d) The density of $23 \%$ fluorosilicic acid is $1.19 \mathrm{~g} / \mathrm{mL}$. Given that the osmotic pressure of this solution at $25^{\circ} \mathrm{C}$ is 242 atm , calculate the molar mass of fluorosilicic acid.
[ 14 Sample Problems 13.9 and 13.10]
e) Hydrofluoric acid (HF) is another compound that can be used in the fluoridation of water. HF is a weak acid that only partially ionizes in solution. If an aqueous solution that is 0.15 M in HF has an osmotic pressure of 3.9 atm at $25^{\circ} \mathrm{C}$, what is the percent ionization of HF at this concentration? [ 14 Sample Problem 13.12]

Student Annotation: Elevated levels of fluoride are associated with osteomalacia, a condition marked by debilitating bone pain and muscle weakness.

## Chapter Summary

## Section 13.1

- Solutions are homogeneous mixtures of two or more substances, which may be solids, liquids, or gases.
- Saturated solutions contain the maximum possible amount of dissolved solute.
- The amount of solute dissolved in a saturated solution is the solubility of the solute in the specified solvent at the specified temperature.
- Unsaturated solutions contain less than the maximum possible amount of solute.
- Supersaturated solutions contain more solute than specified by the solubility.

## Section 13.2

- Substances with similar intermolecular forces tend to be soluble in one another. "Like dissolves like." Two liquids that are soluble in each other are called miscible.
- Solution formation may be endothermic or exothermic overall. An increase in entropy is the driving force for solution formation. Solute particles are surrounded by solvent molecules in a process called solvation.

## Section 13.3

- In addition to molarity $(M)$ and mole fraction $(\chi)$, molality $(\boldsymbol{m})$ and percent by mass are used to express the concentrations of solutions.
- Molality is defined as the number of moles of solute per kilogram of solvent. Percent by mass is defined as the mass of solute divided by the total mass of the solution, all multiplied by 100 percent.
- Molality and percent by mass have the advantage of being temperature independent. Conversion among molarity, molality, and percent by mass requires solution density.
- The units of concentration used depend on the type of problem to be solved.

## Section 13.4

- Increasing the temperature increases the solubility of most solids in water and decreases the solubility of most gases in water.
- Increasing the pressure increases the solubility of gases in water but does not affect the solubility of solids.
- According to Henry's law, the solubility of a gas in a liquid is directly proportional to the partial pressure of the gas over the solution: $c=k P$.
- The proportionality constant $k$ is the Henry's law constant. Henry's law constants are specific to the gas and solvent, and they are temperature dependent.

## Section 13.5

- Colligative properties depend on the number (but not on the type) of dissolved particles. The colligative properties are vapor-pressure lowering, boiling-point elevation, freezing-point depression, and osmotic pressure.
- A volatile substance is one that has a measurable vapor pressure. A nonvolatile substance is one that does not have a measurable vapor pressure.
- According to Raoult's law, the partial pressure of a substance over a solution is equal to the mole fraction $(\chi)$ of the substance times its pure vapor pressure $\left(P^{\circ}\right)$. An ideal solution is one that obeys Raoult's law.
- Osmosis is the flow of solvent through a semipermeable membrane, one that allows solvent molecules but not solute particles to pass, from a more dilute solution to a more concentrated one.
- Osmotic pressure $(\pi)$ is the pressure required to prevent osmosis from occurring.
- Two solutions with the same osmotic pressure are called isotonic. Hypotonic refers to a solution with a lower osmotic pressure. Hypertonic refers to a solution with a higher osmotic pressure. These terms are often used in reference to human plasma, which has an osmotic pressure of 7.6 atm .
- In electrolyte solutions, the number of dissolved particles is increased by dissociation or ionization. The magnitudes of colligative properties are increased by the van't Hoff factor (i), which indicates the degree of dissociation or ionization.
- The experimentally determined van't Hoff factor is generally smaller than the calculated value due to the formation of ion pairs-especially at high concentrations. Ion pairs are oppositely charged ions that are attracted to each other and effectively become a single "particle" in solution.

## Section 13.6

- Experimentally determined colligative properties can be used to calculate the molar mass of a nonelectrolyte or the percent dissociation (or percent ionization) of a weak electrolyte.

## Section 13.7

- A colloid is a dispersion of particles (about $1 \times 10^{3} \mathrm{pm}$ to $1 \times 10^{6} \mathrm{pm}$ ) of one substance in another substance.
- Colloids can be distinguished from true solutions by the Tyndall effect, which is the scattering of visible light by colloidal particles.
- Colloids are classified either as hydrophilic (water loving) or hydrophobic (water fearing).
- Hydrophobic colloids can be stabilized in water by surface interactions with ions or polar molecules.

## Key Words

Colligative properties, 553
Colloid, 565
Entropy, 542
Henry's law, 551
Henry's law constant (k), 551

## Questions and Problems

## Section 13.1: Types of Solutions

## Review Questions

13.1 Distinguish between an unsaturated solution, a saturated solution, and a supersaturated solution.
13.2 Describe the different types of solutions that can be formed by the combination of solids, liquids, and gases. Give examples of each type of solution.

## Section 13.2: The Solution Process

## Review Questions

13.3 Briefly describe the solution process at the molecular level. Use the dissolution of a solid in a liquid as an example.
13.4 Basing your answer on intermolecular force considerations, explain what "like dissolves like" means.
13.5 What is solvation? What factors influence the extent to which solvation occurs? Give two examples of solvation; include one that involves ion-dipole interaction and one in which dispersion forces come into play.
13.6 As you know, some solution processes are endothermic and others are exothermic. Provide a molecular interpretation for the difference.
13.7 Explain why dissolving a solid almost always leads to an increase in disorder.
13.8 Describe the factors that affect the solubility of a solid in a liquid. What does it mean to say that two liquids are miscible?

## Problems

13.9 Why is naphthalene $\left(\mathrm{C}_{10} \mathrm{H}_{8}\right)$ more soluble than CsF in benzene?
13.10 Explain why ethanol $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right)$ is not soluble in cyclohexane $\left(\mathrm{C}_{6} \mathrm{H}_{12}\right)$.

G13.11 Arrange the following compounds in order of increasing solubility in water: $\mathrm{O}_{2}, \mathrm{LiCl}, \mathrm{Br}_{2}$, methanol $\left(\mathrm{CH}_{3} \mathrm{OH}\right)$.
13.12 Explain the variations in solubility in water of the listed alcohols:

| Compound | Solubility in Water $(\mathbf{g} / \mathbf{1 0 0} \mathbf{g})$ at $\mathbf{2 0}{ }^{\circ} \mathbf{C}$ |
| :--- | :---: |
| $\mathrm{CH}_{3} \mathrm{OH}$ | $\infty$ |
| $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}$ | $\infty$ |
| $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{OH}$ | $\infty$ |
| $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{OH}$ | 9 |
| $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{OH}$ | 2.7 |

Note: $\infty$ means that the alcohol and water are completely miscible in all proportions.

## Section 13.3: Concentration Units

## Review Questions

13.13 Define the following concentration terms and give their units: percent by mass, mole fraction, molarity, molality. Compare their advantages and disadvantages.
13.14 Outline the steps required for conversion between molarity, molality, and percent by mass.

## Problems

H13.15 Calculate the percent by mass of the solute in each of the following aqueous solutions: (a) 5.75 g of NaBr in 67.9 g of solution, (b) 24.6 g of KCl in 114 g of water, (c) 4.8 g of toluene in 39 g of benzene.

E13.16 Calculate the amount of water (in grams) that must be added to (a) 5.00 g of urea $\left(\mathrm{NH}_{2}\right)_{2} \mathrm{CO}$ in the preparation of a 16.2 percent by mass solution, and (b) 26.2 g of $\mathrm{MgCl}_{2}$ in the preparation of a 1.5 percent by mass solution.

E13.17 Calculate the molality of each of the following solutions:
(a) 14.3 g of sucrose $\left(\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}\right)$ in 685 g of water,
(b) 7.15 moles of ethylene glycol $\left(\mathrm{C}_{2} \mathrm{H}_{6} \mathrm{O}_{2}\right)$ in 3505 g of water.
13.18 Calculate the molality of each of the following aqueous solutions:
(a) 2.55 M NaCl solution (density of solution $=1.08 \mathrm{~g} / \mathrm{mL}$ ),
(b) 45.2 percent by mass KBr solution.

I13.19 Calculate the molalities of the following aqueous solutions:
(a) 1.22 M sugar $\left(\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}\right)$ solution (density of solution = $1.12 \mathrm{~g} / \mathrm{mL}$ ), (b) 0.87 M NaOH solution (density of solution $=$ $1.04 \mathrm{~g} / \mathrm{mL}$ ), (c) 5.24 M NaHCO 3 solution (density of solution $=$ $1.19 \mathrm{~g} / \mathrm{mL}$ ).
13.20 For dilute aqueous solutions in which the density of the solution is roughly equal to that of the pure solvent, the molarity of the solution is equal to its molality. Show that this statement is correct for a 0.010 M aqueous urea $\left(\mathrm{NH}_{2}\right)_{2} \mathrm{CO}$ solution.

E13.21 The alcohol content of hard liquor is normally given in terms of the "proof," which is defined as twice the percentage by volume of ethanol $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right)$ present. Calculate the number of grams of alcohol present in 1.00 L of 75 -proof gin. The density of ethanol is $0.798 \mathrm{~g} / \mathrm{mL}$.

Ef 13.22 The concentrated sulfuric acid we use in the laboratory is 98.0 percent $\mathrm{H}_{2} \mathrm{SO}_{4}$ by mass. Calculate the molality and molarity of the acid solution. The density of the solution is $1.83 \mathrm{~g} / \mathrm{mL}$.

EI 13.23 Calculate the molarity and molality of an $\mathrm{NH}_{3}$ solution made up of 35.0 g of $\mathrm{NH}_{3}$ in 75.0 g of water. The density of the solution is $0.982 \mathrm{~g} / \mathrm{mL}$.
$\Psi$ 13.24 The density of an aqueous solution containing 15.0 percent of ethanol $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right)$ by mass is $0.984 \mathrm{~g} / \mathrm{mL}$. (a) Calculate the molality of this solution. (b) Calculate its molarity. (c) What volume of the solution would contain 0.250 mole of ethanol?
13.25 Fish breathe the dissolved air in water through their gills. Assuming the partial pressures of oxygen and nitrogen in air to be 0.20 and 0.80 atm , respectively, calculate the mole fractions of oxygen and nitrogen in the air dissolved in water at 298 K . The solubilities of $\mathrm{O}_{2}$ and $\mathrm{N}_{2}$ in water at 298 K are $1.3 \times 10^{-3} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{atm}$ and $6.8 \times 10^{-4} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{atm}$, respectively. Comment on your results.

## Section 13.4: Factors That Affect Solubility

## Review Questions

13.26 How do the solubilities of most ionic compounds in water change with temperature? With pressure?
13.27 Discuss the factors that influence the solubility of a gas in a liquid.
13.28 What is thermal pollution? Why is it harmful to aquatic life?
13.29 What is Henry's law? Define each term in the equation, and give its units. How would you account for the law in terms of the kinetic molecular theory of gases? Give two exceptions to Henry's law.
13.30 A student is observing two beakers of water. One beaker is heated to $30^{\circ} \mathrm{C}$, and the other is heated to $100^{\circ} \mathrm{C}$. In each case, bubbles form in the water. Are these bubbles of the same origin? Explain.
13.31 A man bought a goldfish in a pet shop. Upon returning home, he put the goldfish in a bowl of recently boiled water that had been cooled quickly. A few minutes later the fish was found dead. Explain what happened to the fish.

## Problems

E 13.32 A 3.20-g sample of a salt dissolves in 9.10 g of water to give a saturated solution at $25^{\circ} \mathrm{C}$. What is the solubility (in g salt $/ 100 \mathrm{~g}$ of $\mathrm{H}_{2} \mathrm{O}$ ) of the salt?

E13.33 The solubility of $\mathrm{KNO}_{3}$ is 155 g per 100 g of water at $75^{\circ} \mathrm{C}$ and 38.0 g at $25^{\circ} \mathrm{C}$. What mass (in grams) of $\mathrm{KNO}_{3}$ will crystallize out of solution if exactly 100 g of its saturated solution at $75^{\circ} \mathrm{C}$ is cooled to $25^{\circ} \mathrm{C}$ ?

E 13.34 A $50-\mathrm{g}$ sample of impure $\mathrm{KClO}_{3}$ (solubility $=7.1 \mathrm{~g}$ per $100 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}$ at $20^{\circ} \mathrm{C}$ ) is contaminated with 10 percent of KCl (solubility $=25.5 \mathrm{~g}$ per 100 g of $\mathrm{H}_{2} \mathrm{O}$ at $20^{\circ} \mathrm{C}$ ). Calculate the minimum quantity of $20^{\circ} \mathrm{C}$ water needed to dissolve all the KCl from the sample. How much $\mathrm{KClO}_{3}$ will be left after this treatment? (Assume that the solubilities are unaffected by the presence of the other compound.)
13.35 A miner working 260 m below sea level opened a carbonated soft drink during a lunch break. To his surprise, the soft drink tasted rather "flat." Shortly afterward, the miner took an elevator to the surface. During the trip up, he could not stop belching. Why?
13.36 A beaker of water is initially saturated with dissolved air. Explain what happens when He gas at 1 atm is bubbled through the solution for a long time.

- 13.37 The solubility of $\mathrm{CO}_{2}$ in water at $25^{\circ} \mathrm{C}$ and 1 atm is $0.034 \mathrm{~mol} / \mathrm{L}$. What is its solubility under atmospheric conditions? (The partial pressure of $\mathrm{CO}_{2}$ in air is 0.0003 atm .) Assume that $\mathrm{CO}_{2}$ obeys Henry's law.
13.38 The solubility of $\mathrm{N}_{2}$ in blood at $37^{\circ} \mathrm{C}$ and at a partial pressure of 0.80 atm is $5.6 \times 10^{-4} \mathrm{~mol} / \mathrm{L}$. A deep-sea diver breathes compressed air with the partial pressure of $\mathrm{N}_{2}$ equal to 4.0 atm . Assume that the total volume of blood in the body is 5.0 L . Calculate the amount of $\mathrm{N}_{2}$ gas released (in liters at $37^{\circ} \mathrm{C}$ and 1 atm ) when the diver returns to the surface of the water, where the partial pressure of $\mathrm{N}_{2}$ is 0.80 atm .
13.39 A student carried out the following experiment to measure the pressure of carbon dioxide in the space above the carbonated soft drink in a bottle. First, she weighed the bottle ( 853.5 g ). Next, she carefully removed the cap to let the $\mathrm{CO}_{2}$ gas escape. She then reweighed the bottle with the cap ( 851.3 g). Finally, she measured the volume of the soft drink $(452.4 \mathrm{~mL})$. Given that the Henry's law constant for $\mathrm{CO}_{2}$ in water at $25^{\circ} \mathrm{C}$ is $3.4 \times 10^{-2} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{atm}$, calculate the pressure of $\mathrm{CO}_{2}$ over the soft drink in the bottle before it was opened. Explain why this pressure is only an estimate of the true value.

## Section 13.5: Colligative Properties

## Review Questions

13.40 What are colligative properties? What is the meaning of the word colligative in this context?
13.41 Give two examples of (a) a volatile liquid and (b) a nonvolatile liquid.
13.42 Write the equation representing Raoult's law, and express it in words.
13.43 Use a solution of benzene in toluene to explain what is meant by an ideal solution.
13.44 Write the equations relating boiling-point elevation and freezing-point depression to the concentration of the solution. Define all the terms, and give their units.
13.45 How is vapor-pressure lowering related to a rise in the boiling point of a solution?
13.46 Use a phase diagram to show the difference in freezing points and boiling points between an aqueous urea solution and pure water.
13.47 What is osmosis? What is a semipermeable membrane?
13.48 Write the equation relating osmotic pressure to the concentration of a solution. Define all the terms, and specify their units.
13.49 What does it mean when we say that the osmotic pressure of a sample of seawater is 25 atm at a certain temperature?
13.50 Explain why molality is used for boiling-point elevation and freezing-point depression calculations and molarity is used in osmotic pressure calculations.
13.51 Why is the discussion of the colligative properties of electrolyte solutions more involved than that of nonelectrolyte solutions?
13.52 What are ion pairs? What effect does ion-pair formation have on the colligative properties of a solution? How does the ease of ion-pair formation depend on (a) charges on the ions, (b) size of the ions, (c) nature of the solvent (polar versus nonpolar), (d) concentration?
13.53 Indicate which compound in each of the following pairs is more likely to form ion pairs in water: (a) NaCl or $\mathrm{Na}_{2} \mathrm{SO}_{4}$, (b) $\mathrm{MgCl}_{2}$ or $\mathrm{MgSO}_{4}$, (c) LiBr or KBr .
13.54 What is the van't Hoff factor? What information does it provide?
13.55 For most intravenous injections, great care is taken to ensure that the concentration of solutions to be injected is comparable to that of blood plasma. Explain.

## Problems

El13.56 A solution is prepared by dissolving 396 g of sucrose $\left(\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}\right)$ in 624 g of water. What is the vapor pressure of this solution at $30^{\circ} \mathrm{C}$ ? (The vapor pressure of water is 31.8 mmHg at $30^{\circ} \mathrm{C}$.)

G13.57 How many grams of sucrose $\left(\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}\right)$ must be added to 552 g of water to give a solution with a vapor pressure 2.0 mmHg less than that of pure water at $20^{\circ} \mathrm{C}$ ? (The vapor pressure of water at $20^{\circ} \mathrm{C}$ is 17.5 mmHg .)

H 13.58 The vapor pressure of benzene is 100.0 mmHg at $26.1^{\circ} \mathrm{C}$. Calculate the vapor pressure of a solution containing 24.6 g of camphor $\left(\mathrm{C}_{10} \mathrm{H}_{16} \mathrm{O}\right)$ dissolved in 98.5 g of benzene. (Camphor is a low-volatility solid.)
13.59 The vapor pressures of ethanol $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right)$ and 1-propanol $\left(\mathrm{C}_{3} \mathrm{H}_{7} \mathrm{OH}\right)$ at $35^{\circ} \mathrm{C}$ are 100 and 37.6 mmHg , respectively. Assume ideal behavior and calculate the partial pressures of ethanol and 1-propanol at $35^{\circ} \mathrm{C}$ over a solution of ethanol in 1-propanol, in which the mole fraction of ethanol is 0.300 .

EI 13.60 The vapor pressure of ethanol $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right)$ at $20^{\circ} \mathrm{C}$ is 44 mmHg , and the vapor pressure of methanol $\left(\mathrm{CH}_{3} \mathrm{OH}\right)$ at the same temperature is 94 mmHg . A mixture of 30.0 g of methanol and 45.0 g of ethanol is prepared (and can be assumed to behave as an ideal solution). (a) Calculate the vapor pressure of methanol and ethanol above this solution at $20^{\circ} \mathrm{C}$. (b) Calculate the mole fraction of methanol and ethanol in the vapor above this solution at $20^{\circ} \mathrm{C}$. (c) Suggest a method for separating the two components of the solution.

H13.61 How many grams of urea $\left[\left(\mathrm{NH}_{2}\right)_{2} \mathrm{CO}\right]$ must be added to 658 g of water to give a solution with a vapor pressure 2.50 mmHg lower than that of pure water at $30^{\circ} \mathrm{C}$ ? (The vapor pressure of water at $30^{\circ} \mathrm{C}$ is 31.8 mmHg .)

H13.62 What are the boiling point and freezing point of a 3.12 m solution of naphthalene in benzene? (The boiling point and freezing point of benzene are $80.1^{\circ} \mathrm{C}$ and $5.5^{\circ} \mathrm{C}$, respectively.)
13.63 An aqueous solution contains the amino acid glycine $\left(\mathrm{NH}_{2} \mathrm{CH}_{2} \mathrm{COOH}\right)$. Assuming that the acid does not ionize in water, calculate the molality of the solution if it freezes at $-1.1^{\circ} \mathrm{C}$.

E1 13.64 How many liters of the antifreeze ethylene glycol $\left[\mathrm{CH}_{2}(\mathrm{OH}) \mathrm{CH}_{2}(\mathrm{OH})\right]$ would you add to a car radiator containing
6.50 L of water if the coldest winter temperature in your area is $-20^{\circ} \mathrm{C}$ ? Calculate the boiling point of this water-ethylene glycol mixture. (The density of ethylene glycol is $1.11 \mathrm{~g} / \mathrm{mL}$.)
$\Psi$ 13.65 A solution is prepared by condensing 4.00 L of a gas, measured at $27^{\circ} \mathrm{C}$ and 748 mmHg pressure, into 75.0 g of benzene. Calculate the freezing point of this solution.
\& 13.66 What is the osmotic pressure (in atm) of a 1.57 M aqueous solution of urea $\left[\left(\mathrm{NH}_{2}\right)_{2} \mathrm{CO}\right]$ at $27.0^{\circ} \mathrm{C}$ ?
13.67 Which of the following aqueous solutions has (a) the higher boiling point, (b) the higher freezing point, and (c) the lower vapor pressure: 0.35 m CaCl 2 or 0.90 m urea? Explain. Assume complete dissociation.
13.68 Consider two aqueous solutions, one of sucrose $\left(\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}\right)$ and the other of nitric acid $\left(\mathrm{HNO}_{3}\right)$. Both solutions freeze at $-1.5^{\circ} \mathrm{C}$. What other properties do these solutions have in common?

E13.69 Arrange the following solutions in order of decreasing freezing point: $0.10 m \mathrm{Na}_{3} \mathrm{PO}_{4}, 0.35 \mathrm{~m} \mathrm{NaCl}, 0.20 m \mathrm{MgCl}_{2}, 0.15 \mathrm{~m}$ $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}, 0.15 \mathrm{~m} \mathrm{CH}_{3} \mathrm{COOH}$.
13.70 Arrange the following aqueous solutions in order of decreasing freezing point, and explain your reasoning: $0.50 \mathrm{~m} \mathrm{HCl}, 0.50 \mathrm{~m}$ glucose, $0.50 m$ acetic acid.

E13.71 What are the normal freezing points and boiling points of the following solutions: (a) 21.2 g NaCl in 135 mL of water and (b) 15.4 g of urea in 66.7 mL of water?
13.72 At $25^{\circ} \mathrm{C}$, the vapor pressure of pure water is 23.76 mmHg and that of seawater is 22.98 mmHg . Assuming that seawater contains only NaCl , estimate its molal concentration.
13.73 Both NaCl and $\mathrm{CaCl}_{2}$ are used to melt ice on roads and sidewalks in winter. What advantages do these substances have over sucrose or urea in lowering the freezing point of water?
13.74 A 0.86 percent by mass solution of NaCl is called "physiological saline" because its osmotic pressure is equal to that of the solution in blood cells. Calculate the osmotic pressure of this solution at normal body temperature $\left(37^{\circ} \mathrm{C}\right)$. Note that the density of the saline solution is $1.005 \mathrm{~g} / \mathrm{mL}$.

E13.75 The osmotic pressure of $0.010 M$ solutions of $\mathrm{CaCl}_{2}$ and urea at $25^{\circ} \mathrm{C}$ are 0.605 and 0.245 atm , respectively. Calculate the van't Hoff factor for the $\mathrm{CaCl}_{2}$ solution.
13.76 Calculate the osmotic pressure of a $0.0500 M \mathrm{MgSO}_{4}$ solution at $25^{\circ} \mathrm{C}$. (Hint: See Table 13.3.)
13.77 The tallest trees known are the redwoods in California. Assuming the height of a redwood to be 105 m (about 350 ft ), estimate the osmotic pressure required to push water up to the tree top.
13.78 Calculate the difference in osmotic pressure (in atm) at the normal body temperature between the blood plasma of a diabetic patient and that of a healthy adult. Assume that the sole difference between the two people is due to the higher glucose level in the diabetic patient. The glucose levels are 1.75 and $0.84 \mathrm{~g} / \mathrm{L}$, respectively. Based on your result, explain why such a patient frequently feels thirsty.

## Section 13.6: Calculations Using Colligative Properties

## Review Questions

13.79 Describe how you would use freezing-point depression and osmotic pressure measurements to determine the molar mass of a compound. Why are boiling-point elevation and vapor-pressure lowering normally not used for this purpose?
13.80 Describe how you would use the osmotic pressure to determine the percent ionization of a weak, monoprotic acid.

## Problems

E13.81 Pheromones are compounds secreted by the females of many insect species to attract males. One of these compounds contains 80.78 percent $\mathrm{C}, 13.56$ percent H , and 5.66 percent O . A solution of 1.00 g of this pheromone in 8.50 g of benzene freezes at $3.37^{\circ} \mathrm{C}$. What are the molecular formula and molar mass of the compound? (The normal freezing point of pure benzene is $5.50^{\circ} \mathrm{C}$.)

