What is its vapor pressure at $55.8^{\circ} \mathrm{C}$ ? $\left(\Delta H_{\text {vap }}\right.$ for ethanol is $39.3 \mathrm{~kJ} / \mathrm{mol}$.)

HPractice Problem B Estimate the molar heat of vaporization of a liquid whose vapor pressure doubles when the temperature is raised from $85^{\circ} \mathrm{C}$ to $95^{\circ} \mathrm{C}$. At what temperature will the vapor pressure be five times the value at $85^{\circ}$ ?

## Checkpoint 12.2 Properties of Liquids

12.2.1 At what temperature would diethyl ether have a vapor pressure of 250 mmHg ? Use the vapor pressure at $18^{\circ} \mathrm{C}$ and $\Delta H_{\text {vap }}$ given in Sample Problem 12.2.
a) $5.6^{\circ} \mathrm{C}$
b) $280^{\circ} \mathrm{C}$
c) $17^{\circ} \mathrm{C}$
d) $6.5^{\circ} \mathrm{C}$
e) $-270^{\circ} \mathrm{C}$
12.2.2 Given the following information for $\mathrm{C}_{6} \mathrm{~F}_{6}$, calculate its $\Delta H_{\text {vap }}$. At 300 K , the vapor pressure is 92.47 mmHg , and at 320 K , the vapor pressure is 225.1 mmHg .
a) $208 \mathrm{~kJ} / \mathrm{mol}$
b) $411 \mathrm{~kJ} / \mathrm{mol}$
c) $16.4 \mathrm{~kJ} / \mathrm{mol}$
d) $10.3 \mathrm{~kJ} / \mathrm{mol}$
e) $35.5 \mathrm{~kJ} / \mathrm{mol}$
12.2.3 Using the graph, estimate the vapor pressure of the liquid at $100^{\circ} \mathrm{C}$.

a) 100 atm
b) 0.75 atm
c) 1.00 atm
d) 110 atm
e) 1.50 atm
12.2.4 Using the result from question 12.2 .3 and another point from the graph, estimate $\Delta H_{\text {vap }}$ for the liquid.
a) $15 \mathrm{~kJ} / \mathrm{mol}$
b) $35 \mathrm{~kJ} / \mathrm{mol}$
c) $55 \mathrm{~kJ} / \mathrm{mol}$
d) $75 \mathrm{~kJ} / \mathrm{mol}$
e) $95 \mathrm{~kJ} / \mathrm{mol}$

### 12.3 Crystal Structure

Solids can be categorized as either crystalline or amorphous. A crystalline solid possesses rigid and long-range order; its atoms, molecules, or ions occupy specific positions. The arrangement of the particles in a crystalline solid, which we call the lattice structure, depends on the nature and the size of the particles involved. The forces responsible for the stability of a crystal can be ionic forces, covalent bonds, van der Waals forces, hydrogen bonds, or a combination of some of these forces. Amorphous solids lack a well-defined arrangement and long-range molecular order. In this section, we will concentrate on the nature of crystalline solids. (Amorphous solids are discussed in Section 12.5.)

## Unit Cells

A unit cell is the basic repeating structural unit of a crystalline solid. Figure 12.13 shows a unit cell and its extension in three dimensions. Each sphere represents an atom, ion, or molecule and is called a lattice point. For the purpose of clarity, we will limit our discussion in this section to metal crystals in which each lattice point is occupied by an atom.

Every crystalline solid can be described in terms of one of the seven types of unit cells shown in Figure 12.14. The geometry of the cubic unit cell is particularly simple because all sides and all angles are equal. Any of the unit cells, when repeated in space in all three dimensions, forms the lattice structure characteristic of a crystalline solid.

Student Annotation: Ice is a crystalline solid. Glass is an amorphous solid.

(a)

(b)

Figure 12.13 (a) A single unit cell and (b) a lattice (three-dimensional array) made up of many unit cells. Each sphere represents a lattice point, which may be an atom, a molecule, or an ion.

Figure 12.14 The seven types of unit cells. Angle $\alpha$ is defined by edges $b$ and $c$, angle $\beta$ by edges $a$ and $c$, and angle $\gamma$ by edges $a$ and $b$.

## Packing Spheres

We can understand the geometric requirements for crystal formation by considering the different ways of packing a number of identical atoms to form an ordered three-dimensional structure. The way the atoms are arranged in layers determines the type of unit cell.

In the simplest case, a layer of atoms can be arranged as shown in Figure 12.15(a). The three-dimensional structure can be generated by placing a layer above and below this layer in such a way that atoms in one layer are directly over the atoms in the layer below. This procedure can be extended to generate many, many layers, as in the case of a crystal. Focusing on the atom labeled with an " $x$," we see that it is in contact with four atoms in its own layer, one atom in the layer above it, and one atom in the layer below it. Each atom in this arrangement is said to have a coordination number of 6 because it has six immediate neighbors. The coordination number is defined as the number of atoms surrounding an atom in a crystal lattice. The value of the coordination number indicates how tightly the atoms are packed together-the larger the coordination number, the closer the atoms are to one another. The basic repeating unit in the array of atoms is called a simple cubic cell (scc) [Figure 12.15(b)].

The other types of cubic cells, shown in Figure 12.16, are the body-centered cubic cell (bcc) and the face-centered cubic cell (fcc). Unlike the simple cube, the second layer of atoms in the body-centered cubic arrangement fits into the depressions of the first layer and the third layer fits into the depressions of the second layer (Figure 12.17).

Figure 12.15 Arrangement of identical spheres in a simple cubic cell. (a) Top view of one layer of spheres. (b) Definition of a simple cubic cell.

Figure 12.16 Three types of cubic cells. The top view makes it easier to see the locations of the lattice points, but the bottom view is more realistic, with the spheres touching one another.

Figure 12.17 In the body-centered cubic arrangement, the spheres in each layer rest in the depressions between spheres in the previous layer.

The coordination number of each atom in the bcc structure is 8 (each sphere is in contact with four others in the layer above and four others in the layer below). In the face-centered cubic cell, there are atoms at the center of each of the six faces of the cube, in addition to the eight corner atoms. The coordination number in the face-centered cubic cell is 12 (each sphere is in contact with four others in its own layer, four others in the layer above, and four others in the layer below).

Because every unit cell in a crystalline solid is adjacent to other unit cells, most of a cell's atoms are shared by neighboring cells. (The atom at the center of the body-centered cubic cell is an exception.) In all types of cubic cells, for example, each corner atom belongs to eight unit cells whose corners all touch [Figure 12.18(a)]. An atom that lies on an edge, on the other hand, is shared by four unit cells [Figure 12.18(b)], and a face-centered atom is shared by two unit cells [Figure 12.18(c)]. Because a simple cubic cell has lattice points only at each of the eight corners, and because each corner atom is shared by eight unit cells, there will be the equivalent of only one complete atom contained within a simple cubic unit cell (Figure 12.19). A body-centered cubic cell contains the equivalent of two complete atoms, one in the center and eight shared corner atoms. A face-centered cubic cell contains the equivalent of four complete atoms-three from the six face-centered atoms and one from the eight shared corner atoms.

Figure 12.18 (a) A corner atom in any cell is shared by eight unit cells. (b) An edge atom is shared by four unit cells. (c) A face-centered atom in a cubic cell is shared by two unit cells.

Figure 12.19 Because each sphere is shared by eight unit cells and there are eight corners in a cube, there is the equivalent of one complete sphere inside a simple cubic unit cell.

## Closest Packing

There is more empty space in the simple cubic and body-centered cubic cells than in the facecentered cubic cell. Closest packing, the most efficient arrangement of atoms, starts with the structure shown in Figure 12.20(a), which we call layer A. Focusing on the only atom that is surrounded completely by other atoms, we see that it has six immediate neighbors in its own layer. In the second layer, which we call layer B, atoms are packed into the depressions between the atoms in the first layer so that all the atoms are as close together as possible [Figure $12.20(\mathrm{~b})$ ].

There are two ways that a third layer of atoms can be arranged. They may sit in the depressions between second-layer atoms such that the third-layer atoms lie directly over atoms in the first layer [Figure 12.20 (c)]. In this case, the third layer is also labeled A. Alternatively, atoms in the third layer may sit in a different set of depressions such that they do not lie directly over atoms in the first layer [Figure 12.20(d)]. In this case, we label the third layer C.

Figure 12.21 shows the exploded views and the structures resulting from these two arrangements. The ABA arrangement [Figure 12.21(a)] is known as the hexagonal close-packed (hcp) structure, and the ABC arrangement [Figure 12.21(b)] is the cubic close-packed (ccp) structure, which corresponds to the face-centered cube already described. In the hcp structure, the spheres in every other layer occupy the same vertical position (ABABAB . . .), while in the ccp structure, the spheres in every fourth layer occupy the same vertical position (ABCABCA . . .). In both structures, each sphere has a coordination number of 12 (each sphere is in contact with six spheres in

Figure 12.20 (a) In a close-packed layer, each sphere is in contact with six others. (b) Spheres in the second layer fit into the depressions between the first-layer spheres. (c) In the hexagonal close-packed structure, each third-layer sphere is directly over a first-layer sphere. (d) In the cubic close-packed structure, each third-layer sphere fits into a depression that is directly over a depression in the first layer.

Figure 12.21 Exploded views of (a) a hexagonal close-packed structure and (b) a cubic close-packed structure. This view is tilted to show the face-centered cubic unit cell more clearly. Note that this arrangement is the same as the face-centered unit cell.

$a=\sqrt{8} r$
(c)

Figure 12.22 The relationship between the edge length (a) and radius ( $r$ ) of atoms in the (a) simple cubic cell, (b) body-centered cubic cell, and (c) face-centered cubic cell.
its own layer, three spheres in the layer above, and three spheres in the layer below). Both the hcp and ccp structures represent the most efficient way of packing identical spheres in a unit cell, and the coordination number cannot exceed 12 .

Many metals form crystals with hcp or ccp structures. For example, magnesium, titanium, and zinc crystallize with their atoms in an hcp array, while aluminum, nickel, and silver crystallize in the ccp arrangement. A substance will crystallize with the arrangement that maximizes the stability of the solid.

Figure 12.22 summarizes the relationship between the atomic radius $r$ and the edge length $a$ of a simple cubic cell, a body-centered cubic cell, and a face-centered cubic cell. This relationship can be used to determine the atomic radius of a sphere in which the density of the crystal is known.

Student Annotation: The noble gases, which are monatomic, crystallize in the ccp structure, with the exception of helium, which crystallizes in the hcp structure.

## How Do We Know the Structures of Crystals?

Virtually all we know about crystal structure has been learned from X-ray diffraction studies. $X$-ray diffraction is the scattering of X rays by the units of a crystalline solid. The scattering, or diffraction patterns, produced are used to deduce the arrangement of particles in the solid lattice.

In Section 6.1 we discussed the interference phenomenon associated with waves (see Figure 6.4). Because X rays are a form of electromagnetic radiation (i.e., they are waves), they exhibit interference phenomena under suitable conditions. In 1912 Max von Laue ${ }^{4}$ correctly suggested that, because the wavelength of X rays is comparable in magnitude to the distances between lattice points in a crystal, the lattice should be able to diffract X rays. An X-ray diffraction pattern is the result of interference in the waves associated with X rays.

Figure 12.23 shows a typical X-ray diffraction setup. A beam of X rays is directed at a mounted crystal. When X-ray photons encounter the electrons in the atoms of a crystalline solid, some of the incoming radiation is reflected, much as visible light is reflected by a mirror; the process is called the scattering of X rays.

To understand how a diffraction pattern arises, consider the scattering of $X$ rays by the atoms in two parallel planes (Figure 12.24). Initially, the two incident rays are in phase with each other (their maxima and minima occur at the same positions). The upper wave is scattered, or reflected, by an atom in the first layer, while the lower wave is scattered by an atom in the second layer. For these two scattered waves to be in phase again, the extra distance traveled by the lower wave (the sum of the distance between points B and C and the distance between points C and D ) must be an integral multiple of the wavelength $(\lambda)$ of the X ray; that is,

Equation $12.5 \quad \mathrm{BC}+\mathrm{CD}=2 d \sin \theta=n \lambda \quad n=1,2,3, \ldots$

(b)

Figure 12.23 (a) Arrangement for obtaining the X-ray diffraction pattern of a crystal. The shield prevents the intense beam of undiffracted X rays from damaging the photographic plate. (b) X-ray diffraction pattern.

[^33]
where $\theta$ is the angle between the X rays and the plane of the crystal and $d$ is the distance between adjacent planes. Equation 12.5 is known as the Bragg equation, after William H. Bragg and Sir William L. Bragg. ${ }^{5}$ The reinforced waves produce a dark spot on a photographic film for each value of $\theta$ that satisfies the Bragg equation.

## Sample Problem 12.3

X rays of wavelength 0.154 nm strike an aluminum crystal; the rays are reflected at an angle of $19.3^{\circ}$. Assuming that $n=1$, calculate the spacing between the planes of aluminum atoms (in pm) that is responsible for this angle of reflection.

Strategy Use Equation 12.5 to solve for $d$.
Setup $\theta=19.3^{\circ}, n=1$, and $\lambda=154 \mathrm{pm}$.
Solution

$$
d=\frac{n \lambda}{2 \sin \theta}=\frac{154 \mathrm{pm}}{2 \sin 19.3^{\circ}}=233 \mathrm{pm}
$$

Practice Problem A X rays of wavelength 0.154 nm are diffracted from a crystal at an angle of $14.17^{\circ}$. Assuming that $n=1$, calculate the distance (in pm ) between layers in the crystal.
\&Practice Problem B At what angle will X rays of wavelength 0.154 nm be diffracted from a crystal if the distance (in pm) between layers in the crystal is 188 pm ? (Assume $n=1$.)

The X-ray diffraction technique offers the most accurate method for determining bond lengths and bond angles in molecules in solids. Because X rays are scattered by electrons, chemists can construct an electron-density contour map from the diffraction patterns by using a complex mathematical procedure. Basically, an electron-density contour map tells us the relative electron densities at various locations in a molecule. The densities reach a maximum near the center of each atom. In this manner, we can determine the positions of the nuclei and hence the geometric parameters of the molecule.

[^34]Figure 12.24 Reflection of X rays from two layers of atoms. The lower wave travels a distance $2 d \sin \theta$ longer than the upper wave does. For the two waves to be in phase again after reflection, it must be true that $2 d \sin \theta=n \lambda$, where $\lambda$ is the wavelength of the X ray and $n=1$, $2,3, \ldots$ The sharply defined spots in Figure 12.23 are observed only if the crystal is large enough to consist of hundreds of parallel layers.

Student Annotation: $1 \mathrm{~nm}=1000 \mathrm{pm}$.

Think About It The distance between layers of atoms in a crystal should be similar in magnitude to the wavelength of the X rays diffracted by the crystal (compare 0.154 nm with 0.233 nm ).

Sample Problem 12.4 illustrates the relationships between the unit cell type, cell dimensions, and density of a metal.

## Sample Problem 12.4

Gold crystallizes in a cubic close-packed structure (face-centered cubic unit cell) and has a density of $19.3 \mathrm{~g} / \mathrm{cm}^{3}$. Calculate the atomic radius of an Au atom in angstroms $(\AA)$.

Strategy Using the given density and the mass of gold contained within a face-centered cubic unit cell, determine the volume of the unit cell. Then, use the volume to determine the value of $a$, and use the equation supplied in Figure 12.22(c) to find $r$. Be sure to use consistent units for mass, length, and volume.

Setup The face-centered cubic unit cell contains a total of four atoms of gold [six faces, each shared by two unit cells, and eight corners, each shared by eight unit cells-Figure 12.24(c)]. $D=m / V$ and $V=a^{3}$.

Solution First, we determine the mass of gold (in grams) contained within a unit cell:

$$
m=\frac{4 \text { atoms }}{\text { unit cell }} \times \frac{1 \text { mot }}{6.022 \times 10^{23} \text { atoms }} \times \frac{197.0 \mathrm{~g} \mathrm{Au}}{1 \mathrm{~mol} \mathrm{Au}}=1.31 \times 10^{-21} \mathrm{~g} / \mathrm{unit} \text { cell }
$$

Then we calculate the volume of the unit cell in $\mathrm{cm}^{3}$ :

$$
V=\frac{m}{d}=\frac{1.31 \times 10^{-21} \mathrm{~g}}{19.3 \mathrm{~g} / \mathrm{cm}^{3}}=6.78 \times 10^{-23} \mathrm{~cm}^{3}
$$

Using the calculated volume and the relationship $V=a^{3}$ (rearranged to solve for $a$ ), we determine the length of a side of a unit cell:

$$
a=\sqrt[3]{V}=\sqrt[3]{6.78 \times 10^{-23} \mathrm{~cm}^{3}}=4.08 \times 10^{-8} \mathrm{~cm}
$$

Using the relationship provided in Figure 12.22(c) (rearranged to solve for $r$ ), we determine the radius of a gold atom in centimeters:

$$
r=\frac{a}{\sqrt{8}}=\frac{4.08 \times 10^{-8} \mathrm{~cm}}{\sqrt{8}}=1.44 \times 10^{-8} \mathrm{~cm}
$$

Finally, we convert centimeters to angstroms:

$$
1.44 \times 10^{-8} \mathrm{~cm} \times \frac{1 \times 10^{-2} \mathrm{~m}}{1 \mathrm{~cm}} \times \frac{1 \AA}{1 \times 10^{-10} \mathrm{~m}}=1.44 \AA
$$

tend to be on the order of $1 \AA$, so this answer is reasonable.

Practice Problem A When silver crystallizes, it forms face-centered cubic cells. The unit cell edge length is $4.087 \AA$. Calculate the density of silver.

HPractice Problem B The density of sodium metal is $0.971 \mathrm{~g} / \mathrm{cm}^{3}$, and the unit cell edge length is $4.285 \AA$. Determine the unit cell (simple, body-centered, or face-centered cubic) of sodium metal.

## Checkpoint 12.3 Crystal Structure

12.3.1 Nickel has a face-centered cubic unit cell with an edge length of 352.4 pm . Calculate the density of nickel.
a) $2.227 \mathrm{~g} / \mathrm{cm}^{3}$
b) $4.455 \mathrm{~g} / \mathrm{cm}^{3}$
c) $38.99 \mathrm{~g} / \mathrm{cm}^{3}$
d) $8.908 \mathrm{~g} / \mathrm{cm}^{3}$
e) $11.14 \mathrm{~g} / \mathrm{cm}^{3}$
12.3.2 At what angle would you expect $X$ rays of wavelength 0.154 nm to be reflected from a crystal in which the distance between layers is 312 pm ? (Assume $n=1$.)
a) $1.6^{\circ}$
b) $29.6^{\circ}$
c) $0.25^{\circ}$
d) $6.8^{\circ}$
e) $14.3^{\circ}$

### 12.4 Types of Crystals

The structures and properties of crystalline solids, such as melting point, density, and hardness, are determined by the kinds of forces that hold the particles together. We can classify any crystal as one of four types: ionic, covalent, molecular, or metallic.

## Ionic Crystals

Ionic crystals are composed of charged spheres (cations and anions) that are held together by Coulombic attraction. Anions typically are considerably bigger than cations [/44 Section 7.6], and the relative sizes and relative numbers of the ions in a compound determine how the ions are arranged in the solid lattice. NaCl adopts a face-centered cubic arrangement as shown in Figure 12.25. Note the positions of ions within the unit cell, and within the lattice overall. Both the $\mathrm{Na}^{+}$ions and the $\mathrm{Cl}^{-}$ions adopt face-centered cubic arrangements, and the unit cell defined by the arrangement of cations overlaps with the unit cell defined by the arrangement of anions. Look closely at the unit cell shown in Figure 12.25(a). It is defined as fcc by the positions of the $\mathrm{Cl}^{-}$ions. Recall that there is the equivalent of four spheres contained in the fcc unit cell (half a sphere at each of six faces and one-eighth of a sphere at each of eight corners). In this case the spheres are $\mathrm{Cl}^{-}$ions, so the unit cell of NaCl contains four $\mathrm{Cl}^{-}$ions. Now look at the positions of the $\mathrm{Na}^{+}$ions. There are $\mathrm{Na}^{+}$ions centered on each edge of the cube, in addition to one $\mathrm{Na}^{+}$at the center. Each sphere on the cube's edge is shared by four unit cells, and there are 12 such edges. Thus, the unit cell in Figure 12.25(a) also contains four $\mathrm{Na}^{+}$ions (one-quarter sphere at each of 12 edges, giving three spheres, and one sphere at the center). The unit cell of an ionic compound always contains the same ratio of cations to anions as the empirical formula of the compound.

Figure 12.26 shows the crystal structures of three ionic compounds: $\mathrm{CsCl}, \mathrm{ZnS}$, and $\mathrm{CaF}_{2}$. Cesium chloride [Figure 12.26(a)] has the simple cubic lattice. Despite the apparent similarity of the formulas of CsCl and $\mathrm{NaCl}, \mathrm{CsCl}$ adopts a different arrangement because the $\mathrm{Cs}^{+}$ion is much larger than the $\mathrm{Na}^{+}$ion. Zinc sulfide [Figure 12.26(b)] has the zincblende structure, which is based on the face-centered cubic lattice. If the $\mathrm{S}^{2-}$ ions occupy the lattice points, the smaller $\mathrm{Zn}^{2+}$ ions are arranged tetrahedrally about each $\mathrm{S}^{2-}$ ion. Other ionic compounds that have the zincblende structure include $\mathrm{CuCl}, \mathrm{BeS}, \mathrm{CdS}$, and HgS . Calcium fluoride [Figure 12.26(c)] has the fluorite structure. The unit cell in Figure 12.26(c) is defined based on the positions of the cations, rather than the positions of the anions. The $\mathrm{Ca}^{2+}$ ions occupy the lattice points, and each $\mathrm{F}^{-}$ion is surrounded tetrahedrally by four $\mathrm{Ca}^{2+}$ ions. The compounds $\mathrm{SrF}_{2}, \mathrm{BaF}_{2}, \mathrm{BaCl}_{2}$, and $\mathrm{PbF}_{2}$ also have the fluorite structure.

(a)

(b)

(c)

Figure 12.25 The unit cell of an ionic compound can be defined either by (a) the positions of anions or (b) the positions of cations.

Student Annotation: It is important to realize that the lattice points used to define a unit cell must all be identical. We can define the unit cell of NaCl based on the positions of the $\mathrm{Na}^{+}$ ions or the positions of the $\mathrm{Cl}^{-}$ions.

Student Annotation: It is a common mistake to identify the CsCl structure as body-centered cubic. Remember that the lattice points used to define a unit cell must all be identical. In this case, they are all $\mathrm{Cl}^{-}$ions. CsCl has a simple cubic unit cell.

Figure 12.26 Crystal structures of (a) CsCl , (b) ZnS , and (c) $\mathrm{CaF}_{2}$. In each case, the smaller sphere represents the cation.

Think About It Make sure that the ratio of cations to anions that you determine for a unit cell matches the ratio expressed in the compound's empirical formula.

Sample Problems 12.5 and 12.6 show how to determine the number of ions in a unit cell and the density of an ionic crystal, respectively.

## Sample Problem 12.5

How many of each ion are contained within a unit cell of ZnS ?
Strategy Determine the contribution of each ion in the unit cell based on its position.
Setup Referring to Figure 12.26 , the unit cell has four $\mathrm{Zn}^{2+}$ ions completely contained within the unit cell, and $\mathrm{S}^{2-}$ ions at each of the eight corners and at each of the six faces. Interior ions (those completely contained within the unit cell) contribute one, those at the corners each contribute oneeighth, and those on the faces each contribute one-half.
Solution The ZnS unit cell contains four $\mathrm{Zn}^{2+}$ ions (interior) and four $\mathrm{S}^{2-}$ ions [ $8 \times \frac{1}{8}$ (corners) and $6 \times \frac{1}{2}$ (faces)].

Student Annotation: Note that the mass of an atomic ion is treated the same as the mass of the parent atom. In these cases, the mass of an electron is not significant [ 14 Section 2.2, Table 2.1].

Think About It If you were to hold a cubic centimeter $\left(1 \mathrm{~cm}^{3}\right)$ of salt in your hand, how heavy would you expect it to be? Common errors in this type of problem include errors of unit conversion-especially with regard to length and volume. Such errors can lead to results that are off by many orders of magnitude. Often you can use common sense to gauge whether or not a calculated answer is reasonable. For instance, simply getting the centimeter-meter conversion upside down would result in a calculated density of $2.16 \times 10^{12} \mathrm{~g} / \mathrm{cm}^{3}$ ! You know that a cubic centimeter of salt doesn't have a mass that large. (That's billions of kilograms!) If the magnitude of a result is not reasonable, go back and check your work.

Practice Problem A Referring to Figure 12.26, determine how many of each ion are contained within a unit cell of $\mathrm{CaF}_{2}$.

EPractice Problem B Referring to Figure 12.26, determine how many of each ion are contained within a unit cell of CsCl .

## Sample Problem 12.6

The edge length of the NaCl unit cell is 564 pm . Determine the density of NaCl in $\mathrm{g} / \mathrm{cm}^{3}$.
Strategy Use the number of $\mathrm{Na}^{+}$and $\mathrm{Cl}^{-}$ions in a unit cell (four of each) to determine the mass of a unit cell. Calculate volume using the edge length given in the problem statement. Density is mass divided by volume $(d=m / V)$. Be careful to use units consistently.