H13.82 The elemental analysis of an organic solid extracted from gum arabic (a gummy substance used in adhesives, inks, and pharmaceuticals) showed that it contained 40.0 percent C, 6.7 percent H , and 53.3 percent O . A solution of 0.650 g of the solid in 27.8 g of the solvent diphenyl gave a freezing-point depression of $1.56^{\circ} \mathrm{C}$. Calculate the molar mass and molecular formula of the solid. ( $K_{\mathrm{f}}$ for diphenyl is $8.00^{\circ} \mathrm{C} / \mathrm{m}$.)

H13.83 A solution of 2.50 g of a compound having the empirical formula $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{P}$ in 25.0 g of benzene is observed to freeze at $4.3^{\circ} \mathrm{C}$. Calculate the molar mass of the solute and its molecular formula.
13.84 The molar mass of benzoic acid $\left(\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COOH}\right)$ determined by measuring the freezing-point depression in benzene is twice what we would expect for the molecular formula, $\mathrm{C}_{7} \mathrm{H}_{6} \mathrm{O}_{2}$. Explain this apparent anomaly.
13.85 A solution containing 0.8330 g of a polymer of unknown structure in 170.0 mL of an organic solvent was found to have an osmotic pressure of 5.20 mmHg at $25^{\circ} \mathrm{C}$. Determine the molar mass of the polymer.
13.86 A quantity of 7.480 g of an organic compound is dissolved in water to make 300.0 mL of solution. The solution has an osmotic pressure of 1.43 atm at $27^{\circ} \mathrm{C}$. The analysis of this compound shows that it contains 41.8 percent $\mathrm{C}, 4.7$ percent H , 37.3 percent O , and 16.3 percent N . Calculate the molecular formula of the compound.
13.87 A solution of 6.85 g of a carbohydrate in 100.0 g of water has a density of $1.024 \mathrm{~g} / \mathrm{mL}$ and an osmotic pressure of 4.61 atm at $20.0^{\circ} \mathrm{C}$. Calculate the molar mass of the carbohydrate.
13.88 A 0.036 M aqueous nitrous acid $\left(\mathrm{HNO}_{2}\right)$ solution has an osmotic pressure of 0.93 atm at $25^{\circ} \mathrm{C}$. Calculate the percent ionization of the acid.
13.89 A $0.100 M$ aqueous solution of the base HB has an osmotic pressure of 2.83 atm at $25^{\circ} \mathrm{C}$. Calculate the percent ionization of the base.

## Section 13.7: Colloids

## Review Questions

13.90 What are colloids? Referring to Table 13.5, why is there no colloid in which both the dispersed phase and the dispersing medium are gases?
13.91 Describe how hydrophilic and hydrophobic colloids are stabilized in water.
13.92 Describe and give an everyday example of the Tyndall effect.

## Additional Problems

113.93 Lysozyme is an enzyme that cleaves bacterial cell walls. A sample of lysozyme extracted from egg white has a molar mass of $13,930 \mathrm{~g}$. A quantity of 0.100 g of this enzyme is dissolved in

150 g of water at $25^{\circ} \mathrm{C}$. Calculate the vapor-pressure lowering, the depression in freezing point, the elevation in boiling point, and the osmotic pressure of this solution. (The vapor pressure of water at $25^{\circ} \mathrm{C}$ is 23.76 mmHg .)
13.94 Solutions A and B have osmotic pressures of 2.4 and 4.6 atm , respectively, at a certain temperature. What is the osmotic pressure of a solution prepared by mixing equal volumes of A and $B$ at the same temperature?
13.95 The blood sugar (glucose) level of a diabetic patient is approximately 0.140 g of glucose $/ 100 \mathrm{~mL}$ of blood. Every time the patient ingests 40 g of glucose, her blood glucose level rises to approximately $0.240 \mathrm{~g} / 100 \mathrm{~mL}$ of blood. Calculate the number of moles of glucose per milliliter of blood and the total number of moles and grams of glucose in the blood before and after consumption of glucose. (Assume that the total volume of blood in her body is 5.0 L .)
13.96 Trees in cold climates may be subjected to temperatures as low as $-60^{\circ} \mathrm{C}$. Estimate the concentration of an aqueous solution in the body of the tree that would remain unfrozen at this temperature. Is this a reasonable concentration? Comment on your result.
13.97 A cucumber placed in concentrated brine (saltwater) shrivels into a pickle. Explain.
E 13.98 Two liquids A and B have vapor pressures of 76 and 132 mmHg , respectively, at $25^{\circ} \mathrm{C}$. What is the total vapor pressure of the ideal solution made up of (a) 1.00 mole of A and 1.00 mole of B and (b) 2.00 moles of A and 5.00 moles of B ?
© 13.99 Determine the van't Hoff factor of $\mathrm{Na}_{3} \mathrm{PO}_{4}$ in a 0.40 m solution whose freezing point is $-2.6^{\circ} \mathrm{C}$.

G13.100 A $262-\mathrm{mL}$ sample of a sugar solution containing 1.22 g of the sugar has an osmotic pressure of 30.3 mmHg at $35^{\circ} \mathrm{C}$. What is the molar mass of the sugar?
G13.101 Consider the three mercury manometers shown in the diagram. One of them has 1 mL of water on top of the mercury, another has 1 mL of a $1 m$ urea solution on top of the mercury, and the third one has 1 mL of a 1 m NaCl solution placed on top of the mercury. Which of these solutions is in the tube labeled X , which is in Y , and which is in Z ?

13.102 A forensic chemist is given a white powder for analysis. She dissolves 0.50 g of the substance in 8.0 g of benzene. The solution freezes at $3.9^{\circ} \mathrm{C}$. Can the chemist conclude that the compound is cocaine $\left(\mathrm{C}_{17} \mathrm{H}_{21} \mathrm{NO}_{4}\right)$ ? What assumptions are made in the analysis?
$\boldsymbol{\$ 1 3 . 1 0 3}$ "Time-release" drugs have the advantage of releasing the drug to the body at a constant rate so that the drug concentration at any time is not too high as to have harmful side effects or too low as to be ineffective. A schematic diagram of a pill that works on this basis is shown. Explain how it works.

13.104 A solution of 1.00 g of anhydrous aluminum chloride $\left(\mathrm{AlCl}_{3}\right)$ in 50.0 g of water freezes at $-1.11^{\circ} \mathrm{C}$. Does the molar mass determined from this freezing point agree with that calculated from the formula? Why?
13.105 Explain why reverse osmosis is (theoretically) more desirable as a desalination method than distillation or freezing. What minimum pressure must be applied to seawater at $25^{\circ} \mathrm{C}$ for reverse osmosis to occur? (Treat seawater as a 0.70 M NaCl solution.)

E13.106 What masses of sodium chloride, magnesium chloride, sodium sulfate, calcium chloride, potassium chloride, and sodium bicarbonate are needed to produce 1 L of artificial seawater for an aquarium? The required ionic concentrations are $[\mathrm{Na}+]=$ $2.56 \mathrm{M},[\mathrm{K}+]=0.0090 \mathrm{M},\left[\mathrm{Mg}^{2+}\right]=0.054 \mathrm{M},\left[\mathrm{Ca}^{2+}\right]=$ $0.010 \mathrm{M},\left[\mathrm{HCO}_{3}^{-}\right]=0.0020 \mathrm{M},\left[\mathrm{Cl}^{-}\right]=2.60 \mathrm{M},\left[\mathrm{SO}_{4}^{2-}\right]=$ 0.051 M.
13.107 The osmotic pressure of blood plasma is approximately 7.5 atm at $37^{\circ} \mathrm{C}$. Estimate the total concentration of dissolved species and the freezing point of blood.

E 13.108 The antibiotic gramicidin A can transport $\mathrm{Na}^{+}$ions into a certain cell at the rate of $5.0 \times 10^{7} \mathrm{Na}^{+}$ions/channel $\cdot$ s. Calculate the time in seconds to transport enough $\mathrm{Na}^{+}$ions to increase its concentration by $8.0 \times 10^{-3} M$ in a cell whose intracellular volume is $2.0 \times 10^{-10} \mathrm{~mL}$.
13.109 A protein has been isolated as a salt with the formula $\mathrm{Na}_{20} \mathrm{P}$ (this notation means that there are $20 \mathrm{Na}^{+}$ions associated with a negatively charged protein $\mathrm{P}^{20-}$ ). The osmotic pressure of a $10.0-\mathrm{mL}$ solution containing 0.225 g of the protein is 0.257 atm at $25.0^{\circ} \mathrm{C}$. (a) Calculate the molar mass of the protein from these data. (b) Calculate the actual molar mass of the protein.

G13.110 A nonvolatile organic compound Z was used to make up two solutions. Solution A contains 5.00 g of Z dissolved in 100 g of water, and solution B contains 2.31 g of $Z$ dissolved in 100 g of benzene. Solution A has a vapor pressure of 754.5 mmHg at the normal boiling point of water, and solution $B$ has the same vapor pressure at the normal boiling point of benzene. Calculate the molar mass of Z in solutions A and B , and account for the difference.

C13.111 Hydrogen peroxide with a concentration of $3.0 \%$ ( 3.0 g of $\mathrm{H}_{2} \mathrm{O}_{2}$ in 100 mL of solution) is sold in drugstores for use as an antiseptic. For a $10.0-\mathrm{mL} 3.0 \% \mathrm{H}_{2} \mathrm{O}_{2}$ solution, calculate (a) the oxygen gas produced (in liters) at STP when the compound undergoes complete decomposition and (b) the ratio of the volume of $\mathrm{O}_{2}$ collected to the initial volume of the $\mathrm{H}_{2} \mathrm{O}_{2}$ solution.
13.112 State which of the alcohols listed in Problem 13.12 you would expect to be the best solvent for each of the following substances, and explain why: (a) $\mathrm{I}_{2}$, (b) KBr , (c) $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3}$.
13.113 Before a carbonated beverage bottle is sealed, it is pressurized with a mixture of air and carbon dioxide. (a) Explain the effervescence that occurs when the cap of the bottle is removed. (b) What causes the fog to form near the mouth of the bottle right after the cap is removed?
13.114 Iodine $\left(\mathrm{I}_{2}\right)$ is only sparingly soluble in water (above left photo). Yet upon the addition of iodide ions (for example, from KI), iodine is converted to the triiodide ion, which readily dissolves (above right photo):

$$
\mathrm{I}_{2}(s)+\mathrm{I}^{-}(a q) \rightleftarrows \mathrm{I}_{3}^{-}(a q)
$$

Describe the change in solubility of $\mathrm{I}_{2}$ in terms of the change in intermolecular forces.

13.115 (a) The root cells of plants contain a solution that is hypertonic in relation to water in the soil. Thus, water can move into the roots by osmosis. Explain why salts such as NaCl and $\mathrm{CaCl}_{2}$ spread on roads to melt ice can be harmful to nearby trees. (b) Just before urine leaves the human body, the collecting ducts in the kidney (which contain the urine) pass through a fluid whose salt concentration is considerably greater than is found in the blood and tissues. Explain how this action helps conserve water in the body.

E 13.116 Hemoglobin, the oxygen-transport protein, binds about 1.35 mL of oxygen per gram of the protein. The concentration of hemoglobin in normal blood is $150 \mathrm{~g} / \mathrm{L}$ blood. Hemoglobin is about 95 percent saturated with $\mathrm{O}_{2}$ in the lungs and only 74 percent saturated with $\mathrm{O}_{2}$ in the capillaries. Calculate the volume of $\mathrm{O}_{2}$ released by hemoglobin when 100 mL of blood flows from the lungs to the capillaries.

G13.117 Two beakers, one containing a $50-\mathrm{mL}$ aqueous 1.0 M glucose solution and the other a $50-\mathrm{mL}$ aqueous 2.0 M glucose solution, are placed under a tightly sealed bell jar at room temperature. What are the volumes in these two beakers at equilibrium?
13.118 In the apparatus shown, what will happen if the membrane is
(a) permeable to both water and the $\mathrm{Na}^{+}$and $\mathrm{Cl}^{-}$ions,
(b) permeable to water and the $\mathrm{Na}^{+}$ions but not to the $\mathrm{Cl}^{-}$ions,
(c) permeable to water but not to the $\mathrm{Na}^{+}$and $\mathrm{Cl}^{-}$ions?

13.119 Concentrated hydrochloric acid is usually available at a concentration of 37.7 percent by mass. What is its molar concentration? (The density of the solution is $1.19 \mathrm{~g} / \mathrm{mL}$.)
13.120 Explain each of the following statements: (a) The boiling point of seawater is higher than that of pure water. (b) Carbon dioxide escapes from the solution when the cap is removed from a carbonated soft drink bottle. (c) Molal and molar concentrations of dilute aqueous solutions are approximately equal. (d) In discussing the colligative properties of a solution (other than osmotic pressure), it is preferable to express the concentration in units of molality rather than in molarity. (e) Methanol (b.p. $65^{\circ} \mathrm{C}$ ) is useful as an antifreeze, but it should be removed from the car radiator during the summer season.
$\leftrightarrows$ 13.121 A mixture of NaCl and sucrose $\left(\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{12}\right)$ of combined mass 10.2 g is dissolved in enough water to make up a $250-\mathrm{mL}$ solution. The osmotic pressure of the solution is 7.32 atm at $23^{\circ} \mathrm{C}$. Calculate the mass percent of NaCl in the mixture.

I 13.122 A 1.32-g sample of a mixture of cyclohexane $\left(\mathrm{C}_{6} \mathrm{H}_{12}\right)$ and naphthalene $\left(\mathrm{C}_{10} \mathrm{H}_{8}\right)$ is dissolved in 18.9 g of benzene $\left(\mathrm{C}_{6} \mathrm{H}_{6}\right)$. The freezing point of the solution is $2.2^{\circ} \mathrm{C}$. Calculate the mass percent of the mixture. (See Table 13.2 for constants.)
13.123 How does each of the following affect the solubility of an ionic compound: (a) lattice energy, (b) solvent (polar versus nonpolar), (c) enthalpies of hydration of cation and anion?
13.124 A solution contains two volatile liquids A and B. Complete the following table, in which the symbol $\longleftrightarrow$ indicates attractive intermolecular forces.

| Attractive Forces | Deviation from <br> Raoult's Law | $\boldsymbol{\Delta} \boldsymbol{H}_{\text {soln }}$ |
| :--- | :--- | :---: |
| $\mathrm{A} \longleftrightarrow \mathrm{A}, \mathrm{B} \longleftrightarrow \mathrm{B}>$ |  |  |
| $\mathrm{A} \longleftrightarrow \mathrm{B}$ |  |  |
|  | Negative |  |
|  |  | Zero |

$\boldsymbol{\Psi}$ 13.125 The concentration of commercially available concentrated nitric acid is 70.0 percent by mass, or 15.9 M . Calculate the density and the molality of the solution.

E 13.126 A mixture of ethanol and 1-propanol behaves ideally at $36^{\circ} \mathrm{C}$ and is in equilibrium with its vapor. If the mole fraction of ethanol in the solution is 0.62 , calculate its mole fraction in the vapor phase at this temperature. (The vapor pressures of pure ethanol and 1-propanol at $36^{\circ} \mathrm{C}$ are 108 and 40.0 mmHg , respectively.)
13.127 Ammonia $\left(\mathrm{NH}_{3}\right)$ is very soluble in water, but nitrogen trichloride $\left(\mathrm{NCl}_{3}\right)$ is not. Explain.
13.128 For ideal solutions, the volumes are additive. This means that if 5 mL of A and 5 mL of B form an ideal solution, the volume of the solution is 10 mL . Provide a molecular interpretation for this observation. When 500 mL of ethanol $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right)$ is mixed with 500 mL of water, the final volume is less than 1000 mL . Why?

E13.129 Acetic acid is a weak acid that ionizes in solution as follows:

$$
\mathrm{CH}_{3} \mathrm{COOH}(a q) \rightleftarrows \mathrm{CH}_{3} \mathrm{COO}^{-}(a q)+\mathrm{H}^{+}(a q)
$$

If the freezing point of a $0.106 \mathrm{~m} \mathrm{CH}_{3} \mathrm{COOH}$ solution is $-0.203^{\circ} \mathrm{C}$, calculate the percent of the acid that has undergone ionization.
13.130 Aluminum sulfate $\left[\mathrm{Al}_{2}\left(\mathrm{SO}_{4}\right)_{3}\right]$ is sometimes used in municipal water treatment plants to remove undesirable particles. Explain how this process works.
13.131 Making mayonnaise involves beating oil into small droplets in water, in the presence of egg yolk. What is the purpose of the egg yolk? (Hint: Egg yolk contains lecithins, which are molecules with a polar head and a long nonpolar hydrocarbon tail.)

H13.132 Acetic acid is a polar molecule and can form hydrogen bonds with water molecules. Therefore, it has a high solubility in water. Yet acetic acid is also soluble in benzene $\left(\mathrm{C}_{6} \mathrm{H}_{6}\right)$, a nonpolar solvent that lacks the ability to form hydrogen bonds. A solution of 3.8 g of $\mathrm{CH}_{3} \mathrm{COOH}$ in $80 \mathrm{~g} \mathrm{C}_{6} \mathrm{H}_{6}$ has a freezing point of $3.5^{\circ} \mathrm{C}$. Calculate the molar mass of the solute, and suggest what its structure might be. (Hint: Acetic acid molecules can form hydrogen bonds between themselves.)
$\leftrightarrows 13.133$ A 2.6-L sample of water contains $192 \mu \mathrm{~g}$ of lead. Does this concentration of lead exceed the safety limit of 0.050 ppm of lead per liter of drinking water?
13.134 Fish in the Antarctic Ocean swim in water at about $-2^{\circ} \mathrm{C}$. (a) To prevent their blood from freezing, what must be the concentration (in molality) of the blood? Is this a reasonable physiological concentration? (b) In recent years, scientists have discovered a special type of protein in the blood of these fish
that, although present in quite low concentrations $(\leq 0.001 \mathrm{~m})$, has the ability to prevent the blood from freezing. Suggest a mechanism for its action.

13.135 Why are ice cubes (for example, those you see in the trays in the freezer of a refrigerator) cloudy inside?
13.136 If a soft drink can is shaken and then opened, the drink escapes violently. However, if after shaking the can, we tap it several times with a metal spoon, no such "explosion" of the drink occurs. Why?
13.137 Two beakers are placed in a closed container. Beaker A initially contains 0.15 mole of naphthalene $\left(\mathrm{C}_{10} \mathrm{H}_{8}\right)$ in 100 g of benzene $\left(\mathrm{C}_{6} \mathrm{H}_{6}\right)$, and beaker B initially contains 31 g of an unknown compound dissolved in 100 g of benzene. At equilibrium, beaker A is found to have lost 7.0 g of benzene. Assuming ideal behavior, calculate the molar mass of the unknown compound. State any assumptions made.
13.138 (a) Derive the equation relating the molality $(m)$ of a solution to its molarity ( $M$ )

$$
m=\frac{M}{d-\frac{M M}{1000}}
$$

where $d$ is the density of the solution $(\mathrm{g} / \mathrm{mL})$ and $\mathcal{M}$ is the molar mass of the solute $(\mathrm{g} / \mathrm{mol})$. (Hint: Start by expressing the solvent in kilograms in terms of the difference between the mass of the solution and the mass of the solute.) (b) Show that, for dilute aqueous solutions, $m$ is approximately equal to $M$.
13.139 At $27^{\circ} \mathrm{C}$, the vapor pressure of pure water is 23.76 mmHg and that of an aqueous solution of urea is 22.98 mmHg . Calculate the molality of urea in the solution.
13.140 A very long pipe is capped at one end with a semipermeable membrane. How deep (in meters) must the pipe be immersed into the sea for fresh water to begin to pass through the membrane? Assume the water to be at $20^{\circ} \mathrm{C}$, and treat it as a 0.70 M NaCl solution. The density of seawater is $1.03 \mathrm{~g} / \mathrm{cm}^{3}$, and the acceleration due to gravity is $9.81 \mathrm{~m} / \mathrm{s}^{2}$.

G13.141 A mixture of liquids A and B exhibits ideal behavior. At $84^{\circ} \mathrm{C}$, the total vapor pressure of a solution containing 1.2 moles of A and 2.3 moles of B is 331 mmHg . Upon the addition of another mole of B to the solution, the vapor pressure increases to 347 mmHg . Calculate the vapor pressure of pure A and B at $84^{\circ} \mathrm{C}$.
13.142 Use Henry's law and the ideal gas equation to prove the statement that the volume of a gas that dissolves in a given amount of solvent is independent of the pressure of the gas. (Hint: Henry's law can be modified as $n=k P$, where $n$ is the number of moles of the gas dissolved in the solvent.)
$\leftrightarrows$ 13.143 At 298 K , the osmotic pressure of a glucose solution is 10.50 atm . Calculate the freezing point of the solution. The density of the solution is $1.16 \mathrm{~g} / \mathrm{mL}$.
13.144 Valinomycin is an antibiotic. It functions by binding $\mathrm{K}^{+}$ions and transporting them across the membrane into cells to offset the ionic balance. The molecule is represented here by its skeletal structure in which the end of each straight line corresponds to
a carbon atom (unless a different atom is shown at the end of the line). There are as many H atoms attached to each C atom as necessary to give each C atom a total of four bonds. Using the "like dissolves like" principle, explain how the molecule functions. (Hint: The $-\mathrm{CH}_{3}$ groups at the two ends of each Y shape are nonpolar.)

13.145 The diagram here shows vapor pressure curves for pure benzene and a solution of a nonvolatile solute in benzene. Estimate the molality of the solution.

## Pre-Professional Practice Exam Problems: Physical and Biological Sciences

A mixture of two volatile liquids is said to be ideal if each component obeys Raoult's law:

$$
P_{\mathrm{i}}=\chi_{\mathrm{i}} P_{\mathrm{i}}^{\circ}
$$

Two volatile liquids A (molar mass $100 \mathrm{~g} / \mathrm{mol}$ ) and B (molar mass $110 \mathrm{~g} /$ mol ) form an ideal solution. At $55^{\circ} \mathrm{C}$, A has a vapor pressure of 98 mmHg and $B$ has a vapor pressure of 42 mmHg . A solution is prepared by mixing equal masses of $A$ and $B$.

1. Calculate the mole fraction of each component in the solution.
a) $\chi_{\mathrm{A}}=0.50, \chi_{\mathrm{B}}=0.50$
b) $\chi_{\mathrm{A}}=0.52, \chi_{\mathrm{B}}=0.48$
c) $\chi_{\mathrm{A}}=1.0, \chi_{\mathrm{B}}=0.91$
d) $\chi_{\mathrm{A}}=0.09, \chi_{\mathrm{B}}=0.91$
2. Calculate the partial pressures of A and B over the solution at $55^{\circ} \mathrm{C}$.
a) $P_{\mathrm{A}}=98 \mathrm{mmHg}, P_{\mathrm{B}}=42 \mathrm{mmHg}$
b) $P_{\mathrm{A}}=49 \mathrm{mmHg}, P_{\mathrm{B}}=21 \mathrm{mmHg}$
c) $P_{\mathrm{A}}=70 \mathrm{mmHg}, P_{\mathrm{B}}=70 \mathrm{mmHg}$
d) $P_{\mathrm{A}}=51 \mathrm{mmHg}, P_{\mathrm{B}}=20 \mathrm{mmHg}$
3. Suppose that some of the vapor over the solution at $55^{\circ} \mathrm{C}$ is condensed to a liquid. Calculate the mole fraction of each component in the condensed liquid.
a) $\chi_{\mathrm{A}}=0.50, \chi_{\mathrm{B}}=0.50$
b) $\chi_{\mathrm{A}}=0.52, \chi_{\mathrm{B}}=0.48$
c) $\chi_{\mathrm{A}}=0.72, \chi_{\mathrm{B}}=0.28$
d) $\chi_{\mathrm{A}}=1.0, \chi_{\mathrm{B}}=0.86$
4. Calculate the partial pressures of the components above the condensed liquid at $55^{\circ} \mathrm{C}$.
a) $P_{\mathrm{A}}=98 \mathrm{mmHg}, P_{\mathrm{B}}=42 \mathrm{mmHg}$
b) $P_{\mathrm{A}}=30 \mathrm{mmHg}, P_{\mathrm{B}}=27 \mathrm{mmHg}$
c) $P_{\mathrm{A}}=71 \mathrm{mmHg}, P_{\mathrm{B}}=12 \mathrm{mmHg}$
d) $P_{\mathrm{A}}=72 \mathrm{mmHg}, P_{\mathrm{B}}=28 \mathrm{mmHg}$

## How Relative Rates of Chemical Reactions Have Been Used to Save Lives

The medical community sometimes uses the relative speeds at which reactions occur to benefit a patient who has ingested a poison, such as methanol. Accidental or intentional ingestion of methanol can cause headache, nausea, blindness, seizures, and even death. In the liver, methanol is metabolized by the enzyme alcohol dehydrogenase (ADH) to yield formaldehyde:

$$
\underset{\text { methanol }}{\mathrm{CH}_{3} \mathrm{OH}}+\mathrm{NAD}^{+} \longrightarrow \underset{\text { formaldehyde }}{\mathrm{HCHO}}+\mathrm{NADH}+\mathrm{H}^{+}
$$

The formaldehyde is subsequently converted to formic acid by another enzyme, aldehyde dehydrogenase (ALDH).

Formaldehyde and formic acid are the species responsible for the toxic effects of methanol poisoning-including metabolic acidosis, in which the blood becomes dangerously acidic.

To treat methanol poisoning, we must prevent ADH from metabolizing any more methanol. Historically, this has been done by administering large quantities of ethanol, which has an affinity for ADH of roughly 100 times that of methanol, making the reaction of ADH with ethanol significantly faster than the reaction with methanol. In this treatment, while the body's supply of ADH is busy converting ethanol to acetaldehyde (a reaction analogous to the conversion of methanol to formaldehyde), the methanol is removed from the body by dialysis. This treatment is not without complications, however, as the quantity of ethanol required typically causes significant inebriation and central nervous system (CNS) depression. The metabolic products of ethanol (acetaldehyde and acetic acid) are also toxic-although generally to a lesser degree than those of methanol. In fact, acetaldehyde is the species responsible for the collection of symptoms known as a hangover.

In 2000, the FDA approved the drug fomepizole, marketed under the name Antizol, for the treatment of methanol poisoning. Fomepizole $\left(\mathrm{C}_{4} \mathrm{H}_{6} \mathrm{~N}_{2}\right)$ has an affinity for ADH approximately 8000 times that of methanol and is used to treat methanol toxicity without the intoxication and CNS depression caused by ethanol. Dialysis is still used to remove methanol from the blood.

Understanding chemical kinetics can make it possible to minimize the damage done by undesirable reactions. It also enables us to enhance the speed of desirable reactions.

Student Annotation: NAD ${ }^{+}$and NADH are, respectively, the oxidized and reduced forms of nicotinamide adenine dinucleotide, an electron carrier in metabolic oxidation.

Student Annotation: NADP ${ }^{+}$and NADPH are the oxidized and reduced forms of nicotinamide adenine dinucleotide with an added phosphate group.

At the end of this chapter, you will be able to solve a series of problems related to the kinetics of methanol production [ $\quad$ Page 616].

## In This Chapter, You Will Learn:

How rates of chemical reaction are determined and expressed and about the factors that influence the rates of reactions.

## Before you begin, you should review

- The value of $R$ expressed in $\mathrm{J} / \mathrm{mol}$ [ Kt Section 11.3, Table 11.4]
- Use of logarithms [ $\boldsymbol{H}$ Appendix 1]

### 14.1 Reaction Rates

Chemical kinetics is the study of how fast reactions take place. Many familiar reactions, such as the initial steps in vision and photosynthesis happen almost instantaneously, whereas others, such as the rusting of iron or the conversion of diamond to graphite, take place on a timescale of days or even millions of years.

Knowledge of kinetics is important to many scientific endeavors, including drug design, pollution control, and food processing. The job of an industrial chemist often is to work on increasing the rate of a reaction rather than maximizing its yield or developing a new process.

A chemical reaction can be represented by the general equation

$$
\text { reactants } \longrightarrow \text { products }
$$

This equation tells us that during the course of a reaction, reactants are consumed while products are formed. We can follow the progress of a reaction by monitoring either the decrease in concentration of the reactants or the increase in the concentrations of the products. The method used to monitor changes in reactant or product concentrations depends on the specific reaction. In a reaction that either consumes or produces a colored species, we can measure the intensity of the color over time with a spectrometer. In a reaction that either consumes or produces a gas, we can measure the change in pressure over time with a manometer. Electrical conductance measurement can be used to monitor the progress if ionic species are consumed or produced.

## Average Reaction Rate

Consider the hypothetical reaction represented by

$$
\mathrm{A} \longrightarrow \mathrm{~B}
$$

in which A molecules are converted to B molecules. Figure 14.1 shows the progress of this reaction as a function of time.

The decrease in the number of A molecules and the increase in the number of B molecules with time are also shown in Figure 14.2. It is generally convenient to express the rate in terms of the change in concentration with time. Thus, for the reaction $A \longrightarrow B$, we can express the rate as

$$
\text { rate }=-\frac{\Delta[\mathrm{A}]}{\Delta t} \quad \text { or } \quad \text { rate }=\frac{\Delta[\mathrm{B}]}{\Delta t}
$$

where $\Delta[\mathrm{A}]$ and $\Delta[\mathrm{B}]$ are the changes in concentration (molarity) over a time period $\Delta t$. The rate expression containing $\Delta[\mathrm{A}]$ has a minus sign because the concentration of A decreases during the time interval-that is, $\Delta[\mathrm{A}]$ is a negative quantity. The rate expression containing $\Delta[\mathrm{B}]$ does not have a minus sign because the concentration of B increases during the time interval. Rate is always a positive quantity, so when it is expressed in terms of the change in a reactant concentration, a minus sign is needed in the rate expression to make the rate positive. When the rate is expressed in terms of the change in a product concentration, no negative sign is needed to make the rate positive because the product concentration increases with time. Rates calculated in this way are average rates over the time period $\Delta t$.

Figure 14.1 The progress of the reaction $\mathrm{A} \longrightarrow \mathrm{B}$. Initially, only A molecules (grey spheres) are present. As time progresses, there are more and more B molecules (red spheres).

To understand rates of chemical reactions and how they are determined, it is useful to consider some specific reactions. First, we consider the aqueous reaction of molecular bromine $\left(\mathrm{Br}_{2}\right)$ with formic acid $(\mathrm{HCOOH})$ :

$$
\mathrm{Br}_{2}(a q)+\mathrm{HCOOH}(a q) \longrightarrow 2 \mathrm{Br}^{-}(a q)+2 \mathrm{H}^{+}(a q)+\mathrm{CO}_{2}(g)
$$

Molecular bromine is reddish-brown, whereas all the other species in the reaction are colorless. As the reaction proceeds, the concentration of bromine decreases and its color fades (Figure 14.3). The decrease in intensity of the color (and, therefore in the concentration of bromine) can be monitored with a spectrometer, which registers the amount of visible light absorbed by bromine (Figure 14.4).

Measuring the bromine concentration at some initial time and then at some final time enables us to determine the average rate of the reaction during that time interval:

$$
\begin{aligned}
\text { average rate } & =-\frac{\Delta\left[\mathrm{Br}_{2}\right]}{\Delta t} \\
& =-\frac{\left[\mathrm{Br}_{2}\right]_{\text {final }}-\left[\mathrm{Br}_{2}\right]_{\text {initial }}}{t_{\text {final }}-t_{\text {initial }}}
\end{aligned}
$$

Figure 14.2 The rate of reaction $A \longrightarrow B$ represented as the decrease of A molecules with time and as the increase of B molecules with time.

Figure 14.3 From left to right: The decrease in bromine concentration as time elapses is indicated by the loss of color.

Figure 14.4 Plot of the absorption of bromine versus wavelength. The maximum absorption of visible light by bromine occurs at 393 nm . As the reaction progresses ( $t_{1}$ to $t_{3}$ ), the absorption, which is proportional to $\left[\mathrm{Br}_{2}\right]$, decreases.

bromine has been reduced by half (i.e., reduced to 0.00500 M ), at 250 s , the rate is also reduced by half (i.e., reduced to $1.75 \times 10^{-5} \mathrm{M} / \mathrm{s}$ ):

$$
\frac{\left[\mathrm{Br}_{2}\right]_{50 \mathrm{~s}}}{\left[\mathrm{Br}_{2}\right]_{250 \mathrm{~s}}} \approx 2 \quad \text { and } \quad \frac{\text { rate at } 50.0 \mathrm{~s}}{\text { rate at } 250.0 \mathrm{~s}}=\frac{3.52 \times 10^{-5} \mathrm{M} / \mathrm{s}}{1.75 \times 10^{-5} \mathrm{M} / \mathrm{s}} \approx 2
$$

Thus, the rate is directly proportional to the concentration of bromine:

$$
\begin{aligned}
& \text { rate } \propto\left[\mathrm{Br}_{2}\right] \\
& \text { rate }=k\left[\mathrm{Br}_{2}\right]
\end{aligned}
$$

where $k$, the proportionality constant, is called the rate constant.
Rearranging the preceding equation gives

$$
k=\frac{\text { rate }}{\left[\mathrm{Br}_{2}\right]}
$$

We can use the concentration and rate data from Table 14.1 for any value of $t$ to calculate the value of $k$ for this reaction. For example, using the data for $t=50.0 \mathrm{~s}$ gives

$$
k=\frac{3.52 \times 10^{-5} \mathrm{M} / \mathrm{s}}{0.0101 \mathrm{M}}=3.49 \times 10^{-3} \mathrm{~s}^{-1} \quad(\text { at } t=50.0 \mathrm{~s})
$$

Likewise, using the data for $t=300.0 \mathrm{~s}$ gives

$$
k=\frac{1.48 \times 10^{-5} \mathrm{M} / \mathrm{s}}{0.00420 \mathrm{M}}=3.52 \times 10^{-3} \mathrm{~s}^{-1} \quad(\text { at } t=300 \mathrm{~s})
$$

Slight variations in the calculated values of $k$ are due to experimental deviations in rate measurements. To two significant figures, we get $k=3.5 \times 10^{-3} \mathrm{~s}^{-1}$ for this reaction, regardless of which line of data we chose from Table 14.1. It is important to note that the value of $k$ does not depend on the concentration of bromine. The rate constant is constant at constant temperature. (In Section 14.4 we discuss how $k$ depends on temperature.)

We now consider another specific reaction, the decomposition of hydrogen peroxide:

$$
2 \mathrm{H}_{2} \mathrm{O}_{2}(a q) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{O}_{2}(g)
$$

Because one of the products is a gas, we can monitor the progress of this reaction by measuring the pressure with a manometer. Pressure is converted to concentration using the ideal gas equation:

$$
P V=n R T
$$

or

$$
P_{\mathrm{O}_{2}}=\frac{n}{V} R T=\left[\mathrm{O}_{2}\right] R T
$$

where $n / V$ gives the molarity of the oxygen gas. Rearranging the equation and solving for $\left[\mathrm{O}_{2}\right]$, we get

$$
\left[\mathrm{O}_{2}\right]=\frac{1}{R T} P_{\mathrm{O}_{2}}
$$

Figure 14.6 The instantaneous rates of the reaction between molecular bromine and formic acid at $t=100$, 200 , and 300 s are given by the slopes of the tangents at these times.

Figure 14.7 (a) The rate of hydrogen peroxide decomposition can be measured with a manometer, which (b) shows the increase in the oxygen gas pressure with time.

Student Annotation: Many students prefer simply to convert pressures to concentrations using the ideal gas equation [ 14 Section 11.3] and then determine the rate using the familiar form of the equation: rate $=\Delta\left[\mathrm{O}_{2}\right] / \Delta t$.

(a)

(b)

The reaction rate, which is expressed as the rate of oxygen production, can now be written as

$$
\text { rate }=\frac{\Delta\left[\mathrm{O}_{2}\right]}{\Delta t}=\frac{1}{R T} \frac{\Delta P_{\mathrm{O}_{2}}}{\Delta t}
$$

Determining the rate from pressure data is possible only if the temperature (in kelvins) at which the reaction is carried out is known. Figure 14.7 (a) shows the apparatus used to monitor the pressure change in the decomposition of hydrogen peroxide. Figure 14.7(b) shows the plot of oxygen pressure, $P_{\mathrm{O}_{2}}$, versus time. As we did in Figure 14.6, we can draw a tangent to the curve in Figure 14.7(b) to determine the instantaneous rate at any point.

## Stoichiometry and Reaction Rate

For stoichiometrically simple reactions of the type $\mathrm{A} \longrightarrow \mathrm{B}$, the rate can be expressed either in terms of the decrease in reactant concentration with time, $-\Delta[\mathrm{A}] / \Delta t$, or in terms of the increase in product concentration with time, $\Delta[\mathrm{B}] / \Delta t$-both expressions give the same result. For reactions in which one or more of the stoichiometric coefficients is something other than 1 , we must take extra care in expressing the rate. For example, consider again the reaction between molecular bromine and formic acid:

$$
\mathrm{Br}_{2}(a q)+\mathrm{HCOOH}(a q) \longrightarrow 2 \mathrm{Br}^{-}(a q)+2 \mathrm{H}^{+}(a q)+\mathrm{CO}_{2}(g)
$$

We have expressed the rate of this reaction in terms of the disappearance of bromine. But what if we chose instead to express the rate in terms of the appearance of bromide ion? According to the balanced equation, 2 moles of $\mathrm{Br}^{-}$are generated for each mole of $\mathrm{Br}_{2}$ consumed. Thus, $\mathrm{Br}^{-}$ appears at twice the rate that $\mathrm{Br}_{2}$ disappears. To avoid the potential ambiguity of reporting the rate of disappearance or appearance of a specific chemical species, we report the rate of reaction. We determine the rate of reaction such that the result is the same regardless of which species we monitor. For the hypothetical reaction,

$$
\mathrm{A} \longrightarrow 2 \mathrm{~B}
$$

the rate of reaction can be written as either

$$
\text { rate }=-\frac{\Delta[\mathrm{A}]}{\Delta t} \quad \text { or } \quad \text { rate }=\frac{1}{2} \frac{\Delta[\mathrm{~B}]}{\Delta t}
$$

both of which give the same result. For the bromine and formic acid reaction, we can write the rate of reaction as either

$$
\text { rate }=-\frac{\Delta\left[\mathrm{Br}_{2}\right]}{\Delta t}
$$

as we did earlier, or

$$
\text { rate }=\frac{1}{2} \frac{\Delta\left[\mathrm{Br}^{-}\right]}{\Delta t}
$$

In general, for the reaction

$$
a \mathrm{~A}+b \mathrm{~B} \longrightarrow c \mathrm{C}+d \mathrm{D}
$$

the rate is given by

$$
\text { rate }=-\frac{1}{a} \frac{\Delta[\mathrm{~A}]}{\Delta t}=-\frac{1}{b} \frac{\Delta[\mathrm{~B}]}{\Delta t}=\frac{1}{c} \frac{\Delta[\mathrm{C}]}{\Delta t}=\frac{1}{d} \frac{\Delta[\mathrm{D}]}{\Delta t}
$$

Equation 14.1

Expressing the rate in this fashion ensures that the rate of reaction is the same regardless of which species we measure to monitor the reaction's progress.

Sample Problems 14.1 and 14.2 show how to write expressions for reaction rates and how to take stoichiometry into account in rate expressions.

## Sample Problem 14.1

Write the rate expressions for each of the following reactions:
(a) $\mathrm{I}^{-}(a q)+\mathrm{OCl}^{-}(a q) \longrightarrow \mathrm{Cl}^{-}(a q)+\mathrm{OI}^{-}(a q)$
(b) $2 \mathrm{O}_{3}(\mathrm{~g}) \longrightarrow 3 \mathrm{O}_{2}(\mathrm{~g})$
(c) $4 \mathrm{NH}_{3}(g)+5 \mathrm{O}_{2}(g) \longrightarrow 4 \mathrm{NO}(g)+6 \mathrm{H}_{2} \mathrm{O}(g)$

Strategy Use Equation 14.1 to write rate expressions for each of the reactions.
Setup For reactions containing gaseous species, progress is generally monitored by measuring pressure. Pressures are converted to molar concentrations using the ideal gas equation, and rate expressions are written in terms of molar concentrations.

Solution (a) All the coefficients in this equation are 1. Therefore,

$$
\text { rate }=-\frac{\Delta\left[\mathrm{I}^{-}\right]}{\Delta t}=-\frac{\Delta\left[\mathrm{OCl}^{-}\right]}{\Delta t}=\frac{\Delta\left[\mathrm{Cl}^{-}\right]}{\Delta t}=\frac{\Delta\left[\mathrm{OI}^{-}\right]}{\Delta t}
$$

(b) rate $=-\frac{1}{2} \frac{\Delta\left[\mathrm{O}_{3}\right]}{\Delta t}=\frac{1}{3} \frac{\Delta\left[\mathrm{O}_{2}\right]}{\Delta t}$
(c) rate $=-\frac{1}{4} \frac{\Delta\left[\mathrm{NH}_{3}\right]}{\Delta t}=-\frac{1}{5} \frac{\Delta\left[\mathrm{O}_{2}\right]}{\Delta t}=\frac{1}{4} \frac{\Delta[\mathrm{NO}]}{\Delta t}=\frac{1}{6} \frac{\Delta\left[\mathrm{H}_{2} \mathrm{O}\right]}{\Delta t}$

Practice Problem A Write the rate expressions for each of the following reactions:
(a) $\mathrm{CO}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(g) \longrightarrow \mathrm{CH}_{4}(g)+2 \mathrm{O}_{2}(g)$
(b) $3 \mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{O}_{3}(\mathrm{~g})$
(c) $2 \mathrm{NO}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{NO}_{2}(g)$
$\mathbb{H}$ Practice Problem B Write the balanced equation corresponding to the following rate expressions:
(a) rate $=-\frac{1}{3} \frac{\Delta\left[\mathrm{CH}_{4}\right]}{\Delta t}=-\frac{1}{2} \frac{\Delta\left[\mathrm{H}_{2} \mathrm{O}\right]}{\Delta t}=-\frac{\Delta\left[\mathrm{CO}_{2}\right]}{\Delta t}=\frac{1}{4} \frac{\Delta\left[\mathrm{CH}_{3} \mathrm{OH}\right]}{\Delta t}$
(b) rate $=-\frac{1}{2} \frac{\Delta\left[\mathrm{~N}_{2} \mathrm{O}_{5}\right]}{\Delta t}=\frac{1}{2} \frac{\Delta\left[\mathrm{~N}_{2}\right]}{\Delta t}=\frac{1}{5} \frac{\Delta\left[\mathrm{O}_{2}\right]}{\Delta t}$
(c) rate $=-\frac{\Delta\left[\mathrm{H}_{2}\right]}{\Delta t}=-\frac{\Delta[\mathrm{CO}]}{\Delta t}=-\frac{\Delta\left[\mathrm{O}_{2}\right]}{\Delta t}=\frac{\Delta\left[\mathrm{H}_{2} \mathrm{CO}_{3}\right]}{\Delta t}$

## Sample Problem 14.2

Consider the reaction

$$
4 \mathrm{NO}_{2}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{~N}_{2} \mathrm{O}_{5}(g)
$$

At a particular time during the reaction, nitrogen dioxide is being consumed at the rate of $0.00130 \mathrm{M} / \mathrm{s}$. (a) At what rate is molecular oxygen being consumed? (b) At what rate is dinitrogen pentoxide being produced?

Strategy Determine the rate of reaction using Equation 14.1, and, using the stoichiometry of the reaction, convert to rates of change for the specified individual species.

Student Annotation: The rate of change in concentration of each species is divided by the coefficient of that species in the balanced equation.

Think About It Make sure that the change in concentration of each species is divided by the corresponding coefficient in the balanced equation. Also make sure that the rate expressions written in terms of reactant concentrations have a negative sign to make the resulting rate positive.

Think About It Remember that the negative sign in a rate expression indicates that a species is being consumed rather than produced. Rates are always expressed as positive quantities.

## Setup

$$
\text { rate }=-\frac{1}{4} \frac{\Delta\left[\mathrm{NO}_{2}\right]}{\Delta t}=-\frac{\Delta\left[\mathrm{O}_{2}\right]}{\Delta t}=\frac{1}{2} \frac{\Delta\left[\mathrm{~N}_{2} \mathrm{O}_{5}\right]}{\Delta t}
$$

We are given

$$
\frac{\Delta\left[\mathrm{NO}_{2}\right]}{\Delta t}=-0.0013 \mathrm{M} / \mathrm{s}
$$

where the minus sign indicates that the concentration of $\mathrm{NO}_{2}$ is decreasing with time. The rate of reaction, therefore, is

$$
\begin{aligned}
\text { rate } & =-\frac{1}{4} \frac{\Delta\left[\mathrm{NO}_{2}\right]}{\Delta t}=-\frac{1}{4}(-0.0013 \mathrm{M} / \mathrm{s}) \\
& =3.25 \times 10^{-4} \mathrm{M} / \mathrm{s}
\end{aligned}
$$

Solution (a) $3.25 \times 10^{-4} \mathrm{M} / \mathrm{s}=-\frac{\Delta\left[\mathrm{O}_{2}\right]}{\Delta t}$

$$
\frac{\Delta\left[\mathrm{O}_{2}\right]}{\Delta t}=-3.25 \times 10^{-4} \mathrm{M} / \mathrm{s}
$$

Molecular oxygen is being consumed at a rate of $3.25 \times 10^{-4} \mathrm{M} / \mathrm{s}$.
(b) $3.25 \times 10^{-4} \mathrm{M} / \mathrm{s}=\frac{1}{2} \frac{\Delta\left[\mathrm{~N}_{2} \mathrm{O}_{5}\right]}{\Delta t}$
$2\left(3.25 \times 10^{-4} \mathrm{M} / \mathrm{s}\right)=\frac{\Delta\left[\mathrm{N}_{2} \mathrm{O}_{5}\right]}{\Delta t}$

$$
\frac{\Delta\left[\mathrm{N}_{2} \mathrm{O}_{5}\right]}{\Delta t}=6.50 \times 10^{-4} \mathrm{M} / \mathrm{s}
$$

Dinitrogen pentoxide is being produced at a rate of $6.50 \times 10^{-4} \mathrm{M} / \mathrm{s}$.

Practice Problem A Consider the reaction

$$
4 \mathrm{PH}_{3}(g) \longrightarrow \mathrm{P}_{4}(g)+6 \mathrm{H}_{2}(g)
$$

At a particular point during the reaction, molecular hydrogen is being formed at the rate of $0.168 \mathrm{M} / \mathrm{s}$. (a) At what rate is $\mathrm{P}_{4}$ being produced? (b) At what rate is $\mathrm{PH}_{3}$ being consumed?

EIPractice Problem B Consider the following unbalanced equation:

$$
\mathrm{A}+\mathrm{B} \longrightarrow \mathrm{C}
$$

When C is being formed at the rate of $0.086 \mathrm{M} / \mathrm{s}$, A is being consumed at a rate of $0.172 \mathrm{M} / \mathrm{s}$ and B is being consumed at a rate of $0.258 \mathrm{M} / \mathrm{s}$. Balance the equation based on the relative rates of formation and consumption of products and reactants.

## Checkpoint 14.1 Reaction Rates

14.1.1 Which expressions are correct for the rate of the following reaction?

$$
\mathrm{F}_{2}(g)+2 \mathrm{ClO}_{2}(g) \longrightarrow 2 \mathrm{FClO}_{2}(g)
$$

(Select all that apply.)
a) rate $=-\frac{\Delta\left[\mathrm{F}_{2}\right]}{\Delta t}$
b) rate $=-\frac{\Delta\left[\mathrm{ClO}_{2}\right]}{\Delta t}$
c) rate $=-\frac{1}{2} \frac{\Delta\left[\mathrm{~F}_{2}\right]}{\Delta t}$
d) rate $=-\frac{1}{2} \frac{\Delta\left[\mathrm{ClO}_{2}\right]}{\Delta t}$
e) rate $=\frac{\Delta\left[\mathrm{FClO}_{2}\right]}{\Delta t}$
14.1.2 In the same reaction,

$$
\mathrm{F}_{2}(g)+2 \mathrm{ClO}_{2}(g) \longrightarrow 2 \mathrm{FClO}_{2}(g)
$$

if the concentration of $\mathrm{F}_{2}$ is changing at a rate of $0.026 \mathrm{M} / \mathrm{s}$, what is the rate of change in the concentration of $\mathrm{ClO}_{2}$ ?
a) $0.026 \mathrm{M} / \mathrm{s}$
b) $0.052 \mathrm{M} / \mathrm{s}$
c) $0.013 \mathrm{M} / \mathrm{s}$
d) $0.078 \mathrm{M} / \mathrm{s}$
e) $0.004 \mathrm{M} / \mathrm{s}$

### 14.2 Dependence of Reaction Rate on Reactant Concentration

We saw in Section 14.1 that the rate of reaction between bromine and formic acid is proportional to the concentration of bromine and that the proportionality constant $k$ is the rate constant. We will now explore how the rate, the rate constant, and the reactant concentrations are related.

## The Rate Law

The equation relating the rate of reaction to the concentration of molecular bromine,

$$
\text { rate }=k\left[\mathrm{Br}_{2}\right]
$$

is an example of a rate law. The rate law is an equation that relates the rate of reaction to the concentrations of reactants. For the general reaction,

$$
a \mathrm{~A}+b \mathrm{~B} \longrightarrow c \mathrm{C}+d \mathrm{D}
$$

the rate law is

$$
\text { rate }=k[\mathrm{~A}]^{x}[\mathrm{~B}]^{y}
$$

Equation 14.2
where $k$ is the rate constant and the exponents $x$ and $y$ are numbers that must be determined experimentally. When we know the values of $k, x$, and $y$, we can use Equation 14.2 to calculate the rate of the reaction, given the concentrations of A and B.

In the case of the reaction of molecular bromine and formic acid, the rate law is

$$
\text { rate }=k\left[\mathrm{Br}_{2}\right]^{x}[\mathrm{HCOOH}]^{y}
$$

where $x=1$ and $y=0$.
The value of the exponents in the rate law indicate the order of the reaction with respect to each reactant. In the reaction of bromine and formic acid, for example, the exponent for the bromine concentration, $x=1$, means that the reaction is first order with respect to bromine. The exponent of 0 for the formic acid concentration indicates that the reaction is zeroth order with respect to formic acid. The sum of $x$ and $y$ is called the overall reaction order. Thus, the reaction of bromine and formic acid is first order in bromine, zeroth order in formic acid, and first order $(1+0=1)$ overall.