Setup The masses of $\mathrm{Na}^{+}$and $\mathrm{Cl}^{-}$ions are 22.99 amu and 35.45 amu , respectively. The conversion factor from amu to grams is

$$
\frac{1 \mathrm{~g}}{6.022 \times 10^{23} \mathrm{amu}}
$$

so the masses of the $\mathrm{Na}^{+}$and $\mathrm{Cl}^{-}$ions are $3.818 \times 10^{-23} \mathrm{~g}$ and $5.887 \times 10^{-23} \mathrm{~g}$, respectively. The unit cell length is

$$
564 \mathrm{pMI} \times \frac{1 \times 10^{-12} \mathrm{nK}}{1 \mathrm{pMK}} \times \frac{1 \mathrm{~cm}}{1 \times 10^{-2} \mathrm{MK}}=5.64 \times 10^{-8} \mathrm{~cm}
$$

Solution The mass of a unit cell is $3.882 \times 10^{-22} \mathrm{~g}\left(4 \times 3.818 \times 10^{-23} \mathrm{~g}+4 \times 5.887 \times 10^{-23} \mathrm{~g}\right)$. The volume of a unit cell is $1.794 \times 10^{-22} \mathrm{~cm}^{3}\left[\left(5.64 \times 10^{-8} \mathrm{~cm}\right)^{3}\right]$. Therefore, the density is given by

$$
d=\frac{3.882 \times 10^{-22} \mathrm{~g}}{1.794 \times 10^{-22} \mathrm{~cm}^{3}}=2.16 \mathrm{~g} / \mathrm{cm}^{3}
$$

Practice Problem A LiF has the same unit cell as NaCl (fcc). The edge length of the LiF unit cell is 402 pm . Determine the density of LiF in $\mathrm{g} / \mathrm{cm}^{3}$.

EPractice Problem B NiO also adopts the face-centered-cubic arrangement. Given that the density of NiO is $6.67 \mathrm{~g} / \mathrm{cm}^{3}$, calculate the length of the edge of its unit cell (in pm ).

Most ionic crystals have high melting points, which is an indication of the strong cohesive forces holding the ions together. A measure of the stability of ionic crystals is the lattice energy [ I W Section 8.2]; the higher the lattice energy, the more stable the compound. Ionic solids do not conduct electricity because the ions are fixed in position. In the molten (melted) state or when dissolved in water, however, the compound's ions are free to move and the resulting liquid conducts electricity.

## Covalent Crystals

In covalent crystals, atoms are held together in an extensive three-dimensional network entirely by covalent bonds. Well-known examples are two of carbon's allotropes: diamond and graphite. In diamond, each carbon atom is $s p^{3}$-hybridized and bonded to four other carbon atoms [Figure 12.27(a)]. The strong covalent bonds in three dimensions contribute to diamond's unusual hardness (it is the hardest material known) and very high melting point $\left(3550^{\circ} \mathrm{C}\right)$. In graphite, carbon atoms are arranged in six-membered rings [Figure 12.27(b)]. The atoms are all $s p^{2}$-hybridized, and each atom is bonded to three other atoms. The remaining unhybridized $2 p$ orbital on each carbon atom is used in pi bonding. In fact, each layer of graphite has the kind of delocalized molecular orbital that is present in benzene [ 14 Section 9.7]. Because electrons are free to move around in this extensively delocalized molecular orbital, graphite is a good conductor of electricity in directions along the planes of the carbon atoms. The layers are held together by weak van der Waals forces. The covalent bonds in graphite account for its hardness; however, because the layers can slide past one another, graphite is slippery to the touch and is effective as a lubricant. It is also used as the "lead" in pencils.

Another covalent crystal is quartz $\left(\mathrm{SiO}_{2}\right)$. The arrangement of silicon atoms in quartz is similar to that of carbon in diamond, but in quartz there is an oxygen atom between each pair of Si atoms. Because Si and O have different electronegativities, the $\mathrm{Si}-\mathrm{O}$ bond is polar. Nevertheless, $\mathrm{SiO}_{2}$ is similar to diamond in many respects, such as being very hard and having a high melting point $\left(1610^{\circ} \mathrm{C}\right)$.

## Molecular Crystals

In a molecular crystal, the lattice points are occupied by molecules, so the attractive forces between them are van der Waals forces and/or hydrogen bonding. An example of a molecular crystal is solid sulfur dioxide ( $\mathrm{SO}_{2}$ ), in which the predominant attractive force is a dipole-dipole interaction. Intermolecular hydrogen bonding is mainly responsible for maintaining the three-dimensional lattice of ice (Figure 12.28). Other examples of molecular crystals are $\mathrm{I}_{2}, \mathrm{P}_{4}$, and $\mathrm{S}_{8}$.

Figure 12.27 Structures of (a) diamond and (b) graphite. Note that in diamond, each carbon atom is bonded in a tetrahedral arrangement to four other carbon atoms. In graphite, each carbon atom is bonded in a trigonal planar arrangement to three other carbon atoms. The distance between layers in graphite is 335 pm .

Figure 12.28 The threedimensional structure of ice. The covalent bonds are shown by short solid lines and the weaker hydrogen bonds by long dotted lines between O and H . The empty space in the structure accounts for the low density of ice, relative to liquid water.

Figure 12.29 A cross section of a metallic crystal. Each circled positive charge represents the nucleus and inner electrons of a metal atom. The grey area surrounding the positive metal ions indicates the mobile "sea" of electrons.

Except in ice, molecules in molecular crystals are generally packed together as closely as their size and shape allow. Because van der Waals forces and hydrogen bonding are usually quite weak compared with covalent and ionic bonds, molecular crystals are more easily broken apart than ionic and covalent crystals. Indeed, most molecular crystals melt at temperatures below $100^{\circ} \mathrm{C}$.

## Metallic Crystals

Every lattice point in a metallic crystal is occupied by an atom of the same metal. Metallic crystals are generally body-centered cubic, face-centered cubic, or hexagonal close-packed. Consequently, metallic elements are usually very dense.

The bonding in metals is quite different from that in other types of crystals. In a metal, the bonding electrons are delocalized over the entire crystal. In fact, metal atoms in a crystal can be imagined as an array of positive ions immersed in a sea of delocalized valence electrons (Figure 12.29). The great cohesive force resulting from delocalization is responsible for a metal's strength, whereas the mobility of the delocalized electrons makes metals good conductors of heat and electricity. Table 12.4 summarizes the properties of the four different types of crystals discussed. Note that the data in Table 12.4 refer to the solid phase of each substance listed.

TABLE 12.4 Types of Crystals and Their General Properties

| Type of Crystal | Cohesive Forces <br> Ionic <br> Coulombic attraction <br> and dispersion forces |
| :--- | :--- |
| Covalent | Covalent bonds |
| Molecular $^{\dagger}$ | Dispersion and dipole-dipole <br> forces, hydrogen bonds |
| Metallic | Metallic bonds |

[^35]
## General Properties

Hard, brittle, high melting point, poor conductor of heat and electricity
Hard, brittle, high melting point, poor conductor of heat and electricity
Soft, low melting point, poor conductor of heat and electricity
Variable hardness and melting point, good conductor of heat and electricity

## Examples

$\mathrm{NaCl}, \mathrm{LiF}, \mathrm{MgO}, \mathrm{CaCO}_{3}$

C (diamond), ${ }^{*} \mathrm{SiO}_{2}$ (quartz)
$\mathrm{Ar}, \mathrm{CO}_{2}, \mathrm{I}_{2}, \mathrm{H}_{2} \mathrm{O}, \mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}$
All metallic elements, such as $\mathrm{Na}, \mathrm{Mg}, \mathrm{Fe}, \mathrm{Cu}$

## Sample Problem 12.7

The metal iridium (Ir) crystallizes with a face-centered cubic unit cell. Given that the length of the edge of a unit cell is 383 pm , determine the density of iridium in $\mathrm{g} / \mathrm{cm}^{3}$.

Strategy A face-centered metallic crystal contains four atoms per unit cell [ $8 \times \frac{1}{8}$ (corners) and $6 \times$ $\frac{1}{2}$ (faces)]. Use the number of atoms per cell and the atomic mass to determine the mass of a unit cell. Calculate volume using the edge length given in the problem statement. Density is then mass divided by volume $(d=m / V)$. Be sure to make all necessary unit conversions.

Setup The mass of an Ir atom is 192.2 amu . The conversion factor from amu to grams is

$$
\frac{1 \mathrm{~g}}{6.022 \times 10^{23} \mathrm{amu}}
$$

so the mass of an Ir atom is $3.192 \times 10^{-22} \mathrm{~g}$. The unit cell length is

$$
383 \mathrm{pm} \times \frac{1 \times 10^{-12} \mathrm{~m}}{1 \mathrm{pm}} \times \frac{1 \mathrm{~cm}}{1 \times 10^{-2} \mathrm{~m}}=3.83 \times 10^{-8} \mathrm{~cm}
$$

Solution The mass of a unit cell is $1.277 \times 10^{-21} \mathrm{~g}\left(4 \times 3.192 \times 10^{-22} \mathrm{~g}\right)$. The volume of a unit cell is $5.618 \times 10^{-23} \mathrm{~cm}^{3}\left[\left(3.83 \times 10^{-8} \mathrm{~cm}\right)^{3}\right]$. Therefore, the density is given by

$$
d=\frac{1.277 \times 10^{-21} \mathrm{~g}}{5.62 \times 10^{-23} \mathrm{~cm}^{3}}=22.7 \mathrm{~g} / \mathrm{cm}^{3}
$$

Practice Problem A Aluminum metal crystallizes in a face-centered cubic unit cell. If the length of the cell edge is 404 pm , what is the density of aluminum in $\mathrm{g} / \mathrm{cm}^{3}$ ?

EPractice Problem B Copper crystallizes in a face-centered cubic lattice. If the density of the metal is $8.96 \mathrm{~g} / \mathrm{cm}^{3}$, what is the length of the unit cell edge in picometers?

### 12.5 Amorphous Solids

Solids are most stable in crystalline form. However, if a solid is formed rapidly (e.g., when a liquid is cooled quickly), its atoms or molecules do not have time to align themselves and may become locked in positions other than those of a regular crystal. The resulting solid is said to be amorphous. Amorphous solids, such as glass, lack a regular three-dimensional arrangement of atoms. In this section, we will briefly discuss the properties of glass.

Glass is one of civilization's most valuable and versatile materials. It is also one of the oldestglass articles date back as far as 1000 b.c. Glass commonly refers to an optically transparent fusion product of inorganic materials that has cooled to a rigid state without crystallizing. By fusion product we mean that the glass is formed by mixing molten silicon dioxide $\left(\mathrm{SiO}_{2}\right)$, its chief component, with compounds such as sodium oxide $\left(\mathrm{Na}_{2} \mathrm{O}\right)$, boron oxide $\left(\mathrm{B}_{2} \mathrm{O}_{3}\right)$, and certain transition metal oxides for color and other properties. In some respects, glass behaves more like a liquid than a solid.

There are about 800 different types of glass in common use today. Figure 12.30 shows twodimensional schematic representations of crystalline quartz and amorphous quartz glass. Table 12.5 lists the composition and properties of quartz, Pyrex, and soda-lime glass. The color of glass is due largely to the presence of oxides of metal ions-mostly transition metal ions. For example, green glass contains iron(III) oxide $\left(\mathrm{Fe}_{2} \mathrm{O}_{3}\right)$ or copper(II) oxide $(\mathrm{CuO})$, yellow glass contains uranium(IV) oxide $\left(\mathrm{UO}_{2}\right)$, blue glass contains cobalt(II) and copper(II) oxides ( CoO and CuO ), and red glass contains small particles of gold and copper.

### 12.6 Phase Changes

A phase is a homogeneous part of a system that is separated from the rest of the system by a welldefined boundary. When an ice cube floats in a glass of water, for example, the liquid water is one

Think About It Metals typically have high densities, so common sense can help you decide whether or not your calculated answer is reasonable.

Figure 12.30 Two-dimensional representation of (a) crystalline quartz and (b) noncrystalline (amorphous) quartz glass. The small spheres represent silicon. In reality, the structure of quartz is three dimensional. Each Si atom is bonded in a tetrahedral arrangement to four O atoms.

Student Annotation: Phase changes are physical changes [ 144 Section 1.4].

Student Annotation: The temperature at which the vapor pressure of a liquid is equal to 1 atm is called the normal boiling point.

## TABLE 12.5

Composition and Properties of Three Types of Glass

Pure quartz glass

| Pyrex glass | $60 \%-80 \% \mathrm{SiO}_{2}$, <br> $10 \%-25 \% \mathrm{~B}_{2} \mathrm{O}_{3}$, <br> some $\mathrm{Al}_{2} \mathrm{O}_{3}$ |
| :--- | :--- |
| Soda-lime glass | $75 \% \mathrm{SiO}_{2}$, <br>  <br>  <br>  <br>  <br>  <br>  <br>  <br>  <br>  $\mathbf{1 5 \% \mathrm { Na } _ { 2 } \mathrm { O } ,}$ |
|  | CaO |

Low thermal expansion, transparent to a wide range of wavelengths. Used in optical research.
Low thermal expansion; transparent to visible and infrared, but not to ultraviolet light. Used in cookware and laboratory glassware.
Easily attacked by chemicals and sensitive to thermal shocks. Transmits visible light but absorbs ultraviolet light. Used in windows and bottles.
phase and the solid water (the ice cube) is another. Although the chemical properties of water are the same in both phases, the physical properties of a solid are different from those of a liquid.

When a substance goes from one phase to another phase, we say that it has undergone a phase change. Phase changes in a system are generally caused by the addition or removal of energy, usually in the form of heat. Familiar examples of phase changes include the following:

| Example | Phase Change |
| :--- | :--- |
| Freezing of water | $\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}_{2} \mathrm{O}(s)$ |
| Evaporation (or vaporization) of water | $\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}_{2} \mathrm{O}(g)$ |
| Melting (fusion) of ice | $\mathrm{H}_{2} \mathrm{O}(s) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)$ |
| Condensation of water vapor | $\mathrm{H}_{2} \mathrm{O}(g) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)$ |
| Sublimation of dry ice | $\mathrm{CO}_{2}(s) \longrightarrow \mathrm{CO}_{2}(g)$ |

The establishment of an equilibrium vapor pressure, as described in Section 12.2, involved two of these phase changes: vaporization and condensation. Figure 12.31 summarizes the various types of phase changes.

## Liquid-Vapor Phase Transition

In Section 12.2 we learned that the vapor pressure of a liquid increases with increasing temperature. When the vapor pressure reaches the external pressure, the liquid boils. In fact, the boiling point of a substance is defined as the temperature at which its vapor pressure equals the external, atmospheric pressure. As a result, the boiling point of a substance varies with the external pressure. At the top of a mountain, for example, where the atmospheric pressure is lower than that at sea level, the vapor pressure of water (or any liquid) reaches the external pressure at a lower temperature. Thus, the boiling point is lower than it would be at sea level.

Because the boiling point is defined in terms of the vapor pressure of the liquid, the boiling point is related to the molar heat of vaporization $\left(\Delta \boldsymbol{H}_{\text {vap }}\right)$, the amount of heat required to vaporize a mole of substance at its boiling point. Indeed, the data in Table 12.6 show that the boiling point generally increases as $\Delta H_{\text {vap }}$ increases. Ultimately, both the boiling point and $\Delta H_{\text {vap }}$ are determined by the strength of intermolecular forces. For example, argon (Ar) and methane $\left(\mathrm{CH}_{4}\right)$, which have

TABLE 12.6 Molar Heats of Vaporization for Selected Liquids

| Substance | Boiling Point $\left({ }^{\circ} \mathrm{C}\right)$ | $\boldsymbol{\Delta} \boldsymbol{H}_{\text {vap }}(\mathbf{k J} / \mathrm{mol})$ |
| :--- | :---: | :---: |
| Argon $(\mathrm{Ar})$ | -186 | 6.3 |
| Benzene $\left(\mathrm{C}_{6} \mathrm{H}_{6}\right)$ | 80.1 | 31.0 |
| Ethanol $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right)$ | 78.3 | 39.3 |
| Diethyl ether $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OC}_{2} \mathrm{H}_{5}\right)$ | 34.6 | 26.0 |
| Mercury $(\mathrm{Hg})$ | 357 | 59.0 |
| Methane $\left(\mathrm{CH}_{4}\right)$ | -164 | 9.2 |
| Water $\left(\mathrm{H}_{2} \mathrm{O}\right)$ | 100 | 40.79 |

only relatively weak dispersion forces, have low boiling points and small molar heats of vaporization. Diethyl ether $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OC}_{2} \mathrm{H}_{5}\right)$ has a dipole moment, and the dipole-dipole forces account for its moderately high boiling point and $\Delta H_{\text {vap }}$. Both ethanol $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right)$ and water have strong hydrogen bonding, which accounts for their high boiling points and large $\Delta H_{\text {vap }}$ values. Strong metallic bonding causes mercury to have the highest boiling point and $\Delta H_{\text {vap }}$ of the liquids in Table 12.6. Interestingly, benzene $\left(\mathrm{C}_{6} \mathrm{H}_{6}\right)$, although nonpolar, has a high polarizability due to the distribution of its electrons in delocalized $\pi$ molecular orbitals. The dispersion forces that result can be as strong as (or even stronger than) dipole-dipole forces and/or hydrogen bonds.

The opposite of vaporization is condensation. In principle, a gas can be liquefied (made to condense) either by cooling or by applying pressure. Cooling a sample of gas decreases the kinetic energy of its molecules, so eventually the molecules aggregate to form small drops of liquid. Applying pressure to the gas (compression), on the other hand, reduces the distance between molecules, so they can be pulled together by intermolecular attractions. Many liquefication processes use a combination of reduced temperature and increased pressure.

Every substance has a critical temperature ( $\boldsymbol{T}_{c}$ ) above which its gas phase cannot be liquefied, no matter how great the applied pressure. Critical pressure $\left(\boldsymbol{P}_{c}\right)$ is the minimum pressure that must be applied to liquefy a substance at its critical temperature. At temperatures above the critical temperature, there is no fundamental distinction between a liquid and a gas-we simply have a fluid. A fluid at a temperature and pressure that exceed $T_{\mathrm{c}}$ and $P_{\mathrm{c}}$, respectively, is called a supercritical fluid. Supercritical fluids have some remarkable properties and are used as solvents in a wide variety of industrial applications. The first such large-scale industrial use was the decaffeination of coffee with supercritical $\mathrm{CO}_{2}$.

Table 12.7 lists the critical temperatures and critical pressures of a number of common substances. The critical temperature of a substance reflects the strength of its intermolecular forces. Benzene, ethanol, mercury, and water, which have strong intermolecular forces, also have high critical temperatures compared with the other substances listed in the table.

Figure 12.31 The six possible phase changes: melting (fusion), vaporization, sublimation, deposition, condensation, and freezing.

Student Annotation: $T_{\mathrm{C}}$ is the highest temperature at which a substance can exist as a liquid.

TABLE 12.7 $\quad$ Critical Temperatures and Critical Pressures of Selected Substances

| Substance | $\boldsymbol{T}_{\mathbf{c}}\left({ }^{\circ} \mathrm{C}\right)$ | $\boldsymbol{P}_{\mathbf{c}}(\mathrm{atm})$ |
| :--- | :---: | :---: |
| Ammonia $\left(\mathrm{NH}_{3}\right)$ | 132.4 | 111.5 |
| Argon $(\mathrm{Ar})$ | -122.2 | 6.3 |
| Benzene $\left(\mathrm{C}_{6} \mathrm{H}_{6}\right)$ | 288.9 | 47.9 |
| Carbon dioxide $\left(\mathrm{CO}_{2}\right)$ | 31.0 | 73.0 |
| Ethanol $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right)$ | 243 | 63.0 |
| Diethyl ether $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OC}_{2} \mathrm{H}_{5}\right)$ | 192.6 | 35.6 |
| Mercury $(\mathrm{Hg})$ | 1462 | 1036 |
| Methane $\left(\mathrm{CH}_{4}\right)$ | -83.0 | 45.6 |
| Molecular hydrogen $\left(\mathrm{H}_{2}\right)$ | -239.9 | 12.8 |
| Molecular nitrogen $\left(\mathrm{N}_{2}\right)$ | -147.1 | 33.5 |
| Molecular oxygen $\left(\mathrm{O}_{2}\right)$ | -118.8 | 49.7 |
| Sulfur hexafluoride $\left(\mathrm{SF}_{6}\right)$ | 45.5 | 37.6 |
| Water $\left(\mathrm{H}_{2} \mathrm{O}\right)$ | 374.4 | 219.5 |

## Solid-Liquid Phase Transition

The transformation of liquid to solid is called freezing, and the reverse process is called melting, or fusion. The melting point of a solid or the freezing point of a liquid is the temperature at which solid and liquid phases coexist in equilibrium. The normal melting (or freezing) point of a substance is the temperature at which it melts (or freezes) at 1 atm .

The most familiar liquid-solid equilibrium is probably that of water and ice. At $0^{\circ} \mathrm{C}$ and 1 atm , the dynamic equilibrium is represented by

$$
\text { ice } \rightleftarrows \text { water }
$$

or

$$
\mathrm{H}_{2} \mathrm{O}(s) \rightleftarrows \mathrm{H}_{2} \mathrm{O}(l)
$$

A glass of ice water at $0^{\circ} \mathrm{C}$ provides a practical illustration of this dynamic equilibrium. As the ice cubes melt to form water, some of the water between ice cubes may freeze, thus joining the cubes together. Remember that in a dynamic equilibrium, forward and reverse processes are occurring at the same rate [ $W_{4}$ Section 4.1].

Because molecules are more strongly held in the solid phase than in the liquid phase, heat is required to melt a solid into a liquid. The heating curve in Figure 12.32 shows that when a solid is heated, its temperature increases gradually until point A is reached. At this point, the solid begins to melt. During the melting period $(\mathrm{A} \longrightarrow \mathrm{B})$, the first flat portion of the curve in Figure 12.32, heat is being absorbed by the system, yet its temperature remains constant. The heat helps the molecules overcome the attractive forces in the solid. Once the sample has melted completely (point B), the heat absorbed increases the average kinetic energy of the liquid molecules and the liquid temperature rises $(B \longrightarrow C)$. The vaporization process $(C \longrightarrow D)$ can be explained similarly. The temperature remains constant during the period when the increased kinetic energy is used to overcome the cohesive forces in the liquid. When all molecules are in the gas phase, the temperature rises again.

The molar heat of fusion $\left(\Delta \boldsymbol{H}_{\text {fus }}\right)$ is the energy, usually expressed in $\mathrm{kJ} / \mathrm{mol}$, required to melt 1 mole of a solid. Table 12.8 lists the molar heats of fusion for the substances in Table 12.6. A comparison of the data in the two tables shows that $\Delta H_{\text {fus }}$ is smaller than $\Delta H_{\text {vap }}$ for each substance. This is consistent with the fact that molecules in a liquid are still fairly closely packed together, so some energy (but not a lot of energy, relatively speaking) is needed to bring about the rearrangement from solid to liquid. When a liquid is vaporized, on the other hand, its molecules become completely separated from one another, so considerably more energy is required to overcome the intermolecular attractive forces.

Cooling a substance has the opposite effect of heating it. If we remove heat from a gas sample at a steady rate, its temperature decreases. As the liquid is being formed, heat is given off

## TABLE 12.8 Molar Heats of Fusion for Selected Substances

| Substance | Melting Point $\left({ }^{\circ} \mathrm{C}\right)$ | $\boldsymbol{\Delta} \boldsymbol{H}_{\text {fus }}(\mathbf{k J} / \mathrm{mol})$ |
| :--- | :---: | :---: |
| Argon $(\mathrm{Ar})$ | -190 | 1.3 |
| Benzene $\left(\mathrm{C}_{6} \mathrm{H}_{6}\right)$ | 5.5 | 10.9 |
| Ethanol $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right)$ | -117.3 | 7.61 |
| Diethyl ether $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OC}_{2} \mathrm{H}_{5}\right)$ | -116.2 | 6.90 |
| Mercury $(\mathrm{Hg})$ | -39 | 23.4 |
| Methane $\left(\mathrm{CH}_{4}\right)$ | -183 | 0.84 |
| Water $\left(\mathrm{H}_{2} \mathrm{O}\right)$ | 0 | 6.01 |

by the system, because its potential energy is decreasing. For this reason, the temperature of the system remains constant over the condensation period ( $\mathrm{D} \longrightarrow \mathrm{C}$ ). After all the vapor has condensed, the temperature of the liquid begins to drop again. Continued cooling of the liquid finally leads to freezing $(\mathrm{B} \longrightarrow \mathrm{A})$.

Supercooling is a phenomenon in which a liquid can be temporarily cooled to below its freezing point. Supercooling occurs when heat is removed from a liquid so rapidly that the molecules literally have no time to assume the ordered structure of a solid. A supercooled liquid is unstable. Gentle stirring or the addition to it of a small "seed" crystal of the same substance will cause it to solidify quickly.

## Solid-Vapor Phase Transition

Solids can be vaporized, so solids, too, have a vapor pressure. Sublimation is the process by which molecules go directly from the solid phase to the vapor phase. The reverse process, in which molecules go directly from the vapor phase to the solid phase, is called deposition. Naphthalene, which is the substance used to make mothballs, has a fairly high vapor pressure for a solid ( 1 mmHg at $53^{\circ} \mathrm{C}$ ); thus, its pungent vapor quickly permeates an enclosed space. Iodine also sublimes. At room temperature, the violet color of iodine vapor is easily visible in a closed container.

Because molecules are more tightly held in a solid, the vapor pressure of a solid is generally much less than that of the corresponding liquid. The molar enthalpy of sublimation $\left(\Delta \boldsymbol{H}_{\text {sub }}\right)$ of a substance is the energy, usually expressed in kilojoules, required to sublime 1 mole of a solid. It is equal to the sum of the molar enthalpies of fusion and vaporization:

$$
\Delta H_{\text {sub }}=\Delta H_{\text {fus }}+\Delta H_{\text {vap }}
$$

Equation 12.6

Figure 12.32 A typical heating curve, from the solid phase through the liquid phase to the gas phase of a substance. Because $\Delta H_{\text {fus }}$ is smaller than $\Delta H_{\text {vap }}$, a substance melts in less time than it takes to boil. This explains why $A B$ is shorter than $C D$. The steepness of the solid, liquid, and vapor heating lines is determined by the specific heat of the substance in each state.

Solid iodine in equilibrium with its vapor.

Figure 12.33 Heating curve of water.

Student Annotation: Equation 12.6 is generally used to approximate $\Delta H_{\text {sub }}$. It only holds strictly when all the phase changes occur at the same temperature.

Student Annotation: You may want to review the calculation of the heat exchanged between the system and surroundings for temperature changes and phase changes [ 14 Sections 5.3 and 5.4].

Equation 12.6 is an illustration of Hess's law [ 144 Section 5.5]. The enthalpy, or heat change, for the overall process is the same whether the substance changes directly from the solid to the vapor phase or if it changes from the solid to the liquid and then to the vapor phase.

## Bringing Chemistry to Life

## The Dangers of Phase Changes

If you have ever suffered a steam burn, you know that it can be far more serious than a burn caused simply by boiling water-even though steam and boiling water are both at the same temperature. A heating curve helps explain why this is so (see Figure 12.33). When boiling water touches your skin, it is cooled to body temperature because it deposits the heat it contains on your skin. The heat deposited on your skin by a sample of boiling water at $100^{\circ} \mathrm{C}$ can be represented by the orange line under the curve. When an equivalent mass of steam contacts your skin, it first deposits heat as it condenses and then cools to body temperature. The heat deposited on your skin by a sample of steam is represented by the red line under the curve. Notice how much more heat is deposited by steam than by liquid water at the same temperature. The steam contains more heat because it has been heated and vaporized. The additional heat that was absorbed by the water to vaporize it is what makes a steam burn worse than a burn from boiling water.

A heating curve can also be used to explain why hikers stranded by blizzards are warned not to consume snow in an effort to stay hydrated. When you drink cold water, your body expends energy to warm the water you consume to body temperature. If you consume snow, your body must first expend the energy necessary to melt the snow, and then to warm it. Because a phase change is involved, the amount of energy required to assimilate snow is much greater than the amount necessary to assimilate an equal mass of water-even if the water is ice-cold. This can contribute to hypothermia, a potentially dangerous drop in body temperature.

## Sample Problem 12.8

(a) Calculate the amount of heat deposited on the skin of a person burned by 1.00 g of liquid water at $100.0^{\circ} \mathrm{C}$ and (b) the amount of heat deposited by 1.00 g of steam at $100.0^{\circ} \mathrm{C}$. (c) Calculate the amount of energy necessary to warm 100.0 g of water from $0.0^{\circ} \mathrm{C}$ to body temperature and (d) the amount of heat required to melt 100.0 g of ice at $0.0^{\circ} \mathrm{C}$ and then warm it to body temperature. (Assume that body temperature is $37.0^{\circ} \mathrm{C}$.)

Strategy For the purpose of following the sign conventions, we can designate the water as the system and the body as the surroundings. (a) Heat is transferred from hot water to the skin in a single
step: a temperature change. (b) The transfer of heat from steam to the skin takes place in two steps: a phase change and a temperature change. (c) Cold water is warmed to body temperature in a single step: a temperature change. (d) The melting of ice and the subsequent warming of the resulting liquid water takes place in two steps: a phase change and a temperature change. In each case, the heat transferred during a temperature change depends on the mass of the water, the specific heat of water, and the change in temperature. For the phase changes, the heat transferred depends on the amount of water (in moles) and the molar heat of vaporization ( $\Delta H_{\text {vap }}$ ) or molar heat of fusion $\left(\Delta H_{\text {fus }}\right)$. In each case, the total energy transferred or required is the sum of the energy changes for the individual steps.

Setup The required specific heats $(s)$ are $4.184 \mathrm{~J} / \mathrm{g} \cdot{ }^{\circ} \mathrm{C}$ for water and $1.99 \mathrm{~J} / \mathrm{g} \cdot{ }^{\circ} \mathrm{C}$ for steam. (Assume that the specific heat values do not change over the range of temperatures in the problem.) From Table 12.6, the molar heat of vaporization $\left(\Delta H_{\text {vap }}\right)$ of water is $40.79 \mathrm{~kJ} / \mathrm{mol}$, and from Table 12.8, the molar heat of fusion $\left(\Delta H_{\text {fus }}\right)$ of water is $6.01 \mathrm{~kJ} / \mathrm{mol}$. The molar mass of water is $18.02 \mathrm{~g} / \mathrm{mol}$. Note: The $\Delta H_{\text {vap }}$ of water is the amount of heat required to vaporize a mole of water. In this problem, however, we want to know how much heat is deposited when water vapor condenses, so we must use the negative, $-40.79 \mathrm{~kJ} / \mathrm{mol}$.

## Solution

(a) $\Delta T=37.0^{\circ} \mathrm{C}-100.0^{\circ} \mathrm{C}=-63.0^{\circ} \mathrm{C}$

From Equation 5.13, we write

$$
q=m s \Delta T=1.00 \mathrm{~g} \times \frac{4.184 \mathrm{~J}}{\mathrm{~g} \cdot{ }^{\circ} \mathrm{C}} \times-63.0^{\circ} \mathrm{C}=-2.64 \times 10^{2} \mathrm{~J}=-0.264 \mathrm{~kJ}
$$

Thus, 1.00 g of water at $100.0^{\circ} \mathrm{C}$ deposits 0.264 kJ of heat on the skin. (The negative sign indicates that heat is given off by the system and absorbed by the surroundings.)
(b) $\frac{1.00 \mathrm{~g}}{18.02 \mathrm{~g} / \mathrm{mol}}=0.0555 \mathrm{~mol}$ water

$$
\begin{aligned}
& q_{1}=n \Delta H_{\text {vap }}=0.0555 \mathrm{~mol} \times \frac{-40.79 \mathrm{~kJ}}{\mathrm{~mol}}=-2.26 \mathrm{~kJ} \\
& q_{2}=m s \Delta T=1.00 \mathrm{~g} \times \frac{4.184 \mathrm{~J}}{\mathrm{~g} \cdot{ }^{\circ} \mathrm{C}} \times-63.0^{\circ} \mathrm{C}=-2.64 \times 10^{2} \mathrm{~J}=-0.264 \mathrm{~kJ}
\end{aligned}
$$

The overall energy deposited on the skin by 1.00 g of steam is the sum of $q_{1}$ and $q_{2}$ :

$$
-2.26 \mathrm{~kJ}+(-0.264 \mathrm{~kJ})=-2.53 \mathrm{~kJ}
$$

The negative sign indicates that the system (steam) gives off the energy.
(c) $\Delta T=37.0^{\circ} \mathrm{C}-0.0^{\circ} \mathrm{C}=37.0^{\circ} \mathrm{C}$

$$
q=m s \Delta T=100.0 \mathrm{~g} \times \frac{4.184 \mathrm{~J}}{\mathrm{~g} \cdot{ }^{\circ} \mathrm{C}} \times 37.0^{\circ} \mathrm{C}=1.55 \times 10^{4} \mathrm{~J}=15.5 \mathrm{~kJ}
$$

The energy required to warm 100.0 g of water from $0.0^{\circ} \mathrm{C}$ to $37.0^{\circ} \mathrm{C}$ is 15.5 kJ .
(d) $\frac{100.0 \mathrm{~g}}{18.02 \mathrm{~g} / \mathrm{mol}}=5.55 \mathrm{~mol}$

$$
\begin{aligned}
& q_{1}=n \Delta H_{\mathrm{fus}}=5.55 \mathrm{~mol} \times \frac{6.01 \mathrm{~kJ}}{\mathrm{~mol}}=33.4 \mathrm{~kJ} \\
& q_{2}=m s \Delta T=100.0 \mathrm{~g} \times \frac{4.184 \mathrm{~J}}{\mathrm{~g} \cdot{ }^{\circ} \mathrm{C}} \times 37.0^{\circ} \mathrm{C}=1.55 \times 10^{4} \mathrm{~J}=15.5 \mathrm{~kJ}
\end{aligned}
$$

The energy required to melt 100.0 g of ice at $0.0^{\circ} \mathrm{C}$ and warm it to $37.0^{\circ} \mathrm{C}$ is the sum of $q_{1}$ and $q_{2}$ :

$$
33.4 \mathrm{~kJ}+15.5 \mathrm{~kJ}=48.9 \mathrm{~kJ}
$$

Practice Problem A Calculate the amount of energy (in kJ ) necessary to convert 346 g of liquid water from $0^{\circ} \mathrm{C}$ to water vapor at $182^{\circ} \mathrm{C}$.

EPractice Problem B Determine the final state and temperature of 100 g of water originally at $25.0^{\circ} \mathrm{C}$ after 50.0 kJ of heat have been added to it.

Think About It In problems that include phase changes, the $q$ values corresponding to the phase-change steps will be the largest contributions to the total. If you find that this is not the case in your solution, check to see if you have made the common error of neglecting to convert the $q$ values corresponding to temperature changes from J to kJ .

## Checkpoint 12.6 Phase Changes

12.6.1 How much energy (in kJ ) is required to convert 25.0 g of liquid water at room temperature $\left(25^{\circ} \mathrm{C}\right)$ to steam at $110^{\circ} \mathrm{C}$ ?
a) 64.9 kJ
b) 562 kJ
c) 1339 kJ
d) 1.34 kJ
e) 26.9 kJ
12.6.2 How much energy (in kJ ) is given off when 1.0 g of steam at $100^{\circ} \mathrm{C}$ cools to room temperature $\left(25^{\circ} \mathrm{C}\right)$ ?
a) 0.326 kJ
b) 316 kJ
c) 2.58 kJ
d) 48.9 kJ
e) 22.1 kJ

### 12.7 Phase Diagrams

The relationships between the phases of a substance can be represented in a single graph known as a phase diagram. A phase diagram summarizes the conditions (temperature and pressure) at which a substance exists as a solid, liquid, or gas. Figure 12.34(a) shows the phase diagram of $\mathrm{CO}_{2}$, which is typical of many substances. The graph is divided into three regions, each of which represents a pure phase. The line separating any two regions, called a phase boundary line, indicates conditions under which these two phases can exist in equilibrium. The point at which all three phase boundary lines meet is called the triple point. The triple point is the only combination of temperature and pressure at which all three phases of a substance can be in equilibrium with one another. The point at which the liquid-vapor phase boundary line abruptly ends is the critical point, corresponding to the critical temperature $\left(T_{\mathrm{c}}\right)$ and the critical pressure $\left(P_{\mathrm{c}}\right)$.

In order to understand the information in a phase diagram, consider the dashed lines between numbered points in Figure 12.34 (b). If we start with a sample of $\mathrm{CO}_{2}$ at 1 atm and $-100^{\circ} \mathrm{C}$, the sample is initially a solid (point 1 ). If we then add heat to the sample at 1 atm , its temperature increases until it reaches $-78^{\circ} \mathrm{C}$, the sublimation point of $\mathrm{CO}_{2}$ at 1 atm (point 2). When the entire sample has sublimed at $-78^{\circ} \mathrm{C}$, the temperature of the resulting vapor will begin to increase. We continue adding heat until the temperature of the vapor is $-25^{\circ} \mathrm{C}$ (point 3 ). At this point, we maintain the temperature at $-25^{\circ} \mathrm{C}$ and begin increasing the pressure until the vapor condenses, which would occur at a pressure of about 70 atm (point 4). With a phase diagram, we can tell in what phase a substance will exist at any given temperature and pressure. Furthermore, we can tell what phase changes will occur as the result of increases or decreases in temperature, pressure, or both.

One of the interesting things about the phase diagram of $\mathrm{CO}_{2}$ is that its triple point occurs above atmospheric pressure $-57^{\circ} \mathrm{C}, 5.2 \mathrm{~atm}$. This means that there is no liquid phase at atmospheric pressure, the condition that makes dry ice "dry." At elevated pressure, solid $\mathrm{CO}_{2}$ does melt. In fact, liquid $\mathrm{CO}_{2}$ is used as the solvent in many dry-cleaning operations.

The phase diagram of water (Figure 12.35) is unusual because the solid-liquid phaseboundary line has a negative slope. (Compare this with the solid-liquid phase-boundary line of $\mathrm{CO}_{2}$ in Figure 12.34.) As a result, ice can be liquefied within a narrow temperature range by applying pressure.

(a)

(b)

Sample Problem 12.9 lets you practice interpreting the information in a phase diagram.

## Sample Problem 12.9

Using the following phase diagram, (a) determine the normal boiling point and the normal melting point of the substance, (b) determine the physical state of the substance at 2 atm and $110^{\circ} \mathrm{C}$, and (c) determine the pressure and temperature that correspond to the triple point of the substance.

Strategy Each point on the phase diagram corresponds to a pressure-temperature combination. The normal boiling and melting points are the temperatures at which the substance undergoes phase changes. These points fall on the phase boundary lines. The triple point is where the three phase boundaries meet.

Setup By drawing lines corresponding to a given pressure and/or temperature, we can determine the temperature at which a phase change occurs, or the physical state of the substance under specified conditions.

(a)

(b)

(c)
(Continued)

Think About It The triple point of this substance occurs at a pressure below atmospheric pressure. Therefore, it will melt rather than sublime when it is heated under ordinary conditions.

## Solution

(a) The normal boiling and melting points are $\sim 140^{\circ} \mathrm{C}$ and $\sim 205^{\circ} \mathrm{C}$, respectively.
(b) At 2 atm and $110^{\circ} \mathrm{C}$ the substance is a solid.
(c) The triple point occurs at $\sim 0.8 \mathrm{~atm}$ and $\sim 115^{\circ} \mathrm{C}$.

Practice Problem A Use the following phase diagram to (a) determine the normal boiling point and melting point of the substance, and (b) the physical state of the substance at 1.2 atm and $100^{\circ} \mathrm{C}$.

- Practice Problem B Sketch the phase diagram of a substance using the following data:

| Pressure (atm) | Melting Point $\left({ }^{\circ} \mathbf{C}\right)$ | Boiling Point $\left({ }^{\circ} \mathbf{C}\right)$ | Sublimation Point $\left({ }^{\circ} \mathbf{C}\right)$ |
| :---: | :---: | :---: | :---: |
| 0.5 | - | - | 0 |
| 1.0 | 60 | 110 | - |
| 1.5 | 75 | 200 | - |
| 2.0 | 105 | 250 | - |
| 2.5 | 125 | 275 | - |

The triple point is at 0.75 atm and $45^{\circ} \mathrm{C}$.

## Checkpoint 12.7 Phase Diagrams

Refer to the following phase diagrams to answer questions 12.7.1 and 12.7.2.

$T$

$T$
12.7.1 Which phase diagram corresponds to a substance that will sublime rather than melt as it is heated at 1 atm ?
a) 1
b) 1 and 2
c) 1,2 , and 4
d) 3
e) none

$T$

$T$
12.7.2 Which phase diagram corresponds to a substance that will liquefy when pressure is increased at a temperature below its freezing point?
a) 1
b) 1 and 2
c) 1, 2, and 4
d) 3
e) none

## Applying What You've Learned

The melamine tragedy in China caused an epidemic of unusual kidney stones in infants, a condition that is ordinarily very rare. In the general population of adults, though, kidney stones are relatively common with roughly 10 percent of adults experiencing symptoms during their lifetimes. The most common type of kidney stone is composed of calcium oxalate $\left(\mathrm{CaC}_{2} \mathrm{O}_{4}\right)$, and several different approaches can be used for treatment and/or prevention. One method of treatment involves the use of diuretics-drugs that cause elimination of water from the body in the form of urine. Increasing the volume of fluid that passes through the kidneys can help to reduce the amount of calcium available for stone formation. It can also facilitate the passing of a stone that has already formed. Two of the drugs that are prescribed for the treatment and prevention of kidney stones are hydrochlorothiazide and chlorthalidone.

Hydrochlorothiazide

Chlorthalidone

## Problems:

a) What types of intermolecular forces exist between chlorthalidone molecules and between hydrochlorothiazide molecules? [ 14 Sample Problem 12.1]
b) Calcium is one of the components of the most common type of kidney stone. Calcium metal crystallizes in a face-centered cubic unit cell with a cell edge length of 558.84 pm . Calculate the radius of a calcium atom in angstroms ( $\AA$ ). [ 144 Sample Problem 12.3]
c) How many Ca atoms are contained within a unit cell? [ $\mathrm{K4}$ Sample Problem 12.5]
d) Calculate the density of calcium metal in $\mathrm{g} / \mathrm{cm}^{3}$. [ WA Sample Problem 12.6]
e) Patients who have suffered from kidney stones often are advised to drink extra water to help prevent the formation of additional stones. An article on WebMD.com recommends drinking at least three quarts $(2.84 \mathrm{~L})$ of water every day-nearly 50 percent more than the amount recommended for healthy adults. How much energy must the body expend to warm this amount of water consumed at $10^{\circ} \mathrm{C}$ to body temperature $\left(37^{\circ} \mathrm{C}\right)$ ? How much more energy would have to be expended if the same quantity of water were consumed as ice at $0^{\circ} \mathrm{C}$ ? $\Delta H_{\text {fus }}$ for water is $6.01 \mathrm{~kJ} / \mathrm{mol}$. Assume the density and specific heat of water are $1.00 \mathrm{~g} / \mathrm{cm}^{3}$ and $4.184 \mathrm{~J} / \mathrm{g} \cdot{ }^{\circ} \mathrm{C}$, respectively, and that both quantities are independent of temperature. [ 144 Sample Problem 12.7].

## Chapter Summary

## Section 12.1

- The particles (atoms, molecules, or ions) in the condensed phases (solids and liquids) are held together by intermolecular forces. Intermolecular forces are electrostatic attractions between opposite charges or partial charges.
- Intermolecular forces acting between atoms or molecules in a pure substance are called van der Waals forces and include dipole-dipole interactions (including hydrogen bonding) and London dispersion forces (also called simply dispersion forces).
- Dipole-dipole interactions exist between polar molecules, whereas nonpolar molecules are held together by dispersion forces alone. Dispersion forces are those between instantaneous dipoles and induced dipoles. When a nonpolar molecule acquires an instantaneous dipole, it is said to be polarized. Dispersion forces act between all molecules, nonpolar and polar.
- Hydrogen bonding is an especially strong type of dipole-dipole interaction that occurs in molecules that contain $\mathrm{H}-\mathrm{N}, \mathrm{H}-\mathrm{O}$, or $\mathrm{H}-\mathrm{F}$ bonds.
- Ion-dipole interactions are those that occur (in solutions) between ions and polar molecules.

## Section 12.2

- Physical properties of liquids that result from intermolecular forces include surface tension, viscosity, and vapor pressure.
- Surface tension is the net pull inward on molecules at the surface of a liquid. Surface tension is related to cohesion, the attractive forces between molecules within a substance, and adhesion, the attractive forces between molecules in a substance and their container. The balance between cohesion and adhesion determines whether a liquid meniscus is concave or convex. It also gives rise to capillary action, in which liquid is drawn upward into a narrow tube against gravity.
- Viscosity is resistance to flow, reflecting how easily molecules move past one another.
- Evaporation (also known as vaporization) is the phase change from liquid to vapor. Condensation is the phase change from vapor to liquid. In a closed system, when vaporization and condensation are occurring at the same rate, a state of dynamic equilibrium exists and the vapor pressure is equal to the equilibrium vapor pressure. Vapor pressure measures how easily molecules escape to the vapor phase. A volatile substance has a high vapor pressure.
- Surface tension, viscosity, and vapor pressure are all temperature dependent. The Clausius-Clapeyron equation relates the vapor pressure of a substance to its absolute temperature.

## Section 12.3

- The spheres (molecules, atoms, or ions) in a crystalline solid are arranged in a three-dimensional lattice structure consisting of a repeating pattern of unit cells. The type of unit cell is determined by the positions of the lattice points.
- Cubic unit cells may be simple cubic, body-centered cubic, or face-centered cubic, containing a total of one, two, or four spheres, respectively. The coordination number is the number of spheres surrounding each sphere.
- Closest packing is the most efficient arrangement of spheres in a solid. It may be hexagonal or cubic. Each has a coordination number of 12 .
- $\boldsymbol{X}$-ray diffraction is used to analyze crystal structure. The wavelength of X rays, the angle of diffraction, and the spacing between atoms in a lattice are related by the Bragg equation.

## Section 12.4

- Crystals may be ionic, covalent, molecular, or metallic. Each type of crystalline solid has characteristics determined in part by the types of interactions holding it together.

## Section 12.5

- Amorphous solids such as glass lack regular three-dimensional structure.

## Section 12.6

- The possible phase changes are melting or fusion $(s \longrightarrow l)$, freezing $(l \longrightarrow s)$, vaporization $(l \longrightarrow g)$, condensation $(g \longrightarrow l)$, sublimation $(s \longrightarrow g)$, and deposition $(g \longrightarrow s)$.
- The boiling point of a substance is the temperature at which its vapor pressure equals the external pressure. The normal boiling point is the temperature at which its vapor pressure equals 1 atm . Boiling point is pressure dependent. The molar heat of vaporization $\left(\Delta \boldsymbol{H}_{\text {vap }}\right)$ is the amount of heat required to vaporize 1 mole of a substance at its boiling point.
- The critical temperature $\left(\boldsymbol{T}_{c}\right)$ is the temperature above which a gas cannot be liquefied by applying pressure. The critical pressure $\left(\boldsymbol{P}_{\boldsymbol{c}}\right)$ is the pressure necessary to liquefy a gas at its critical temperature. A substance above its critical temperature and pressure is a supercritical fluid.
- The melting point or freezing point is the temperature at which the solid and liquid phases are in equilibrium. The molar heat of fusion $\left(\Delta \boldsymbol{H}_{f u s}\right)$ is the amount of heat required to melt 1 mole of a substance at its melting point. Supercooling is the process of rapidly lowering a liquid's temperature below its freezing point.
- The molar heat of sublimation $\left(\Delta \boldsymbol{H}_{\text {sub }}\right)$ is equal to the sum of the molar heats of fusion and vaporization: $\Delta H_{\text {sub }}=\Delta H_{\text {fus }}+\Delta H_{\text {vap }}$

## Section 12.7

- A phase diagram indicates the phase of a substance under any combination of temperature and pressure. Lines between phases are called phase boundaries.
- The triple point is where all three phase boundaries meet. This is the temperature and pressure combination at which all three phases are in equilibrium.

## Key Equations

$$
\begin{array}{ll}
12.1 & \ln P=-\frac{\Delta H_{\text {vap }}}{R T}+C \\
12.2 & \ln P_{1}=-\frac{\Delta H_{\text {vap }}}{R T_{1}}+C \\
12.3 & \ln P_{2}=-\frac{\Delta H_{\text {vap }}}{R T_{2}}+C \\
12.4 & \ln \frac{P_{1}}{P_{2}}=\frac{\Delta H_{\text {vap }}}{R}\left(\frac{1}{T_{2}}-\frac{1}{T_{1}}\right) \\
12.5 & \mathrm{BC}+\mathrm{CD}=2 d \sin \theta=n \lambda \quad n=1,2,3, \ldots \\
12.6 & \Delta H_{\text {sub }}=\Delta H_{\text {fus }}+\Delta H_{\text {vap }}
\end{array}
$$

## Questions and Problems

## Section 12.1: Intermolecular Forces

## Review Questions

12.1 Give an example for each type of intermolecular force:
(a) dipole-dipole interaction, (b) ion-dipole interaction,
(c) dispersion forces, (d) van der Waals forces.
12.2 Explain the term polarizability. What kind of molecules tend to have high polarizabilities? What is the relationship between polarizability and intermolecular forces?
12.3 Explain the difference between a temporary dipole moment and a permanent dipole moment.
12.4 What evidence can you cite that all molecules exert attractive forces on one another?
12.5 What physical properties are determined by the strength of intermolecular forces in solids and in liquids?
12.6 Explain why hydrogen bonding is exhibited by some hydrogen-containing compounds and not by others.
12.7 Describe the types of intermolecular forces that govern the folding of a protein molecule into its physiologically functioning threedimensional state.

## Problems

12.8 The compounds $\mathrm{Br}_{2}$ and ICl are isoelectronic (have the same number of electrons) and have similar molar masses, yet $\mathrm{Br}_{2}$ melts at $-7.2^{\circ} \mathrm{C}$ and ICl melts at $27.2^{\circ} \mathrm{C}$. Explain.
12.9 If you lived in Alaska, which of the following natural gases could you keep in an outdoor storage tank in winter: methane $\left(\mathrm{CH}_{4}\right)$, propane $\left(\mathrm{C}_{3} \mathrm{H}_{8}\right)$, or butane $\left(\mathrm{C}_{4} \mathrm{H}_{10}\right)$ ? Explain why.
12.10 The binary hydrogen compounds of the Group 4A elements and their boiling points are: $\mathrm{CH}_{4},-162^{\circ} \mathrm{C} ; \mathrm{SiH}_{4},-112^{\circ} \mathrm{C} ; \mathrm{GeH}_{4}$, $-88^{\circ} \mathrm{C}$; and $\mathrm{SnH}_{4},-52^{\circ} \mathrm{C}$. Explain the increase in boiling points from $\mathrm{CH}_{4}$ to $\mathrm{SnH}_{4}$.
$\boldsymbol{Y}$ 12.11 List the types of intermolecular forces that exist between molecules (or atoms or ions) in each of the following species: (a) benzene $\left(\mathrm{C}_{6} \mathrm{H}_{6}\right)$, (b) $\mathrm{CH}_{3} \mathrm{Cl}$, (c) $\mathrm{PF}_{3}$, (d) NaCl , (e) $\mathrm{CS}_{2}$.
12.12 Ammonia is both a donor and an acceptor of hydrogen in hydrogen-bond formation. Draw a diagram showing the hydrogen bonding of an ammonia molecule with two other ammonia molecules.

EI 12.13 Which of the following species are capable of hydrogen-bonding among themselves: (a) $\mathrm{C}_{2} \mathrm{H}_{6}$, (b) HI , (c) KF , (d) $\mathrm{BeH}_{2}$, (e) $\mathrm{CH}_{3} \mathrm{COOH}$ ?

E12.14 Arrange the following in order of increasing boiling point: RbF , $\mathrm{CO}_{2}, \mathrm{CH}_{3} \mathrm{OH}, \mathrm{CH}_{3} \mathrm{Br}$. Explain your reasoning.
12.15 Diethyl ether has a boiling point of $34.5^{\circ} \mathrm{C}$, and 1-butanol has a boiling point of $117^{\circ} \mathrm{C}$ :

Diethyl ether

1-Butanol

Both of these compounds have the same numbers and types of atoms. Explain the difference in their boiling points.