## Experimental Determination of the Rate Law

To see how a rate law is determined from experimental data, consider the following reaction between fluorine and chlorine dioxide:

$$
\mathrm{F}_{2}(g)+2 \mathrm{ClO}_{2}(g) \longrightarrow 2 \mathrm{FClO}_{2}(g)
$$

Rate laws are commonly determined using a table of starting reactant concentrations and initial rates. The initial rate is the instantaneous rate at the beginning of the reaction. By varying the starting concentrations of reactants and observing the changes that result in the initial rate, we can determine how the rate depends on each reactant concentration.

Table 14.2 shows the initial rate data for the reaction of fluorine and chlorine dioxide being carried out three different times. Each time, the combination of reactant concentrations is different, and each time the initial rate is different.

To determine the values of the exponents $x$ and $y$ in the rate law,

$$
\text { rate }=k\left[\mathrm{~F}_{2}\right]^{x}\left[\mathrm{ClO}_{2}\right]^{y}
$$

\section*{TABLE 14.2 | Initial Rate Data for the Reaction Between $\mathrm{F}_{2}$ and $\mathrm{ClO}_{2}$ |
| :--- | :--- |}

| Experiment | $\left[\mathbf{F}_{2}\right](\boldsymbol{M})$ | $\left[\mathbf{C l O}_{2}\right](\boldsymbol{M})$ | Initial Rate $(\mathbf{M} / \mathbf{s})$ |
| :---: | :---: | :---: | :---: |
| 1 | 0.10 | 0.010 | $1.2 \times 10^{-3}$ |
| 2 | 0.10 | 0.040 | $4.8 \times 10^{-3}$ |
| 3 | 0.20 | 0.010 | $2.4 \times 10^{-3}$ |

Student Annotation: It is important to emphasize that the exponents in a rate law must be determined from experimental data and that, in general, they are not equal to the coefficients from the chemical equation.

Student Annotation: Recall that when an exponent is 1 , it need not be shown [14 Section 3.3].
we must compare two experiments in which one reactant concentration changes, and the other remains constant. For example, we first compare the data from experiments 1 and 3:

| Experiment | $\left[\mathbf{F}_{2}\right](\boldsymbol{M})$ | $\left[\mathbf{C l O}_{2}\right](\boldsymbol{M})$ | Initial Rate $(\mathbf{M} / \mathbf{s})$ |
| :---: | :---: | :---: | :---: |
| 1 | $\left[\mathrm{~F}_{2}\right]$ doubles $\{$ |  |  |
| 2 | $\left\{\begin{array}{lll}0.10 \\ 0.10 \\ 0.20\end{array}\right.$ | $\left[\mathrm{ClO}_{2}\right]$ unchanged |  |
| 3 | $\left[\begin{array}{l}0.010 \\ 0.040 \\ 0.010\end{array}\right.$ | Rate doubles $\left\{\begin{array}{l}1.2 \times 10^{-3} \\ 4.8 \times 10^{-3} \\ 2.4 \times 10^{-3}\end{array}\right.$ |  |

When the concentration of fluorine doubles, with the chlorine dioxide concentration held constant, the rate doubles.

$$
\frac{\left[\mathrm{F}_{2}\right]_{3}}{\left[\mathrm{~F}_{2}\right]_{1}}=\frac{0.20 \mathrm{M}}{0.10 \mathrm{M}}=2 \quad \frac{\mathrm{rate}_{3}}{\operatorname{rate}_{1}}=\frac{2.4 \times 10^{-3} \mathrm{M} / \mathrm{s}}{1.2 \times 10^{-3} \mathrm{M} / \mathrm{s}}=2
$$

This indicates that the rate is directly proportional to the concentration of fluorine, and the value of $x$ is 1 .

$$
\text { rate }=k\left[\mathrm{~F}_{2}\right]\left[\mathrm{ClO}_{2}\right]^{y}
$$

Similarly, we can compare experiments 1 and 2:

| Experiment | $\left[\mathbf{F}_{\mathbf{2}}\right](\mathbf{M})$ | $\left[\mathbf{C l O}_{\mathbf{2}}\right](\boldsymbol{M})$ | Initial Rate $(\mathbf{M} / \mathbf{s})$ |
| :---: | :---: | :---: | :---: |
| 1 | $\left[\mathrm{~F}_{2}\right]$ unchanged $\begin{cases}0.10 \\ 0.10\end{cases}$ |  |  |
| 2 | $\left[\mathrm{ClO}_{2}\right]$ quadruples $\left\{\begin{array}{l}0.010 \\ 0.040\end{array}\right.$ | Rate quadruples $\left\{\begin{array}{l}1.2 \times 10^{-3} \\ 4.8 \times 10^{-3}\end{array}\right.$ |  |
| 3 | 0.20 | 0.010 | $2.4 \times 10^{-3}$ |

We find that the rate quadruples when the concentration of chlorine dioxide is quadrupled, but the fluorine concentration is held constant.

$$
\frac{\left[\mathrm{ClO}_{2}\right]_{2}}{\left[\mathrm{ClO}_{2}\right]_{1}}=\frac{0.040 \mathrm{M}}{0.010 \mathrm{M}}=4 \quad \frac{\mathrm{rate}_{2}}{\mathrm{rate}_{1}}=\frac{4.8 \times 10^{-3} \mathrm{M} / \mathrm{s}}{1.2 \times 10^{-3} \mathrm{M} / \mathrm{s}}=4
$$

This indicates that the rate is also directly proportional to the concentration of chlorine dioxide, so the value of $y$ is also 1 . Thus, we can write the rate law as follows:

$$
\text { rate }=k\left[\mathrm{~F}_{2}\right]\left[\mathrm{ClO}_{2}\right]
$$

Because the concentrations of $\mathrm{F}_{2}$ and $\mathrm{ClO}_{2}$ are each raised to the first power, we say that the reaction is first order in $\mathrm{F}_{2}$ and first order in $\mathrm{ClO}_{2}$. The reaction is second order overall.

Knowing the rate law, we can then use the data from any one of the experiments to calculate the rate constant. Using the data for the first experiment in Table 14.2, we can write

$$
k=\frac{\text { rate }}{\left[\mathrm{F}_{2}\right]\left[\mathrm{ClO}_{2}\right]}=\frac{1.2 \times 10^{-3} \mathrm{M} / \mathrm{s}}{(0.10 \mathrm{M})(0.010 \mathrm{M})}=1.2 \mathrm{M}^{-1} \cdot \mathrm{~s}^{-1}
$$

Table 14.3 contains initial rate data for the hypothetical reaction

$$
a \mathrm{~A}+b \mathrm{~B} \longrightarrow c \mathrm{C}+d \mathrm{D}
$$

which has the general rate law

$$
\text { rate }=k[\mathrm{~A}]^{x}[\mathrm{~B}]^{y}
$$

## TABLE 14.3 Initial Rate Data for the Reaction Between A and B

| Experiment | [A] $(\boldsymbol{M})$ | [B] $(\boldsymbol{M})$ | Initial Rate $(\boldsymbol{M} / \mathbf{s})$ |
| :---: | :---: | :---: | :---: |
| 1 | 0.10 | 0.015 | $2.1 \times 10^{-4}$ |
| 2 | 0.20 | 0.015 | $4.2 \times 10^{-4}$ |
| 3 | 0.10 | 0.030 | $8.4 \times 10^{-4}$ |

Comparing experiments 1 and 2, we see that when [A] doubles, with [B] unchanged, the rate also doubles.

| Experiment | $[\mathbf{A}](\boldsymbol{M})$ | $[\mathbf{B}](\boldsymbol{M})$ | Initial Rate $(\mathbf{M} / \mathbf{s})$ |
| :---: | :---: | :---: | :---: |
| 1 | $[\mathrm{~A}]$ doubles $\left\{\begin{array}{l}0.10 \\ 0.20\end{array}\right.$ | [B] unchanged $\left\{\begin{array}{l}0.015 \\ 0.015\end{array}\right.$ | Rate doubles $\left\{\begin{array}{l}2.1 \times 10^{-4} \\ 4.2 \times 10^{-4} \\ 2\end{array}\right.$ |
| 0.10 | 0.030 | $8.4 \times 10^{-4}$ |  |

Thus, $x=1$.

## TABLE 14.4 Units of the Rate Constant $k$ for Reactions of Various Overall Orders

Overall Reaction Order

| 0 | rate $=k$ |
| :--- | :--- |
| 1 | rate $=k[\mathrm{~A}]$ or rate $=k[\mathrm{~B}]$ |
| 2 | rate $=k[\mathrm{~A}]^{2}$, rate $=k[\mathrm{~B}]^{2}$, or rate $=k[\mathrm{~A}][\mathrm{B}]$ |
| $3^{*}$ | rate $=k[\mathrm{~A}]^{2}[\mathrm{~B}]$ or rate $=k[\mathrm{~A}][\mathrm{B}]^{2}$ |

## Sample Rate Law

of
$M \cdot \mathrm{~s}^{-1}$
$\mathrm{s}^{-1}$
$M^{-1} \cdot \mathrm{~s}^{-1}$
$M^{-2} \cdot \mathrm{~s}^{-1}$
*Another possibility for a third-order reaction is rate $=k[\mathrm{~A}][\mathrm{B}][\mathrm{C}]$, although such reactions are very rare.

Comparing experiments 1 and 3 , when $[B]$ doubles with $[A]$ unchanged, we see that the rate quadruples.

| Experiment | $[\mathbf{A}](\boldsymbol{M})$ | $[\mathbf{B}](\boldsymbol{M})$ | Initial Rate $(\boldsymbol{M} / \mathbf{s})$ |
| :---: | :---: | :---: | :---: |
| 1 | $[A]$ unchanged $\begin{cases}0.10 \\ 0.20 \\ 0.10\end{cases}$ | $[B]$ doubles | $\left\{\begin{array}{l}0.015 \\ 0.015 \\ 0.030\end{array}\right.$ |
| 3 | Rate quadruples $\left\{\begin{array}{l}2.1 \times 10^{-4} \\ 4.2 \times 10^{-4} \\ 8.4 \times 10^{-4}\end{array}\right.$ |  |  |

Thus, the rate is not directly proportional to $[\mathrm{B}]$ to the first power, but rather it is directly proportional to $[\mathrm{B}]$ to the second power (i.e., $y=2$ ):

$$
\text { rate } \propto[B]^{2}
$$

The overall rate law is

$$
\text { rate }=k[\mathrm{~A}][\mathrm{B}]^{2}
$$

This reaction is therefore first order in A , second order in B , and third order overall.
Once again, knowing the rate law, we can use data from any of the experiments in the table to calculate the rate constant. Using the data from experiment 1 , we get

$$
k=\frac{\text { rate }}{[\mathrm{A}][\mathrm{B}]^{2}}=\frac{2.1 \times 10^{-4} \mathrm{M} / \mathrm{s}}{(0.10 M)(0.015 \mathrm{M})^{2}}=9.3 \mathrm{M}^{-2} \cdot \mathrm{~s}^{-1}
$$

Note that the units of this rate constant are different from those for the rate constant we calculated for the $\mathrm{F}_{2}-\mathrm{ClO}_{2}$ reaction and the bromine reaction. In fact, the units of a rate constant depend on the overall order of the reaction. Table 14.4 compares the units of the rate constant for reactions that are zeroth-, first-, second-, and third-order overall.

The following are three important things to remember about the rate law:

1. The exponents in a rate law must be determined from a table of experimental data-in general, they are not related to the stoichiometric coefficients in the balanced chemical equation.
2. Comparing changes in individual reactant concentrations with changes in rate shows how the rate depends on each reactant concentration.
3. Reaction order is always defined in terms of reactant concentrations, never product concentrations.
Sample Problem 14.3 shows how to use initial rate data to determine a rate law.

## Sample Problem 14.3

The gas-phase reaction of nitric oxide with hydrogen at $1280^{\circ} \mathrm{C}$ is

$$
2 \mathrm{NO}(g)+2 \mathrm{H}_{2}(g) \longrightarrow \mathrm{N}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(g)
$$

From the following data collected at $1280^{\circ} \mathrm{C}$, determine (a) the rate law, (b) the rate constant, including units, and (c) the rate of the reaction when $[\mathrm{NO}]=4.8 \times 10^{-3} \mathrm{M}$ and $\left[\mathrm{H}_{2}\right]=6.2 \times 10^{-3} \mathrm{M}$.

| Experiment | $[\mathbf{N O}](\boldsymbol{M})$ | $\left[\mathbf{H}_{\mathbf{2}}\right](\boldsymbol{M})$ | Initial Rate $(\boldsymbol{M} / \mathbf{s})$ |
| :---: | :---: | :---: | :---: |
| 1 | $5.0 \times 10^{-3}$ | $2.0 \times 10^{-3}$ | $1.3 \times 10^{-5}$ |
| 2 | $1.0 \times 10^{-2}$ | $2.0 \times 10^{-3}$ | $5.0 \times 10^{-5}$ |
| 3 | $1.0 \times 10^{-2}$ | $4.0 \times 10^{-3}$ | $1.0 \times 10^{-4}$ |

Student Annotation: A quotient of numbers, each raised to the same power, is equal to the quotient raised to that power: $x^{n} / y^{n}=(x / y)^{n}$.

Think About It The exponent for the concentration of $\mathrm{H}_{2}$ in the rate law is 1 , whereas the coefficient for $\mathrm{H}_{2}$ in the balanced equation is 2 . It is a common error to try to write a rate law using the stoichiometric coefficients as the exponents. Remember that, in general, the exponents in the rate law are not related to the coefficients in the balanced equation. Rate laws must be determined by examining a table of experimental data.

Strategy Compare two experiments at a time to determine how the rate depends on the concentration of each reactant.

Setup The rate law is rate $=k[\mathrm{NO}]^{x}\left[\mathrm{H}_{2}\right]^{y}$. Comparing experiments 1 and 2, we see that the rate increases by approximately a factor of 4 when [NO] is doubled but $\left[\mathrm{H}_{2}\right]$ is held constant. Comparing experiments 2 and 3 shows that the rate doubles when $\left[\mathrm{H}_{2}\right]$ doubles but [ NO ] is held constant.

Solution (a) Dividing the rate from experiment 2 by the rate from experiment 1 , we get

$$
\frac{\text { rate }_{2}}{\operatorname{rate}_{1}}=\frac{5.0 \times 10^{-5} M \cdot \mathrm{~s}}{1.3 \times 10^{-5} M \cdot \mathrm{~s}} \approx 4=\frac{k\left(1.0 \times 10^{-2} M\right)^{x}\left(2.0 \times 10^{-3} M\right)^{y}}{k\left(5.0 \times 10^{-3} M\right)^{x}\left(2.0 \times 10^{-3} M\right)^{y}}
$$

Canceling identical terms in the numerator and denominator gives

$$
\frac{\left(1.0 \times 10^{-2} M\right)^{x}}{\left(5.0 \times 10^{-3} M\right)^{x}}=2^{x}=4
$$

Therefore, $x=2$. The reaction is second order in NO.
Dividing the rate from experiment 3 by the rate from experiment 2, we get

$$
\frac{\text { rate }_{3}}{\operatorname{rate}_{2}}=\frac{1.0 \times 10^{-4} M-1}{5.0 \times 10^{-5} M-10^{-2} M}=2=\frac{k\left(1.0 \times 10^{-2} M\right)^{x}\left(4.0 \times 10^{-3} M\right)^{y}}{k\left(1.0 \times 10^{-2} M\right)^{x}\left(2.0 \times 10^{-3} M\right)^{y}}
$$

Canceling identical terms in the numerator and denominator gives

$$
\frac{\left(4.0 \times 10^{-3} M\right)^{y}}{\left(2.0 \times 10^{-3} M\right)^{y}}=2^{y}=2
$$

Therefore, $y=1$. The reaction is first order in $\mathrm{H}_{2}$. The overall rate law is

$$
\text { rate }=k[\mathrm{NO}]^{2}\left[\mathrm{H}_{2}\right]
$$

(b) We can use data from any of the experiments to calculate the value and units of $k$. Using the data from experiment 1 gives

$$
k=\frac{\text { rate }}{[\mathrm{NO}]^{2}\left[\mathrm{H}_{2}\right]}=\frac{1.3 \times 10^{-5} \mathrm{M} / \mathrm{s}}{\left(5.0 \times 10^{-3} M\right)^{2}\left(2.0 \times 10^{-3} \mathrm{M}\right)}=2.6 \times 10^{2} \mathrm{M}^{-2} \cdot \mathrm{~s}^{-1}
$$

(c) Using the rate constant determined in part (b) and the concentrations of NO and $\mathrm{H}_{2}$ given in the problem statement, we can determine the reaction rate as follows:

$$
\begin{aligned}
\text { rate } & =\left(2.6 \times 10^{2} M^{-2} \cdot \mathrm{~s}^{-1}\right)\left(4.8 \times 10^{-3} M\right)^{2}\left(6.2 \times 10^{-3} M\right) \\
& =3.7 \times 10^{-5} \mathrm{M} / \mathrm{s}
\end{aligned}
$$

Practice Problem A The reaction of peroxydisulfate ion $\left(\mathrm{S}_{2} \mathrm{O}_{8}^{2-}\right)$ with iodide ion $\left(\mathrm{I}^{-}\right)$is

$$
\mathrm{S}_{2} \mathrm{O}_{8}^{2-}(a q)+3 \mathrm{I}^{-}(a q) \longrightarrow 2 \mathrm{SO}_{4}^{2-}(a q)+\mathrm{I}_{3}^{-}(a q)
$$

From the following data collected at a certain temperature, determine the rate law and calculate the rate constant, including its units.

| Experiment | $\left[\mathbf{S}_{\mathbf{2}} \mathbf{O}_{\mathbf{8}}^{\mathbf{2 -}} \mathbf{]}(\boldsymbol{M})\right.$ | $\left[\mathbf{I}^{-}\right](\boldsymbol{M})$ | Initial Rate $(\boldsymbol{M} / \mathbf{s})$ |
| :---: | :---: | :---: | :---: |
| 1 | 0.080 | 0.034 | $2.2 \times 10^{-4}$ |
| 2 | 0.080 | 0.017 | $1.1 \times 10^{-4}$ |
| 3 | 0.16 | 0.017 | $2.2 \times 10^{-4}$ |

IPractice Problem B For the following general reaction, rate $=k[\mathrm{~A}]^{2}$ and $k=1.3 \times 10^{-2} \mathrm{M}^{-1} \cdot \mathrm{~s}^{-1}$ :

$$
\mathrm{A}+\mathrm{B} \longrightarrow 2 \mathrm{C}
$$

Use this information to fill in the missing table entries.

| Experiment | $[\mathbf{A}](\boldsymbol{M})$ | $[\mathbf{B}](\boldsymbol{M})$ | Initial Rate $(\boldsymbol{M} / \mathbf{s})$ |
| :---: | :---: | :---: | :---: |
| 1 | 0.013 | 0.250 | $2.20 \times 10^{-6}$ |
| 2 | 0.026 | 0.250 |  |
| 3 |  | 0.500 | $2.20 \times 10^{-6}$ |

## Checkpoint 14.2 Dependence of Reaction Rate on Reactant Concentration

Answer Questions 14.2.1 through 14.2.4 using the table of initial rate data for the reaction

$$
\mathrm{A}+2 \mathrm{~B} \longrightarrow 2 \mathrm{C}+\mathrm{D}
$$

| Experiment | $[\mathbf{A}](\boldsymbol{M})$ | $[\mathbf{B}](\boldsymbol{M})$ | Initial <br> Rate $(\boldsymbol{M} / \mathbf{s})$ |
| :---: | :---: | :---: | :---: |
| 1 | 0.12 | 0.010 | $2.2 \times 10^{-3}$ |
| 2 | 0.36 | 0.010 | $6.6 \times 10^{-3}$ |
| 3 | 0.12 | 0.020 | $2.2 \times 10^{-3}$ |

14.2.1 What is the rate law for the reaction?
a) rate $=k[\mathrm{~A}][\mathrm{B}]^{2}$
b) rate $=k[\mathrm{~A}]^{2}[\mathrm{~B}]$
c) rate $=k[\mathrm{~A}]^{3}$
d) rate $=k[\mathrm{~A}]^{2}$
e) rate $=k[\mathrm{~A}]$
14.2.2 Calculate the rate constant.
a) $0.15 \mathrm{M}^{-1} \cdot \mathrm{~s}^{-1}$
b) $0.15 \mathrm{M} \cdot \mathrm{s}^{-1}$
c) $0.15 \mathrm{~s}^{-1}$
d) $0.018 \mathrm{~s}^{-1}$
e) $0.018 M^{-1} \cdot \mathrm{~s}^{-1}$
14.2.3 What is the overall order of the reaction?
a) 0
b) 1
c) 2
d) 3
e) 4
14.2.4 Determine the rate when $[\mathrm{A}]=0.50 \mathrm{M}$ and $[\mathrm{B}]=0.25 \mathrm{M}$.
a) $9.2 \times 10^{-3} \mathrm{M} / \mathrm{s}$
b) $2.3 \times 10^{-3} \mathrm{M} / \mathrm{s}$
c) $4.5 \times 10^{-3} \mathrm{M} / \mathrm{s}$
d) $5.0 \times 10^{-3} \mathrm{M} / \mathrm{s}$
e) $1.3 \times 10^{-2} \mathrm{M} / \mathrm{s}$
14.2.5 The diagrams represent three experiments in which the reaction $\mathrm{A}+\mathrm{B} \longrightarrow \mathrm{C}$ is carried out with varied initial concentrations of A and B . Determine the rate law for the reaction. ( $\mathrm{A}=$ green, $\mathrm{B}=$ yellow, $\mathrm{C}=$ red.)

a) rate $=k[\mathrm{~A}][\mathrm{B}]$
b) rate $=k[\mathrm{~A}]^{2}[\mathrm{~B}]$
c) rate $=k[\mathrm{~A}][\mathrm{B}]^{2}$
d) rate $=k[\mathrm{~A}]^{2}$
e) rate $=k[\mathrm{~B}]$

### 14.3 Dependence of Reactant Concentration on Time

We can use the rate law to determine the rate of a reaction using the rate constant and the reactant concentrations:

A rate law can also be used to determine the remaining concentration of a reactant at a specific time during a reaction. We will illustrate this use of rate laws using reactions that are first order overall and reactions that are second order overall.

Student Annotation: It is not necessary for you to be able to do the calculus required to arrive at Equation 14.3, but it is very important that you know how to use Equation 14.3.

## First-Order Reactions

A first-order reaction is a reaction whose rate depends on the concentration of one of the reactants raised to the first power. Two examples are the decomposition of ethane $\left(\mathrm{C}_{2} \mathrm{H}_{6}\right)$ into highly reactive fragments called methyl radicals $\left(\cdot \mathrm{CH}_{3}\right)$, and the decomposition of dinitrogen pentoxide $\left(\mathrm{N}_{2} \mathrm{O}_{5}\right)$ into nitrogen dioxide $\left(\mathrm{NO}_{2}\right)$ and molecular oxygen $\left(\mathrm{O}_{2}\right)$ :

$$
\begin{array}{rlrl}
\mathrm{C}_{2} \mathrm{H}_{6} \longrightarrow 2 \cdot \mathrm{CH}_{3} & \text { rate }=k\left[\mathrm{C}_{2} \mathrm{H}_{6}\right] \\
2 \mathrm{~N}_{2} \mathrm{O}_{5}(g) \longrightarrow 4 \mathrm{NO}_{2}(g)+\mathrm{O}_{2}(g) & & \text { rate }=k\left[\mathrm{~N}_{2} \mathrm{O}_{5}\right]
\end{array}
$$

In a first-order reaction of the type

$$
\mathrm{A} \longrightarrow \text { product }
$$

the rate can be expressed as the rate of change in reactant concentration,

$$
\text { rate }=-\frac{\Delta[\mathrm{A}]}{\Delta t}
$$

as well as in the form of the rate law:

$$
\text { rate }=k[\mathrm{~A}]
$$

Setting these two expressions of the rate equal to each other we get

$$
-\frac{\Delta[\mathrm{A}]}{\Delta t}=k[\mathrm{~A}]
$$

Applying calculus to the preceding equation, we can show that

$$
\text { Equation } 14.3 \quad \ln \frac{[\mathrm{~A}]_{t}}{[\mathrm{~A}]_{0}}=-k t
$$

where $\ln$ is the natural logarithm, and $[\mathrm{A}]_{0}$ and $[\mathrm{A}]_{t}$ are the concentrations of A at times 0 and $t$, respectively. In general, time 0 refers to any specified time during a reaction-not necessarily the beginning of the reaction. Time $t$ refers to any specified time after time 0 . Equation 14.3 is sometimes called the integrated rate law.

In Sample Problem 14.4 we apply Equation 14.3 to a specific reaction.