E12.16 Which member of each of the following pairs of substances would you expect to have a higher boiling point: (a) $\mathrm{O}_{2}$ and $\mathrm{Cl}_{2}$, (b) $\mathrm{SO}_{2}$ and $\mathrm{CO}_{2}$, (c) HF and HI ?
12.17 Which substance in each of the following pairs would you expect to have the higher boiling point: (a) Ne or Xe , (b) $\mathrm{CO}_{2}$ or $\mathrm{CS}_{2}$, (c) $\mathrm{CH}_{4}$ or $\mathrm{Cl}_{2}$, (d) $\mathrm{F}_{2}$ or LiF , (e) $\mathrm{NH}_{3}$ or $\mathrm{PH}_{3}$ ? Explain why.
12.18 Explain in terms of intermolecular forces why (a) $\mathrm{NH}_{3}$ has a higher boiling point than $\mathrm{CH}_{4}$ and (b) KCl has a higher melting point than $I_{2}$.
12.19 What kind of attractive forces must be overcome to (a) melt ice, (b) boil molecular bromine, (c) melt solid iodine, and (d) dissociate $\mathrm{F}_{2}$ into F atoms?
\& 12.20 The following compounds have the same molecular formulas $\left(\mathrm{C}_{4} \mathrm{H}_{10}\right)$. Which one would you expect to have a higher boiling point?

12.21 Explain the difference in the melting points of the following compounds:

m.p. $45^{\circ} \mathrm{C} \quad$ m.p. $115^{\circ} \mathrm{C}$
(Hint: One of the two can form intramolecular hydrogen bonds.)

## Section 12.2: Properties of Liquids

## Review Questions

12.22 Explain why liquids, unlike gases, are virtually incompressible.
12.23 What is surface tension? What is the relationship between intermolecular forces and surface tension? How does surface tension change with temperature?
12.24 Despite the fact that stainless steel is much denser than water, a stainless-steel razor blade can be made to float on water. Why?
12.25 Use water and mercury as examples to explain adhesion and cohesion.
12.26 A glass can be filled slightly above the rim with water. Explain why the water does not overflow.
12.27 Draw diagrams showing the capillary action of (a) water and (b) mercury in three tubes of different radii.
12.28 What is viscosity? What is the relationship between intermolecular forces and viscosity?
12.29 Why does the viscosity of a liquid decrease with increasing temperature?
12.30 Why is ice less dense than water?
12.31 Outdoor water pipes have to be drained or insulated in winter in a cold climate. Why?

## Problems

E12.32 Predict which of the following liquids has greater surface tension: ethanol $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right)$ or dimethyl ether $\left(\mathrm{CH}_{3} \mathrm{OCH}_{3}\right)$.
12.33 Predict the viscosity of ethylene glycol relative to that of ethanol and glycerol (see Table 12.3).

$$
\begin{aligned}
& \mathrm{CH}_{2}-\mathrm{OH} \\
& \stackrel{\mathrm{C}}{2}-\mathrm{OH}
\end{aligned}
$$

Ethylene glycol
12.34 Vapor pressure measurements at several different temperatures are shown for mercury. Determine graphically the molar heat of vaporization for mercury.

| $T\left({ }^{\circ} \mathrm{C}\right)$ | 200 | 250 | 300 | 320 | 340 |
| :--- | :---: | :---: | :--- | :--- | :--- |
| $P(\mathrm{mmHg})$ | 17.3 | 74.4 | 246.8 | 376.3 | 557.9 |

12.35 The vapor pressure of benzene $\left(\mathrm{C}_{6} \mathrm{H}_{6}\right)$ is 40.1 mmHg at $7.6^{\circ} \mathrm{C}$. What is its vapor pressure at $60.6^{\circ} \mathrm{C}$ ? The molar heat of vaporization of benzene is $31.0 \mathrm{~kJ} / \mathrm{mol}$.
12.36 The vapor pressure of liquid X is lower than that of liquid Y at $20^{\circ} \mathrm{C}$, but higher at $60^{\circ} \mathrm{C}$. What can you deduce about the relative magnitude of the molar heats of vaporization of X and Y ?
$\boldsymbol{H}$ 12.37 Estimate the molar heat of vaporization of a liquid whose vapor pressure doubles when the temperature is raised from $75^{\circ} \mathrm{C}$ to $100^{\circ} \mathrm{C}$.

## Section 12.3: Crystal Structure

## Review Questions

12.38 Define the following terms: crystalline solid, lattice point, unit cell, coordination number, closest packing.
12.39 Describe the geometries of the following cubic cells: simple cubic, body-centered cubic, face-centered cubic. Which of these structures would give the highest density for the same type of atoms? Which the lowest?
12.40 Classify the solid states in terms of crystal types of the elements in the third period of the periodic table. Predict the trends in their melting points and boiling points.

G12.41 The melting points of the oxides of the third-period elements are given in parentheses: $\mathrm{Na}_{2} \mathrm{O}\left(1275^{\circ} \mathrm{C}\right), \mathrm{MgO}\left(2800^{\circ} \mathrm{C}\right), \mathrm{Al}_{2} \mathrm{O}_{3}$ $\left(2045^{\circ} \mathrm{C}\right), \mathrm{SiO}_{2}\left(1610^{\circ} \mathrm{C}\right), \mathrm{P}_{4} \mathrm{O}_{10}\left(580^{\circ} \mathrm{C}\right), \mathrm{SO}_{3}\left(16.8^{\circ} \mathrm{C}\right), \mathrm{Cl}_{2} \mathrm{O}_{7}$ $\left(-91.5^{\circ} \mathrm{C}\right)$. Classify these solids in terms of crystal types.
12.42 Define X-ray diffraction. What are the typical wavelengths (in nm ) of X rays? (See Figure 6.1.)
12.43 Write the Bragg equation. Define every term and describe how this equation can be used to measure interatomic distances.

## Problems

12.44 What is the coordination number of each sphere in (a) a simple cubic cell, (b) a body-centered cubic cell, and (c) a face-centered cubic cell? Assume the spheres are all the same.

G12.45 Calculate the number of spheres that would be found within a simple cubic cell, body-centered cubic cell, and face-centered cubic cell. Assume that the spheres are the same.

G
12.46 Metallic iron crystallizes in a cubic lattice. The unit cell edge length is 287 pm . The density of iron is $7.87 \mathrm{~g} / \mathrm{cm}^{3}$. How many iron atoms are within a unit cell?
12.47 Barium metal crystallizes in a body-centered cubic lattice (the Ba atoms are at the lattice points only). The unit cell edge length is 502 pm , and the density of the metal is $3.50 \mathrm{~g} / \mathrm{cm}^{3}$. Using this information, calculate Avogadro's number. [Hint: First calculate the volume (in $\mathrm{cm}^{3}$ ) occupied by 1 mole of Ba atoms in the unit cells. Next calculate the volume (in $\mathrm{cm}^{3}$ ) occupied by one Ba atom in the unit cell. Assume that 68 percent of the unit cell is occupied by Ba atoms.]

E 12.48 Vanadium crystallizes in a body-centered cubic lattice (the V atoms occupy only the lattice points). How many V atoms are present in a unit cell?

E12.49 Europium crystallizes in a body-centered cubic lattice (the Eu atoms occupy only the lattice points). The density of Eu is $5.26 \mathrm{~g} / \mathrm{cm}^{3}$. Calculate the unit cell edge length in picometers.

EI 12.50 Crystalline silicon has a cubic structure. The unit cell edge length is 543 pm . The density of the solid is $2.33 \mathrm{~g} / \mathrm{cm}^{3}$. Calculate the number of Si atoms in one unit cell.
12.51 A face-centered cubic cell contains 8 X atoms at the corners of the cell and 6 Y atoms at the faces. What is the empirical formula of the solid?

E12.52 When X rays of wavelength 0.090 nm are diffracted by a metallic crystal, the angle of first-order diffraction $(n=1)$ is measured to be $15.2^{\circ}$. What is the distance (in pm) between the layers of atoms responsible for the diffraction?

E12.53 The distance between layers in an NaCl crystal is 282 pm . X rays are diffracted from these layers at an angle of $23.0^{\circ}$. Assuming that $n=1$, calculate the wavelength of the X rays in nanometers.

EI 12.54 Identify the unit cell of molecular iodine $\left(\mathrm{I}_{2}\right)$ shown here. (Hint: Consider the position of iodine molecules, not individual iodine atoms.)

EI 12.55 Shown here is a zinc oxide unit cell. What is the formula of zinc oxide?

## Section 12.4: Types of Crystals

## Review Questions

12.56 Describe and give examples of the following types of crystals:
(a) ionic crystals, (b) covalent crystals, (c) molecular crystals,
(d) metallic crystals.
12.57 Why are metals good conductors of heat and electricity? Why does the ability of a metal to conduct electricity decrease with increasing temperature?

## Problems

E 12.58 A solid is hard, brittle, and electrically nonconducting. Its melt (the liquid form of the substance) and an aqueous solution containing the substance conduct electricity. Classify the solid.
12.59 A solid is soft and has a low melting point (below $100^{\circ} \mathrm{C}$ ). The solid, its melt, and an aqueous solution containing the substance are all nonconductors of electricity. Classify the solid.

E12.60 A solid is very hard and has a high melting point. Neither the solid nor its melt conducts electricity. Classify the solid.
12.61 Which of the following are molecular solids and which are covalent solids: $\mathrm{Se}_{8}, \mathrm{HBr}, \mathrm{Si}, \mathrm{CO}_{2}, \mathrm{C}, \mathrm{P}_{4} \mathrm{O}_{6}, \mathrm{SiH}_{4}$ ?
12.62 Classify the solid state of the following substances as ionic crystals, covalent crystals, molecular crystals, or metallic crystals: (a) $\mathrm{CO}_{2}$, (b) $\mathrm{B}_{12}$, (c) $\mathrm{S}_{8}$, (d) KBr , (e) Mg , (f) $\mathrm{SiO}_{2}$, (g) LiCl , (h) Cr .
12.63 Explain why diamond is harder than graphite. Why is graphite an electrical conductor but diamond is not?

## Section 12.5: Amorphous Solids

## Review Questions

12.64 What is an amorphous solid? How does it differ from a crystalline solid?
12.65 Define glass. What is the chief component of glass? Name three types of glass.

## Section 12.6: Phase Changes

## Review Questions

12.66 What is a phase change? Name all possible changes that can occur among the vapor, liquid, and solid phases of a substance.
12.67 What is the equilibrium vapor pressure of a liquid? How is it measured, and how does it change with temperature?
12.68 Use any one of the phase changes to explain what is meant by dynamic equilibrium.
12.69 Define the following terms: (a) molar heat of vaporization, (b) molar heat of fusion, (c) molar heat of sublimation. What are their typical units?

E12.70 How is the molar heat of sublimation related to the molar heats of vaporization and fusion? On what law are these relationships based?
12.71 What can we learn about the intermolecular forces in a liquid from the molar heat of vaporization?
12.72 The greater the molar heat of vaporization of a liquid, the greater its vapor pressure. True or false?
12.73 Define boiling point. How does the boiling point of a liquid depend on external pressure? Referring to Table 11.5, what is the boiling point of water when the external pressure is 187.5 mmHg ?
12.74 As a liquid is heated at constant pressure, its temperature rises. This trend continues until the boiling point of the liquid is reached. No further rise in temperature of the liquid can be induced by heating. Explain.
12.75 What is critical temperature? What is the significance of critical temperature in condensation of gases?
12.76 What is the relationship between intermolecular forces in a liquid and the liquid's boiling point and critical temperature? Why is the critical temperature of water greater than that of most other substances?
12.77 How do the boiling points and melting points of water and carbon tetrachloride vary with pressure? Explain any difference in behavior of these two substances.
12.78 Why is solid carbon dioxide called dry ice?
12.79 The vapor pressure of a liquid in a closed container depends on which of the following: (a) the volume above the liquid, (b) the amount of liquid present, (c) temperature, (d) intermolecular forces between the molecules in the liquid?
12.80 Wet clothes dry more quickly on a hot, dry day than on a hot, humid day. Explain.
12.81 Which of the following phase transitions gives off more heat: (a) 1 mole of steam to 1 mole of water at $100^{\circ} \mathrm{C}$, or (b) 1 mole of water to 1 mole of ice at $0^{\circ} \mathrm{C}$ ?
12.82 A beaker of water is heated to boiling by a Bunsen burner. Would adding another burner raise the temperature of the boiling water? Explain.
12.83 Explain why splashing a small amount of liquid nitrogen (b.p. 77 K ) is not as harmful as splashing boiling water on your skin.

## Problems

EI 12.84 Calculate the amount of heat (in kJ ) required to convert 150.2 g of water to steam at $100^{\circ} \mathrm{C}$.
$\Psi 12.85$ How much heat (in kJ ) is needed to convert 866 g of ice at $-15^{\circ} \mathrm{C}$ to steam at $146^{\circ} \mathrm{C}$ ? (The specific heats of ice and steam are 2.03 and $1.99 \mathrm{~J} / \mathrm{g} \cdot{ }^{\circ} \mathrm{C}$, respectively.)
12.86 How is the rate of evaporation of a liquid affected by
(a) temperature, (b) the surface area of a liquid exposed to air, (c) intermolecular forces?
12.87 The molar heats of fusion and sublimation of molecular iodine are 15.27 and $62.30 \mathrm{~kJ} / \mathrm{mol}$, respectively. Estimate the molar heat of vaporization of liquid iodine.
§12.88 The following compounds, listed with their boiling points, are liquid at $-10^{\circ} \mathrm{C}$ : butane, $-0.5^{\circ} \mathrm{C}$; ethanol, $78.3^{\circ} \mathrm{C}$; toluene, $110.6^{\circ} \mathrm{C}$. At $-10^{\circ} \mathrm{C}$, which of these liquids would you expect to have the highest vapor pressure? Which the lowest? Explain.
12.89 Freeze-dried coffee is prepared by freezing brewed coffee and then removing the ice component with a vacuum pump. Describe the phase changes taking place during these processes.
12.90 A student hangs wet clothes outdoors on a winter day when the temperature is $-15^{\circ} \mathrm{C}$. After a few hours, the clothes are found to be fairly dry. Describe the phase changes in this drying process.
12.91 Explain why steam at $100^{\circ} \mathrm{C}$ causes more serious burns than water at $100^{\circ} \mathrm{C}$.

## Section 12.7: Phase Diagrams

## Review Questions

12.92 What is a phase diagram? What useful information can be obtained from studying a phase diagram?
12.93 Explain how water's phase diagram differs from those of most substances. What property of water causes the difference?

## Problems

12.94 The blades of ice skates are quite thin, so the pressure exerted on ice by a skater can be substantial. Explain how this facilitates skating on ice.
12.95 A length of wire is placed on top of a block of ice. The ends of the wire extend over the edges of the ice, and a heavy weight is attached to each end. It is found that the ice under the wire gradually melts, so the wire slowly moves through the ice block. At the same time, the water above the wire refreezes. Explain the phase changes that accompany this phenomenon.
12.96 The boiling point and freezing point of sulfur dioxide are $-10^{\circ} \mathrm{C}$ and $-72.7^{\circ} \mathrm{C}$ (at 1 atm ), respectively. The triple point is $-75.5^{\circ} \mathrm{C}$ and $1.65 \times 10^{-3} \mathrm{~atm}$, and its critical point is at $157^{\circ} \mathrm{C}$ and 78 atm . On the basis of this information, draw a rough sketch of the phase diagram of $\mathrm{SO}_{2}$.
12.97 A phase diagram of water is shown. Label the regions. Predict what would happen as a result of the following changes:
(a) Starting at A, we raise the temperature at constant pressure.
(b) Starting at B, we lower the pressure at constant temperature.
(c) Starting at C, we lower the temperature at constant pressure.

## Additional Problems

E 12.98 Name the kinds of attractive forces that must be overcome to (a) boil liquid ammonia, (b) melt solid phosphorus $\left(\mathrm{P}_{4}\right)$, (c) dissolve CsI in liquid HF, (d) melt potassium metal.

H12.99 Which of the following properties indicates very strong intermolecular forces in a liquid: (a) very low surface tension, (b) very low critical temperature, (c) very low boiling point, (d) very low vapor pressure?
12.100 At $-35^{\circ} \mathrm{C}$, liquid HI has a higher vapor pressure than liquid HF . Explain.
12.101 Based on the following properties of elemental boron, classify it as one of the crystalline solids discussed in Section 12.4: high melting point $\left(2300^{\circ} \mathrm{C}\right)$, poor conductor of heat and electricity, insoluble in water, very hard substance.

H12.102 Referring to Figure 12.34, determine the stable phase of $\mathrm{CO}_{2}$ at (a) 4 atm and $-60^{\circ} \mathrm{C}$ and (b) 0.5 atm and $-20^{\circ} \mathrm{C}$.
12.103 Which of the following substances has the highest polarizability: $\mathrm{CH}_{4}, \mathrm{H}_{2}, \mathrm{CCl}_{4}, \mathrm{SF}_{6}, \mathrm{H}_{2} \mathrm{~S}$ ?

E 12.104 Given two complementary strands of DNA containing 100 base pairs each, calculate the ratio of two separate strands to hydrogen-bonded double helix in solution at 300 K. (Hint: The formula for calculating this ratio is $e^{-\Delta E / R T}$, where $\Delta E$ is the energy difference between hydrogen-bonded double-strand DNAs and single-strand DNAs and $R$ is the gas constant.) Assume the energy of hydrogen bonds per base pair to be $10 \mathrm{~kJ} / \mathrm{mol}$.
12.105 The average distance between base pairs measured parallel to the axis of a DNA molecule is $3.4 \AA$. The average molar mass of a pair of nucleotides is $650 \mathrm{~g} / \mathrm{mol}$. Estimate the length in centimeters of a DNA molecule of molar mass $5.0 \times 10^{9} \mathrm{~g} / \mathrm{mol}$. Roughly how many base pairs are contained in this molecule?
$12.106 \mathrm{~A} \mathrm{CO}_{2}$ fire extinguisher is located on the outside of a building in Massachusetts. During the winter months, one can hear a sloshing sound when the extinguisher is gently shaken. In the summertime there is often no sound when it is shaken. Explain. Assume that the extinguisher has no leaks and that it has not been used.
12.107 What is the vapor pressure of mercury at its normal boiling point $\left(357^{\circ} \mathrm{C}\right)$ ?
12.108 A flask of water is connected to a powerful vacuum pump. When the pump is turned on, the water begins to boil. After a few minutes, the same water begins to freeze. Eventually, the ice disappears. Explain what happens at each step.
12.109 The liquid-vapor boundary line in the phase diagram of any substance always stops abruptly at a certain point. Why?
12.110 The interionic distances of several alkali halide crystals are as follows:

| Crystal | NaCl | NaBr | NaI | KCl | KBr | KI |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Interionic | 282 | 299 | 324 | 315 | 330 | 353 |

distance (pm)
Plot lattice energy versus the reciprocal interionic distance. How would you explain the plot in terms of the dependence of lattice energy on the distance of separation between ions? What law governs this interaction? (For lattice energies, see Table 8.1.)
12.111 Which has a greater density, crystalline $\mathrm{SiO}_{2}$ or amorphous $\mathrm{SiO}_{2}$ ? Why?

E12.112 A student is given four solid samples labeled W, X, Y, and Z. All have a metallic luster. She is told that the solids could be gold, lead sulfide, mica (which is quartz, or $\mathrm{SiO}_{2}$ ), and iodine. The results of her investigations are: (a) W is a good electrical conductor; $\mathrm{X}, \mathrm{Y}$, and Z are poor electrical conductors. (b) When the solids are hit with a hammer, W flattens out, X shatters into many pieces, Y is smashed into a powder, and Z is not affected. (c) When the solids are heated with a Bunsen burner, Y melts with some sublimation, but $\mathrm{X}, \mathrm{W}$, and Z do not melt. (d) In treatment with $6 \mathrm{HNO}_{3}$, X dissolves; there is no effect on W , Y, or Z. On the basis of these test results, identify the solids.
12.113 Which of the following statements are false? (a) Dipole-dipole interactions between molecules are greatest if the molecules possess only temporary dipole moments. (b) All compounds containing hydrogen atoms can participate in hydrogen-bond formation. (c) Dispersion forces exist between all atoms, molecules, and ions.
12.114 The diagram shows a kettle of boiling water. Identify the phases in regions A and B.

12.115 The south pole of Mars is covered with solid carbon dioxide, which partly sublimes during the summer. The $\mathrm{CO}_{2}$ vapor recondenses in the winter when the temperature drops to 150 K . Given that the heat of sublimation of $\mathrm{CO}_{2}$ is $25.9 \mathrm{~kJ} / \mathrm{mol}$, calculate the atmospheric pressure on the surface of Mars. [Hint: Use Figure 12.34 to determine the normal sublimation temperature of dry ice and Equation 12.4, which also applies to sublimations.]
12.116 The properties of gases, liquids, and solids differ in a number of respects. How would you use the kinetic molecular theory (see Section 11.6) to explain the following observations? (a) Ease of compressibility decreases from gas to liquid to solid. (b) Solids retain a definite shape, but gases and liquids do not. (c) For most substances, the volume of a given amount of material increases as it changes from solid to liquid to gas.
12.117 Select the substance in each pair that should have the higher boiling point. In each case identify the principal intermolecular forces involved and account briefly for your choice: (a) $\mathrm{K}_{2} \mathrm{~S}$ or $\left(\mathrm{CH}_{3}\right)_{3} \mathrm{~N}$, (b) $\mathrm{Br}_{2}$ or $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3}$.
12.118 A small drop of oil in water assumes a spherical shape. Explain. (Hint: Oil is made up of nonpolar molecules, which tend to avoid contact with water.)
12.119 Under the same conditions of temperature and density, which of the following gases would you expect to behave less ideally: $\mathrm{CH}_{4}$ or $\mathrm{SO}_{2}$ ? Explain.
$\$ 12.120$ The fluorides of the second-period elements and their melting points are: $\mathrm{LiF}, 845^{\circ} \mathrm{C} ; \mathrm{BeF}_{2}, 800^{\circ} \mathrm{C} ; \mathrm{BF}_{3},-126.7^{\circ} \mathrm{C} ; \mathrm{CF}_{4}$, $-184^{\circ} \mathrm{C} ; \mathrm{NF}_{3},-206.6^{\circ} \mathrm{C} ; \mathrm{OF}_{2},-223.8^{\circ} \mathrm{C} ; \mathrm{F}_{2},-219.6^{\circ} \mathrm{C}$. Classify the type(s) of intermolecular forces present in each compound.
$\boldsymbol{Y}$ 12.121 The standard enthalpy of formation of gaseous molecular iodine is $62.4 \mathrm{~kJ} / \mathrm{mol}$. Use this information to calculate the molar heat of sublimation of molecular iodine at $25^{\circ} \mathrm{C}$.
12.122 The distance between $\mathrm{Li}^{+}$and $\mathrm{Cl}^{-}$is 257 pm in solid LiCl and 203 pm in an LiCl unit in the gas phase. Explain the difference in the bond lengths.
12.123 Heat of hydration, that is, the heat change that occurs when ions become hydrated in solution, is largely due to ion-dipole interactions. The heats of hydration for the alkali metal ions are $\mathrm{Li}^{+},-520 \mathrm{~kJ} / \mathrm{mol} ; \mathrm{Na}^{+},-405 \mathrm{~kJ} / \mathrm{mol} ; \mathrm{K}^{+},-321 \mathrm{~kJ} / \mathrm{mol}$. Account for the trend in these values.
12.124 If water were a linear molecule, (a) would it still be polar, and (b) would the water molecules still be able to form hydrogen bonds with one another?
12.125 Calculate the $\Delta H^{\circ}$ for the following processes at $25^{\circ} \mathrm{C}$ : (a) $\mathrm{Br}_{2}(l) \longrightarrow \mathrm{Br}_{2}(g)$ and (b) $\mathrm{Br}_{2}(g) \longrightarrow 2 \mathrm{Br}(g)$. Comment on the relative magnitudes of these $\Delta H^{\circ}$ values in terms of the forces involved in each case. (Hint: See Table 8.6.)
12.126 Which liquid would you expect to have a greater viscosity, water or diethyl ether? The structure of diethyl ether is shown in Problem 12.15.
12.127 A beaker of water is placed in a closed container. Predict the effect on the vapor pressure of the water when (a) its temperature is lowered, (b) the volume of the container is doubled, (c) more water is added to the beaker.
12.128 Ozone $\left(\mathrm{O}_{3}\right)$ is a strong oxidizing agent that can oxidize all the common metals except gold and platinum. A convenient test for ozone is based on its action on mercury. When exposed to ozone, mercury becomes dull looking and sticks to glass tubing (instead of flowing freely through it). Write a balanced equation for the reaction. What property of mercury is altered by its interaction with ozone?
12.129 A sample of limestone $\left(\mathrm{CaCO}_{3}\right)$ is heated in a closed vessel until it is partially decomposed. Write an equation for the reaction, and state how many phases are present.
12.130 Carbon and silicon belong to Group 4A of the periodic table and have the same valence electron configuration $\left(n s^{2} n p^{2}\right)$. Why does silicon dioxide $\left(\mathrm{SiO}_{2}\right)$ have a much higher melting point than carbon dioxide $\left(\mathrm{CO}_{2}\right)$ ?
12.131 Gaseous or highly volatile liquid anesthetics are often preferred in surgical procedures because once inhaled, these vapors can quickly enter the bloodstream through the alveoli and then enter the brain. Several common gaseous anesthetics are shown with their boiling points:

Halothane $50^{\circ} \mathrm{C}$

Isoflurane $48.5^{\circ} \mathrm{C}$

Enflurane $56.5^{\circ} \mathrm{C}$

Based on intermolecular force considerations, explain the advantages of using these anesthetics. (Hint: The brain barrier is made of membranes that have a nonpolar interior region.)
12.132 Given the general properties of water and ammonia, comment on the problems that a biological system (as we know it) would have developing in an ammonia medium.

|  | $\mathrm{H}_{2} \mathrm{O}$ | $\mathrm{NH}_{3}$ |
| :--- | :--- | :--- |
| Boiling point | 373.15 K | 239.65 K |
| Melting point | 273.15 K | 195.3 K |
| Molar heat capacity | $75.3 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$ | $8.53 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$ |
| Molar heat of vaporization | $40.79 \mathrm{~kJ} / \mathrm{mol}$ | $23.3 \mathrm{~kJ} / \mathrm{mol}$ |
| Molar heat of fusion | $6.0 \mathrm{~kJ} / \mathrm{mol}$ | $5.9 \mathrm{~kJ} / \mathrm{mol}$ |
| Viscosity | $0.001 \mathrm{~N} \cdot \mathrm{~s} / \mathrm{m}^{2}$ | $0.0254 \mathrm{~N} \cdot \mathrm{~s} / \mathrm{m}^{2}$ |
|  |  | $($ at 240 K$)$ |
| Dipole moment | 1.82 D | 1.46 D |
| Phase at 300 K | Liquid | Gas |

12.133 A pressure cooker is a sealed container that allows steam to escape when it exceeds a predetermined pressure. How does this device reduce the time needed for cooking?

E 12.134 A 1.20-g sample of water is injected into an evacuated 5.00-L flask at $65^{\circ} \mathrm{C}$. What percentage of the water will be vapor when the system reaches equilibrium? Assume ideal behavior of water vapor and that the volume of liquid water is negligible. The vapor pressure of water at $65^{\circ} \mathrm{C}$ is 187.5 mmHg .
12.135 What are the advantages of cooking the vegetable broccoli with steam instead of boiling it in water?

G12.136 A quantitative measure of how efficiently spheres pack into unit cells is called packing efficiency, which is the percentage of the cell space occupied by the spheres. Calculate the packing efficiencies of a simple cubic cell, a body-centered cubic cell, and a face-centered cubic cell. (Hint: Refer to Figure 12.24 and use the relationship that the volume of a sphere is $\frac{4}{3} \pi r^{3}$, where $r$ is the radius of the sphere.)
12.137 The phase diagram of helium is shown. Helium is the only known substance that has two different liquid phases: helium-I and helium-II. (a) What is the maximum temperature at which helium-II can exist? (b) What is the minimum pressure at which solid helium can exist? (c) What is the normal boiling point of helium-I? (d) Can solid helium sublime?

G12.138 The phase diagram of sulfur is shown. (a) How many triple points are there? (b) Which is the more stable allotrope under ordinary atmospheric conditions? (c) Describe what happens when sulfur at 1 atm is heated from $80^{\circ} \mathrm{C}$ to $200^{\circ} \mathrm{C}$.

12.139 Provide an explanation for each of the following phenomena: (a) Solid argon (m.p. $-189.2^{\circ} \mathrm{C}$; b.p. $-185.7^{\circ} \mathrm{C}$ ) can be prepared by immersing a flask containing argon gas in liquid nitrogen (b.p. $-195.8^{\circ} \mathrm{C}$ ) until it liquefies and then connecting the flask to a vacuum pump. (b) The melting point of cyclohexane $\left(\mathrm{C}_{6} \mathrm{H}_{12}\right)$ increases with increasing pressure exerted on the solid cyclohexane. (c) Certain high-altitude clouds contain water droplets at $-10^{\circ} \mathrm{C}$. (d) When a piece of dry ice is added to a beaker of water, fog forms above the water.
12.140 Argon crystallizes in the face-centered cubic arrangement at 40 K . Given that the atomic radius of argon is 191 pm , calculate the density of solid argon.

E 12.141 Given the phase diagram of carbon, answer the following questions: (a) How many triple points are there and what are the phases that can coexist at each triple point? (b) Which has a higher density, graphite or diamond? (c) Synthetic diamond can be made from graphite. Using the phase diagram, how would you go about making diamond?

12.142 A chemistry instructor performed the following mystery demonstration. Just before the students arrived in class, she heated some water to boiling in an Erlenmeyer flask. She then removed the flask from the flame and closed the flask with a rubber stopper. After the class commenced, she held the flask in front of the students and announced that she could make the water boil simply by rubbing an ice cube on the outside walls of the flask. To the amazement of everyone, it worked. Give an explanation for this phenomenon.
12.143 Swimming coaches sometimes suggest that a drop of alcohol (ethanol) placed in an ear plugged with water "draws out the water." Explain this action from a molecular point of view.
12.144 Use the concept of intermolecular forces to explain why the far end of a walking cane rises when one raises the handle.
12.145 Why do citrus growers spray their trees with water to protect them from freezing?
12.146 What is the origin of dark spots on the inner glass walls of an old tungsten lightbulb? What is the purpose of filling these lightbulbs with argon gas?
12.147 A student heated a beaker of cold water (on a tripod) with a Bunsen burner. When the gas was ignited, she noticed that there was water condensed on the outside of the beaker. Explain what happened.
12.148 The compound dichlorodifluoromethane $\left(\mathrm{CCl}_{2} \mathrm{~F}_{2}\right)$ has a normal boiling point of $-30^{\circ} \mathrm{C}$, a critical temperature of $112^{\circ} \mathrm{C}$, and a corresponding critical pressure of 40 atm . If the gas is compressed to 18 atm at $20^{\circ} \mathrm{C}$, will the gas condense? Your answer should be based on a graphical interpretation.
12.149 Iron crystallizes in a body-centered cubic lattice. The cell length as determined by X-ray diffraction is 286.7 pm . Given that the density of iron is $7.874 \mathrm{~g} / \mathrm{cm}^{3}$, calculate Avogadro's number.
12.150 Sketch the cooling curves of water from about $110^{\circ} \mathrm{C}$ to about $-10^{\circ} \mathrm{C}$. How would you also show the formation of supercooled liquid below $0^{\circ} \mathrm{C}$ that then freezes to ice? The pressure is at 1 atm throughout the process. The curves need not be drawn quantitatively.
12.151 The boiling point of methanol is $65.0^{\circ} \mathrm{C}$, and the standard enthalpy of formation of methanol vapor is $-201.2 \mathrm{~kJ} / \mathrm{mol}$. Calculate the vapor pressure of methanol (in mmHg ) at $25^{\circ} \mathrm{C}$. (Hint: See Appendix 2 for other thermodynamic data of methanol.)
E12.152 A sample of water shows the following behavior as it is heated at a constant rate:

If twice the mass of water has the same amount of heat transferred to it, which of the following graphs best describes the temperature variation? Note that the scales for all the graphs are the same.

12.153 A closed vessel of volume 9.6 L contains 2.0 g of water. Calculate the temperature (in ${ }^{\circ} \mathrm{C}$ ) at which only half of the water remains in the liquid phase. (See Table 11.5 for vapor pressures of water at different temperatures.)
12.154 The electrical conductance of copper metal decreases with increasing temperature, but that of a CuSO solution increases with increasing temperature. Explain.
12.155 Assuming ideal behavior, calculate the density of gaseous HF at its normal boiling point $\left(19.5^{\circ} \mathrm{C}\right)$. The experimentally measured density under the same conditions is $3.10 \mathrm{~g} / \mathrm{L}$. Account for the difference between your calculated result and the experimental value.
12.156 Explain why drivers are advised to use motor oil with lower viscosity in the winter and higher viscosity in the summer.
12.157 Which of the following compounds is most likely to exist as a liquid at room temperature: ethane $\left(\mathrm{C}_{2} \mathrm{H}_{6}\right)$, hydrazine $\left(\mathrm{N}_{2} \mathrm{H}_{4}\right)$, fluoromethane $\left(\mathrm{CH}_{3} \mathrm{~F}\right)$ ? Explain.

## Pre-Professional Practice Exam Problems: Physical and Biological Sciences

Silicon used in computer chips must have an impurity level below $10^{-9}$ (that is, fewer than one impurity atom for every $10^{9} \mathrm{Si}$ atoms). Silicon is prepared by the reduction of quartz $\left(\mathrm{SiO}_{2}\right)$ with coke (a form of carbon made by the destructive distillation of coal) at about $2000^{\circ} \mathrm{C}$ :

$$
\mathrm{SiO}_{2}(s)+2 \mathrm{C}(s) \longrightarrow \mathrm{Si}(l)+2 \mathrm{CO}(g)
$$

Next, solid silicon is separated from other solid impurities by treatment with hydrogen chloride at $350^{\circ} \mathrm{C}$ to form gaseous trichlorosilane $\left(\mathrm{SiCl}_{3} \mathrm{H}\right)$ :

$$
\mathrm{Si}(s)+3 \mathrm{HCl}(g) \longrightarrow \mathrm{SiCl}_{3} \mathrm{H}(g)+\mathrm{H}_{2}(g)
$$

Finally, ultrapure Si can be obtained by reversing the preceding reaction at $1000^{\circ} \mathrm{C}$ :

$$
\mathrm{SiCl}_{3} \mathrm{H}(g)+\mathrm{H}_{2}(g) \longrightarrow \mathrm{Si}(s)+3 \mathrm{HCl}(g)
$$

1. The molar heat of vaporization of trichlorosilane is $28.8 \mathrm{~kJ} / \mathrm{mol}$. Using this information and the equation

$$
\ln \frac{P_{1}}{P_{2}}=\frac{\Delta H_{\text {vap }}}{R}\left(\frac{1}{T_{2}}-\frac{1}{T_{1}}\right)
$$

determine the normal boiling point of trichlorosilane.
a) $-28.0^{\circ} \mathrm{C}$
b) $-276^{\circ} \mathrm{C}$
c) $30.1^{\circ} \mathrm{C}$
d) $275^{\circ} \mathrm{C}$
2. What kind(s) of intermolecular forces exist between trichlorosilane molecules?
a) Dispersion, dipole-dipole, and hydrogen bonding
b) Dispersion and dipole-dipole
c) Ion-ion
d) Dipole-dipole
3. Each cubic unit cell (edge length $a=543 \mathrm{pm}$ ) contains eight Si atoms. If there are $1.0 \times 10^{13}$ boron atoms per cubic centimeter in a sample of pure silicon, how many Si atoms are there for every B atom in the sample?
a) $5 \times 10^{22}$
b) $2 \times 10^{-10}$
c) $2 \times 10^{-22}$
d) $5 \times 10^{9}$
4. Calculate the density of pure silicon.
a) $2.33 \mathrm{~g} / \mathrm{cm}^{3}$
b) $0.292 \mathrm{~g} / \mathrm{cm}^{3}$
c) $4.67 \mathrm{~g} / \mathrm{cm}^{3}$
d) $3.72 \times 10^{-22} \mathrm{~g} / \mathrm{cm}^{3}$

## Answers to In-Chapter Materials

## Answers to Practice Problems

12.1A (a) Dispersion forces, (b) dipole-dipole forces, H bonding and dispersion forces, (c) dipole-dipole and dispersion forces, (d) dispersion forces. 12.1B (a) Dipole-dipole and dispersion forces, (b) dipole-dipole forces, H bonding and dispersion forces, (c) dipole-dipole forces, H bonding and dispersion forces, (d) dispersion forces. 12.2A 265 mmHg . 12.2B $75.9 \mathrm{~kJ} / \mathrm{mol}, 109^{\circ} \mathrm{C}$. 12.3A 315 pm . 12.3B $24.2^{\circ}$. 12.4A $10.5 \mathrm{~g} / \mathrm{cm}^{3}$. 12.4B Body-centered cubic. 12.5A $4 \mathrm{Ca}, 8 \mathrm{~F} . \mathbf{1 2 . 5 B} 1 \mathrm{Cs}, 1 \mathrm{Cl}$.
12.6A $2.65 \mathrm{~g} / \mathrm{cm}^{3}$. 12.6B 421 pm . 12.7A $2.72 \mathrm{~g} / \mathrm{cm}^{3}$. 12.7B 361 pm . 12.8A 984 kJ . $\mathbf{1 2 . 8 B} 100^{\circ} \mathrm{C}$, liquid and vapor in equilibrium.
12.9A (a) $\sim 110^{\circ} \mathrm{C}, \sim-10^{\circ} \mathrm{C}$, (b) liquid.
12.9B

## Answers to Checkpoints

12.1.1 a. 12.1.2 d. 12.2.1 a. 12.2.2 e. 12.2.3 b. 12.2.4 b. 12.3.1 d. 12.3.2 e. 12.6.1 a. 12.6.2 c. 12.7.1 a. 12.7.2 e.

## Answers to Applying What You've Learned

a) Both molecules exhibit dipole-dipole forces (including hydrogen bonding) and dispersion forces. b) 1.9758 A. c) 4 . d) $1.526 \mathrm{~g} / \mathrm{cm}^{3}$. e) $3.2 \times 10^{2} \mathrm{~kJ}, 1.1 \times 10^{3} \mathrm{~kJ}$.

## How an Ordinarily Beneficial Property of Solutions Can Put Dialysis Patients at Risk

In 1993, nine patients who had undergone routine hemodialysis treatment at the University of Chicago Hospitals became seriously ill, and three of them died. The illnesses and deaths were attributed to fluoride poisoning, which occurred when the equipment meant to remove fluoride from the water failed. Although hemodialysis is supposed to remove impurities from the blood, the inadvertent use of fluoridated water in the process actually added a toxin to the patients' blood.

Hemodialysis, often called simply dialysis, is the cleansing of toxins from the blood of patients whose kidneys are not functioning properly. It works by routing a patient's blood temporarily through a special filter called a dialyzer. Inside the dialyzer, the blood is separated (by an artificial porous membrane) from an aqueous solution called the dialysate. The dialysate contains a variety of dissolved substances, typically including sodium chloride, sodium bicarbonate or sodium acetate, calcium chloride, potassium chloride, magnesium chloride, and sometimes glucose. Its composition mimics that of blood plasma. When the two solutions, blood and dialysate, are separated by a porous membrane, the smallest of the dissolved solutes pass through the membrane from the side where the concentration is high to the side where the concentration is low. Because the dialysate contains vital components of blood in concentrations equal to those in blood, no net passage of these substances occurs through the membrane. However, the harmful substances that accumulate in the blood of patients whose kidneys do not function properly pass through the membrane into the dialysate, in which their concentration is initially zero, and are thereby removed from the blood. Properly done, hemodialysis therapy can add years to the life of a patient with kidney failure.

The development and refinement of medical procedures such as hemodialysis require an understanding of the properties of solutions.

At the end of this chapter, you will be able to solve a series of problems related to aqueous fluoride solutions [ $\|$ Page 569].

## In This Chapter, You Will Learn:

About the energy changes associated with solution formation, how the concentration of a solution is expressed, and how concentration determines certain properties of a solution.

Before you begin, you should review

- Intermolecular forces [ $\mathrm{K4}$ Section 12.1]
- Molecular geometry and polarity [K4 Section 9.2]
- Solution stoichiometry [ $\mathrm{K4}$ Section 4.5]

Student Annotation: The term solubility was also defined in Section 4.1.

### 13.1 Types of Solutions

As we noted in Section 1.2, a solution is a homogeneous mixture of two or more substances. Recall that a solution consists of a solvent and one or more solutes [14 Section 4.1]. Although many of the most familiar solutions are those in which a solid is dissolved in a liquid (e.g., saltwater or sugar water), the components of a solution may be solid, liquid, or gas. The possible combinations give rise to seven distinct types of solutions, which we classify by the original states of the solution components. Table 13.1 gives an example of each type.

In this chapter, we will focus on solutions in which the solvent is a liquid; and the liquid solvent we will encounter most often is water. Recall that solutions in which water is the solvent are called aqueous solutions [14t Section 4.1].

Solutions can also be classified by the amount of solute dissolved relative to the maximum amount that can be dissolved. A saturated solution is one that contains the maximum amount of a solute that will dissolve in a solvent at a specific temperature. The amount of solute dissolved in a given volume of a saturated solution is called the solubility. It is important to realize that solubility refers to a specific solute, a specific solvent, and a specific temperature. For example, the solubility of NaCl in water at $20^{\circ} \mathrm{C}$ is 36 g per 100 mL . The solubility of NaCl at another temperature, or in another solvent, would be different. An unsaturated solution is one that contains less solute than it has the capacity to dissolve. A supersaturated solution, on the other hand, contains more dissolved solute than is present in a saturated solution (Figure 13.1). It is generally not stable, and eventually the dissolved solute will come out of solution. An example of this phenomenon is shown in Figure 13.2.

TABLE 13.1 Types of Solutions

| Solute | Solvent | State of Resulting Solution | Example |
| :--- | :--- | :--- | :--- |
| Gas | Gas | Gas $^{*}$ | Air |
| Gas | Liquid | Liquid | Carbonated water |
| Gas | Solid | Solid | $\mathrm{H}_{2}$ gas in palladium |
| Liquid | Liquid | Liquid | Ethanol in water |
| Liquid | Solid | Solid | Mercury in silver |
| Solid | Liquid | Liquid | Saltwater |
| Solid | Solid | Solid | Brass $(\mathrm{Cu} / \mathrm{Zn})$ |

*Gaseous solutions can only contain gaseous solutes.

Figure 13.1 (a) Many solutions consist of a solid dissolved in water. (b) When all the solid dissolves, the solution is unsaturated. (c) If more solid is added than will dissolve, the solution is saturated. (d) A saturated solution is, by definition, in contact with undissolved solid. (e) Some saturated solutions can be made into supersaturated solutions by heating to dissolve more solid, and cooling carefully to prevent crystallization.

Figure 13.2 In a supersaturated solution, (a) addition of a tiny seed crystal initiates crystallization of excess solute. (b)-(e) Crystallization proceeds rapidly to give a saturated solution and the crystallized solid.

### 13.2 The Solution Process

In Chapter 4, we learned guidelines that helped us predict whether or not an ionic solid is soluble in water. We now take a more general look at the factors that determine solubility. This discussion will enable us to understand why so many ionic substances are soluble in water, which is a polar solvent; and it will help us to predict the solubility of ionic and molecular compounds in both polar and nonpolar solvents.

The intermolecular forces that hold molecules together in liquids and solids play a central role in the solution process. When the solute dissolves in the solvent, molecules of the solute disperse throughout the solvent. They are, in effect, separated from one another and each solute molecule is surrounded by solvent molecules-a process known as solvation. The ease with which solute molecules are separated from one another and surrounded by solvent molecules depends on the relative strengths of three types of interactions:

1. Solute-solute interactions
2. Solvent-solvent interactions
3. Solute-solvent interactions

Unlike the intermolecular forces covered in Chapter 12, all of which were between the molecules, atoms, or ions of a pure substance, solute-solvent interactions are those that exist in a mixture of different substances. Because the components of a mixture can have different properties, there is a greater variety of intermolecular forces to consider. In addition to dispersion forces, which exist between all substances, dipole-dipole forces, which exist between polar molecules, and ion-ion forces, which exist between ions, solutions can exhibit the following intermolecular forces:

Student Annotation: A hemoglobin molecule contains four $\mathrm{Fe}^{2+}$ ions. In the early stages of $\mathrm{O}_{2}$ binding, oxygen molecules are attracted to the $\mathrm{Fe}^{2+}$ ions by an ion-induced dipole interaction.

# Why Do Some Things Dissolve and Not Others? 

Previously, we learned that the driving force behind some processes is the lowering of the system's potential energy. Recall the minimization of potential energy when two hydrogen atoms are 74 pm apart [ 144 Section 9.3]. However, because there are substances that dissolve endothermically, meaning that the process increases the system's potential energy, something else must be involved in determining whether or not a substance will dissolve. That something else is entropy.

The entropy of a system is a measure of how dispersed or spread out its energy is. Consider two samples of different gases separated by a physical barrier. When we remove the barrier, the gases mix, forming a solution. Under ordinary conditions, we can treat the gases as ideal, meaning we can assume that there are no attractive forces between the molecules in either sample before they mix (no solute-solute or solvent-solvent attractions to break)-and no attractive forces between the molecules in the mixture (no solute-solvent attractions form). The energy of the system does not change-and yet the gases mix spontaneously. The reason such a solution forms is that, although there is no change in the energy of either of the original samples of gas, the energy possessed by each sample of gas spreads out into a larger volume. This increased dispersal of the system's energy is an increase in the entropy of the system. There is a natural tendency for entropy to increase; that is, for the energy of a system to become more dispersed-unless there is something preventing that dispersal. Initially, the physical barrier between the two gases prevented their energy from spreading out into the larger volume. It is the increase in entropy that drives the formation of this solution-and many others.

Now consider the case of solid ammonium nitrate $\left(\mathrm{NH}_{4} \mathrm{NO}_{3}\right)$, which dissolves in water in an endothermic process. In this case, the dissolution increases the potential energy of the system. However, the energy possessed by the ammonium nitrate solid spreads out to occupy the volume of the resulting solution causing the entropy of the system to increase. Ammonium nitrate dissolves in water because the favorable increase in the system's entropy outweighs the unfavorable increase in its potential energy. Although the process being endothermic is a barrier to solution formation, it is not enough of a barrier to prevent it.

In some cases, a process is so endothermic that even an increase in entropy is not enough to allow it to happen spontaneously. Sodium chloride $(\mathrm{NaCl})$ is not soluble in a nonpolar solvent such as benzene, for example, because the solvent-solute interactions that would result are too weak to compensate for the energy required to separate the network of positive and negative ions in sodium chloride. The magnitude of the exothermic step in solution formation $\left(\Delta H_{3}\right)$ is so small compared to the combined magnitude of the endothermic steps $\left(\Delta H_{1}\right.$ and $\left.\Delta H_{2}\right)$ that the overall process is very endothermic and does not happen to any significant degree despite the increase in entropy that would result.

Student Annotation: Like the formation of chemical bonds [ 14 Section 8.9], the formation of intermolecular attractions is exothermic. If that isn't intuitively obvious, think of it this way: It would require energy to separate molecules that are attracted to each other. The reverse process, the combination of molecules that attract each other, would give off an equal amount of energy [ 14 Section 5.3].

For simplicity, we can imagine the solution process taking place in the three distinct steps shown in Figure 13.3. Step 1 is the separation of solute molecules from one another, and step 2 is the separation of solvent molecules from one another. Both of these steps require an input of energy to overcome intermolecular attractions, so they are endothermic. In step 3 the solvent and solute molecules mix. This process is usually exothermic. The enthalpy change for the overall process, $\Delta H_{\text {soln }}$, is given by

## Sample Problem 13.1

Determine for each solute whether the solubility will be greater in water, which is polar, or in benzene $\left(\mathrm{C}_{6} \mathrm{H}_{6}\right)$, which is nonpolar: (a) bromine ( $\mathrm{Br}_{2}$ ), (b) sodium iodide ( NaI ), (c) carbon tetrachloride $\left(\mathrm{CCl}_{4}\right)$, and (d) formaldehyde $\left(\mathrm{CH}_{2} \mathrm{O}\right)$.

Strategy Consider the structure of each solute to determine whether or not it is polar. For molecular solutes, start with a Lewis structure and apply the VSEPR theory [14 Section 9.1]. We expect polar solutes, including ionic compounds, to be more soluble in water. Nonpolar solutes will be more soluble in benzene.

## Setup

(a) Bromine is a homonuclear diatomic molecule and is nonpolar.
(b) Sodium iodide is ionic.
(c) Carbon tetrachloride has the following Lewis structure:

With four electron domains around the central atom, we expect a tetrahedral arrangement. A symmetrical arrangement of identical bonds results in a nonpolar molecule.
(d) Formaldehyde has the following Lewis structure:

Crossed arrows can be used to represent the individual bond dipoles [14 Section 9.2]. This molecule is polar and can form hydrogen bonds with water.

## Solution

(a) Bromine is more soluble in benzene.
(b) Sodium iodide is more soluble in water.
(c) Carbon tetrachloride is more soluble in benzene.
(d) Formaldehyde is more soluble in water.

Practice Problem A Predict whether iodine $\left(\mathrm{I}_{2}\right)$ is more soluble in liquid ammonia $\left(\mathrm{NH}_{3}\right)$ or in carbon disulfide ( $\mathrm{CS}_{2}$ ).
$\boldsymbol{H}$ Practice Problem $\mathbf{B}$ Which of the following should you expect to be more soluble in benzene than in water: $\mathrm{C}_{3} \mathrm{H}_{8}, \mathrm{HCl}, \mathrm{I}_{2}, \mathrm{CS}_{2}$ ?

$$
\Delta H_{\text {soln }}=\Delta H_{1}+\Delta H_{2}+\Delta H_{3}
$$

The overall solution-formation process is exothermic $\left(\Delta H_{\text {soln }}<0\right)$ when the energy given off in step 3 is greater than the sum of energy required for steps 1 and 2 . The overall process is endothermic $\left(\Delta H_{\text {soln }}>0\right)$ when the energy given off in step 3 is less than the total required for steps 1 and 2. (Figure 13.3 depicts a solution formation that is endothermic overall.)

Think About It Remember that molecular formula alone is not sufficient to determine the shape or the polarity of a polyatomic molecule. It must be determined by starting with a correct Lewis structure and applying the VSEPR theory [14 Section 9.2].

Figure 13.3 A molecular view of the solution process portrayed as taking place in three steps: First the solute and solvent molecules are separated (steps 1 and 2 , respectively-both endothermic). Then the solvent and solute molecules mix (step 3-exothermic).

Student Annotation: Solvation refers in a general way to solute particles being surrounded by solvent molecules. When the solvent is water, we use the more specific term hydration [ 14 Section 4.1].

The saying "like dissolves like" is useful in predicting the solubility of a substance in a given solvent. What this expression means is that two substances with intermolecular forces of similar type and magnitude are likely to be soluble in each other. For example, both carbon tetrachloride $\left(\mathrm{CCl}_{4}\right)$ and benzene $\left(\mathrm{C}_{6} \mathrm{H}_{6}\right)$ are nonpolar liquids. The only intermolecular forces present in these substances are dispersion forces [ 14 Section 12.1]. When these two liquids are mixed, they readily dissolve in each other, because the attraction between $\mathrm{CCl}_{4}$ and $\mathrm{C}_{6} \mathrm{H}_{6}$ molecules is comparable in magnitude to the forces between molecules in pure $\mathrm{CCl}_{4}$ and those between molecules in pure $\mathrm{C}_{6} \mathrm{H}_{6}$. Two liquids are said to be miscible if they are completely soluble in each other in all proportions. Alcohols such as methanol, ethanol, and 1,2-ethylene glycol are miscible with water because they can form hydrogen bonds with water molecules:

Methanol

Ethanol

1,2-Ethylene glycol

The guidelines listed in Tables 4.2 and 4.3 enable us to predict the solubility of a particular ionic compound in water. When sodium chloride dissolves in water, the ions are stabilized in solution by hydration, which involves ion-dipole interactions. In general, ionic compounds are much more soluble in polar solvents, such as water, liquid ammonia, and liquid hydrogen fluoride, than in nonpolar solvents. Because the molecules of nonpolar solvents, such as benzene and carbon tetrachloride, do not have a dipole moment, they cannot effectively solvate the $\mathrm{Na}^{+}$and $\mathrm{Cl}^{-}$ions. The predominant intermolecular interaction between ions and nonpolar compounds is an ion-induced dipole interaction, which typically is much weaker than ion-dipole interactions. Consequently, ionic compounds usually have extremely low solubility in nonpolar solvents.