## Sample Problem 14.4

The decomposition of hydrogen peroxide is first order in $\mathrm{H}_{2} \mathrm{O}_{2}$.

$$
2 \mathrm{H}_{2} \mathrm{O}_{2}(a q) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{O}_{2}(g)
$$

The rate constant for this reaction at $20^{\circ} \mathrm{C}$ is $1.8 \times 10^{-5} \mathrm{~s}^{-1}$. If the starting concentration of $\mathrm{H}_{2} \mathrm{O}_{2}$ is 0.75 M , determine (a) the concentration of $\mathrm{H}_{2} \mathrm{O}_{2}$ remaining after 3 h and (b) how long it will take for the $\mathrm{H}_{2} \mathrm{O}_{2}$ concentration to drop to 0.10 M .

Strategy Use Equation 14.3 to find $\left[\mathrm{H}_{2} \mathrm{O}_{2}\right]_{t, \text {, where } t}=3 \mathrm{~h}$, and then solve Equation 14.3 for $t$ to determine how much time must pass for $\left[\mathrm{H}_{2} \mathrm{O}_{2}\right]_{t}$ to equal 0.10 M .

Setup $\left[\mathrm{H}_{2} \mathrm{O}_{2}\right]_{0}=0.75 \mathrm{M}$; time $t$ for part (a) is $(3 \mathrm{~h})(60 \mathrm{~min} / \mathrm{h})(60 \mathrm{~s} / \mathrm{min})=10,800 \mathrm{~s}$.
Solution (a) $\ln \frac{\left[\mathrm{H}_{2} \mathrm{O}_{2}\right]_{t}}{\left[\mathrm{H}_{2} \mathrm{O}_{2}\right]_{0}}=-k t$

$$
\ln \frac{\left[\mathrm{H}_{2} \mathrm{O}_{2}\right]_{t}}{0.75 \mathrm{M}}=-\left(1.8 \times 10^{-5} \mathrm{~s}^{-1}\right)(10,800 \mathrm{~s})=-0.1944
$$

Take the inverse natural logarithm of both sides of the equation to get

$$
\begin{aligned}
& \frac{\left[\mathrm{H}_{2} \mathrm{O}_{2}\right]_{t}}{0.75 \mathrm{M}}=e^{-0.1944}=0.823 \\
& {\left[\mathrm{H}_{2} \mathrm{O}_{2}\right]_{t}=(0.823)(0.75 \mathrm{M})=0.62 \mathrm{M}}
\end{aligned}
$$

The concentration of $\mathrm{H}_{2} \mathrm{O}_{2}$ after 3 h is 0.62 M .
(b) $\ln \left(\frac{0.10 \mathrm{M}}{0.75 \mathrm{M}}\right)=-2.015=-\left(1.8 \times 10^{-5} \mathrm{~s}^{-1}\right) t$
$\frac{2.015}{1.8 \times 10^{-5} \mathrm{~s}^{-1}}=t=1.12 \times 10^{5} \mathrm{~s}$
The time required for the peroxide concentration to drop to 0.10 M is $1.1 \times 10^{5} \mathrm{~s}$ or about 31 h .

Practice Problem A The rate constant for the reaction $2 \mathrm{~A} \longrightarrow \mathrm{~B}$ is $7.5 \times 10^{-3} \mathrm{~s}^{-1}$ at $110^{\circ} \mathrm{C}$. The reaction is first order in A. How long (in seconds) will it take for [A] to decrease from 1.25 M to 0.71 M ?

HPractice Problem $B$ Refer again to the reaction $2 \mathrm{~A} \longrightarrow \mathrm{~B}$, for which $k=7.5 \times 10^{-3} \mathrm{~s}^{-1}$ at $110^{\circ} \mathrm{C}$. With a starting concentration of $[\mathrm{A}]=2.25 \mathrm{M}$, what will $[\mathrm{A}]$ be after 2.0 min ?

Equation 14.3 can be rearranged as follows:

$$
\begin{equation*}
\ln [\mathrm{A}]_{t}=-k t+\ln [\mathrm{A}]_{0} \tag{Equation 14.4}
\end{equation*}
$$

Equation 14.4 has the form of the linear equation $y=m x+b$ :

$$
\begin{aligned}
\ln [\mathrm{A}]_{t} & =(-k)(t)+\ln [\mathrm{A}]_{0} \\
y & =m \quad x+b
\end{aligned}
$$

Figure 14.8(a) shows the decrease in concentration of reactant A during the course of the reaction. As we saw in Section 14.1, the plot of reactant concentration as a function of time is not a straight line. For a first-order reaction, however, we do get a straight line if we plot the natural $\log$ of reactant concentration $\left(\ln [\mathrm{A}]_{t}\right)$ versus time ( $y$ versus $x$ ). The slope of the line is equal to $-k$ [Figure 14.8(b)], so we can determine the rate constant from the slope of this plot.

Sample Problem 14.5 shows how a rate constant can be determined from experimental data.

## Sample Problem 14.5

The rate of decomposition of azomethane is studied by monitoring the partial pressure of the reactant as a function of time:

$$
\mathrm{CH}_{3}-\mathrm{N}=\mathrm{N}-\mathrm{CH}_{3}(g) \longrightarrow \mathrm{N}_{2}(g)+\mathrm{C}_{2} \mathrm{H}_{6}(g)
$$

The data obtained at $300^{\circ} \mathrm{C}$ are listed in the following table:

| Time (s) | $\boldsymbol{P}_{\text {azomethane }}(\mathbf{m m H g})$ |
| :---: | :---: |
| 0 | 284 |
| 100 | 220 |
| 150 | 193 |
| 200 | 170 |
| 250 | 150 |
| 300 | 132 |

Determine the rate constant of the reaction at this temperature.

Think About It We could equally well have determined the rate constant by calculating the slope of the plot of $\ln P$ versus $t$. Using the two points labeled on the plot, we get

$$
\begin{aligned}
\text { slope } & =\frac{5.011-5.394}{250-100} \\
& =-2.55 \times 10^{-3} \mathrm{~s}^{-1}
\end{aligned}
$$

Remember that slope $=-k$, so $k=2.55 \times 10^{-3} \mathrm{~s}^{-1}$.

Strategy We can use Equation 14.3 only for first-order reactions, so we must first determine if the decomposition of azomethane is first order. We do this by plotting $\ln P$ against time. If the reaction is first order, we can use Equation 14.3 and the data at any two of the times in the table to determine the rate constant.

Setup The table expressed as $\ln P$ is

| Time $(\mathbf{s})$ | $\ln \boldsymbol{P}$ |
| :---: | :---: |
| 0 | 5.649 |
| 100 | 5.394 |
| 150 | 5.263 |
| 200 | 5.136 |
| 250 | 5.011 |
| 300 | 4.883 |

Plotting these data gives a straight line, indicating that the reaction is indeed first order. Thus, we can use Equation 14.3 expressed in terms of pressure.

$$
\ln \frac{P_{t}}{P_{0}}=-k t
$$

$P_{t}$ and $P_{0}$ can be pressures at any two times during the experiment. $P_{0}$ need not be the pressure at 0 s-it need only be at the earlier of the two times.

Solution Using data from times 100 s and 250 s of the original table ( $P_{\text {azomethane }}$ versus $t$ ), we get

$$
\begin{aligned}
\ln \frac{150 \mathrm{mmHg}}{220 \mathrm{mmHg}} & =-k(150 \mathrm{~s}) \\
\ln 0.682 & =-k(150 \mathrm{~s}) \\
k & =2.55 \times 10^{-3} \mathrm{~s}^{-1}
\end{aligned}
$$

Practice Problem A Ethyl iodide $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{I}\right)$ decomposes at a certain temperature in the gas phase as follows:

$$
\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{I}(g) \longrightarrow \mathrm{C}_{2} \mathrm{H}_{4}(g)+\mathrm{HI}(g)
$$

From the following data, determine the rate constant of this reaction. Begin by constructing a plot to verify that the reaction is first order.

| Time (min) | $\left[\mathbf{C}_{\mathbf{2}} \mathbf{H}_{\mathbf{5}} \mathbf{I}\right](\boldsymbol{M})$ |
| :---: | :---: |
| 0 | 0.36 |
| 15 | 0.30 |
| 30 | 0.25 |
| 48 | 0.19 |
| 75 | 0.13 |

Practice Problem B Use the calculated $k$ from Practice Problem A to fill in the missing values in the following table:

| Time (min) | $\left[\mathbf{C}_{\mathbf{2}} \mathbf{H}_{\mathbf{5}} \mathbf{I}\right](\boldsymbol{M})$ |
| :---: | :---: |
| 0 | 0.45 |
| 10 | - |
| 20 | - |
| 30 | - |
| 40 | - |

We often describe the rate of a reaction using the half-life. The half-life $\left(t_{1 / 2}\right)$ is the time required for the reactant concentration to drop to half its original value. We obtain an expression for $t_{1 / 2}$ for a first-order reaction as follows:

$$
t=\frac{1}{k} \ln \frac{[\mathrm{~A}]_{0}}{[\mathrm{~A}]_{t}}
$$

According to the definition of half-life, $t=t_{1 / 2}$ when $[\mathrm{A}]_{t}=\frac{1}{2}[\mathrm{~A}]_{0}$, so

$$
t_{1 / 2}=\frac{1}{k} \ln \frac{[\mathrm{~A}]_{0}}{\frac{1}{2}[\mathrm{~A}]_{0}}
$$

Because $\frac{[\mathrm{A}]_{0}}{\frac{1}{2}[\mathrm{~A}]_{0}}=2$, and $\ln 2=0.693$, the expression for $t_{1 / 2}$ simplifies to

$$
t_{1 / 2}=\frac{0.693}{k}
$$

Equation 14.5

According to Equation 14.5, the half-life of a first-order reaction is independent of the initial concentration of the reactant. Thus, it takes the same time for the concentration of the reactant to decrease from 1.0 M to 0.50 M as it does for the concentration to decrease from 0.10 M to 0.050 M (Figure 14.9). Measuring the half-life of a reaction is one way to determine the rate constant of a first-order reaction.

The half-life of a first-order reaction is inversely proportional to its rate constant, so a short half-life corresponds to a large rate constant. Consider, for example, two radioactive isotopes used in nuclear medicine: ${ }^{24} \mathrm{Na}\left(t_{1 / 2}=14.7 \mathrm{~h}\right)$ and ${ }^{60} \mathrm{Co}\left(t_{1 / 2}=5.3 \mathrm{yr}\right)$. Sodium-24, with the shorter half-life, decays faster. If we started with an equal number of moles of each isotope, most of the sodium- 24 would be gone in a week whereas most of the cobalt- 60 would remain unchanged.

Sample Problem 14.6 shows how to calculate the half-life of a first-order reaction, given the rate constant.

## Sample Problem 14.6

The decomposition of ethane $\left(\mathrm{C}_{2} \mathrm{H}_{6}\right)$ to methyl radicals $\left(\mathrm{CH}_{3}\right)$ is a first-order reaction with a rate constant of $5.36 \times 10^{-4} \mathrm{~s}^{-1}$ at $700^{\circ} \mathrm{C}$ :

$$
\mathrm{C}_{2} \mathrm{H}_{6} \longrightarrow 2 \mathrm{CH}_{3}
$$

Calculate the half-life of the reaction in minutes.
Strategy Use Equation 14.5 to calculate $t_{1 / 2}$ in seconds, and then convert to minutes.

Figure 14.9 A plot of $[\mathrm{A}]$ versus time for the first-order reaction $\mathrm{A} \longrightarrow$ products. The half-life of the reaction is 1 min . The concentration of A is halved every half-life.

Think About It Half-lives and rate constants can be expressed using any units of time and reciprocal time, respectively. Track units carefully when you convert from one unit of time to another.

Figure 14.10 Second-order reaction characteristics: (a) Decrease of reactant concentration with time.
(b) A plot of $\frac{1}{[\mathrm{~A}]_{t}}$ versus $t$. The slope of the line is equal to $k$, and the $y$ intercept is equal to $\frac{1}{[\mathrm{~A}]_{0}}$.

## Setup

$$
\text { seconds } \times \frac{1 \text { minute }}{60 \text { seconds }}=\text { minutes }
$$

## Solution

$$
\begin{aligned}
t_{1 / 2} & =\frac{0.693}{k}=\frac{0.693}{5.36 \times 10^{-4} \mathrm{~s}^{-1}}=1293 \mathrm{~s} \\
1293 \mathrm{~s} \times \frac{1 \mathrm{~min}}{60 \mathrm{~s}} & =21.5 \mathrm{~min}
\end{aligned}
$$

The half-life of ethane decomposition at $700^{\circ} \mathrm{C}$ is 21.6 min .

Practice Problem A Calculate the half-life of the decomposition of azomethane, discussed in Sample Problem 14.5.

EPractice Problem B Calculate the rate constant for the first-order decay of ${ }^{24} \mathrm{Na}\left(t_{1 / 2}=14.7 \mathrm{~h}\right)$.

## Second-Order Reactions

A second-order reaction is a reaction whose rate depends on the concentration of one reactant raised to the second power or on the product of the concentrations of two different reactants (each raised to the first power). For simplicity, we will consider only the first type of reaction:

$$
\mathrm{A} \longrightarrow \text { product }
$$

where the rate can be expressed as

$$
\text { rate }=-\frac{\Delta[\mathrm{A}]}{\Delta t}
$$

or as

$$
\text { rate }=k[\mathrm{~A}]^{2}
$$

As before, we can combine the two expressions of the rate:

$$
-\frac{\Delta[\mathrm{A}]}{\Delta t}=k[\mathrm{~A}]^{2}
$$

Again, using calculus, we obtain the following integrated rate law:

Equation 14.6

$$
\frac{1}{[\mathrm{~A}]_{t}}=k t+\frac{1}{[\mathrm{~A}]_{0}}
$$

Thus, for a second-order reaction, we obtain a straight line when we plot the reciprocal of concentration $\left(1 /[\mathrm{A}]_{t}\right)$ against time (Figure 14.10), and the slope of the line is equal to the rate constant, $k$. As before, we can obtain the expression for the half-life by setting $[\mathrm{A}]_{t}=\frac{1}{2}[\mathrm{~A}]_{0}$ in Equation 14.6.

$$
\frac{1}{\frac{1}{2}[\mathrm{~A}]_{0}}=k t_{1 / 2}+\frac{1}{[\mathrm{~A}]_{0}}
$$

(a)

(b)

Solving for $t_{1 / 2}$, we obtain

Equation 14.7

$$
t_{1 / 2}=\frac{1}{k[\mathrm{~A}]_{0}}
$$

Note that unlike the half-life of a first-order reaction, which is independent of the starting concentration, the half-life of a second-order reaction is inversely proportional to the initial reactant concentration. Determining the half-life at several different initial concentrations is one way to distinguish between first-order and second-order reactions.

Sample Problem 14.7 shows how to use Equations 14.6 and 14.7 to calculate reactant concentrations and the half-life of a second-order reaction.

## Sample Problem 14.7

Iodine atoms combine to form molecular iodine in the gas phase:

$$
\mathrm{I}(g)+\mathrm{I}(g) \longrightarrow \mathrm{I}_{2}(g)
$$

This reaction is second order and has a rate constant of $7.0 \times 10^{9} \mathrm{M}^{-1} \cdot \mathrm{~s}^{-1}$ at $23^{\circ} \mathrm{C}$. (a) If the initial concentration of I is 0.086 M , calculate the concentration after 2.0 min . (b) Calculate the half-life of the reaction when the initial concentration of $I$ is 0.60 M and when the initial concentration of $I$ is 0.42 M.

Strategy Use Equation 14.6 to determine $[\mathrm{I}]_{t}$ at $t=2.0 \mathrm{~min}$; use Equation 14.7 to determine $t_{1 / 2}$ when $[\mathrm{I}]_{0}=0.60 \mathrm{M}$ and when $[\mathrm{I}]_{0}=0.42 \mathrm{M}$.

Setup

$$
t=(2.0 \mathrm{~min})(60 \mathrm{~s} / \mathrm{min})=120 \mathrm{~s}
$$

Solution (a) $\frac{1}{[\mathrm{~A}]_{t}}=k t+\frac{1}{[\mathrm{~A}]_{0}}$

$$
\begin{aligned}
& =\left(7.0 \times 10^{9} \mathrm{M}^{-1} \cdot \mathrm{~s}^{-1}\right)(120 \mathrm{~s})+\frac{1}{0.086 \mathrm{M}} \\
& =8.4 \times 10^{11} \mathrm{M}^{-1} \\
{[\mathrm{~A}]_{t} } & =\frac{1}{8.4 \times 10^{11} \mathrm{M}^{-1}}=1.2 \times 10^{-12} \mathrm{M}
\end{aligned}
$$

The concentration of atomic iodine after 2.0 min is $1.2 \times 10^{-12} \mathrm{M}$.
(b) When $[\mathrm{I}]_{0}=0.60 \mathrm{M}$,

$$
t_{1 / 2}=\frac{1}{k[\mathrm{~A}]_{0}}=\frac{1}{\left(7.0 \times 10^{9} \mathrm{M}^{-1} \cdot \mathrm{~s}^{1}\right)(0.60 \mathrm{M})}=2.4 \times 10^{-10} \mathrm{~s}
$$

When $[\mathrm{I}]_{0}=0.42 \mathrm{M}$,

$$
t_{1 / 2}=\frac{1}{k[\mathrm{~A}]_{0}}=\frac{1}{\left(7.0 \times 10^{9} \mathrm{M}^{-1} \cdot \mathrm{~s}^{-1}\right)(0.42 \mathrm{M})}=3.4 \times 10^{-10} \mathrm{~s}
$$

Practice Problem A The reaction $2 \mathrm{~A} \longrightarrow \mathrm{~B}$ is second order in A with a rate constant of $32.0 \mathrm{M}^{-1} \cdot \mathrm{~s}^{-1}$ at $25.0^{\circ} \mathrm{C}$. (a) Starting with $[\mathrm{A}]_{0}=0.0075 \mathrm{M}$, how long will it take for the concentration of A to drop to $0.0018 M$ ? (b) Calculate the half-life of the reaction for $[\mathrm{A}]_{0}=0.0075 \mathrm{M}$ and for $[\mathrm{A}]_{0}=0.0025 \mathrm{M}$.

IPractice Problem B Determine the initial concentration, $[\mathrm{A}]_{0}$, for the reaction in Practice Problem A necessary for the half-life to be (a) 1.50 s , (b) 25.0 s , and (c) 175 s .

Student Annotation: This equation can also be written as $21(g) \longrightarrow I_{2}(g)$.

Think About It (a) Iodine, like the other halogens, exists as diatomic molecules at room temperature. It makes sense, therefore, that atomic iodine would react quickly, and essentially completely, to form $\mathrm{I}_{2}$ at room temperature. The very low remaining concentration of I after 2.0 min makes sense. (b) As expected, the half-life of this second-order reaction is not constant. (A constant half-life is a characteristic of first-order reactions.)

First- and second-order reactions are the most common reaction types. Reactions of overall order zero exist but are relatively rare. For a zeroth-order reaction

$$
\mathrm{A} \longrightarrow \text { product }
$$

TABLE 14.5

## Order

$$
0
$$

1
$2 \quad$ rate $=k[\mathrm{~A}]^{2}$

Integrated Rate Law
Half-Life
$\frac{[\mathrm{A}]_{0}}{2 k}$
$\ln \frac{[\mathrm{A}]_{t}}{[\mathrm{~A}]_{0}}=-k t$
$\frac{0.693}{k}$
$\frac{1}{[\mathrm{~A}]_{t}}=k t+\frac{1}{[\mathrm{~A}]_{0}}$
$\frac{1}{k[\mathrm{~A}]_{0}}$
the rate law is given by

$$
\text { rate }=k[\mathrm{~A}]^{0}=k
$$

Thus, the rate of a zeroth-order reaction is a constant, independent of reactant concentration. Thirdorder and higher-order reactions are quite rare and too complex to be covered in this book. Table 14.5 summarizes the kinetics for first-order and second-order reactions of the type $\mathrm{A} \longrightarrow$ product.

## Checkpoint 14.3 Dependence of Reactant Concentration on Time

The first-order decomposition of dinitrogen pentoxide $\left(\mathrm{N}_{2} \mathrm{O}_{5}\right)$ is represented by

$$
2 \mathrm{~N}_{2} \mathrm{O}_{5}(g) \longrightarrow 4 \mathrm{NO}_{2}(g)+\mathrm{O}_{2}(g)
$$

Use the table of data to answer questions 14.3.1 and 14.3.2:

| $\boldsymbol{t}(\mathbf{s})$ | $\left[\mathbf{N}_{2} \mathbf{O}_{\mathbf{5}}\right](\boldsymbol{M})$ |
| ---: | :---: |
| 0 | 0.91 |
| 300 | 0.75 |
| 600 | 0.64 |
| 1200 | 0.44 |
| 3000 | 0.16 |

14.3.1 What is the rate constant for the decomposition of $\mathrm{N}_{2} \mathrm{O}_{5}$ ?
a) $9 \times 10^{-4} \mathrm{~s}^{-1}$
b) $4 \times 10^{-4} \mathrm{~s}^{-1}$
c) $6 \times 10^{-4} \mathrm{~s}^{-1}$
d) $5 \times 10^{-3} \mathrm{~s}^{-1}$
e) $1 \times 10^{-3} \mathrm{~s}^{-1}$
14.3.2 Approximately how long will it take for $\left[\mathrm{N}_{2} \mathrm{O}_{5}\right.$ ] to fall from 0.62 M to 0.10 M ?
a) 1000 s
b) 2000 s
c) 3000 s
d) 4000 s
e) 5000 s
14.3.3 Consider the first-order reaction $\mathrm{A} \longrightarrow \mathrm{B}$ in which A molecules (blue spheres) are converted to B molecules (yellow spheres). What is the half-life for the reaction?

a) 5 s
b) 10 s
c) 15 s
d) 20 s
e) 30 s

b) i, ii, iii
c) iii, i, ii
d) ii, i, iii
e) i, iii, ii

### 14.4 Dependence of Reaction Rate on Temperature

Nearly all reactions happen faster at higher temperatures. For example, the time required to cook food depends largely on the boiling point of water. The reaction involved in hard-boiling an egg happens faster at $100^{\circ} \mathrm{C}$ (about 10 min ) than at $80^{\circ} \mathrm{C}$ (about 30 min ). The dependence of reaction rate on temperature is the reason we keep food in a refrigerator-and why food keeps even longer in a freezer. The lower the temperature, the slower the processes that cause food to spoil.

## Collision Theory

Chemical reactions generally occur as a result of collisions between reacting molecules. A greater frequency of collisions usually leads to a higher reaction rate. According to the collision theory of chemical kinetics, the reaction rate is directly proportional to the number of molecular collisions per second:

$$
\text { rate } \propto \frac{\text { number of collisions }}{\mathrm{s}}
$$

Consider the reaction of A molecules with B molecules to form some product. Suppose that each product molecule is formed by the direct combination of an A molecule and a B molecule. If we doubled the concentration of A , then the number of $\mathrm{A}-\mathrm{B}$ collisions would also double, because there would be twice as many A molecules that could collide with B molecules in any given volume. Consequently, the rate would increase by a factor of 2 . Similarly, doubling the concentration of B molecules would increase the rate twofold. Thus, we can express the rate law as

$$
\text { rate }=k[\mathrm{~A}][\mathrm{B}]
$$

The reaction is first order in both $A$ and $B$ and is second order overall.
This view of collision theory is something of a simplification, though, because not every collision between molecules results in a reaction. A collision that does result in a reaction is called an effective collision. A molecule in motion possesses kinetic energy; the faster it is moving, the greater its kinetic energy. When molecules collide, part of their kinetic energy is converted to vibrational energy. If the initial kinetic energies are large, then the colliding molecules will vibrate so strongly as to break some of the chemical bonds. This bond breaking is the first step toward product formation. If the initial kinetic energies are small, the molecules will merely bounce off of each other intact. There is a minimum amount of energy, the activation energy $\left(\boldsymbol{E}_{\mathrm{a}}\right)$, required to initiate a chemical reaction. Without this minimum amount of energy at impact, a collision will be ineffective; that is, it will not result in a reaction.

When molecules react (as opposed to when atoms react), having sufficient kinetic energy is not the only requirement for a collision to be effective. Molecules must also be oriented in a way that favors reaction. The reaction between chlorine atoms and nitrosyl chloride $(\mathrm{NOCl})$ illustrates this point:

$$
\mathrm{Cl}+\mathrm{NOCl} \longrightarrow \mathrm{Cl}_{2}+\mathrm{NO}
$$

This reaction is most favorable when a free Cl atom collides directly with the Cl atom in the NOCl molecule [Figure 14.11(a)]. Otherwise, the reactants simply bounce off of each other and no reaction occurs [Figure 14.11(b)].

When molecules collide (in an effective collision), they form an activated complex (also called the transition state), a temporary species formed by the reactant molecules as a result of the collision. Figure 14.12 shows a potential energy profile for the reaction between Cl and NOCl .

Student Annotation: Cookbooks sometimes give alternate directions for cooking at high altitudes, where the lower atmospheric pressure results in water boiling at a lower temperature [ 14 Section 12.6].