## Bringing Chemistry to Life

## Vitamin Solubility

Vitamins can be categorized as either water soluble or fat soluble. An excess of a fat-soluble vitamin can be stored in the body, whereas excesses of most water-soluble vitamins are eliminated in the urine.

The difference between water-soluble and fat-soluble vitamins is their molecular structures. Water-soluble vitamins, such as vitamin $\mathrm{C}\left(\mathrm{C}_{6} \mathrm{H}_{8} \mathrm{O}_{6}\right)$, have multiple polar groups that can interact with water to form hydrogen bonds:

Vitamin C
In general, fats are nonpolar molecules containing hydrocarbon chains. Fat-soluble vitamins, such as vitamin E, tend to be more hydrocarbon-like. They may have a polar group or two, but the molecule is predominantly nonpolar:

Vitamin E

## Sample Problem 13.2

Predict whether each vitamin will be water soluble or fat soluble.

(b) Vitamin $\mathrm{B}_{2}$ (riboflavin)

Vitamin $\mathrm{B}_{6}$
Strategy Consider the number of polar groups, and determine whether each molecule is predominantly polar or predominantly nonpolar. Predominantly polar molecules tend to be water soluble. Predominantly nonpolar molecules tend to be fat soluble.

Think About It Elimination of vitamin C causes the urine to be more acidic, which can inhibit the growth of some bacteria responsible for urinary tract infections. Taking larger doses than the official recommended daily amount of 60 mg is recommended by many physicians to lower the incidence of such infections. Fat-soluble vitamins cannot be eliminated in this way, and taking too much can lead to vitamin toxicity.

Setup Polar groups include those containing O atoms or N atoms (atoms with lone pairs). Vitamin D contains only one polar group and is therefore predominantly nonpolar. Vitamin $B_{2}$ contains 10 polar groups (six O atoms and four N atoms) making it predominantly polar.

## Solution

(a) Fat soluble
(b) Water soluble

Practice Problem A Predict whether vitamin $\mathrm{B}_{6}$, also known as pyridoxine, is water soluble or fat soluble.
\&Practice Problem B Predict whether vitamin A is water soluble or fat soluble.

Vitamin A

## Checkpoint 13.2 The Solution Process

13.2.1 Which compounds do you expect to be more soluble in benzene than in water? (Select all that apply.)
a) $\mathrm{SO}_{2}$
b) $\mathrm{CO}_{2}$
c) $\mathrm{Na}_{2} \mathrm{SO}_{4}$
d) $\mathrm{C}_{2} \mathrm{H}_{6}$
e) $\mathrm{Br}_{2}$
13.2.2 Which vitamins (see the given structures) do you expect to be water soluble? (Select all that apply.)
a) Pantothenic acid only
b) Nicotinic acid only
c) Pantothenic acid and nicotinic acid
d) Vitamin K only
e) Nicotinic acid and vitamin K

Pantothenic acid

Nicotinic acid

Vitamin K
13.2.3 Which of the following solutions exhibits hydrogen bonding between the solute and solvent? (Select all that apply.)
a) $\mathrm{H}_{2}(g)$ in $\mathrm{H}_{2} \mathrm{O}(l)$
b) $\mathrm{CH}_{3} \mathrm{OH}(l)$ in $\mathrm{H}_{2} \mathrm{O}(l)$
c) $\mathrm{CO}_{2}(g)$ in $\mathrm{H}_{2} \mathrm{O}(l)$
d) $\mathrm{NH}_{3}(g)$ in $\mathrm{H}_{2} \mathrm{O}(l)$
e) $\mathrm{NaCl}(s)$ in $\mathrm{H}_{2} \mathrm{O}(l)$
13.2.4 What best explains why dissolving a gas in water is always exothermic?
a) There are no solute-solute interactions to break up.
b) There are no solvent-solvent interactions to break up.
c) The resulting solute-solvent interactions are especially powerful.
d) The solubility of gases in water is higher at high temperature.
e) Water is a polar solvent.

### 13.3 Concentration Units

We learned in Chapter 4 that chemists often express concentration of solutions in units of molarity. Recall that molarity, $M$, is defined as the number of moles of solute divided by the number of liters of solution [144 Section 4.5].

$$
\text { molarity }=M=\frac{\text { moles of solute }}{\text { liters of solution }}
$$

Mole fraction, $\chi$, which is defined as the number of moles of solute divided by the total number of moles, is also an expression of concentration [ 14 Section 11.5].

$$
\text { mole fraction of component } \mathrm{A}=\chi_{A}=\frac{\text { moles of } \mathrm{A}}{\text { sum of moles of all components }}
$$

In this section, we will learn about molality and percent by mass, two additional ways to express the concentration of a mixture component. How a chemist expresses concentration depends on the type of problem being solved.

## Molality

Molality ( $\boldsymbol{m}$ ) is the number of moles of solute dissolved in $1 \mathrm{~kg}(1000 \mathrm{~g})$ of solvent:

$$
\text { molality }=m=\frac{\text { moles of solute }}{\text { mass of solvent (in } \mathrm{kg})} \quad \text { Equation } 13.1
$$

For example, to prepare a 1 molal $(1 \mathrm{~m})$ aqueous sodium sulfate solution, we must dissolve 1 mole $(142.0 \mathrm{~g})$ of $\mathrm{Na}_{2} \mathrm{SO}_{4}$ in 1 kg of water.

## Percent by Mass

The percent by mass (also called percent by weight) is the ratio of the mass of a solute to the mass of the solution, multiplied by 100 percent. Because the units of mass cancel on the top and bottom of the fraction, any units of mass can be used-provided they are used consistently:

$$
\text { percent by mass }=\frac{\text { mass of solute }}{\text { mass of solute }+ \text { mass of solvent }} \times 100 \% \text { Equation } 13.2
$$

For example, we can express the concentration of the 1 m aqueous sodium sulfate solution as

$$
\text { percent by mass } \begin{aligned}
\mathrm{Na}_{2} \mathrm{SO}_{4} & =\frac{\text { mass of } \mathrm{Na}_{2} \mathrm{SO}_{4}}{\text { mass of } \mathrm{Na}_{2} \mathrm{SO}_{4}+\text { mass of water }} \times 100 \% \\
& =\frac{142.0 \mathrm{~g}}{1142.0 \mathrm{~g}} \times 100 \%=12.4 \%
\end{aligned}
$$

The term percent literally means "parts per hundred." If we were to use Equation 13.2 but multiply by 1000 instead of 100 , we would get "parts per thousand"; multiplying by $1,000,000$ would give "parts per million" or ppm; and so on. Parts per million, parts per billion, parts per trillion, and so forth, usually are used to express very low concentrations, such as those of some pollutants in the atmosphere or a body of water. For example, if a $1-\mathrm{kg}$ sample of water is found to contain $3 \mu \mathrm{~g}$ $\left(3 \times 10^{-6} \mathrm{~g}\right)$ of arsenic, its concentration can be expressed in parts per billion ( ppb ) as follows:

$$
\frac{3 \times 10^{-6} \mathrm{~g}}{1000 \mathrm{~g}} \times 10^{9}=3 \mathrm{ppb}
$$

Sample Problem 13.3 shows how to calculate the concentration in molality and in percent by mass.

Student Annotation: We have already used percent by mass to describe the composition of a pure substance [ 14 Section 3.2]. In this chapter, we will use percent by mass to describe solutions.

Student Annotation: It is a common mistake to confuse molarity and molality. Molarity depends on the volume of the solution. Molality depends on the mass of the solvent.

Think About It Pay careful attention to units in problems such as this. Most require conversions between grams and kilograms and/or liters and milliliters.

## Sample Problem 13.3

A solution is made by dissolving 170.1 g of glucose $\left(\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}\right)$ in enough water to make a liter of solution. The density of the solution is $1.062 \mathrm{~g} / \mathrm{mL}$. Express the concentration of the solution in (a) molality, (b) percent by mass, and (c) parts per million.

Strategy Use the molar mass of glucose to determine the number of moles of glucose in a liter of solution. Use the density (in $\mathrm{g} / \mathrm{L}$ ) to calculate the mass of a liter of solution. Subtract the mass of glucose from the mass of solution to determine the mass of water. Use Equation 13.1 to determine the molality. Knowing the mass of glucose and the total mass of solution in a liter, use Equation 13.2 to calculate the percent concentration by mass.

Setup The molar mass of glucose is $180.2 \mathrm{~g} / \mathrm{mol}$; the density of the solution is $1.062 \mathrm{~g} / \mathrm{mL}$.

## Solution

(a)

$$
\begin{aligned}
& \text { (a) } \frac{170.1 \mathrm{~g}}{180.2 \mathrm{~g} / \mathrm{mol}}=0.9440 \mathrm{~mol} \text { glucose per liter of solution } \\
& 1 \text { liter of solution } \times \frac{1062 \mathrm{~g}}{\mathrm{~L}}=1062 \mathrm{~g} \\
& 1062 \mathrm{~g} \text { solution }-170.1 \mathrm{~g} \text { glucose }=892 \mathrm{~g} \text { water }=0.892 \mathrm{~kg} \text { water } \\
& \frac{0.9440 \mathrm{~mol} \text { glucose }}{0.892 \mathrm{~kg} \text { water }}=1.06 \mathrm{~m} \\
& \text { (b) } \frac{170.1 \mathrm{~g} \text { glucose }}{1062 \mathrm{~g} \text { solution }} \times 100 \%=16.02 \% \text { glucose by mass } \\
& \text { (c) } \frac{170.1 \mathrm{~g} \text { glucose }}{1062 \mathrm{~g} \text { solution }} \times 1,000,000=1.602 \times 10^{5} \mathrm{ppm} \text { glucose }
\end{aligned}
$$

Practice Problem A Determine (a) the molality and (b) the percent by mass of urea for a solution prepared by dissolving 5.46 g urea $\left[\left(\mathrm{NH}_{2}\right)_{2} \mathrm{CO}\right]$ in 215 g of water.

EPractice Problem B Determine the molality of an aqueous solution that is 4.5 percent urea by mass.

Student Annotation: For very dilute aqueous solutions, molarity and molality have the same value. The mass of a liter of water is 1 kg , and in a very dilute solution, the mass of solute is negligible compared to that of the solvent.

## Comparison of Concentration Units

The choice of a concentration unit is based on the purpose of the experiment. For instance, we typically use molarity to express the concentrations of solutions for titrations and gravimetric analyses. Mole fractions are used to express the concentrations of gases-and of solutions when we are working with vapor pressures, which we will discuss in Section 13.5.

The advantage of molarity is that it is generally easier to measure the volume of a solution, using precisely calibrated volumetric flasks, than to weigh the solvent. Molality, on the other hand, has the advantage of being temperature independent. The volume of a solution typically increases slightly with increasing temperature, which would change the molarity. The mass of solvent in a solution, however, does not change with temperature.

Percent by mass is similar to molality in that it is independent of temperature. Furthermore, because it is defined in terms of the ratio of the mass of solute to the mass of solution, we do not need to know the molar mass of the solute to calculate the percent by mass.

Often it is necessary to convert the concentration of a solution from one unit to another. For example, the same solution may be used for different experiments that require different concentration units for calculations. Suppose we want to express the concentration of a 0.396 m aqueous glucose $\left(\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}\right)$ solution (at $25^{\circ} \mathrm{C}$ ) in molarity. We know there is 0.396 mole of glucose in 1000 g of the solvent. We need to determine the volume of this solution to calculate molarity. To determine volume, we must first calculate its mass:

$$
\begin{aligned}
& 0.396 \underline{\mathrm{~mol}_{6} \mathrm{H}_{12} \mathrm{O}_{6}} \times \frac{180.2 \mathrm{~g}}{1 \underline{\mathrm{molC}_{6} \mathrm{H}_{12} \mathrm{O}_{6}}}=71.4 \mathrm{~g} \mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6} \\
& 71.4 \mathrm{~g} \mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}+1000 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}=1071 \mathrm{~g} \text { solution }
\end{aligned}
$$

Once we have determined the mass of the solution, we use the density of the solution, which is typically determined experimentally, to determine its volume. The density of a 0.396 m glucose solution is $1.16 \mathrm{~g} / \mathrm{mL}$ at $25^{\circ} \mathrm{C}$. Therefore, its volume is

$$
\begin{aligned}
\text { volume } & =\frac{\text { mass }}{\text { density }} \\
& =\frac{1071 \mathrm{~g}}{1.16 \mathrm{~g} / \mathrm{mL}} \times \frac{1 \mathrm{~L}}{1000 \mathrm{~mL}} \\
& =0.923 \mathrm{~L}
\end{aligned}
$$

Having determined the volume of the solution, the molarity is given by

$$
\begin{aligned}
\text { molarity } & =\frac{\text { moles of solute }}{\text { liters of solution }} \\
& =\frac{0.396 \mathrm{~mol}}{0.923 \mathrm{~L}} \\
& =0.429 \mathrm{~mol} / \mathrm{L}=0.429 \mathrm{M}
\end{aligned}
$$

Sample Problem 13.4 shows how to convert from one unit of concentration to another.

## Sample Problem 13.4

"Rubbing alcohol" is a mixture of isopropyl alcohol $\left(\mathrm{C}_{3} \mathrm{H}_{7} \mathrm{OH}\right)$ and water that is 70 percent isopropyl alcohol by mass (density $=0.79 \mathrm{~g} / \mathrm{mL}$ at $20^{\circ} \mathrm{C}$ ). Express the concentration of rubbing alcohol in (a) molarity and (b) molality.

## Strategy

(a) Use density to determine the total mass of a liter of solution, and use percent by mass to determine the mass of isopropyl alcohol in a liter of solution. Convert the mass of isopropyl alcohol to moles, and divide moles by liters of solution to get molarity.
(b) Subtract the mass of $\mathrm{C}_{3} \mathrm{H}_{7} \mathrm{OH}$ from the mass of solution to get the mass of water. Divide moles of $\mathrm{C}_{3} \mathrm{H}_{7} \mathrm{OH}$ by the mass of water (in kg ) to get molality.

Setup The mass of a liter of rubbing alcohol is 790 g , and the molar mass of isopropyl alcohol is $60.09 \mathrm{~g} / \mathrm{mol}$.

## Solution

(a)

$$
\begin{gathered}
\frac{790 \mathrm{~g} \text { solution }}{\mathrm{L} \text { solution }} \times \frac{70 \mathrm{~g} \mathrm{C}_{3} \mathrm{H}_{7} \mathrm{OH}}{100 \mathrm{~g} \text { solution }}=\frac{553 \mathrm{~g} \mathrm{C}_{3} \mathrm{H}_{7} \mathrm{OH}}{\mathrm{~L} \text { solution }} \\
\frac{553 \mathrm{~g} \mathrm{C}_{3} \mathrm{H}_{7} \mathrm{OH}}{\text { L solution }} \times \frac{1 \mathrm{~mol}}{60.09 \mathrm{~g} \mathrm{C}_{3} \mathrm{H}_{7} \mathrm{OH}}=\frac{9.20 \mathrm{~mol} \mathrm{C}_{3} \mathrm{H}_{7} \mathrm{OH}}{\mathrm{~L} \text { solution }}=9.2 \mathrm{M}
\end{gathered}
$$

(b) 790 g solution $-553 \mathrm{~g} \mathrm{C}_{3} \mathrm{H}_{7} \mathrm{OH}=237 \mathrm{~g}$ water $=0.237 \mathrm{~kg}$ water

$$
\frac{9.20 \mathrm{~mol} \mathrm{C}_{3} \mathrm{H}_{7} \mathrm{OH}}{0.237 \mathrm{~kg} \text { water }}=39 \mathrm{~m}
$$

Rubbing alcohol is 9.2 M and 39 m in isopropyl alcohol.

Practice Problem A An aqueous solution that is 16 percent sulfuric acid $\left(\mathrm{H}_{2} \mathrm{SO}_{4}\right)$ by mass has a density of $1.109 \mathrm{~g} / \mathrm{mL}$ at $25^{\circ} \mathrm{C}$. Determine (a) the molarity and (b) the molality of the solution at $25^{\circ} \mathrm{C}$.
$\boldsymbol{H}$ Practice Problem B Determine the percent sulfuric acid by mass of a 1.49 m aqueous solution of $\mathrm{H}_{2} \mathrm{SO}_{4}$.

Student Annotation: Problems that require conversions between molarity and molality must provide density or sufficient information to determine density.

Student Annotation: You can choose to start with any volume in a problem like this. Choosing 1 L simplifies the math.

Think About It Note the large difference between molarity and molality in this case. Molarity and molality are the same (or similar) only for very dilute aqueous solutions.

## Checkpoint 13.3 Concentration Units

13.3.1 A solution of a particular concentration is prepared at $20^{\circ} \mathrm{C}$. Which of the following does not change when the solution is heated to $75^{\circ} \mathrm{C}$ ? (Select all that apply.)
a) Molarity
b) Molality
c) Percent by mass
d) Mole fraction
e) All of these change.
13.3.2 What is the molality of a solution prepared by dissolving 6.44 g of naphthalene $\left(\mathrm{C}_{10} \mathrm{H}_{8}\right)$ in 80.1 g benzene?
a) 1.13 m
b) 80.4 m
c) 0.804 m
d) 0.627 m
e) 11.7 m
13.3.3 At $20.0^{\circ} \mathrm{C}$, a 0.258 m aqueous solution of glucose $\left(\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}\right)$ has a density of $1.0173 \mathrm{~g} / \mathrm{mL}$. Calculate the molarity of this solution.
a) 0.258 M
b) 0.300 M
c) 0.456 M
d) 0.251 M
e) 0.448 M
13.3.4 At $25.0^{\circ} \mathrm{C}$, an aqueous solution that is 25.0 percent $\mathrm{H}_{2} \mathrm{SO}_{4}$ by mass has a density of $1.178 \mathrm{~g} / \mathrm{mL}$. Calculate the molarity and the molality of this solution.
a) 3.00 M and 3.40 m
b) 3.40 M and 3.40 m
c) 3.00 M and 3.00 m
d) 3.00 M and 2.98 m
e) 3.44 M and 3.14 m

### 13.4 Factors That Affect Solubility

Recall that solubility is defined as the maximum amount of solute that will dissolve in a given quantity of solvent at a specific temperature. Temperature affects the solubility of most substances. In this section we will consider the effects of temperature on the aqueous solubility of solids and gases, and the effect of pressure on the aqueous solubility of gases.

## Temperature

More sugar dissolves in hot tea than in iced tea because the aqueous solubility of sugar, like that of most solid substances, increases as the temperature increases. Figure 13.4 shows the solubility of some common solids in water as a function of temperature. Note how the solubility of a solid and the change in solubility over a particular temperature range vary considerably. The relationship between temperature and solubility is complex and often nonlinear.

The relationship between temperature and the aqueous solubility of gases is somewhat simpler than that of solids. Most gaseous solutes become less soluble in water as temperature increases. If you get a glass of water from your faucet and leave it on the kitchen counter for a while, you will see bubbles forming in the water as it warms to room temperature. As the temperature of the water increases, dissolved gases become less soluble and come out of solu-tion-resulting in the formation of bubbles.

One of the more important consequences of the reduced solubility of gases in water at elevated temperature is thermal pollution. Hundreds of billions of gallons of water are used every year for industrial cooling, mostly in electric power and nuclear power production. This process heats the water, which is then returned to the rivers and lakes from which it was taken. The increased water temperature has a twofold impact on aquatic life. The rate of metabolism of cold-blooded species such as fish increases with increasing temperature, thereby increasing their need for oxygen. At the same time, the increased water temperature causes a decrease in the solubility of oxygen-making less oxygen available. The result can be disastrous for fish populations.

## Pressure

Although pressure does not influence the solubility of a liquid or a solid significantly, it does greatly affect the solubility of a gas. The quantitative relationship between gas solubility and pres-

Figure 13.4 Temperature dependence of the solubility of glucose and several ionic compounds in water.
sure is given by Henry's ${ }^{1}$ law, which states that the solubility of a gas in a liquid is proportional to the pressure of the gas over the solution,

$$
c \propto P
$$

and is expressed as

$$
c=k P
$$

Equation 13.3
where $c$ is the molar concentration ( $\mathrm{mol} / \mathrm{L}$ ) of the dissolved gas, $P$ is the pressure (in atm) of the gas over the solution, and $k$ is a proportionality constant called the Henry's law constant. Henry's law constants are specific to the gas-solvent combination and vary with temperature. The units of $k$ are $\mathrm{mol} / \mathrm{L} \cdot \mathrm{atm}$. If there is a mixture of gases over the solution, then $P$ in Equation 13.3 is the partial pressure of the gas in question.

Henry's law can be understood qualitatively in terms of the kinetic molecular theory [ 14 Section 11.6]. The amount of gas that will dissolve in a solvent depends on how frequently the gas molecules collide with the liquid surface and become trapped by the condensed phase. Suppose we have a gas in dynamic equilibrium [ $1 \mathbb{4}$ Section 12.2] with a solution, as shown in Figure $13.5(\mathrm{a})$. At any point in time, the number of gas molecules entering the solution is equal to the number of dissolved gas molecules leaving the solution and entering the vapor phase. If the partial pressure of the gas is increased [Figure 13.5(b)], more molecules strike the liquid surface, causing more of them to dissolve. As the concentration of dissolved gas increases, the number of gas molecules leaving the solution also increases. These processes continue until the concentration of dissolved gas in the solution reaches the point again where the number of molecules leaving the solution per second equals the number entering the solution per second.

One interesting application of Henry's law is the production of carbonated beverages. Manufacturers put the "fizz" in soft drinks using pressurized carbon dioxide. The pressure of $\mathrm{CO}_{2}$ applied (typically on the order of 5 atm ) is many thousands of times greater than the partial pressure of $\mathrm{CO}_{2}$ in the air. Thus, when a can or bottle of soda is opened, the $\mathrm{CO}_{2}$ dissolved under highpressure conditions comes out of solution-resulting in the bubbles that make carbonated drinks appealing.

Sample Problem 13.5 illustrates the use of Henry's law.

[^36]Student Annotation: Henry's law means that if we double the pressure of a gas over a solution (at constant temperature), we double the concentration of gas dissolved in the solution; triple the pressure, triple the concentration; and so on.

Figure 13.5 A molecular view of Henry's law. When the partial pressure of the gas over the solution increases from (a) to (b), the concentration of the dissolved gas also increases according to Equation 13.3.

Think About It With a pressure approximately 15,000 times smaller in part (b) than in part (a), we expect the concentration of $\mathrm{CO}_{2}$ to be approximately 15,000 times smaller-and it is.

## Sample Problem 13.5

Calculate the concentration of carbon dioxide in a soft drink that was bottled under a partial pressure of $5.0 \mathrm{~atm} \mathrm{CO}_{2}$ at $25^{\circ} \mathrm{C}$ (a) before the bottle is opened and (b) after the soda has gone "flat" at $25^{\circ} \mathrm{C}$. The Henry's law constant for $\mathrm{CO}_{2}$ in water at this temperature is $3.1 \times 10^{-2} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{atm}$. Assume that the partial pressure of $\mathrm{CO}_{2}$ in air is 0.0003 atm and that the Henry's law constant for the soft drink is the same as that for water.

Strategy Use Equation 13.3 and the given Henry's law constant to solve for the molar concentration $(\mathrm{mol} / \mathrm{L})$ of $\mathrm{CO}_{2}$ at $25^{\circ} \mathrm{C}$ and the two $\mathrm{CO}_{2}$ pressures given.

Setup At $25^{\circ} \mathrm{C}$, the Henry's law constant for $\mathrm{CO}_{2}$ in water is $3.1 \times 10^{-2} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{atm}$.
Solution (a) $c=\left(3.1 \times 10^{-2} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{atm}\right)(5.0 \mathrm{~atm})=1.6 \times 10^{-1} \mathrm{~mol} / \mathrm{L}$
(b) $c=\left(3.1 \times 10^{-2} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{atm}\right)(0.0003 \mathrm{~atm})=9 \times 10^{-6} \mathrm{~mol} / \mathrm{L}$

Practice Problem A Calculate the concentration of $\mathrm{CO}_{2}$ in water at $25^{\circ} \mathrm{C}$ when the pressure of $\mathrm{CO}_{2}$ over the solution is 4.0 atm .

EPractice Problem B Calculate the pressure of $\mathrm{O}_{2}$ necessary to generate an aqueous solution that is $3.4 \times 10^{-2} \mathrm{M}$ in $\mathrm{O}_{2}$ at $25^{\circ} \mathrm{C}$. The Henry's law constant for $\mathrm{O}_{2}$ in water at $25^{\circ} \mathrm{C}$ is $1.3 \times 10^{-3} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{atm}$.

## Checkpoint 13.4 Factors That Affect Solubility

13.4.1 The solubility of $\mathrm{N}_{2}$ in water at $25^{\circ} \mathrm{C}$ and an $\mathrm{N}_{2}$ pressure of 1 atm is $6.8 \times 10^{-4} \mathrm{~mol} / \mathrm{L}$. Calculate the concentration of dissolved $\mathrm{N}_{2}$ in water under atmospheric conditions where the partial pressure of $\mathrm{N}_{2}$ is 0.78 atm .
a) $6.8 \times 10^{-4} \mathrm{M}$
b) $8.7 \times 10^{-4} \mathrm{M}$
c) $5.3 \times 10^{-4} \mathrm{M}$
d) $1.5 \times 10^{-4} \mathrm{M}$
e) $3.1 \times 10^{-3} \mathrm{M}$
13.4.2 Calculate the molar concentration of $\mathrm{O}_{2}$ in water at $25^{\circ} \mathrm{C}$ under atmospheric conditions where the partial pressure of $\mathrm{O}_{2}$ is 0.22 atm . The Henry's law constant for $\mathrm{O}_{2}$ is $1.3 \times 10^{-3} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{atm}$.
a) $2.9 \times 10^{-4} \mathrm{M}$
b) $5.9 \times 10^{-3} \mathrm{M}$
c) $1.7 \times 10^{-3} \mathrm{M}$
d) $1.0 \times 10^{-3} \mathrm{M}$
e) $1.3 \times 10^{-3} \mathrm{M}$

### 13.5 Colligative Properties

Colligative properties are properties that depend on the number of solute particles in solution but do not depend on the nature of the solute particles. That is, colligative properties depend on the concentration of solute particles regardless of whether those particles are atoms, molecules, or ions. The colligative properties are vapor-pressure lowering, boiling-point elevation, freezingpoint depression, and osmotic pressure. We begin by considering the colligative properties of relatively dilute solutions ( $\leq 0.2 \mathrm{M}$ ) of nonelectrolytes.