Student Annotation: Kinetic energy is the result of motion of the whole molecule, relative to its surroundings. Vibrational energy is the result of motion of the atoms in a molecule, relative to one another.

Figure 14.11 (a) For an effective collision to take place, the free Cl atom must collide directly with the Cl atom in NOCl. (b) Otherwise, the reactants bounce off of one another and the collision is ineffective-no reaction takes place.

Figure 14.12 Energy profile for the reaction of Cl with NOCl . In addition to being oriented properly, reactant molecules must possess sufficient energy to overcome the activation energy.

Student Annotation: Absolute temperature is expressed in kelvins [14 Section 1.3].

We can think of the activation energy as an energy barrier that prevents less energetic molecules from reacting. Because the number of reactant molecules in an ordinary reaction is very large, the speeds, and therefore also the kinetic energies of the molecules, vary greatly. Normally, only a small fraction of the colliding molecules-the fastest-moving ones-have sufficient kinetic energy to exceed the activation energy. These molecules can therefore take part in the reaction. The relationship between rate and temperature should now make sense. According to kinetic molecular theory, the average kinetic energy of a sample of molecules increases as the temperature increases [ 144 Section 11.6, Figure 11.20]. Thus, a higher percentage of the molecules in the sample have sufficient kinetic energy to exceed the activation energy, and the reaction rate increases.

## The Arrhenius Equation

The dependence of the rate constant of a reaction on temperature can be expressed by the Arrhenius equation,

$$
\begin{equation*}
k=A e^{-E_{a} / R T} \tag{Equation 14.8}
\end{equation*}
$$

where $E_{\mathrm{a}}$ is the activation energy of the reaction (in $\mathrm{kJ} / \mathrm{mol}$ ), $R$ is the gas constant ( $8.314 \mathrm{~J} / \mathrm{K} \cdot$ mol), $T$ is the absolute temperature, and $e$ is the base of the natural logarithm [ Appendix 1]. The quantity $A$ represents the collision frequency and is called the frequency factor. It can be treated as a constant for a given reaction over a reasonably wide temperature range. Equation 14.8 shows that the rate constant decreases with increasing activation energy and increases with increasing temperature. This equation can be expressed in a more useful form by taking the natural logarithm of both sides:

$$
\ln k=\ln A e^{-E_{\mathrm{a}} / R T}
$$

or

$$
\begin{equation*}
\ln k=\ln A-\frac{E_{\mathrm{a}}}{R T} \tag{Equation 14.9}
\end{equation*}
$$

which can be rearranged to give the following linear equation:

$$
\begin{aligned}
\ln k & =\left(-\frac{E_{\mathrm{a}}}{R}\right)\left(\frac{1}{T}\right)+\ln A \\
y & =m \quad x+b
\end{aligned}
$$

Equation 14.10

Thus, a plot of $\ln k$ versus $1 / T$ gives a straight line whose slope is equal to $-E_{\mathrm{a}} / R$ and whose $y$ intercept $(b)$ is equal to $\ln A$.

Sample Problem 14.8 demonstrates a graphical method for determining the activation energy of a reaction.

## Sample Problem 14.8

Rate constants for the reaction

$$
\mathrm{CO}(g)+\mathrm{NO}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g)+\mathrm{NO}(g)
$$

were measured at four different temperatures. The data are shown in the table. Plot $\ln k$ versus $1 / T$, and determine the activation energy (in $\mathrm{kJ} / \mathrm{mol}$ ) for the reaction.

| $\boldsymbol{k}\left(\boldsymbol{M}^{\mathbf{- 1}} \cdot \mathbf{s}^{\mathbf{- 1}}\right)$ | $\boldsymbol{T}(\mathbf{K})$ |
| :---: | :---: |
| 0.0521 | 288 |
| 0.101 | 298 |
| 0.184 | 308 |
| 0.332 | 318 |

Strategy Plot $\ln k$ versus $1 / T$, and determine the slope of the resulting line. According to Equation 14.10, slope $=-E_{\mathrm{a}} / R$.

Setup $R=8.314 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$. Taking the natural $\log$ of each value of $k$ and the inverse of each value of $T$ gives

| $\boldsymbol{\operatorname { l n }} \boldsymbol{k}$ | $\mathbf{1 / T}\left(\mathbf{K}^{\mathbf{1}}\right)$ |
| :--- | :---: |
| -2.95 | $3.47 \times 10^{-3}$ |
| -2.29 | $3.36 \times 10^{-3}$ |
| -1.69 | $3.25 \times 10^{-3}$ |
| -1.10 | $3.14 \times 10^{-3}$ |

Solution A plot of these data yields the following graph:

The slope is determined using the $x$ and $y$ coordinates of any two points on the line. Using the points that are labeled on the graph gives

$$
\text { slope }=\frac{-1.4-(-2.5)}{3.2 \times 10^{-3} \mathrm{~K}^{-1}-3.4 \times 10^{-3} \mathrm{~K}^{-1}}=-5.5 \times 10^{3} \mathrm{~K}
$$

The value of the slope is $-5.5 \times 10^{3} \mathrm{~K}$. Because slope $=-E_{a} / R$,

$$
\begin{aligned}
E_{\mathrm{a}} & =-(\text { slope })(R) \\
& =-\left(-5.5 \times 10^{3} \mathrm{~K}\right)(8.314 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol}) \\
& =4.6 \times 10^{4} \mathrm{~J} / \mathrm{mol} \text { or } 46 \mathrm{~kJ} / \mathrm{mol}
\end{aligned}
$$

The activation energy is $46 \mathrm{~kJ} / \mathrm{mol}$.

Practice Problem A The second-order rate constant for the decomposition of nitrous oxide to nitrogen molecules and oxygen atoms has been determined at various temperatures:

| $\boldsymbol{k}\left(\boldsymbol{M}^{-\mathbf{1}} \cdot \mathbf{s}^{\mathbf{- 1}}\right)$ | $\boldsymbol{T}\left({ }^{\circ} \mathbf{C}\right)$ |
| :---: | :---: |
| $1.87 \times 10^{-3}$ | 600 |
| 0.0113 | 650 |
| 0.0569 | 700 |
| 0.244 | 750 |

Determine the activation energy graphically.
Practice Problem B Each line in the graph shown at right represents a different reaction. List the

Think About It Note that while $k$ has units of $M^{-1} \cdot \mathrm{~s}^{-1}, \ln k$ has no units. reactions in order of increasing activation energy.

Student Annotation: Note that for two different temperatures, the only thing in Equation 14.9 that changes is $k$. The other variables, $A$ and $E_{\mathrm{a}}$ (and of course $R$ ), are constant.

Student Annotation: Equations 14.8 through 14.11 are all "Arrhenius equations," but Equation 14.11 is the form you will use most often to solve kinetics problems.

Think About It A good way to check your work is to use the value of $E_{\mathrm{a}}$ that you calculated (and Equation 14.11) to determine the rate constant at 500 K . Make sure it agrees with the value in the table.

We can derive an even more useful form of the Arrhenius equation starting with Equation 14.9 written for two different temperatures, $T_{1}$ and $T_{2}$ :

$$
\begin{aligned}
& \ln k_{1}=\ln A-\frac{E_{\mathrm{a}}}{R T_{1}} \\
& \ln k_{2}=\ln A-\frac{E_{\mathrm{a}}}{R T_{2}}
\end{aligned}
$$

Subtracting $\ln k_{2}$ from $\ln k_{1}$ gives

$$
\begin{gathered}
\ln k_{1}-\ln k_{2}=\left(\ln A-\frac{E_{\mathrm{a}}}{R T_{1}}\right)-\left(\ln A-\frac{E_{\mathrm{a}}}{R T_{2}}\right) \\
\ln \frac{k_{1}}{k_{2}}=\frac{E_{\mathrm{a}}}{R}\left(-\frac{1}{T_{1}}+\frac{1}{T_{2}}\right) \\
\ln \frac{k_{1}}{k_{2}}=\frac{E_{\mathrm{a}}}{R}\left(\frac{1}{T_{2}}-\frac{1}{T_{1}}\right)
\end{gathered}
$$

Equation 14.11

Equation 14.11 enables us to do two things:

1. If we know the rate constant at two different temperatures, we can calculate the activation energy.
2. If we know the activation energy and the rate constant at one temperature, we can determine the value of the rate constant at any other temperature.

Sample Problems 14.9 and 14.10 show how to use Equation 14.11.

## Sample Problem 14.9

The rate constant for a particular first-order reaction is given for three different temperatures:

| $\boldsymbol{T}(\mathbf{K})$ | $\boldsymbol{k}\left(\mathbf{s}^{\mathbf{- 1}}\right)$ |
| :---: | :---: |
| 400 | $2.9 \times 10^{-3}$ |
| 450 | $6.1 \times 10^{-2}$ |
| 500 | $7.0 \times 10^{-1}$ |

Using these data, calculate the activation energy of the reaction.
Strategy Use Equation 14.11 to solve for $E_{\mathrm{a}}$.
Setup Solving Equation 14.11 for $E_{\mathrm{a}}$ gives

$$
E_{\mathrm{a}}=R\left(\frac{\ln \frac{k_{1}}{k_{2}}}{\frac{1}{T_{2}}-\frac{1}{T_{1}}}\right)
$$

Solution Using the rate constants for $400 \mathrm{~K}\left(T_{1}\right)$ and $450 \mathrm{~K}\left(T_{2}\right)$, we get

$$
\begin{aligned}
E_{\mathrm{a}} & =\frac{8.314 \mathrm{~J}}{\mathrm{~K} \cdot \mathrm{~mol}}\left(\frac{\ln \frac{2.9 \times 10^{-3} \mathrm{~s}^{-1}}{6.1 \times 10^{-2} \mathrm{~s}^{-1}}}{\frac{1}{450 \mathrm{~K}}-\frac{1}{400 \mathrm{~K}}}\right) \\
& =91,173 \mathrm{~J} / \mathrm{mol}=91 \mathrm{~kJ} / \mathrm{mol}
\end{aligned}
$$

The activation energy of the reaction is $91 \mathrm{~kJ} / \mathrm{mol}$.

Practice Problem A Use the data in the following table to determine the activation energy of the reaction:

| $\boldsymbol{T}(\mathbf{K})$ | $\boldsymbol{k}\left(\mathbf{s}^{\mathbf{- 1}}\right)$ |
| :---: | :---: |
| 625 | $1.1 \times 10^{-4}$ |
| 635 | $1.5 \times 10^{-4}$ |
| 645 | $2.0 \times 10^{-4}$ |

EPractice Problem B Based on the data shown in Practice Problem A, what will be the value of $k$ at 655 K?

## Sample Problem 14.10

A certain first-order reaction has an activation energy of $83 \mathrm{~kJ} / \mathrm{mol}$. If the rate constant for this reaction is $2.1 \times 10^{-2} \mathrm{~s}^{-1}$ at $150^{\circ} \mathrm{C}$, what is the rate constant at $300^{\circ} \mathrm{C}$ ?

Strategy Use Equation 14.11 to solve for $k_{2}$. Pay particular attention to units in this type of problem.
Setup Solving Equation 14.11 for $k_{2}$ gives

$$
k_{2}=\frac{k_{1}}{e^{\left(\frac{E_{\mathrm{a}}}{R}\right)\left(\frac{1}{T_{2}}-\frac{1}{T_{1}}\right)}}
$$

$E_{\mathrm{a}}=8.3 \times 10^{4} \mathrm{~J}, T_{1}=423 \mathrm{~K}, T_{2}=573 \mathrm{~K}, R=8.314 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$, and $k_{1}=2.1 \times 10^{-2} \mathrm{~s}^{-1}$.

## Solution

$$
\begin{aligned}
k_{2} & =\frac{2.1 \times 10^{-2} \mathrm{~s}^{-1}}{e^{\left(\frac{8.3 \times 10^{4} \mathrm{~J} / \mathrm{mol}}{8.314 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol}}\right)\left(\frac{1}{573 \mathrm{~K}}-\frac{1}{423 \mathrm{~K}}\right)}} \\
& =1.0 \times 10^{1} \mathrm{~s}^{-1}
\end{aligned}
$$

The rate constant at $300^{\circ} \mathrm{C}$ is $10 \mathrm{~s}^{-1}$.

Practice Problem A Calculate the rate constant at $200^{\circ} \mathrm{C}$ for a reaction that has a rate constant of $8.1 \times 10^{-4} \mathrm{~s}^{-1}$ at $90^{\circ} \mathrm{C}$ and an activation energy of $99 \mathrm{~kJ} / \mathrm{mol}$.

EPractice Problem B Calculate the rate constant at $200^{\circ} \mathrm{C}$ for a reaction that has a rate constant of $8.1 \times 10^{-4} \mathrm{~s}^{-1}$ at $90^{\circ} \mathrm{C}$ and an activation energy of $59 \mathrm{~kJ} / \mathrm{mol}$.

Student Annotation: Note that $E_{\mathrm{a}}$ is converted to joules so that the units will cancel properly. Alternatively, the $R$ could be expressed as $0.008314 \mathrm{~kJ} / \mathrm{K} \cdot \mathrm{mol}$. Also note again that $T$ must be expressed in kelvins.

Think About It Make sure that the rate constant you calculate at a higher temperature is in fact higher than the original rate constant. According to the Arrhenius equation, the rate constant always increases with increasing temperature. If you get a smaller $k$ at a higher temperature, check your solution for mathematical errors.

## Checkpoint 14.4 Dependence of Reaction Rate on Temperature

Use the table of data collected for a first-order reaction to answer questions 14.4.1 and 14.4.2:

| $\boldsymbol{T}(\mathbf{K})$ | $\boldsymbol{k}\left(\mathbf{s}^{\mathbf{- 1}}\right)$ |
| :---: | :---: |
| 300 | $3.9 \times 10^{-2}$ |
| 310 | $1.1 \times 10^{-1}$ |
| 320 | $2.8 \times 10^{-1}$ |

14.4.1 What is the activation energy of the reaction?
a) $88 \mathrm{~kJ} / \mathrm{mol}$
b) $8.8 \times 10^{4} \mathrm{~kJ} / \mathrm{mol}$
c) $8.0 \times 10^{4} \mathrm{~kJ} / \mathrm{mol}$
d) $8.8 \times 10^{-3} \mathrm{~kJ} / \mathrm{mol}$
e) $80 \mathrm{~kJ} / \mathrm{mol}$
14.4.2 What is the rate constant at $80^{\circ} \mathrm{C}$ ?
a) $5.8 \times 10^{-40} \mathrm{~s}^{-1}$
b) $4.8 \mathrm{~s}^{-1}$
c) $2.8 \mathrm{~s}^{-1}$
d) $5.2 \times 10^{-3} \mathrm{~s}^{-1}$
e) $1.7 \times 10^{2} \mathrm{~s}^{-1}$
14.4.3 Which of the following changes when temperature changes?
a) Rate
b) Rate law
c) Rate constant
d) Activation energy
e) Reaction order

### 14.5 Reaction Mechanisms

A balanced chemical equation does not tell us much about how a reaction actually takes place. In many cases, the balanced equation is simply the sum of a series of steps. Consider the following hypothetical example. In the first step of a reaction, a molecule of reactant A combines with a molecule of reactant $B$ to form a molecule of $C$ :

$$
\mathrm{A}+\mathrm{B} \longrightarrow \mathrm{C}
$$

In the second step, the molecule of C combines with another molecule of B to produce D :

$$
\mathrm{C}+\mathrm{B} \longrightarrow \mathrm{D}
$$

The overall balanced equation is the sum of these two equations:

$$
\begin{aligned}
& \text { Step 1: } \begin{array}{c}
\mathrm{A}+\mathrm{B} \longrightarrow \not \longrightarrow \\
\text { Step } 2: \\
\frac{\ell+\mathrm{B} \longrightarrow \mathrm{D}}{\mathrm{~A}+2 \mathrm{~B} \longrightarrow \mathrm{D}}
\end{array}
\end{aligned}
$$

The sequence of steps that sum to give the overall reaction is called the reaction mechanism. A reaction mechanism is comparable to the route traveled during a trip, whereas the overall balanced chemical equation specifies only the origin and the destination.

For a specific example of a reaction mechanism, we consider the reaction between nitric oxide and oxygen:

$$
2 \mathrm{NO}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{NO}_{2}(g)
$$

We know that $\mathrm{NO}_{2}$ does not form as the result of a single collision between two NO molecules and one $\mathrm{O}_{2}$ molecule because $\mathrm{N}_{2} \mathrm{O}_{2}$ is detected during the course of the reaction. We can envision the reaction taking place via the following two steps:

$$
\begin{array}{r}
2 \mathrm{NO}(g) \longrightarrow \mathrm{N}_{2} \mathrm{O}_{2}(g) \\
\mathrm{N}_{2} \mathrm{O}_{2}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{NO}_{2}(g)
\end{array}
$$

In the first step, two NO molecules collide to form an $\mathrm{N}_{2} \mathrm{O}_{2}$ molecule. This is followed by the step in which $\mathrm{N}_{2} \mathrm{O}_{2}$ and $\mathrm{O}_{2}$ combine to give two molecules of $\mathrm{NO}_{2}$. The net chemical equation, which represents the overall change, is given by the sum of the first and second steps:

| Step 1: | $\mathrm{NO}+\mathrm{NO} \longrightarrow \mathrm{N}_{2} \mathrm{O}_{2}$ |
| :--- | ---: |
| Step 2: | $\mathrm{N}_{2} \mathrm{O}_{2}+\mathrm{O}_{2} \longrightarrow 2 \mathrm{NO}_{2}$ |
| Overall reaction: | $2 \mathrm{NO}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{NO}_{2}(g)$ |

Species such as $\mathrm{N}_{2} \mathrm{O}_{2}$ (and C in the hypothetical equation) are called intermediates because they appear in the mechanism of the reaction but not in the overall balanced equation. An intermediate is produced in an early step in the reaction and consumed in a later step.

## Elementary Reactions

Each step in a reaction mechanism represents an elementary reaction, one that occurs in a single collision of the reactant molecules. The molecularity of an elementary reaction is essentially the number of reactant molecules involved in the collision. Elementary reactions may be unimolecular (one reactant molecule), bimolecular (two reactant molecules), or termolecular (three reactant molecules). These molecules may be of the same or different types. Each of the elementary steps in the formation of $\mathrm{NO}_{2}$ from NO and $\mathrm{O}_{2}$ is bimolecular, because there are two reactant molecules in each step. Likewise, each of the steps in the hypothetical $\mathrm{A}+2 \mathrm{~B} \longrightarrow \mathrm{D}$ reaction is bimolecular.

Knowing the steps of a reaction enables us to deduce the rate law. Suppose we have the following elementary reaction:

$$
\mathrm{A} \longrightarrow \text { products }
$$

Because there is only one molecule present, this is a unimolecular reaction. It follows that the larger the number of A molecules present, the faster the rate of product formation. Thus, the rate of a unimolecular reaction is directly proportional to the concentration of A-the reaction is first order in A:

$$
\text { rate }=k[\mathrm{~A}]
$$

For a bimolecular elementary reaction involving A and B molecules,

$$
\mathrm{A}+\mathrm{B} \longrightarrow \text { products }
$$

the rate of product formation depends on how frequently A and B collide, which in turn depends on the concentrations of A and B . Thus, we can express the rate as

$$
\text { rate }=k[\mathrm{~A}][\mathrm{B}]
$$

Therefore, this is a second-order reaction. Similarly, for a bimolecular elementary reaction of the type

$$
\mathrm{A}+\mathrm{A} \longrightarrow \text { products }
$$

or

$$
2 \mathrm{~A} \longrightarrow \text { products }
$$

the rate becomes

$$
\text { rate }=k[\mathrm{~A}]^{2}
$$

which is also a second-order reaction. The preceding examples show that the reaction order for each reactant in an elementary reaction is equal to its stoichiometric coefficient in the chemical equation for that step. In general, we cannot tell just by looking at the balanced equation whether the reaction occurs as shown or in a series of steps. This determination must be made using data obtained experimentally.

## Rate-Determining Step

In a reaction mechanism consisting of more than one elementary step, the rate law for the overall process is given by the rate-determining step, which is the slowest step in the sequence. An analogy for a process in which there is a rate-determining step is the amount of time required to buy stamps at the post office when there is a long line of customers. The process consists of several steps: waiting in line, requesting the stamps, receiving the stamps, and paying for the stamps. At a time when the line is very long, the amount of time spent waiting in line (step 1 ) largely determines how much time the overall process takes.

To study reaction mechanisms, we first do a series of experiments to establish initial rates at various reactant concentrations. We then analyze the data to determine the rate constant and overall order of the reaction, and we write the rate law. Finally, we propose a plausible mechanism for the reaction in terms of logical elementary steps. The steps of the proposed mechanism must satisfy two requirements:

1. The sum of the elementary reactions must be the overall balanced equation for the reaction.
2. The rate-determining step must have the same rate law as that determined from the experimental data.
The decomposition of hydrogen peroxide can be facilitated by iodide ions (Figure 14.13). The overall reaction is

$$
2 \mathrm{H}_{2} \mathrm{O}_{2}(a q) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{O}_{2}(g)
$$

By experiment, we find the rate law to be

$$
\text { rate }=k\left[\mathrm{H}_{2} \mathrm{O}_{2}\right]\left[\mathrm{I}^{-}\right]
$$

Thus, the reaction is first order with respect to both $\mathrm{H}_{2} \mathrm{O}_{2}$ and $\mathrm{I}^{-}$.
The decomposition of $\mathrm{H}_{2} \mathrm{O}_{2}$ is not an elementary reaction, because it does not occur in a single step. If it did, the reaction would be second order in $\mathrm{H}_{2} \mathrm{O}_{2}$ (as a result of the collision of two $\mathrm{H}_{2} \mathrm{O}_{2}$ molecules). What's more, the $\mathrm{I}^{-}$ion, which is not even part of the overall equation, would not appear in the rate law expression. How can we reconcile these facts? First, we can account for the observed rate law by assuming that the reaction takes place in two separate elementary steps, each of which is bimolecular.

$$
\begin{array}{lc}
\text { Step 1: } & \mathrm{H}_{2} \mathrm{O}_{2}+\mathrm{I}^{-} \xrightarrow{k_{1}} \mathrm{H}_{2} \mathrm{O}+\mathrm{IO}^{-} \\
\text {Step 2: } & \mathrm{H}_{2} \mathrm{O}_{2}+\mathrm{IO}^{-} \xrightarrow{k_{2}} \mathrm{H}_{2} \mathrm{O}+\mathrm{O}_{2}+\mathrm{I}^{-}
\end{array}
$$

If we further assume that step 1 is the rate-determining step, then the rate of the reaction can be determined from the first step alone:

$$
\text { rate }=k_{1}\left[\mathrm{H}_{2} \mathrm{O}_{2}\right]\left[\mathrm{I}^{-}\right]
$$

Student Annotation: It is important to remember that this is not the case in general. It only applies to elementary reactions-and whether or not a reaction is elementary must be determined experimentally.

Figure 14.13 The decomposition of hydrogen peroxide is catalyzed by the addition of an iodide salt. Some of the iodide ions are oxidized to molecular iodine, which then reacts with iodide ions to form the brown triiodide ion $\left(\mathrm{I}_{3}^{-}\right)$.

Figure 14.14 Potential energy profile for a two-step reaction in which the first step is rate determining. R and $P$ represent reactants and products, respectively.

where $k_{1}=k$. The $\mathrm{IO}^{-}$ion is an intermediate because it is produced in the first step and consumed in the second step. It does not appear in the overall balanced equation. The $\mathrm{I}^{-}$ion also does not appear in the overall equation, but it is consumed in the first step and then produced in the second step. In other words, it is present at the start of the reaction, and it is present at the end. The $\mathrm{I}^{-}$ion is a catalyst, and its function is to speed up the reaction. Catalysts are discussed in greater detail in Section 14.6. Figure 14.14 shows the potential energy profile for a reaction like the decomposition of $\mathrm{H}_{2} \mathrm{O}_{2}$. The first step, which is the rate-determining step, has a larger activation energy than the second step. The intermediate, although stable enough to be observed, reacts quickly to form the products. Its existence is only fleeting.

## Experimental Support for Reaction Mechanisms

When you propose a mechanism based on experimental rate data, and your mechanism satisfies the two requirements listed on page 605, you can say that the proposed mechanism is plausible not that it is necessarily correct. It is not possible to prove that a mechanism is correct using rate data alone. To determine whether or not a proposed reaction mechanism is actually correct, we must conduct other experiments. In the case of hydrogen peroxide decomposition, we might try to detect the presence of the $\mathrm{IO}^{-}$ions. If we can detect them, it will support the proposed mechanism. Similarly, for the hydrogen iodide reaction, detection of iodine atoms would lend support to the proposed two-step mechanism. For example, $\mathrm{I}_{2}$ dissociates into atoms when it is irradiated with visible light. Thus, we might predict that the formation of HI from $\mathrm{H}_{2}$ and $\mathrm{I}_{2}$ would speed up as the intensity of light is increased-because that would increase the concentration of I atoms. Indeed, this is just what is observed.

In one case, chemists wanted to know which $\mathrm{C}-\mathrm{O}$ bond was broken in the reaction between methyl acetate and water to better understand the reaction

The two possibilities of bond breaking are

To distinguish between schemes (a) and (b), chemists used water containing the oxygen-18 isotope instead of ordinary water, which contains the oxygen- 16 isotope. When the ${ }^{18} \mathrm{O}$ water was used, only the acetic acid formed contained ${ }^{18} \mathrm{O}$ :

Thus, the reaction must have occurred via bond-breaking scheme (a), because the product formed via scheme (b) would have retained both of its original oxygen atoms and would contain no ${ }^{18} \mathrm{O}$.

Another example is photosynthesis, the process by which green plants produce glucose from carbon dioxide and water:

$$
6 \mathrm{CO}_{2}+6 \mathrm{H}_{2} \mathrm{O} \longrightarrow \mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}+6 \mathrm{O}_{2}
$$

A question that arose early in the studies of photosynthesis was whether the molecular oxygen produced came from the water, the carbon dioxide, or both. By using water containing only the oxygen-18 isotope, it was concluded that all the oxygen produced by photosynthesis came from the water and none came from the carbon dioxide, because the $\mathrm{O}_{2}$ produced contained only ${ }^{18} \mathrm{O}$.

These examples illustrate how creative chemists must be to study reaction mechanisms.

## Checkpoint 14.5 Reaction Mechanisms

Use the following information to answer questions 14.5 .1 to 14.5.3: For the reaction

$$
\mathrm{A}+\mathrm{B} \longrightarrow \mathrm{C}+\mathrm{D}
$$

the experimental rate law is rate $=k[\mathrm{~B}]^{2}$.
14.5.1 What is the order of the reaction with respect to $A$ and $B$, respectively?
a) 0 and 1
b) 1 and 0
c) 0 and 2
d) 2 and 1
e) 2 and 0
14.5.2 What is the overall order of the reaction?
a) 0
b) 1
c) 2
d) 3
e) 4
14.5.3 Which of the following is a plausible mechanism for the reaction?
a) Step 1: $\mathrm{A}+\mathrm{B} \longrightarrow \mathrm{C}+\mathrm{E}$ (slow) Step 2: $\mathrm{E}+\mathrm{A} \longrightarrow \mathrm{D}$ (fast)
b) Step 1: B $+\mathrm{B} \longrightarrow \mathrm{C}+\mathrm{E}$ (slow) Step 2: $\mathrm{E}+\mathrm{A} \longrightarrow \mathrm{D}+\mathrm{B}$ (fast)
c) Step 1: $\mathrm{A}+\mathrm{A} \longrightarrow \mathrm{B}+\mathrm{D}$ (slow) Step 2: $\mathrm{B}+\mathrm{B} \longrightarrow \mathrm{A}+\mathrm{C}$ (fast)
d) Step 1: B $+B \longrightarrow C+E$ (slow) Step 2: $\mathrm{C}+\mathrm{A} \longrightarrow \mathrm{D}+\mathrm{B}$ (fast)
e) Step 1: $\mathrm{A}+\mathrm{B} \longrightarrow \mathrm{D}+\mathrm{E}$ (slow)
Step 2: $\mathrm{E}+\mathrm{A} \longrightarrow \mathrm{C}$ (fast)
14.5.4 A plausible mechanism for the reaction

$$
\mathrm{H}_{2}+2 \mathrm{IBr} \longrightarrow \mathrm{I}_{2}+2 \mathrm{HBr}
$$

is the following:

$$
\begin{aligned}
& \text { Step 1: } \mathrm{H}_{2}+\mathrm{IBr} \xrightarrow{k_{1}} \mathrm{HI}+\mathrm{HBr} \text { (slow) } \\
& \text { Step 2: } \mathrm{HI}+\mathrm{IBr} \xrightarrow{k_{2}} \mathrm{I}_{2}+\mathrm{HBr} \text { (fast) }
\end{aligned}
$$

Select the rate law that will be determined experimentally.
a) rate $=k\left[\mathrm{H}_{2}\right]^{2}$
b) rate $=k\left[\mathrm{H}_{2}\right][\mathrm{Br}]^{2}$
c) rate $=k[\mathrm{IBr}]^{2}$
d) rate $=k\left[\mathrm{H}_{2}\right][[\mathrm{Br}]$
e) rate $=k[\mathrm{HI}][\mathrm{IBr}]$

## How Can I Tell if a Proposed Reaction Mechanism Is Plausible?

There are two criteria that must be met for a proposed reaction mechanism to be plausible:

1. The individual steps (elementary processes) must sum to the correct overall reaction.
2. The rate-determining step (the slow step) must have the same rate law as the experimentally determined rate law.
Consider the gas-phase reaction of hydrogen with iodine monochloride to form hydrogen chloride and iodine.

$$
\mathrm{H}_{2}+2 \mathrm{ICl} \longrightarrow 2 \mathrm{HCl}+\mathrm{I}_{2}
$$

The experimentally determined rate law for this reaction is rate $=k\left[\mathrm{H}_{2}\right][\mathrm{ICl}]$. We present four different proposed mechanisms.

## Mechanism 1

$$
\begin{array}{ll}
\text { Step 1: } & \mathrm{ICl}+\mathrm{ICl} \longrightarrow \mathrm{I}_{2}+\mathrm{Cl}_{2} \text { (slow) } \\
\text { Step 2: } & \mathrm{Cl}_{2}+\mathrm{H}_{2} \longrightarrow 2 \mathrm{HCl}
\end{array}
$$

The steps in mechanism 1 sum to the correct overall reaction:

$$
\begin{aligned}
& \mathrm{ICl}+\mathrm{ICl} \longrightarrow \mathrm{I}_{2}+\mathrm{C}_{2} \text { (slow) } \\
& \mathrm{C}_{2}+\mathrm{H}_{2} \longrightarrow 2 \mathrm{HCl} \\
& \hline \text { Sum: } \mathrm{H}_{2}+2 \mathrm{ICl} \longrightarrow 2 \mathrm{HCl}+\mathrm{I}_{2}
\end{aligned}
$$

However, the rate law of the rate-determining step is rate $=$ $k[\mathrm{ICl}]^{2}$. Therefore, mechanism 1 is not plausible. It meets criterion 1 , but it does not meet criterion 2 .

## Mechanism 2

$$
\begin{aligned}
& \text { Step 1: } \quad \mathrm{H}_{2}+\mathrm{ICl} \longrightarrow \mathrm{HI}+\mathrm{HCl} \text { (slow) } \\
& \text { Step 2: } \mathrm{ICl}+\mathrm{HCl} \longrightarrow \mathrm{HI}+\mathrm{Cl}_{2}
\end{aligned}
$$

The rate-determining step in mechanism 2 has the correct rate law:

$$
\text { rate }=k\left[\mathrm{H}_{2}\right][\mathrm{ICl}]
$$

However, the steps do not sum to the correct overall reaction:

$$
\begin{gathered}
\mathrm{H}_{2}+\mathrm{ICl} \longrightarrow \mathrm{HI}+\mathrm{HCI} \text { (slow) } \\
\mathrm{ICl}+\mathrm{HCT} \longrightarrow \mathrm{HI}+\mathrm{Cl}_{2} \\
\hline \text { Sum: } \mathrm{H}_{2}+2 \mathrm{ICl} \longrightarrow 2 \mathrm{HI}+\mathrm{Cl}_{2}
\end{gathered}
$$

Therefore, mechanism 2 is not plausible. It meets criterion 2, but it does not meet criterion 1 .

## Mechanism 3

```
Step 1:
```

```
Step 2: \(\mathrm{ICl}+\mathrm{H} \longrightarrow \mathrm{HCl}+\mathrm{I}\)
Step 3: \(\mathrm{H}+\mathrm{I} \longrightarrow \mathrm{HI}\)
```

The rate law for the rate-determining step in mechanism 3 (rate $=k\left[\mathrm{H}_{2}\right]$ ) is not correct.

Furthermore, the steps do not sum to the correct overall reaction:

$$
\begin{aligned}
\mathrm{H}_{2} & \longrightarrow 3 \mathrm{H} \text { (slow) } \\
\mathrm{ICl}+\mathrm{H} & \longrightarrow \mathrm{HCl}+X \\
\mathrm{H}+X & \longrightarrow \mathrm{HI} \\
\text { Sum: } \mathrm{H}_{2}+\mathrm{ICl} & \longrightarrow \mathrm{HCl}+\mathrm{HI}
\end{aligned}
$$

Therefore, mechanism 3 is not plausible. It meets neither criterion 1 nor criterion 2.

## Mechanism 4

$$
\begin{array}{ll}
\text { Step 1: } & \mathrm{H}_{2}+\mathrm{ICl} \longrightarrow \mathrm{HCl}+\mathrm{HI} \text { (slow) } \\
\text { Step 2: } & \mathrm{HI}+\mathrm{ICl} \longrightarrow \mathrm{HCl}+\mathrm{I}_{2}
\end{array}
$$

The rate-determining step in mechanism 4 has the correct rate law:

$$
\text { rate }=k\left[\mathrm{H}_{2}\right][\mathrm{ICl}]
$$

Furthermore, the steps in mechanism 4 sum to the correct overall reaction:

$$
\begin{gathered}
\mathrm{H}_{2}+\mathrm{ICl} \longrightarrow \mathrm{HCl}+\mathrm{HI} \text { (slow) } \\
\mathrm{HI}+\mathrm{ICl} \longrightarrow \mathrm{HCl}+\mathrm{I}_{2} \\
\hline \text { Sum: } \mathrm{H}_{2}+2 \mathrm{ICl} \longrightarrow 2 \mathrm{HCl}+\mathrm{I}_{2}
\end{gathered}
$$

Therefore, mechanism 4 is plausible. It meets both criteria.

Sample Problem 14.11 lets you practice determining if a proposed reaction mechanism is plausible.

## Sample Problem 14.11

The gas-phase decomposition of nitrous oxide $\left(\mathrm{N}_{2} \mathrm{O}\right)$ is believed to occur in two steps:

$$
\begin{array}{lr}
\text { Step 1: } & \mathrm{N}_{2} \mathrm{O} \xrightarrow{k_{1}} \mathrm{~N}_{2}+\mathrm{O} \\
\text { Step 2: } & \mathrm{N}_{2} \mathrm{O}+\mathrm{O} \xrightarrow{k_{2}} \mathrm{~N}_{2}+\mathrm{O}_{2}
\end{array}
$$

Experimentally the rate law is found to be rate $=k\left[\mathrm{~N}_{2} \mathrm{O}\right]$. (a) Write the equation for the overall reaction. (b) Identify the intermediate(s). (c) Identify the rate-determining step.

Strategy Add the two equations, canceling identical terms on opposite sides of the arrow, to obtain the overall reaction. The canceled terms will be the intermediates if they were first generated and then consumed. Write rate laws for each elementary step; the one that matches the experimental rate law will be the rate-determining step.

Setup Intermediates are species that are generated in an earlier step and consumed in a later step. We can write rate laws for elementary reactions simply by using the stoichiometric coefficient for each species as its exponent in the rate law.

$$
\begin{array}{lcl}
\text { Step 1: } & \mathrm{N}_{2} \mathrm{O} \xrightarrow{k_{1}} \mathrm{~N}_{2}+\mathrm{O} & \text { rate }=k\left[\mathrm{~N}_{2} \mathrm{O}\right] \\
\text { Step 2: } & \mathrm{N}_{2} \mathrm{O}+\mathrm{O} \xrightarrow{k_{2}} \mathrm{~N}_{2}+\mathrm{O}_{2} & \text { rate }=k\left[\mathrm{~N}_{2} \mathrm{O}\right][\mathrm{O}]
\end{array}
$$

Solution (a) $2 \mathrm{~N}_{2} \mathrm{O} \longrightarrow 2 \mathrm{~N}_{2}+\mathrm{O}_{2}$
(b) O (atomic oxygen) is the intermediate.
(c) Step 1 is the rate-determining step because its rate law is the same as the experimental rate law: rate $=k\left[\mathrm{~N}_{2} \mathrm{O}\right]$.

Practice Problem A The reaction between $\mathrm{NO}_{2}$ and CO to produce NO and $\mathrm{CO}_{2}$ is thought to occur in two steps:

$$
\begin{array}{ll}
\text { Step 1: } & \mathrm{NO}_{2}+\mathrm{NO}_{2} \xrightarrow{k_{1}} \mathrm{NO}+\mathrm{NO}_{3} \\
\text { Step 2: } & \mathrm{NO}_{3}+\mathrm{CO} \xrightarrow{k_{2}} \mathrm{NO}_{2}+\mathrm{CO}_{2}
\end{array}
$$

The experimental rate law is rate $=k\left[\mathrm{NO}_{2}\right]^{2}$. (a) Write the equation for the overall reaction. (b) Identify the intermediate(s). (c) Identify the rate-determining step.

EPractice Problem B Propose a plausible mechanism for the reaction $\mathrm{F}_{2}+2 \mathrm{ClO}_{2} \longrightarrow 2 \mathrm{FClO}_{2}$, given that the rate law for the reaction is rate $=k\left[\mathrm{~F}_{2}\right]\left[\mathrm{ClO}_{2}\right]$.

Think About It A species that gets canceled when steps are added may be an intermediate or a catalyst. In this case, the canceled species is an intermediate because it was first generated and then consumed. A species that is first consumed and then generated, but doesn't appear in the overall equation, is a catalyst.

## What if the First Step in a Mechanism Is Not the Rate-Determining Step?

For first- and second-order reactions, it is reasonably straightforward to propose a plausible mechanism. We simply use the experimentally determined rate law to write the rate-determining step as the first step, and then write one or more additional steps such that the appropriate species will cancel to give the correct overall equation. Sometimes, however, we will encounter a reaction with an experimentally determined rate law that suggests an unlikely scenario. For example, consider the gaseous reaction of nitric oxide with chlorine to produce nitrosyl chloride,

$$
2 \mathrm{NO}(g)+\mathrm{Cl}_{2}(g) \longrightarrow 2 \mathrm{NOCl}(g)
$$

for which the experimentally determined rate law is rate $=$ $k[\mathrm{NO}]^{2}\left[\mathrm{Cl}_{2}\right]$. Note that the exponents in the rate law are the same as the coefficients in the balanced equation-making this reaction third order overall. Although one possibility is that the reaction is an elementary process, this would require the simultaneous collision of three molecules. As was noted on page 604, such a termolecular reaction is unlikely. A more reasonable mechanism would be one in which a fast first step is followed by the slower, rate-determining step.

$$
\begin{array}{ll}
\text { Step 1: } & \mathrm{NO}(g)+\mathrm{Cl}_{2}(g) \xrightarrow{k_{1}} \mathrm{NOCl}_{2}(g) \quad \text { (fast) } \\
\text { Step 2: } & \mathrm{NOCl}_{2}(g)+\mathrm{NO}(g) \xrightarrow{k_{2}} 2 \mathrm{NOCl}(g) \quad \text { (slow) }
\end{array}
$$

However, when we write the overall rate law using the equation for the rate-determining step, as we have done previously, the resulting rate law

$$
\text { rate }=k_{2}\left[\mathrm{NOCl}_{2}\right][\mathrm{NO}]
$$

includes the concentration of an intermediate $\left(\mathrm{NOCl}_{2}\right)$. Although this rate law is correct for the proposed mechanism, in this form it does not enable us to determine the plausibility of the mechanism by comparison to the experimentally determined rate law. To do this, we must derive a rate law in which only reactants from the overall equation appear.

When the intermediate $\left(\mathrm{NOCl}_{2}\right)$ is not consumed by step 2 as fast as it is produced by step 1, its concentration builds up, causing step 1 to happen in reverse; that is, $\mathrm{NOCl}_{2}$ reacts to produce NO and $\mathrm{Cl}_{2}$. This results in the establishment of a dynamic equilibrium [ 14 Section 4.1], where the forward and reverse of step 1 are occurring at the same rate. We denote this by changing the single reaction arrow in step 1 to equilibrium arrows:

$$
\mathrm{NO}(g)+\mathrm{Cl}_{2}(g) \underset{k_{-1}}{\stackrel{k_{1}}{\leftrightarrows}} \mathrm{NOCl}_{2}(g)
$$

We can write the rate laws for the forward and reverse of step 1 , both elementary processes, as

$$
\text { rate }_{\text {forward }}=k_{1}[\mathrm{NO}]\left[\mathrm{Cl}_{2}\right] \quad \text { and } \quad \text { rate }_{\text {reverse }}=k_{-1}\left[\mathrm{NOCl}_{2}\right]
$$

where $k_{1}$ and $k_{-1}$ are the individual rate constants for the forward and reverse processes, respectively. Because the two rates are equal, we can write

$$
k_{1}[\mathrm{NO}]\left[\mathrm{Cl}_{2}\right]=k_{-1}\left[\mathrm{NOCl}_{2}\right]
$$

Rearranging to solve for the concentration of $\mathrm{NOCl}_{2}$ gives

$$
\underbrace{\frac{k_{1}}{k_{-1}}}[\mathrm{NO}]\left[\mathrm{Cl}_{2}\right]=\left[\mathrm{NOCl}_{2}\right]
$$

When we substitute the result into the original rate law for the concentration of $\mathrm{NOCl}_{2}$, we get

$$
\text { rate }=k_{2}\left[\mathrm{NOCl}_{2}\right][\mathrm{NO}]=k_{2} \frac{k_{1}}{k_{-1}}[\mathrm{NO}]^{2}\left[\mathrm{Cl}_{2}\right]
$$

which agrees with the experimentally determined rate law, rate $=$ $k[\mathrm{NO}]^{2}\left[\mathrm{Cl}_{2}\right]$, where $k$ is equal to $\frac{k_{2} k_{1}}{k_{-1}}$.

Sample Problem 14.12 lets you practice relating the experimentally determined rate law to a reaction mechanism in which a fast first step is followed by a slower, rate-determining step.

### 14.6 Catalysis

Recall from Section 14.5 that the reaction rate for the decomposition of hydrogen peroxide depends on the concentration of iodide ions, even though $\mathrm{I}^{-}$does not appear in the overall equation. Instead, $\mathrm{I}^{-}$acts as a catalyst for the reaction. A catalyst is a substance that increases the rate of a chemical reaction without itself being consumed. The catalyst may react to form an intermediate, but it is regenerated in a subsequent step of the reaction.

Molecular oxygen is prepared in the laboratory by heating potassium chlorate. The reaction is

$$
2 \mathrm{KClO}_{3}(s) \longrightarrow 2 \mathrm{KCl}(s)+3 \mathrm{O}_{2}(g)
$$

## Sample Problem 14.12

Consider the gas-phase reaction of nitric oxide and oxygen that was described at the beginning of Section 14.5:

$$
2 \mathrm{NO}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{NO}_{2}(g)
$$

Show that the following mechanism is plausible. The experimentally determined rate law is rate $=k[\mathrm{NO}]^{2}\left[\mathrm{O}_{2}\right]$.

Step 1: $\quad \mathrm{NO}(g)+\mathrm{NO}(g) \underset{k_{-1}}{\stackrel{k_{1}}{\rightleftarrows}} \mathrm{~N}_{2} \mathrm{O}_{2}(g) \quad$ (fast)
Step 2: $\quad \mathrm{N}_{2} \mathrm{O}_{2}(g)+\mathrm{O}_{2}(g) \xrightarrow{k_{2}} 2 \mathrm{NO}_{2}(g) \quad$ (slow)
Strategy To establish the plausibility of a mechanism, we must compare the rate law of the ratedetermining step to the experimentally determined rate law. In this case, the rate-determining step has an intermediate $\left(\mathrm{N}_{2} \mathrm{O}_{2}\right)$ as one of its reactants, giving us a rate law of rate $=k_{2}\left[\mathrm{~N}_{2} \mathrm{O}_{2}\right]\left[\mathrm{O}_{2}\right]$.
Because we cannot compare this directly to the experimental rate law, we must solve for the intermediate concentration in terms of reactant concentrations.

Setup The first step is a rapidly established equilibrium. Both the forward and reverse of step 1 are elementary processes, which enables us to write their rate laws from the balanced equation.

$$
\operatorname{rate}_{\text {forward }}=k_{1}[\mathrm{NO}]^{2} \quad \text { and } \quad \text { rate }_{\text {reverse }}=k_{-1}\left[\mathrm{~N}_{2} \mathrm{O}_{2}\right]
$$

Solution Because at equilibrium the forward and reverse processes are occurring at the same rate, we can set their rates equal to each other and solve for the intermediate concentration.

$$
\begin{aligned}
k_{1}[\mathrm{NO}]^{2} & =k_{-1}\left[\mathrm{~N}_{2} \mathrm{O}_{2}\right] \\
{\left[\mathrm{N}_{2} \mathrm{O}_{2}\right] } & =\frac{k_{1}[\mathrm{NO}]^{2}}{k_{-1}}
\end{aligned}
$$

Substituting the solution into the original rate law (rate $=k\left[\mathrm{~N}_{2} \mathrm{O}_{2}\right]\left[\mathrm{O}_{2}\right]$ ) gives

$$
\text { rate }=k_{2} \frac{k_{1}[\mathrm{NO}]^{2}}{k_{-1}}\left[\mathrm{O}_{2}\right]=k[\mathrm{NO}]^{2}\left[\mathrm{O}_{2}\right] \quad \text { where } k=\frac{k_{2} k_{1}}{k_{-1}}
$$

Practice Problem A Show that the following mechanism is consistent with the experimentally determined rate law of rate $=k[\mathrm{NO}]^{2}\left[\mathrm{Br}_{2}\right]$ for the reaction of nitric oxide and bromine: $2 \mathrm{NO}(g)+$ $\mathrm{Br}_{2}(g) \longrightarrow 2 \mathrm{NOBr}(g)$.

Step 1: $\quad \mathrm{NO}(g)+\mathrm{Br}_{2}(g) \underset{k_{-1}}{\stackrel{k_{1}}{\rightleftarrows}} \mathrm{NOBr}_{2}(g) \quad$ (fast)
Step 2: $\mathrm{NOBr}_{2}(g)+\mathrm{NO}(g) \xrightarrow{k_{2}} 2 \mathrm{NOBr}(g) \quad$ (slow)
$\boldsymbol{H}$ Practice Problem B The reaction $\mathrm{H}_{2}(g)+\mathrm{I}_{2}(g) \longrightarrow 2 \mathrm{HI}(g)$ proceeds via a two-step mechanism in which the rate law for the rate-determining step is rate $=k\left[\mathrm{H}_{2}\right][I]^{2}$. Write the mechanism and rewrite the rate law using only reactant concentrations.

However, this thermal decomposition process is very slow in the absence of a catalyst. The rate of decomposition can be increased dramatically by adding a small amount of manganese(IV) dioxide $\left(\mathrm{MnO}_{2}\right)$, a black powdery substance. All the $\mathrm{MnO}_{2}$ can be recovered at the end of the reaction, just as all the $\mathrm{I}^{-}$ions remain following the decomposition of $\mathrm{H}_{2} \mathrm{O}_{2}$.

A catalyst speeds up a reaction by providing a set of elementary steps with more favorable kinetics than those that exist in its absence. From Equation 14.8 we know that the rate constant $k$ (and hence the rate) of a reaction depends on the frequency factor $(A)$ and the activation energy $\left(E_{\mathrm{a}}\right)$ - the larger the value of $A$ (or the smaller the value of $E_{\mathrm{a}}$ ), the greater the rate. In many cases, a catalyst increases the rate by lowering the activation energy for the reaction.

Figure 14.15 Comparison of the activation energy barriers of (a) an uncatalyzed reaction and (b) the same reaction with a catalyst. A catalyst lowers the energy barrier but does not affect the energies of the reactants or products. Although the reactants and products are the same in both cases, the reaction mechanisms and rate laws are different in (a) and (b).

Let's assume that the following reaction has a certain rate constant $k$ and an activation energy $E_{\mathrm{a}}$.

$$
\mathrm{A}+\mathrm{B} \xrightarrow{k} \mathrm{C}+\mathrm{D}
$$

In the presence of a catalyst, however, the rate constant is $k_{\mathrm{c}}$, called the catalytic rate constant.
By the definition of a catalyst,

$$
\text { rate }_{\text {catalyzed }}>\text { rate }_{\text {uncatalyzed }}
$$

Figure 14.15 shows the potential energy profiles for both reactions. The total energies of the reactants (A and B) and those of the products ( C and D ) are unaffected by the catalyst; the only difference between the two is a lowering of the activation energy from $E_{\mathrm{a}}$ to $E_{\mathrm{a}}^{\prime}$. Because the activation energy for the reverse reaction is also lowered, a catalyst enhances the rates of the forward and reverse reactions equally.

There are three general types of catalysis, depending on the nature of the rate-increasing substance: heterogeneous catalysis, homogeneous catalysis, and enzyme catalysis.

## Heterogeneous Catalysis

In heterogeneous catalysis, the reactants and the catalyst are in different phases. The catalyst is usually a solid, and the reactants are either gases or liquids. Heterogeneous catalysis is by far the most important type of catalysis in industrial chemistry, especially in the synthesis of many important chemicals. Heterogeneous catalysis is also used in the catalytic converters in automobiles.