## Vapor-Pressure Lowering

We have seen that a liquid exerts a characteristic vapor pressure [ 144 Section 12.2]. When a nonvolatile solute (one that does not exert a vapor pressure) is dissolved in a liquid, the vapor pressure exerted by the liquid decreases. The difference between the vapor pressure of a pure solvent and that of the corresponding solution depends on the concentration of the solute in the solution. This relationship is expressed by Raoult's ${ }^{2}$ law, which states that the partial pressure of a solvent over a solution, $P_{1}$, is given by the vapor pressure of the pure solvent, $P_{1}^{\circ}$, times the mole fraction of the solvent in the solution, $\chi_{1}$ :

$$
P_{1}=\chi_{1} P_{1}^{\circ}
$$

Equation 13.4
In a solution containing only one solute, $\chi_{1}=1-\chi_{2}$, where $\chi_{2}$ is the mole fraction of the solute. Equation 13.4 can therefore be rewritten as

$$
P_{1}=\left(1-\chi_{2}\right) P_{1}^{\circ}
$$

or

$$
P_{1}=P_{1}^{\circ}-\chi_{2} P_{1}^{\circ}
$$

so that

$$
P_{1}^{\circ}-P_{1}=\Delta P=\chi_{2} P_{1}^{\circ}
$$

$$
\text { Equation } 13.5
$$

Thus, the decrease in vapor pressure, $\Delta P$, is directly proportional to the solute concentration expressed as a mole fraction.

To understand the phenomenon of vapor-pressure lowering, we must understand the degree of order associated with the states of matter involved. As we saw in Section 13.2, molecules in the liquid state are fairly highly ordered; that is, they have low entropy. Molecules in the gas phase have significantly less order-they have high entropy. Because there is a natural tendency toward increased entropy, molecules have a certain tendency to leave the region of lower entropy and enter the region of higher entropy. This corresponds to molecules leaving the liquid and entering the gas phase. As we have seen, when a solute is added to a liquid, the liquid's order is disrupted. Thus, the solution has greater entropy than the pure liquid. Because there is a smaller difference in entropy between the solution and the gas phase than there was between the pure liquid and the gas phase, there is a decreased tendency for molecules to leave the solution and enter the gas phase-resulting in a lower vapor pressure exerted by the solvent. This qualitative explanation of vapor-pressure lowering is illustrated in Figure 13.6. The smaller difference in entropy between the solution and gas

Student Annotation: Table 11.5 gives the vapor pressure of water at various temperatures.

Figure 13.6 The smaller difference in entropy between the solution and gas phases, relative to that between the pure liquid and gas phases, results in a decreased tendency for solvent molecules to enter the gas phase. This results in a lowering of vapor pressure. The solvent in a solution always exerts a lower vapor pressure than the pure solvent.

[^37]Think About It This problem can also be solved using Equation 13.5 to calculate the vapor-pressure lowering, $\Delta P$.
phases, relative to that between the pure liquid and gas phases, results in a decreased tendency for solvent molecules to enter the gas phase. This results in a lowering of vapor pressure. The solvent in a solution will always exert a lower vapor pressure than the pure solvent.

Sample Problem 13.6 shows how to use Raoult's law.

## Sample Problem 13.6

Calculate the vapor pressure of water over a solution made by dissolving 225 g of glucose in 575 g of water at $35^{\circ} \mathrm{C}$. (At $35^{\circ} \mathrm{C}, P_{\mathrm{H}_{2} \mathrm{O}}^{\circ}=42.2 \mathrm{mmHg}$.)

Strategy Convert the masses of glucose and water to moles, determine the mole fraction of water, and use Equation 13.4 to find the vapor pressure over the solution.

Setup The molar masses of glucose and water are 180.2 and $18.02 \mathrm{~g} / \mathrm{mol}$, respectively.

## Solution

$$
\begin{gathered}
\frac{225 \mathrm{~g} \text { glucose }}{180.2 \mathrm{~g} / \mathrm{mol}}=(1.25 \mathrm{~mol} \text { glucose }) \frac{575 \mathrm{~g} \text { water }}{18.02 \mathrm{~g} / \mathrm{mol}}=31.9 \mathrm{~mol} \text { water } \\
\chi_{\text {water }}=\frac{31.9 \mathrm{~mol} \text { water }}{1.25 \mathrm{~mol} \text { glucose }+31.9 \mathrm{~mol} \text { water }}=0.962 \\
P_{\mathrm{H}_{2} \mathrm{O}}=\chi_{\text {water }} \times P_{\mathrm{H}_{2} \mathrm{O}}^{\circ}=0.962 \times 42.2 \mathrm{mmHg}=40.6 \mathrm{mmHg}
\end{gathered}
$$

The vapor pressure of water over the solution is 40.6 mmHg .

Practice Problem A Calculate the vapor pressure of a solution made by dissolving 115 g of urea $\left[\left(\mathrm{NH}_{2}\right)_{2} \mathrm{CO}\right.$; molar mass $\left.=60.06 \mathrm{~g} / \mathrm{mol}\right]$ in 485 g of water at $25^{\circ} \mathrm{C}$. $\left(\right.$ At $25^{\circ} \mathrm{C}, P_{\mathrm{H}_{2} \mathrm{O}}^{\circ}=23.8 \mathrm{mmHg}$. $)$
©Practice Problem B Calculate the mass of urea that should be dissolved in 225 g of water at $35^{\circ} \mathrm{C}$ to produce a solution with a vapor pressure of 37.1 mmHg . (At $35^{\circ} \mathrm{C}, P_{\mathrm{H}_{2} \mathrm{O}}^{\circ}=42.2 \mathrm{mmHg}$.)

If both components of a solution are volatile (i.e., have measurable vapor pressure), the vapor pressure of the solution is the sum of the individual partial pressures exerted by the solution components. Raoult's law holds equally well in this case:

$$
\begin{aligned}
& P_{\mathrm{A}}=\chi_{\mathrm{A}} P_{\mathrm{A}}^{\circ} \\
& P_{\mathrm{B}}=\chi_{\mathrm{B}} P_{\mathrm{B}}^{\circ}
\end{aligned}
$$

where $P_{\mathrm{A}}$ and $P_{\mathrm{B}}$ are the partial pressures over the solution for components A and $\mathrm{B}, P_{\mathrm{A}}^{\circ}$ and $P_{\mathrm{B}}^{\circ}$ are the vapor pressures of the pure substances A and B , and $\chi_{\mathrm{A}}$ and $\chi_{\mathrm{B}}$ are their mole fractions. The total pressure is given by Dalton's law of partial pressures [144 Section 11.5]:

$$
P_{\mathrm{T}}=P_{\mathrm{A}}+P_{\mathrm{B}}
$$

or

$$
P_{\mathrm{T}}=\chi_{\mathrm{A}} P_{\mathrm{A}}^{\circ}+\chi_{\mathrm{B}} P_{\mathrm{B}}^{\circ}
$$

For example, benzene and toluene are volatile components that have similar structures and therefore similar intermolecular forces:

Benzene

Toluene

In a solution of benzene and toluene, the vapor pressure of each component obeys Raoult's law. Figure 13.7 shows the dependence of the total vapor pressure $\left(P_{\mathrm{T}}\right)$ in a benzene-toluene solution on the composition of the solution. Because there are only two components in the solution, we need only express the composition of the solution in terms of the mole fraction of one component.

For any value of $\chi_{\text {benzene }}$, the mole fraction of toluene, $\chi_{\text {toluene }}$, is given by the equation $\left(1-\chi_{\text {benzene }}\right)$. The benzene-toluene solution is an example of an ideal solution, which is simply a solution that obeys Raoult's law.

Note that for a mixture in which the mole fractions of benzene and toluene are both 0.5 , although the liquid mixture is equimolar, the vapor above the solution is not. Because pure benzene has a higher vapor pressure ( 75 mmHg at $20^{\circ} \mathrm{C}$ ) than pure toluene ( 22 mmHg at $20^{\circ} \mathrm{C}$ ), the vapor phase over the mixture will contain a higher concentration of the more volatile benzene molecules than it will the less volatile toluene molecules.

## Boiling-Point Elevation

Recall that the boiling point of a substance is the temperature at which its vapor pressure equals the external atmospheric pressure [ WA Section 12.6]. Because the presence of a nonvolatile solute lowers the vapor pressure of a solution, it also affects the boiling point of the solution-relative to that of the pure liquid. Figure 13.8 shows the phase diagram of water and the changes that occur when a nonvolatile solute is added to it. At any temperature the vapor pressure over a solution is lower than that over the pure liquid, so the liquid-vapor curve for the solution lies below that for the pure solvent. Consequently, the dashed solution curve intersects the horizontal line that marks $P=1 \mathrm{~atm}$ at a higher temperature than the normal boiling point of the pure solvent. That is, a higher temperature is needed to make the solvent's vapor pressure equal to atmospheric pressure.

Figure 13.7 The dependence of partial pressures of benzene and toluene on their mole fractions in a benzenetoluene solution $\left(\chi_{\text {toluene }}=1-\chi_{\text {benzene }}\right)$ at $80^{\circ} \mathrm{C}$. This solution is said to be ideal because the vapor pressures obey Raoult's law.

Figure 13.8 Phase diagram illustrating the boiling-point elevation and freezing-point depression of aqueous solutions. The dashed curves pertain to the solution, and the solid curves to the pure solvent. As this diagram shows, the boiling point of the solution is higher than that of water, and the freezing point of the solution is lower than that of water.

Student Annotation: Rearranging this equation, we get the boiling point of the solution by adding $\Delta T_{\mathrm{b}}$ to the boiling point of the pure solvent: $T_{\mathrm{b}}=T_{\mathrm{b}}^{\circ}+\Delta T_{\mathrm{b}}$.

Student Annotation: The practice of adding salt to water in which food is cooked is for the purpose of increasing the boiling point, thereby cooking the food at a higher temperature.

Student Annotation: We get the freezing point of the solution by subtracting $\Delta T_{f}$ from the freezing point of the pure solvent: $T_{f}=T_{f}^{\circ}-\Delta T_{f}$.

The boiling-point elevation $\left(\Delta T_{\mathrm{b}}\right)$ is defined as the difference between the boiling point of the solution $\left(T_{\mathrm{b}}\right)$ and the boiling point of the pure solvent $\left(T_{\mathrm{b}}^{\circ}\right)$ :

$$
\Delta T_{\mathrm{b}}=T_{\mathrm{b}}-T_{\mathrm{b}}^{\circ}
$$

Because $T_{\mathrm{b}}>T_{\mathrm{b}}^{\circ}, \Delta T_{\mathrm{b}}$ is a positive quantity.
The value of $\Delta T_{\mathrm{b}}$ is proportional to the concentration, expressed in molality, of the solute in the solution.

$$
\Delta T_{\mathrm{b}} \propto m
$$

or
Equation 13.6

$$
\Delta T_{\mathrm{b}}=K_{\mathrm{b}} m
$$

where $m$ is the molality of the solution and $K_{\mathrm{b}}$ is the molal boiling-point elevation constant. The units of $K_{\mathrm{b}}$ are ${ }^{\circ} \mathrm{C} / m$. Table 13.2 lists values of $K_{\mathrm{b}}$ for several common solvents. Using the boilingpoint elevation constant for water and Equation 13.6, you can show that the boiling point of a 1.00 m aqueous solution of a nonvolatile, nonelectrolyte would be $100.5^{\circ} \mathrm{C}$ :

$$
\begin{gathered}
\Delta T_{\mathrm{b}}=K_{\mathrm{b}} m=\left(0.52^{\circ} \mathrm{C} / m\right)(1.00 m)=0.52^{\circ} \mathrm{C} \\
T_{\mathrm{b}}=T_{\mathrm{b}}^{\circ}+\Delta T_{\mathrm{b}}=100.0^{\circ} \mathrm{C}+0.52^{\circ} \mathrm{C}=100.5^{\circ} \mathrm{C}
\end{gathered}
$$

## Freezing-Point Depression

If you have ever lived in a cold climate, you may have seen roads and sidewalks that were "salted" in the winter. The application of a salt such as NaCl or $\mathrm{CaCl}_{2}$ thaws ice (or prevents its formation) by lowering the freezing point of water.

The phase diagram in Figure 13.8 shows that in addition to shifting the liquid-vapor phase boundary down, the addition of a nonvolatile solute also shifts the solid-liquid phase boundary to the left. Consequently, this dashed line intersects the solid horizontal line at 1 atm at a temperature lower than the freezing point of pure water. The freezing-point depression $\left(\Delta T_{\mathrm{f}}\right)$ is defined as the difference between the freezing point of the pure solvent and the freezing point of the solution:

$$
\Delta T_{\mathrm{f}}=T_{\mathrm{f}}^{\circ}-T_{\mathrm{f}}
$$

Because $T_{\mathrm{f}}^{\circ}>T_{\mathrm{f}}, \Delta T_{\mathrm{f}}$ is a positive quantity. Again, the change in temperature is proportional to the molal concentration of the solution:

$$
\Delta T_{\mathrm{f}} \propto m
$$

or
Equation 13.7

$$
\Delta T_{\mathrm{f}}=K_{\mathrm{f}} m
$$

where $m$ is the concentration of solute expressed in molality and $K_{\mathrm{f}}$ is the molal freezing-point depression constant (see Table 13.2). Like $K_{\mathrm{b}}, K_{\mathrm{f}}$ has units of ${ }^{\circ} \mathrm{C} / m$.

Like boiling-point elevation, freezing-point depression can be explained in terms of differences in entropy. Freezing involves a transition from the more disordered liquid state to the more ordered solid state. For this to happen, energy must be removed from the system. Because a

## TABLE 13.2

Molal Boiling-Point Elevation and Freezing-Point Depression Constants of Several Common Solvents

| Solvent | Normal Boiling <br> Point $\left({ }^{( } \mathbf{C}\right)$ | $\boldsymbol{K}_{\mathbf{b}}$ <br> $\left({ }^{\circ} \mathbf{C} / \boldsymbol{m}\right)$ | Normal Freezing <br> Point $\left({ }^{\circ} \mathbf{C}\right)$ | $\boldsymbol{K}_{\mathbf{f}}$ <br> $\left({ }^{\circ} \mathbf{C} / \boldsymbol{m}\right)$ |
| :--- | :---: | :---: | :---: | :---: |
| Water | 100.0 | 0.52 | 0.0 | 1.86 |
| Benzene | 80.1 | 2.53 | 5.5 | 5.12 |
| Ethanol | 78.4 | 1.22 | -117.3 | 1.99 |
| Acetic acid | 117.9 | 2.93 | 16.6 | 3.90 |
| Cyclohexane | 80.7 | 2.79 | 6.6 | 20.0 |

solution has greater disorder than the solvent, there is a bigger difference in entropy between the solution and the solid than there is between the pure solvent and the solid (Figure 13.9). The larger difference in entropy means that more energy must be removed for the liquid-solid transition to happen. Thus, the solution freezes at a lower temperature than does the pure solvent. Boiling-point elevation occurs only when the solute is nonvolatile. Freezing-point depression occurs regardless of the solute's volatility.

Sample Problem 13.7 demonstrates a practical application of freezing-point depression and boiling-point elevation.

## Sample Problem 13.7

Ethylene glycol $\left[\mathrm{CH}_{2}(\mathrm{OH}) \mathrm{CH}_{2}(\mathrm{OH})\right]$ is a common automobile antifreeze. It is water soluble and fairly nonvolatile (b.p. $197^{\circ} \mathrm{C}$ ). Calculate (a) the freezing point and (b) the boiling point of a solution containing 685 g of ethylene glycol in 2075 g of water.

Strategy Convert grams of ethylene glycol to moles, and divide by the mass of water in kilograms to get molal concentration. Use molal concentration in Equations 13.7 and 13.6 to determine $\Delta T_{\mathrm{f}}$ and $\Delta T_{\mathrm{b}}$, respectively.

Setup The molar mass of ethylene glycol $\left(\mathrm{C}_{2} \mathrm{H}_{6} \mathrm{O}_{2}\right)$ is $62.07 \mathrm{~g} / \mathrm{mol}$. $K_{\mathrm{b}}$ and $K_{\mathrm{f}}$ for water are $0.52^{\circ} \mathrm{C} / \mathrm{m}$ and $1.86^{\circ} \mathrm{C} / \mathrm{m}$, respectively.

Solution

$$
\frac{685 \mathrm{~g} \mathrm{C}_{2} \mathrm{H}_{6} \mathrm{O}_{2}}{62.07 \mathrm{~g} / \mathrm{mol}}=11.04 \mathrm{~mol} \mathrm{C}_{2} \mathrm{H}_{6} \mathrm{O}_{2} \quad \text { and } \quad \frac{11.04 \mathrm{~mol} \mathrm{C}_{2} \mathrm{H}_{6} \mathrm{O}_{2}}{2.075 \mathrm{~kg} \mathrm{H}_{2} \mathrm{O}}=5.32 \mathrm{~m} \mathrm{C}_{2} \mathrm{H}_{6} \mathrm{O}_{2}
$$

(a) $\Delta T_{\mathrm{f}}=K_{\mathrm{f}} m=\left(1.86^{\circ} \mathrm{C} / m\right)(5.32 \mathrm{~m})=9.89^{\circ} \mathrm{C}$

The freezing point of the solution is $(0-9.89)^{\circ} \mathrm{C}=-9.89^{\circ} \mathrm{C}$.
(b) $\Delta T_{\mathrm{b}}=K_{\mathrm{b}} m=\left(0.52^{\circ} \mathrm{C} / m\right)(5.32 \mathrm{~m})=2.8^{\circ} \mathrm{C}$

The boiling point of the solution is $(100.0+2.8)^{\circ} \mathrm{C}=102.8^{\circ} \mathrm{C}$.

Practice Problem A Calculate the freezing point and boiling point of a solution containing 268 g of ethylene glycol and 1015 g of water.

EPractice Problem B What mass of ethylene glycol must be added to 1525 g of water to raise the boiling point to $103.9^{\circ} \mathrm{C}$ ?

## Osmotic Pressure

Many chemical and biological processes depend on osmosis, the selective passage of solvent molecules through a porous membrane from a more dilute solution to a more concentrated one. Figure 13.10 illustrates osmosis. The left compartment of the apparatus contains pure solvent; the right compartment contains a solution made with the same solvent. The two compartments are separated by a semipermeable membrane, which allows the passage of solvent molecules but blocks the passage of solute molecules. At the beginning, the liquid levels in the two tubes are equal [Figure 13.10(a)]. As time passes, the level in the right tube rises. It continues to rise until equilibrium

Figure 13.9 The solution has greater entropy than the pure solvent. The bigger difference in entropy between the solution and the solid means that more energy must be removed from the solution for it to freeze. Thus, the solution freezes at a lower temperature than the pure solvent.

Student Annotation: When a solution freezes, the solid that separates out is actually pure solvent. The solute remains in the liquid solution.

Think About It Because it both lowers the freezing point and raises the boiling point, antifreeze is useful at both temperature extremes.

Figure 13.10 Osmotic pressure. (a) The levels of the pure solvent (left) and of the solution (right) are equal at the start. (b) During osmosis, the level on the solution side rises as a result of the net flow of solvent from left to right.

is reached, after which no further net change in levels is observed. The osmotic pressure ( $\boldsymbol{\pi}$ ) of a solution is the pressure required to stop osmosis. As shown in Figure 13.10(b), this pressure can be measured directly from the difference in the final liquid levels.

The osmotic pressure of a solution is directly proportional to the concentration, expressed in molarity, of the solute in solution:

$$
\pi \propto M
$$

and is given by
Equation $13.8 \quad \pi=M R T$
where $M$ is the molarity of the solution, $R$ is the gas constant $(0.08206 \mathrm{~L} \cdot \operatorname{atm} / \mathrm{K} \cdot \mathrm{mol})$, and $T$ is the absolute temperature. The osmotic pressure $(\pi)$ is typically expressed in atmospheres.

Like boiling-point elevation and freezing-point depression, osmotic pressure is directly proportional to the concentration of the solution. This is what we would expect, though, because all colligative properties depend only on the number of solute particles in solution, not on the identity of the solute particles. Two solutions of equal concentration have the same osmotic pressure and are said to be isotonic to each other.

## Electrolyte Solutions

So far we have discussed the colligative properties of nonelectrolyte solutions. Because electrolytes undergo dissociation when dissolved in water [ 1 W 4 Section 4.1], we must consider them separately. Recall, for example, that when NaCl dissolves in water, it dissociates into $\mathrm{Na}^{+}(a q)$ and $\mathrm{Cl}^{-}(a q)$. For every mole of NaCl dissolved, we get two moles of ions in solution. Similarly, when a formula unit of $\mathrm{CaCl}_{2}$ dissolves, we get three ions: one $\mathrm{Ca}^{2+}$ ion and two $\mathrm{Cl}^{-}$ions. Thus, for every mole of $\mathrm{CaCl}_{2}$ dissolved, we get three moles of ions in solution. Colligative properties depend only on the number of dissolved particles-not on the type of particles. This means that a 0.1 m solution of NaCl will exhibit a freezing point depression twice that of a 0.1 m solution of a nonelectrolyte, such as sucrose. Similarly, we expect a 0.1 m solution of $\mathrm{CaCl}_{2}$ to depress the freezing point of water three times as much as a 0.1 m sucrose solution. To account for this effect, we introduce and define a quantity called the van't Hoff ${ }^{3}$ factor (i), which is given by

$$
i=\frac{\text { actual number of particles in solution after dissociation }}{\text { number of formula units initially dissolved in solution }}
$$

[^38]Thus, $i$ is 1 for all nonelectrolytes. For strong electrolytes such as NaCl and $\mathrm{KNO}_{3}, i$ should be 2 , and for strong electrolytes such as $\mathrm{Na}_{2} \mathrm{SO}_{4}$ and $\mathrm{CaCl}_{2}, i$ should be 3 . Consequently, the equations for colligative properties must be modified as follows:

| $\Delta T_{\mathrm{f}}=i K_{\mathrm{f}} m$ | Equation 13.9 |
| :--- | :--- |
| $\Delta T_{\mathrm{b}}=i K_{\mathrm{b}} m$ | Equation 13.10 |
| $\pi=i M R T$ | Equation 13.11 |

In reality, the colligative properties of electrolyte solutions are usually smaller than predicted by Equations 13.9 through 13.11, especially at higher concentrations, because of the formation of ion pairs. An ion pair is made up of one or more cations and one or more anions held together by electrostatic forces (Figure 13.11). The presence of an ion pair reduces the number of particles in solution, thus reducing the observed colligative properties. Tables 13.3 and 13.4 list experimentally measured values of $i$ and those calculated using the van't Hoff factor.

Sample Problem 13.8 demonstrates the experimental determination of a van't Hoff factor.

Figure 13.11 (a) Free ions and (b) ion pairs in solution. Ion pairing reduces the number of dissolved particles in a solution, causing a decrease in the observed colligative properties. Furthermore, an ion pair bears no net charge and therefore cannot conduct electricity in solution.

| TABLE 13.3 | Calculated and Measured van't Hoff Factors of <br> Solutions at $25^{\circ} \mathrm{C}$ |  |
| :--- | :---: | :---: |
| Electrolyte | $\boldsymbol{i}$ (Calculated) | $\boldsymbol{i}$ (Measured) |
| Sucrose* | 1 | 1.0 |
| HCl | 2 | 1.9 |
| NaCl | 2 | 1.9 |
| $\mathrm{MgSO}_{4}$ | 2 | 1.3 |
| $\mathrm{MgCl}_{2}$ | 3 | 2.7 |
| $\mathrm{FeCl}_{3}$ | 4 | 3.4 |

*Sucrose is a nonelectrolyte. It is listed here for comparison only.

| TABLE 13.4 | $\begin{array}{l}\text { Experimentally Measured van't Hoff Factors of Sucrose and } \mathrm{NaCl} \\ \text { Solutions at } 25^{\circ} \mathrm{C}\end{array}$ |  |  |  |
| :--- | :--- | :---: | :---: | :---: |
|  |  | Concentration |  |  |$]$

Student Annotation: The amount of vaporpressure lowering would also be affected by dissociation of an electrolyte. In calculating the mole fraction of solute and solvent, the number of moles of solute would have to be multiplied by the appropriate van't Hoff factor.

Think About It The calculated van't Hoff factor for KI is 2. The experimentally determined van't Hoff factor must be less than or equal to the calculated value.

Figure 13.12 A cell in (a) a hypotonic solution, (b) an isotonic solution, and (c) a hypertonic solution. The cell swells and may eventually burst in (a); it shrinks in (c).

## Sample Problem 13.8

The osmotic pressure of a 0.0100 M potassium iodide (KI) solution at $25^{\circ} \mathrm{C}$ is 0.465 atm . Determine the experimental van't Hoff factor for KI at this concentration.

Strategy Use osmotic pressure to calculate the molar concentration of KI, and divide by the nominal concentration of 0.0100 M .

Setup $R=0.08206 \mathrm{~L} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{mol}$, and $T=298 \mathrm{~K}$.
Solution Solving Equation 13.8 for $M$,

$$
\begin{gathered}
M=\frac{\pi}{R T}=\frac{0.465 \mathrm{~atm}}{(0.08206 \mathrm{~L} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{~mol})(298 \mathrm{~K})}=0.0190 \mathrm{M} \\
i=\frac{0.0190 \mathrm{M}}{0.0100 \mathrm{M}}=1.90
\end{gathered}
$$

The experimental van't Hoff factor for KI at this concentration is 1.90 .

Practice Problem A The freezing-point depression of a 0.100 m MgSO 4 solution is $0.225^{\circ} \mathrm{C}$. Determine the experimental van't Hoff factor of $\mathrm{MgSO}_{4}$ at this concentration.

GPractice Problem B Using the experimental van't Hoff factor from Table 13.4, determine the freezing point of a 0.100 m aqueous solution of NaCl . (Assume that the van't Hoff factors do not change with temperature.)

## Bringing Chemistry to Life

## Intravenous Fluids

Human blood consists of red blood cells (erythrocytes), white blood cells (leukocytes), and platelets (thrombocytes) suspended in plasma, an aqueous solution containing a variety of solutes including salts and proteins. Each red blood cell is surrounded by a protective semipermeable membrane. Inside this membrane, the concentration of dissolved substances is about 0.3 M . Likewise, the concentration of dissolved substances in plasma is also about 0.3 M . Having the same concentration (and therefore the same osmotic pressure of $\sim 7.6 \mathrm{~atm}$ at $37^{\circ} \mathrm{C}$ ) inside and outside the red blood cell prevents a net movement of water into or out of the cell through the protective semipermeable membrane [Figure 13.12(a)]. To maintain this balance of osmotic pressure, fluids that are given

intravenously must be isotonic to plasma. Five percent dextrose (sugar) and normal saline, which is $0.9 \%$ sodium chloride, are two of the most commonly used isotonic intravenous fluids.

A solution that has a lower concentration of dissolved substances than plasma is said to be hypotonic to plasma. If a significant volume of pure water were administered intravenously, it would dilute the plasma, lowering its concentration and making it hypotonic to the solution inside the red blood cells. If this were to happen, water would enter the red blood cells via osmosis [Figure 13.12(b)]. The cells would swell and could potentially burst, a process called hemolysis. On the other hand, if red blood cells were placed in a solution with a higher concentration of dissolved substances than plasma, a solution said to be hypertonic to plasma, water would leave the cells via osmosis [Figure 13.12(c)]. The cells would shrink, a process called crenation, which is also potentially dangerous. The osmotic pressure of human plasma must be maintained within a very narrow range to prevent damage to red blood cells. Hypotonic and hypertonic solutions can be administered intravenously to treat specific medical conditions, but the patient must be carefully monitored throughout the treatment.

Interestingly, humans have for centuries exploited the sensitivity of cells to osmotic pressure. The process of "curing" meat with salt or with sugar causes crenation of the bacteria cells that would otherwise cause spoilage.

## Sample Problem 13.9

Ringer's lactate, a solution containing several different salts, is often administered intravenously for the initial treatment of trauma patients. One liter of Ringer's lactate contains 0.102 mole of sodium chloride, $4 \times 10^{-3}$ mole of potassium chloride, $1.5 \times 10^{-3}$ mole of calcium chloride, and $2.8 \times 10^{-2}$ mole of sodium lactate. Determine the osmotic pressure of this solution at normal body temperature $\left(37^{\circ} \mathrm{C}\right)$. Assume no ion pairing. (The formula of the lactate ion is $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{COO}^{-}$.)

Strategy Because the solutes are all ionic, each solute concentration will have to be multiplied by the appropriate van't Hoff factor. (Because we are assuming no ion pairing, we can use calculated van't Hoff factors.) Sum the concentrations for all solutes to determine the total concentration of dissolved particles, and use Equation 13.8 to calculate the osmotic pressure.

Setup Because the volume of the solution described is 1 L , the number of moles is also the molarity for each solute. $R=0.08206 \mathrm{~L} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{mol}, T=310 \mathrm{~K}$, and the van't Hoff factors for the solutes in Ringer's lactate are as follows:

$$
\begin{array}{rlr}
\mathrm{NaCl}(s) & \longrightarrow \mathrm{Na}^{+}(a q)+\mathrm{Cl}^{-}(a q) & i=2 \\
\mathrm{KCl}(s) & \longrightarrow \mathrm{K}^{+}(a q)+\mathrm{Cl}^{-}(a q) & i=2 \\
\mathrm{CaCl}(s) & \longrightarrow \mathrm{Ca}^{2+}(a q)+2 \mathrm{Cl}^{-}(a q) & i=3 \\
\mathrm{NaCH}_{3} \mathrm{CH}_{2} \mathrm{COO}(s) \longrightarrow \mathrm{Na}^{+}(a q)+\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{COO}^{-}(a q) & i=2
\end{array}
$$

Solution The total concentration of ions in solution is the sum of the individual concentrations.

$$
\begin{aligned}
\text { total concentration } & =2[\mathrm{NaCl}]+2[\mathrm{KCl}]+3\left[\mathrm{MgCl}_{2}\right]+2\left[\mathrm{NaCH}_{3} \mathrm{CH}_{2} \mathrm{COO}\right] \\
& =2(0.102 M)+2\left(4 \times 10^{-3} M\right)+3\left(1.5 \times 10^{-3} M\right)+2\left(2.8 \times 10^{-2} M\right) \\
& =2.73 \times 10^{-1} M \\
\pi=M R T & =(0.273 M)(0.08206 \mathrm{~L} \cdot \mathrm{~atm} / \mathrm{K} \cdot \operatorname{mol})(310 \mathrm{~K})=6.93 \mathrm{~atm}
\end{aligned}
$$

Practice Problem A Determine the osmotic pressure of a solution that is 0.200 M in glucose and $0.100 M$ in sodium chloride at $37.0^{\circ} \mathrm{C}$. Assume no ion pairing.

EPractice Problem B Determine the concentration of an aqueous solution that has an osmotic pressure of 5.6 atm at $37^{\circ} \mathrm{C}$ if (a) the solute is glucose, and (b) the solute is sodium chloride. Assume no ion pairing.

Think About It Ringer's lactate is isotonic with human plasma, which is often the case with fluids administered intravenously.

To review:

- Vapor-pressure lowering depends on concentration expressed as mole fraction, $\chi$.
- Boiling-point elevation depends on concentration expressed as molality, $m$.
- Freezing-point depression depends on concentration expressed as molality, $m$.
- Osmotic pressure depends on concentration expressed as molarity, M.

## Checkpoint 13.5 Colligative Properties

13.5.1 A solution contains 75.0 g of glucose (molar mass $180.2 \mathrm{~g} / \mathrm{mol}$ ) in 425 g of water. Determine the vapor pressure of water over the solution at $35^{\circ} \mathrm{C}$. $\left(P_{\mathrm{H}_{2} \mathrm{O}}^{\circ}=42.2 \mathrm{mmHg}\right.$ at $35^{\circ} \mathrm{C}$. $)$
a) 0.732 mmHg
b) 42.9 mmHg
c) 243 mmHg
d) 41.5 mmHg
e) 42.2 mmHg
13.5.2 Determine the boiling point and the freezing point of a solution prepared by dissolving 678 g of glucose in 2.0 kg of water. For water, $K_{\mathrm{b}}=0.52^{\circ} \mathrm{C} / \mathrm{m}$ and $K_{\mathrm{f}}=1.86^{\circ} \mathrm{C} / m$.
a) $101^{\circ} \mathrm{C}$ and $3.5^{\circ} \mathrm{C}$
b) $99^{\circ} \mathrm{C}$ and $-3.5^{\circ} \mathrm{C}$
c) $101^{\circ} \mathrm{C}$ and $-3.5^{\circ} \mathrm{C}$
d) $112^{\circ} \mathrm{C}$ and $6.2^{\circ} \mathrm{C}$
e) $88^{\circ} \mathrm{C}$ and $-6.2^{\circ} \mathrm{C}$
13.5.3 Calculate the osmotic pressure of a solution prepared by dissolving 65.0 g of $\mathrm{Na}_{2} \mathrm{SO}_{4}$ in enough water to make 500 mL of solution at $20^{\circ} \mathrm{C}$. (Assume no ion pairing.)
a) 0.75 atm
b) 66 atm
c) 44 atm
d) $1 \times 10^{-2} \mathrm{~atm}$
e) 22 atm
13.5.4 A 1.00 m solution of HCl has a freezing point of $-3.30^{\circ} \mathrm{C}$. Determine the experimental van't Hoff factor for HCl at this concentration.
a) 1.77
b) 2.01
c) 1.90
d) 2
e) 1

## Bringing Chemistry to Life

## Hemodialysis

Osmosis refers to the movement of solvent through a membrane from the side where the solute concentration is lower to the side where the solute concentration is higher. Hemodialysis involves a more porous membrane, through which both solvent (water) and small solute particles can pass.

The size of the membrane pores is such that only small waste products such as excess potassium ion, creatinine, urea, and extra fluid can pass through. Larger components in blood, such as blood cells and proteins, are too large to pass through the membrane. A solute will pass through the membrane from the side where its concentration is higher to the side where its concentration is lower. The composition of the dialysate ensures that the necessary solutes in the blood (e.g., sodium and calcium ions) are not removed.

Because it is not normally found in blood, fluoride ion, if present in the dialysate, will flow across the membrane into the blood. In fact, this is true of any sufficiently small solute that is not normally found in blood-necessitating requirements for the purity of water used to prepare dialysate solutions that far exceed those for drinking water.

### 13.6 Calculations Using Colligative Properties

The colligative properties of nonelectrolyte solutions provide a means of determining the molar mass of a solute. Although any of the four colligative properties can be used in theory for this purpose, only freezing-point depression and osmotic pressure are used in practice because they show the most pronounced, and therefore the most easily measured, changes. From the experimentally determined freezing-point depression or osmotic pressure, we can calculate the solution's molality or molarity, respectively. Knowing the mass of dissolved solute, we can readily determine its molar mass.

Sample Problems 13.10 and 13.11 illustrate this technique.

## Sample Problem 13.10

Quinine was the first drug widely used to treat malaria, and it remains the treatment of choice for severe cases. A solution prepared by dissolving 10.0 g of quinine in 50.0 mL of ethanol has a freezing point $1.55^{\circ} \mathrm{C}$ below that of pure ethanol. Determine the molar mass of quinine. (The density of ethanol is $0.789 \mathrm{~g} / \mathrm{mL}$.) Assume that quinine is a nonelectrolyte.

Strategy Use Equation 13.7 to determine the molal concentration of the solution. Use the density of ethanol to determine the mass of solvent. The molal concentration of quinine multiplied by the mass of ethanol (in kg ) gives moles of quinine. The mass of quinine (in grams) divided by moles of quinine gives the molar mass.

Setup

$$
\text { mass of ethanol }=50.0 \mathrm{~mL} \times 0.789 \mathrm{~g} / \mathrm{mL}=39.5 \mathrm{~g} \quad \text { or } \quad 3.95 \times 10^{-2} \mathrm{~kg}
$$

$K_{\mathrm{f}}$ for ethanol (from Table 13.2) is $1.99^{\circ} \mathrm{C} / \mathrm{m}$.
Solution Solving Equation 13.7 for molal concentration,

$$
m=\frac{\Delta T_{\mathrm{f}}}{K_{\mathrm{f}}}=\frac{1.55^{\circ} \mathrm{C}}{1.99^{\circ} \mathrm{C} / m}=0.779 \mathrm{~m}
$$

The solution is 0.779 m in quinine (i.e., 0.779 mol quinine $/ \mathrm{kg}$ ethanol solvent).

$$
\begin{aligned}
\left(\frac{0.779 \text { mol quinine }}{\mathrm{kg} \text { ethanol }}\right)\left(3.95 \times 10^{-2} \mathrm{~kg} \text { ethanol }\right) & =0.0308 \mathrm{~mol} \text { quinine } \\
& \text { molar mass of quinine }
\end{aligned}=\frac{10.0 \mathrm{~g} \text { quinine }}{0.0308 \text { mol quinine }}=325 \mathrm{~g} / \mathrm{mol} .
$$

Practice Problem A Calculate the molar mass of naphthalene, the organic compound in "mothballs," if a solution prepared by dissolving 5.00 g of naphthalene in exactly 100 g of benzene has a freezing point $2.00^{\circ} \mathrm{C}$ below that of pure benzene.

HPractice Problem B What mass of naphthalene must be dissolved in $2.00 \times 10^{2} \mathrm{~g}$ of benzene to give a solution with a freezing point $2.50^{\circ} \mathrm{C}$ below that of pure benzene?

Student Annotation: These calculations require Equations 13.7 and 13.8 , respectively.

Think About It Biological molecules can have very high molar masses.

## Sample Problem 13.11

A solution is prepared by dissolving 50.0 g of hemoglobin $(\mathrm{Hb})$ in enough water to make 1.00 L of solution. The osmotic pressure of the solution is measured and found to be 14.3 mmHg at $25^{\circ} \mathrm{C}$. Calculate the molar mass of hemoglobin. (Assume that there is no change in volume when the hemoglobin is added to the water.)

Strategy Use Equation 13.8 to calculate the molarity of the solution. Because the solution volume is 1 L , the molarity is equal to the number of moles of hemoglobin. Dividing the mass of hemoglobin, which is given in the problem statement, by the number of moles gives the molar mass.

Setup $R=0.08206 \mathrm{~L} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{mol}, T=298 \mathrm{~K}$, and $\pi=14.3 \mathrm{mmHg} /(760 \mathrm{mmHg} / \mathrm{atm})=1.88 \times$ $10^{-2} \mathrm{~atm}$.

Solution Rearranging Equation 13.8 to solve for molarity, we get

$$
M=\frac{\pi}{R T}=\frac{1.88 \times 10^{-2} \mathrm{~atm}}{(0.08206 \mathrm{~L} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{~mol})(298 \mathrm{~K})}=7.69 \times 10^{-4} \mathrm{M}
$$

Thus, the solution contains $7.69 \times 10^{-4}$ mole of hemoglobin.

$$
\text { molar mass of hemoglobin }=\frac{50.0 \mathrm{~g}}{7.69 \times 10^{-4} \mathrm{~mol}}=6.50 \times 10^{4} \mathrm{~g} / \mathrm{mol}
$$

Practice Problem A A solution made by dissolving 25 mg of insulin in 5.0 mL of water has an osmotic pressure of 15.5 mmHg at $25^{\circ} \mathrm{C}$. Calculate the molar mass of insulin. (Assume that there is no change in volume when the insulin is added to the water.)
\& Practice Problem B What mass of insulin must be dissolved in 50.0 mL of water to produce a solution with an osmotic pressure of 16.8 mmHg at $25^{\circ} \mathrm{C}$ ?

The colligative properties of an electrolyte solution can be used to determine percent dissociation. Percent dissociation is the percentage of dissolved molecules (or formula units, in the case of an ionic compound) that separate into ions in solution. For a strong electrolyte such as NaCl , there should be complete, or 100 percent, dissociation. However, the data in Table 13.4 indicate that this is not necessarily the case. An experimentally determined van't Hoff factor smaller than the corresponding calculated value indicates less than 100 percent dissociation. As the experimentally determined van't Hoff factors for NaCl indicate, dissociation of a strong electrolyte is more complete at lower concentration. The percent ionization of a weak electrolyte, such as a weak acid, also depends on the concentration of the solution.

Sample Problem 13.12 shows how to use colligative properties to determine the percent dissociation of a weak electrolyte.

## Sample Problem 13.12

A solution that is 0.100 M in hydrofluoric acid (HF) has an osmotic pressure of 2.64 atm at $25^{\circ} \mathrm{C}$. Calculate the percent ionization of HF at this concentration.

Strategy Use the osmotic pressure and Equation 13.8 to determine the molar concentration of the particles in solution. Compare the concentration of particles to the nominal concentration $(0.100 \mathrm{M})$ to determine what percentage of the original HF molecules are ionized.

Setup $R=0.08206 \mathrm{~L} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{mol}$, and $T=298 \mathrm{~K}$.
Solution Rearranging Equation 13.8 to solve for molarity,

$$
M=\frac{\pi}{R T}=\frac{2.64 \mathrm{~atm}}{(0.08206 \mathrm{~L} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{~mol})(298 \mathrm{~K})}=0.108 \mathrm{M}
$$

The concentration of dissolved particles is $0.108 M$. Consider the ionization of HF [ 144 Section 4.3]:

$$
\mathrm{HF}(a q) \rightleftarrows \mathrm{H}^{+}(a q)+\mathrm{F}^{-}(a q)
$$

According to this equation, if $x$ HF molecules ionize, we get $x \mathrm{H}^{+}$ions and $x \mathrm{~F}^{-}$ions. Thus, the total concentration of particles in solution will be the original concentration of HF minus $x$, which gives the concentration of intact HF molecules, plus $2 x$, which is the concentration of ions $\left(\mathrm{H}^{+}\right.$and $\left.\mathrm{F}^{-}\right)$:

$$
(0.100-x)+2 x=0.100+x
$$

Therefore, $0.108=0.100+x$ and $x=0.008$. Because we earlier defined $x$ as the amount of HF ionized, the percent ionization is given by

$$
\text { percent ionization }=\frac{0.008 M}{0.100 M} \times 100 \%=8 \%
$$

At this concentration HF is 8 percent ionized.

Practice Problem A An aqueous solution that is $0.0100 M$ in acetic acid $\left(\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right)$ has an osmotic pressure of 0.255 atm at $25^{\circ} \mathrm{C}$. Calculate the percent ionization of acetic acid at this concentration.

EPractice Problem B An aqueous solution that is $0.015 M$ in acetic acid $\left(\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right)$ is 3.5 percent ionized at $25^{\circ} \mathrm{C}$. Calculate the osmotic pressure of this solution.

## Checkpoint 13.6 Calculations Using Colligative Properties

13.6.1 A solution made by dissolving 14.2 g of sucrose in 100 g of water exhibits a freezing point depression of $0.77^{\circ} \mathrm{C}$. Calculate the molar mass of sucrose.
a) $34 \mathrm{~g} / \mathrm{mol}$
b) $3.4 \times 10^{2} \mathrm{~g} / \mathrm{mol}$
c) $2.4 \mathrm{~g} / \mathrm{mol}$
d) $1.8 \times 10^{2} \mathrm{~g} / \mathrm{mol}$
e) $68 \mathrm{~g} / \mathrm{mol}$
13.6.2 A $0.010 M$ solution of the weak electrolyte HA has an osmotic pressure of 0.27 atm at $25^{\circ} \mathrm{C}$. What is the percent ionization of the electrolyte at this concentration?
a) $27 \%$
b) $10 \%$
c) $15 \%$
d) $81 \%$
e) $90 \%$

### 13.7 Colloids

The solutions discussed so far in this chapter are true homogeneous mixtures. Now consider what happens if we add fine sand to a beaker of water and stir. The sand particles are suspended at first but gradually settle to the bottom of the beaker. This is an example of a heterogeneous mixture. Between the two extremes of homogeneous and heterogeneous mixtures is an intermediate state called a colloidal suspension, or simply, a colloid. A colloid is a dispersion of particles of one substance throughout another substance. Colloidal particles are much larger than the normal solute molecules; they range from $1 \times 10^{3} \mathrm{pm}$ to $1 \times 10^{6} \mathrm{pm}$. Also, a colloidal suspension lacks the homogeneity of a true solution.

Colloids can be further categorized as aerosols (liquid or solid dispersed in gas), foams (gas dispersed in liquid or solid), emulsions (liquid dispersed in another liquid), sols (solid dispersed in liquid or in another solid), and gels (liquid dispersed in a solid). Table 13.5 lists the different types of colloids and gives one or more examples of each.

One way to distinguish a solution from a colloid is by the Tyndall ${ }^{4}$ effect. When a beam of light passes through a colloid, it is scattered by the dispersed phase (Figure 13.13). No such scattering is observed with true solutions because the solute molecules are too small to interact with visible light. Another demonstration of the Tyndall effect is the scattering of light from automobile headlights in fog (Figure 13.14).

[^39]Think About It For weak acids, the lower the concentration, the greater the percent ionization. A $0.010 M$ solution of HF has an osmotic pressure of 0.30 atm , corresponding to 23 percent ionization. A $0.0010 M$ solution of HF has an osmotic pressure of $3.8 \times 10^{-2} \mathrm{~atm}$, corresponding to 56 percent ionization.

Student Annotation: The substance dispersed is called the dispersed phase; the substance in which it is dispersed is called the dispersing medium.

Student Annotation: Styrofoam is a registered trademark of the Dow Chemical Company. It refers specifically to extruded polystyrene used for insulation in home construction. "Styrofoam" cups, coolers, and packing peanuts are not really made of Styrofoam.

TABLE 13.5 Types of Colloids

| Dispersing <br> Medium | Dispersed <br> Phase | Name | Example |
| :--- | :--- | :--- | :--- |
| Gas | Liquid | Aerosol | Fog, mist |
| Gas | Solid | Aerosol | Smoke |
| Liquid | Gas | Foam | Whipped cream, meringue |
| Liquid | Liquid | Emulsion | Mayonnaise |
| Liquid | Solid | Sol | Milk of magnesia |
| Solid | Gas | Foam | Styrofoam |
| Solid | Liquid | Gel | Jelly, butter |
| Solid | Solid | Solid sol | Alloys such as steel, gemstones <br> (glass with dispersed metal) |

Among the most important colloids are those in which the dispersing medium is water. Such colloids can be categorized as hydrophilic (water loving) or hydrophobic (water fearing). Hydrophilic colloids contain extremely large molecules such as proteins. In the aqueous phase, a protein like hemoglobin folds in such a way that the hydrophilic parts of the molecule, the parts that can interact favorably with water molecules by ion-dipole forces or hydrogen-bond formation, are on the outside surface (Figure 13.15).

Figure 13.15 Hydrophilic groups on the surface of a large molecule such as a protein stabilize the molecule in water. Note that all the hydrophilic groups can form hydrogen bonds with water.

Figure 13.16 Diagram showing the stabilization of hydrophobic colloids. Negative ions are adsorbed onto the surface, and the repulsion between like charges prevents aggregation of the particles.

A hydrophobic colloid normally would not be stable in water, and the particles would clump together, like droplets of oil in water merging to form a film at the water's surface. They can be stabilized, however, by the adsorption of ions on their surface (Figure 13.16). Material that collects on the surface is adsorbed, whereas material that passes to the interior is absorbed. The adsorbed ions are hydrophilic and can interact with water to stabilize the colloid. In addition, because adsorption of ions leaves the colloid particles charged, electrostatic repulsion prevents them from clumping together. Soil particles in rivers and streams are hydrophobic particles that are stabilized in this way. When river water enters the sea, the charges on the dispersed particles are neutralized by the high-salt medium. With the charges on their surfaces neutralized, the particles no longer repel one another and they clump together to form the silt that is seen at the mouth of the river.

Another way hydrophobic colloids can be stabilized is by the presence of other hydrophilic groups on their surfaces. Consider sodium stearate, a soap molecule that has a polar group at one end, often called the "head," and a long hydrocarbon "tail" that is nonpolar (Figure 13.17). The cleansing action of soap is due to the dual nature of the hydrophobic tail and the hydrophilic head. The hydrocarbon tail is readily soluble in oily substances, which are also nonpolar, while the ionic $-\mathrm{COO}^{-}$group remains outside the oily surface. When enough soap molecules have surrounded an oil droplet, as shown in Figure 13.18, the entire system becomes stabilized in water because the exterior portion is now largely hydrophilic. This is how greasy substances are removed by the action of soap. In general, the process of stabilizing a colloid that would otherwise not stay dispersed is called emulsification, and a substance used for such stabilization is called an emulsifier or emulsifying agent.

(a)

Hydrophobic tail
(b)

Figure 13.18 The mechanism by which soap removes grease. (a) Grease (oily substance) is not soluble in water. (b) When soap is added to water, the nonpolar tails of soap molecules dissolve in grease. (c) The grease can be washed away when the polar heads of the soap molecules stabilize it in water.

Student Annotation: It is being nonpolar that makes some vitamins soluble in fat. Remember the axiom "like dissolves like."

Figure 13.19 Structure of sodium glycocholate. The hydrophobic tail of sodium glycocholate dissolves in ingested fats, stabilizing them on the aqueous medium of the digestive system.

A mechanism similar to that involving sodium stearate makes it possible for us to digest dietary fat. When we ingest fat, the gallbladder excretes a substance known as bile. Bile contains a variety of substances including bile salts. A bile salt is a derivative of cholesterol with an attached amino acid. Like sodium stearate, a bile salt has both a hydrophobic end and a hydrophilic end. (Figure 13.19 shows the bile salt sodium glycocholate.) The bile salts surround fat particles with their hydrophobic ends oriented toward the fat and their hydrophilic ends facing the water, emulsifying the fat in the aqueous medium of the digestive system. This process allows fats to be digested and other nonpolar substances such as fat-soluble vitamins to be absorbed through the wall of the small intestine.

## Applying What You've Learned

Despite the use of fluoride in municipal water supplies and many topical dental products, acute fluoride poisoning is relatively rare. Fluoride is now routinely removed from the water used to prepare dialysate solutions. However, water-supply fluoridation became common during the 1960s and 1970s-just when hemodialysis was first being made widely available to patients. This unfortunate coincidence resulted in large numbers of early dialysis patients suffering the effects of fluoride poisoning, before the danger of introducing fluoride via dialysis was recognized. The level of fluoride considered safe for the drinking water supply is based on the presumed ingestion by a healthy person of 14 L of water per week. Many dialysis patients routinely are exposed to as much as 50 times that volume, putting them at significantly increased risk of absorbing toxic amounts of fluoride.

## Problems:

a) Early fluoridation of municipal water supplies was done by dissolving enough sodium fluoride to achieve a 1-ppm concentration of fluoride ion. Convert $1.0 \mathrm{ppm} \mathrm{F}^{-}$to percent by mass $\mathrm{F}^{-}$and molality of NaF. [ $\mathrm{K4}$ Sample Problem 13.3]
b) Calculate the boiling point and freezing point of a solution made by dissolving 4.10 g NaF in $100 \mathrm{~mL} \mathrm{H}_{2} \mathrm{O}$. (For water, $d=1 \mathrm{~g} / \mathrm{mL}$.) [ KA Sample Problem 13.7]
c) Many fluoridation facilities now use fluorosilicic acid instead of sodium fluoride. Fluorosilicic acid typically is distributed as a $23 \%(1.596 \mathrm{~m})$ aqueous solution. Calculate the van't Hoff factor of fluorosilicic acid given that a $23 \%$ solution has a freezing point of $-15.5^{\circ} \mathrm{C}$. [14t Sample Problem 13.8]