At high temperatures inside a car's engine, nitrogen and oxygen gases react to form nitric oxide:

$$
\mathrm{N}_{2}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{NO}(g)
$$

When released into the atmosphere, NO rapidly combines with $\mathrm{O}_{2}$ to form $\mathrm{NO}_{2}$. Nitrogen dioxide and other gases emitted by automobiles, such as carbon monoxide ( CO ) and various unburned hydrocarbons, make automobile exhaust a major source of air pollution.

Most new cars are equipped with catalytic converters [Figure 14.16(a)]. An efficient catalytic converter serves two purposes: It oxidizes CO and unburned hydrocarbons to $\mathrm{CO}_{2}$ and $\mathrm{H}_{2} \mathrm{O}$, and it converts NO and $\mathrm{NO}_{2}$ to $\mathrm{N}_{2}$ and $\mathrm{O}_{2}$. Hot exhaust gases into which air has been injected are passed through the first chamber of one converter to accelerate the complete burning of hydrocarbons and to decrease CO emissions. Because high temperatures increase NO production, however, a second chamber containing a different catalyst (a transition metal or a transition metal oxide such as CuO or $\mathrm{Cr}_{2} \mathrm{O}_{3}$ ) and operating at a lower temperature is required to dissociate NO into $\mathrm{N}_{2}$ and $\mathrm{O}_{2}$ before the exhaust is discharged through the tailpipe [Figure 14.16(b)].

## Homogeneous Catalysis

In homogeneous catalysis the reactants and the catalyst are dispersed in a single phase, usually liquid. Acid and base catalyses are the most important types of homogeneous catalysis in liquid solution. For example, the reaction of ethyl acetate with water to form acetic acid and ethanol normally occurs too slowly to be measured.

Figure 14.16 (a) A two-stage catalytic converter for an automobile. (b) In the second stage, NO molecules bind to the surface of the catalyst. The N atoms bond to each other and the O atoms bond to each other, producing $\mathrm{N}_{2}$ and $\mathrm{O}_{2}$, respectively.

Figure 14.17 The lock-and-key model of an enzyme's specificity for substrate molecules.

Figure 14.18 Left to right: The binding of glucose molecule (red) to hexokinase (an enzyme in the metabolic pathway). Note how the region at the active site closes around glucose after binding. Often, the geometries of both the substrate and the active site are altered to fit each other.

Figure 14.19 Comparison of (a) an uncatalyzed reaction and (b) the same reaction catalyzed by an enzyme. The plot in (b) assumes that the catalyzed reaction has a two-step mechanism, in which the second step (ES $\longrightarrow \mathrm{E}+\mathrm{P}$ ) is rate determining.

enzymes, but it contradicts research evidence that a single enzyme binds to substrates of different sizes and shapes. Chemists now know that an enzyme molecule (or at least its active site) has a fair amount of structural flexibility and can modify its shape to accommodate more than one type of substrate. Figure 14.18 shows a molecular model of an enzyme in action.

The mathematical treatment of enzyme kinetics is quite complex, even when we know the basic steps involved in the reaction. A simplified scheme is given by the following elementary steps:

$$
\begin{aligned}
& \mathrm{E}+\mathrm{S} \underset{k_{-1}}{\stackrel{k_{1}}{\longrightarrow}} \mathrm{ES} \\
& \mathrm{ES} \xrightarrow{k_{2}} \mathrm{E}+\mathrm{P}
\end{aligned}
$$

where E, S, and P represent enzyme, substrate, and product, respectively, and ES is the enzymesubstrate intermediate. It is often assumed that the formation of ES and its decomposition back to enzyme and substrate molecules occur rapidly and that the rate-determining step is the formation of product. Figure 14.19 shows the potential-energy profile for the reaction.

In general, the rate of such a reaction is given by the equation

$$
\begin{aligned}
\text { rate } & =\frac{\Delta[\mathrm{P}]}{\Delta t} \\
& =k[\mathrm{ES}]
\end{aligned}
$$

The concentration of the ES intermediate is itself proportional to the amount of the substrate present, and a plot of the rate versus the concentration of substrate typically yields a curve like that shown in Figure 14.20. Initially the rate rises rapidly with increasing substrate concentration. Above a certain concentration, however, all the active sites are occupied, and the reaction becomes zeroth order in the substrate. In other words, the rate remains the same even though the substrate concentration increases. At and beyond this point, the rate of formation of product depends only on how fast the ES intermediate breaks down, not on the number of substrate molecules present.

## Bringing Chemistry to Life

## Catalysis and Hangovers

We learned at the beginning of the chapter that alcohol dehydrogenase (ADH) and aldehyde dehydrogenase (ALDH) catalyze the metabolism of methanol. In analogous reactions, ADH and ALDH catalyze the metabolism of ethanol, the alcohol in alcoholic beverages.

The first reaction converts ethanol to acetaldehyde, which is far more toxic than ethanol:

$$
\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}+\mathrm{NAD}^{+} \longrightarrow \mathrm{CH}_{3} \mathrm{CHO}+\mathrm{NADH}+\mathrm{H}^{+}
$$

It is acetaldehyde $\left(\mathrm{CH}_{3} \mathrm{CHO}\right)$ that causes the misery associated with a hangover-including headache, nausea, and vomiting.

In the second reaction, acetaldehyde is converted to acetic acid, which is harmless:

$$
\mathrm{CH}_{3} \mathrm{CHO}+\mathrm{NADP}^{+}+\mathrm{H}_{2} \mathrm{O} \longrightarrow \mathrm{CH}_{3} \mathrm{COOH}+\mathrm{NADPH}+\mathrm{H}^{+}
$$

An effective but painful part of the treatment for alcohol abuse is to administer disulfiram, marketed under the name Antabuse. Disulfiram blocks the action of ALDH, preventing the conversion of acetaldehyde to acetic acid. The resulting buildup of acetaldehyde causes the patient to feel very sick almost immediately, making the next cocktail far less appealing. The action of disulfiram was discovered accidentally when Danish pharmaceutical researchers who were taking the drug as an experimental treatment for parasitic diseases became very ill every time they consumed alcohol.

Figure 14.20 Plot of the rate of product formation versus substrate concentration in an enzyme-catalyzed reaction.

## Applying What You've Learned

It takes as little as $5 \mathrm{~mL}(1 \mathrm{tsp})$ of methanol to cause permanent blindness or death; and unlike ethanol, methanol can be absorbed in toxic amounts by ingestion, inhalation of vapor, or absorption through the skin. Nevertheless, methanol is present in a number of common household products including antifreeze, windshield-washing fluid, and paint remover.

One method that has been used to synthesize methanol is the combination of carbon monoxide and hydrogen gases at $100^{\circ} \mathrm{C}$ :

$$
\mathrm{CO}(\mathrm{~g})+2 \mathrm{H}_{2}(\mathrm{~g}) \longrightarrow \mathrm{CH}_{3} \mathrm{OH}(\mathrm{~g})
$$

This reaction is catalyzed by a nickel compound.

## Problems:

a) Write the expression for the rate of this reaction in terms of [CO]. [144 Sample Problem 14.1]
b) Write the expression for the rate of this reaction in terms of $\left[\mathrm{H}_{2}\right]$ and in terms of $\left[\mathrm{CH}_{3} \mathrm{OH}\right]$. [14 Sample Problem 14.2]
c) Given the following table of experimental data at $100^{\circ} \mathrm{C}$, determine the rate law and the rate constant for the reaction. Then, determine the initial rate of the reaction when the starting concentration of CO is 16.5 M . [ kt Sample Problem 14.3]

| Experiment | $[\mathbf{C O}](\boldsymbol{M})$ | $\left[\mathbf{H}_{\mathbf{2}}\right](\boldsymbol{M})$ | Initial Rate $(\boldsymbol{M} / \mathbf{s})$ |
| :---: | :---: | :---: | :---: |
| 1 | 5.60 | 11.2 | 0.952 |
| 2 | 5.60 | 22.4 | 0.952 |
| 3 | 11.2 | 11.2 | 1.90 |

d) Calculate the time required for the concentration of CO to be reduced from 16.5 M to 1.91 M . [ 14 Sample Problem 14.4]
e) Calculate $t_{1 / 2}$ of the reaction. [ $\mathrm{k4}$ Sample Problem 14.6]
f) Given that $k$ is $3.0 \mathrm{~s}^{-1}$ at $200^{\circ} \mathrm{C}$, calculate $E_{\mathrm{a}}$ of the reaction. [ 14 Sample Problem 14.9]
g) Use the calculated value of $E_{\mathrm{a}}$ to determine the value of $k$ at $180^{\circ} \mathrm{C}$. [ $k 4$ Sample Problem 14.10]

## Chapter Summary

## Section 14.1

- The rate of a chemical reaction is the change in concentration of reactants or products over time. Rates may be expressed as an average rate over a given time interval or as an instantaneous rate.
- The rate constant $(\boldsymbol{k})$ is a proportionality constant that relates the rate of reaction with the concentration(s) of reactant(s). The rate constant $k$ for a given reaction changes only with temperature.

## Section 14.2

- The rate law is an equation that expresses the relationship between rate and reactant concentration(s). In general, the rate law for the reaction of A and B is rate $=k[\mathrm{~A}]^{x}[\mathrm{~B}]^{y}$.
- The reaction order is the power to which the concentration of a given reactant is raised in the rate law equation. The overall reaction order is the sum of the powers to which reactant concentrations are raised in the rate law.
- The initial rate is the instantaneous rate of reaction when the reactant concentrations are starting concentrations.
- The rate law and reaction order must be determined by comparing changes in the initial rate with changes in starting reactant concentrations. In general, the rate law cannot be determined solely from the balanced equation.

## Section 14.3

- The integrated rate law can be used to determine reactant concentrations after a specified period of time. It can also be used to determine how long it will take to reach a specified reactant concentration.
- The rate of a first-order reaction is proportional to the concentration of a single reactant. The rate of a second-order reaction is proportional to the product of two reactant concentrations ( $[\mathrm{A}][\mathrm{B}]$ ), or on the concentration of a single reactant squared $\left([A]^{2}\right.$ or $\left.[B]^{2}\right)$. The rate of a zeroth-order reaction does not depend on reactant concentration.
- The half-life ( $\boldsymbol{t}_{1 / 2}$ ) of a reaction is the time it takes for half of a reactant to be consumed. The half-life is constant for first-order reactions, and it can be used to determine the rate constant of the reaction.

## Section 14.4

- Collision theory explains why the rate constant, and therefore the reaction rate, increases with increasing temperature. The relationship between temperature and the rate constant is expressed by the Arrhenius equation.
- Reactions occur when molecules of sufficient energy (and appropriate orientation) collide. Effective collisions are those that result in the formation of an activated complex, also called a transition state. Only effective collisions can result in product formation.
- The activation energy $\left(\boldsymbol{E}_{\mathrm{a}}\right)$ is the minimum energy that colliding molecules must possess in order for the collision to be effective.

## Section 14.5

- A reaction mechanism may consist of a series of steps, called elementary reactions. Unlike rate laws in general, the rate law for an elementary reaction can be written from the balanced equation, using the stoichiometric coefficient for each reactant species as its exponent in the rate law.
- A species that is produced in one step of a reaction mechanism and subsequently consumed in another step is called an intermediate. A species that is first consumed and later regenerated is called a catalyst. Neither intermediates nor catalysts appear in the overall balanced equation.
- The rate law of each step in a reaction mechanism indicates the molecularity or overall order of the step. A unimolecular step is first order, involving just one molecule; a bimolecular step is second order, involving the collision of two molecules; and a termolecular step is third order, involving the collision of three molecules. Termolecular processes are relatively rare.
- If one step in a reaction is much slower than all the other steps, it is the rate-determining step. The rate-determining step has a rate law identical to the experimental rate law.

## Section 14.6

- A catalyst speeds up a reaction, usually by lowering the value of the activation energy. Catalysis refers to the process by which a catalyst increases the reaction rate.
- Catalysis may be heterogeneous, in which the catalyst and reactants exist in different phases, or homogeneous, in which the catalyst and reactants exist in the same phase.
- Enzymes are biological catalysts with high specificity for the reactions that they catalyze.

## Questions and Problems

## Section 14.1: Reaction Rates

## Review Questions

14.1 What is meant by the rate of a chemical reaction? What are the units of the rate of a reaction?
14.2 Distinguish between average rate and instantaneous rate. Which of the two rates gives us an unambiguous measurement of reaction rate? Why?
14.3 What are the advantages of measuring the initial rate of a reaction?
14.4 Identify two reactions that are very slow (take days or longer to complete) and two reactions that are very fast (reactions that are over in minutes or seconds).

## Problems

E14.5 Write the reaction rate expressions for the following reactions in terms of the disappearance of the reactants and the appearance of products:
(a) $\mathrm{H}_{2}(g)+\mathrm{I}_{2}(g) \longrightarrow 2 \mathrm{HI}(g)$
(b) $5 \mathrm{Br}^{-}(a q)+\mathrm{BrO}_{3}^{-}(a q)+6 \mathrm{H}^{+}(a q) \longrightarrow 3 \mathrm{Br}_{2}(a q)+3 \mathrm{H}_{2} \mathrm{O}(l)$

E14.6 Write the reaction rate expressions for the following reactions in terms of the disappearance of the reactants and the appearance of products:
(a) $2 \mathrm{H}_{2}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(g)$
(b) $4 \mathrm{NH}_{3}(g)+5 \mathrm{O}_{2}(g) \longrightarrow 4 \mathrm{NO}(g)+6 \mathrm{H}_{2} \mathrm{O}(g)$

H14.7 Consider the reaction

$$
2 \mathrm{NO}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{NO}_{2}(g)
$$

Suppose that at a particular moment during the reaction nitric oxide (NO) is reacting at the rate of $0.066 \mathrm{M} / \mathrm{s}$. (a) At what rate is $\mathrm{NO}_{2}$ being formed? (b) At what rate is molecular oxygen reacting?

E14.8 Consider the reaction

$$
\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \longrightarrow 2 \mathrm{NH}_{3}(g)
$$

Suppose that at a particular moment during the reaction molecular hydrogen is reacting at the rate of $0.082 \mathrm{M} / \mathrm{s}$. (a) At what rate is ammonia being formed? (b) At what rate is molecular nitrogen reacting?

## Section 14.2: Dependence of Reaction Rate on Reactant Concentration

## Review Questions

14.9 Explain what is meant by the rate law of a reaction.
14.10 Explain what is meant by the order of a reaction.
14.11 What are the units for the rate constants of first-order and secondorder reactions?
14.12 Consider the zeroth-order reaction: $\mathrm{A} \longrightarrow$ product. (a) Write the rate law for the reaction. (b) What are the units for the rate constant? (c) Plot the rate of the reaction versus [A].

E 14.13 The rate constant of a first-order reaction is $66 \mathrm{~s}^{-1}$. What is the rate constant in units of minutes?
14.14 On which of the following properties does the rate constant of a reaction depend: (a) reactant concentrations, (b) nature of reactants, (c) temperature?

## Problems

G14.15 The rate law for the reaction

$$
\mathrm{NH}_{4}^{+}(a q)+\mathrm{NO}_{2}^{-}(a q) \longrightarrow \mathrm{N}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(l)
$$

is given by rate $=k\left[\mathrm{NH}_{4}^{+}\right]\left[\mathrm{NO}_{2}^{-}\right]$. At $25^{\circ} \mathrm{C}$, the rate constant is 3.0 $\times 10^{-4} / \mathrm{M} \cdot \mathrm{s}$. Calculate the rate of the reaction at this temperature if $\left[\mathrm{NH}_{4}^{+}\right]=0.36 \mathrm{M}$ and $\left[\mathrm{NO}_{2}^{-}\right]=0.075 \mathrm{M}$.

E 14.16 Use the data in Table 14.2 to calculate the rate of the reaction at the time when $\left[\mathrm{F}_{2}\right]=0.020 \mathrm{M}$ and $\left[\mathrm{ClO}_{2}\right]=0.035 \mathrm{M}$.

E14.17 Consider the reaction

$$
\mathrm{A}+\mathrm{B} \longrightarrow \text { products }
$$

From the following data obtained at a certain temperature, determine the order of the reaction and calculate the rate constant.

| [A] $(\boldsymbol{M})$ | $[\mathbf{B}](\boldsymbol{M})$ | Rate $(\boldsymbol{M} / \mathbf{s})$ |
| :---: | :---: | :---: |
| 1.50 | 1.50 | $3.20 \times 10^{-1}$ |
| 1.50 | 2.50 | $3.20 \times 10^{-1}$ |
| 3.00 | 1.50 | $6.40 \times 10^{-1}$ |

E14.18 Consider the reaction

$$
\mathrm{X}+\mathrm{Y} \longrightarrow \mathrm{Z}
$$

From the following data, obtained at 360 K , (a) determine the order of the reaction, and (b) determine the initial rate of disappearance of X when the concentration of X is 0.30 M and that of Y is 0.40 M .

| Initial Rate of <br> Disappearance of $\mathbf{X}(\boldsymbol{M} / \mathbf{s})$ | $[\mathbf{X}](\boldsymbol{M})$ | $[\mathbf{Y}](\boldsymbol{M})$ |
| :---: | :---: | :---: |
| 0.053 | 0.10 | 0.50 |
| 0.127 | 0.20 | 0.30 |
| 1.02 | 0.40 | 0.60 |
| 0.254 | 0.20 | 0.60 |
| 0.509 | 0.40 | 0.30 |

E14.19 Determine the overall orders of the reactions to which the following rate laws apply: (a) rate $=k\left[\mathrm{NO}_{2}\right]^{2}$, (b) rate $=k$, (c) rate $=k\left[\mathrm{H}_{2}\right]^{2}\left[\mathrm{Br}_{2}\right]^{1 / 2}$, (d) rate $=k[\mathrm{NO}]^{2}\left[\mathrm{O}_{2}\right]$.

E14.20 Consider the reaction

$$
\mathrm{A} \longrightarrow \mathrm{~B}
$$

The rate of the reaction is $1.6 \times 10^{-2} \mathrm{M} / \mathrm{s}$ when the concentration of A is 0.15 M . Calculate the rate constant if the reaction is
(a) first order in A and (b) second order in A.

E14.21 Cyclobutane decomposes to ethylene according to the equation

$$
\mathrm{C}_{4} \mathrm{H}_{8}(g) \longrightarrow 2 \mathrm{C}_{2} \mathrm{H}_{4}(g)
$$

Determine the order of the reaction and the rate constant based on the following pressures, which were recorded when the reaction was carried out at $430^{\circ} \mathrm{C}$ in a constant-volume vessel.

| Time (s) | $\boldsymbol{P}_{\mathbf{C}_{\mathbf{4}} \mathbf{H}_{\mathbf{8}}}(\mathbf{m m H g})$ |
| ---: | :---: |
| 0 | 400 |
| 2,000 | 316 |
| 4,000 | 248 |
| 6,000 | 196 |
| 8,000 | 155 |
| 10,000 | 122 |

14.22 The following gas-phase reaction was studied at $290^{\circ} \mathrm{C}$ by observing the change in pressure as a function of time in a constant-volume vessel:

$$
\mathrm{ClCO}_{2} \mathrm{CCl}_{3}(g) \longrightarrow 2 \mathrm{COCl}_{2}(g)
$$

Determine the order of the reaction and the rate constant based on the following data.

| Time $(\mathbf{s})$ | $\boldsymbol{P}(\mathbf{m m H g})$ |
| :---: | :---: |
| 0 | 15.76 |
| 181 | 18.88 |
| 513 | 22.79 |
| 1164 | 27.08 |

where $P$ is the total pressure.

## Section 14.3: Dependence of Reactant Concentration on Time

## Review Questions

14.23 Write an equation relating the concentration of a reactant A at $t=0$ to that at $t=t$ for a first-order reaction. Define all the terms, and give their units. Do the same for a second-order reaction.
14.24 Define half-life. Write the equation relating the half-life of a first-order reaction to the rate constant.
14.25 Write the equation relating the half-life of a second-order reaction to the rate constant. How does it differ from the equation for a first-order reaction?
14.26 For a first-order reaction, how long will it take for the concentration of reactant to fall to one-eighth its original value? Express your answer in terms of the half-life $\left(t_{1 / 2}\right)$ and in terms of the rate constant $k$.

## Problems

14.27 What is the half-life of a compound if 75 percent of a given sample of the compound decomposes in 60 min ? Assume first-order kinetics.

E 14.28 The thermal decomposition of phosphine $\left(\mathrm{PH}_{3}\right)$ into phosphorus and molecular hydrogen is a first-order reaction:

$$
4 \mathrm{PH}_{3}(g) \longrightarrow \mathrm{P}_{4}(g)+6 \mathrm{H}_{2}(g)
$$

The half-life of the reaction is 35.0 s at $680^{\circ} \mathrm{C}$. Calculate (a) the first-order rate constant for the reaction and (b) the time required for 95 percent of the phosphine to decompose.
$\boldsymbol{\Psi}$ 14.29 The rate constant for the second-order reaction

$$
2 \mathrm{NOBr}(g) \longrightarrow 2 \mathrm{NO}(g)+\mathrm{Br}_{2}(g)
$$

is $0.80 / \mathrm{M} \cdot \mathrm{s}$ at $10^{\circ} \mathrm{C}$. (a) Starting with a concentration of 0.086 M , calculate the concentration of NOBr after 22 s . (b) Calculate the half-lives when $[\mathrm{NOBr}]_{0}=0.072 \mathrm{M}$ and $[\mathrm{NOBr}]_{0}=0.054 \mathrm{M}$.

EI 14.30 The rate constant for the second-order reaction

$$
2 \mathrm{NO}_{2}(g) \longrightarrow 2 \mathrm{NO}(g)+\mathrm{O}_{2}(g)
$$

is $0.54 / \mathrm{M} \cdot \mathrm{s}$ at $300^{\circ} \mathrm{C}$. How long (in seconds) would it take for the concentration of $\mathrm{NO}_{2}$ to decrease from 0.65 M to 0.18 M ?

H14.31 The second-order rate constant for the dimerization of a protein (P)

$$
\mathrm{P}+\mathrm{P} \longrightarrow \mathrm{P}_{2}
$$

is $6.2 \times 10^{-3} / \mathrm{M} \cdot \mathrm{s}$ at $25^{\circ} \mathrm{C}$. If the concentration of the protein is $2.7 \times 10^{-4} \mathrm{M}$, calculate the initial rate $(\mathrm{M} / \mathrm{s})$ of formation of $\mathrm{P}_{2}$. How long (in seconds) will it take to decrease the concentration of P to $2.7 \times 10^{-5} M$ ?
14.32 Consider the first-order reaction $X \longrightarrow$ Y shown here. (a) What is the half-life of the reaction? (b) Draw pictures showing the number of X (red) and Y (blue) molecules at 20 s and at 30 s .

$t=0 \mathrm{~s}$

$t=10 \mathrm{~s}$
$\leftrightarrows 14.33$ The reaction $A \longrightarrow B$ shown here follows first-order kinetics. Initially different amounts of A molecules are placed in three containers of equal volume at the same temperature. (a) What are the relative rates of the reaction in these three containers? (b) How would the relative rates be affected if the volume of each container were doubled? (c) What are the relative half-lives of the reactions in (i) to (iii)?

## Section 14.4: Dependence of Reaction Rate on Temperature

## Review Questions

14.34 Define activation energy. What role does activation energy play in chemical kinetics?
14.35 Write the Arrhenius equation, and define all terms.
14.36 Use the Arrhenius equation to show why the rate constant of a reaction (a) decreases with increasing activation energy and (b) increases with increasing temperature.
14.37 The burning of methane in oxygen is a highly exothermic reaction. Yet a mixture of methane and oxygen gas can be kept indefinitely without any apparent change. Explain.
14.38 Sketch a potential energy versus reaction progress plot for the following reactions:
(a) $\mathrm{S}(s)+\mathrm{O}_{2}(g) \longrightarrow \mathrm{SO}_{2}(g) \quad \Delta H^{\circ}=-296 \mathrm{~kJ} / \mathrm{mol}$
(b) $\mathrm{Cl}_{2}(g) \longrightarrow \mathrm{Cl}(g)+\mathrm{Cl}(g) \quad \Delta H^{\circ}=243 \mathrm{~kJ} / \mathrm{mol}$
14.39 The reaction $\mathrm{H}+\mathrm{H}_{2} \longrightarrow \mathrm{H}_{2}+\mathrm{H}$ has been studied for many years. Sketch a potential energy versus reaction progress diagram for this reaction.
14.40 Over the range of about $\pm 3^{\circ} \mathrm{C}$ from normal body temperature, the metabolic rate, $M_{T}$, is given by $M_{T}=M_{37}(1.1)^{\Delta T}$, where $M_{37}$ is the normal rate (at $37^{\circ} \mathrm{C}$ ) and $\Delta T$ is the change in $T$. Discuss this equation in terms of a possible molecular interpretation.

## Problems

14.41 Variation of the rate constant with temperature for the first-order reaction

$$
2 \mathrm{~N}_{2} \mathrm{O}_{5}(g) \longrightarrow 2 \mathrm{~N}_{2} \mathrm{O}_{4}(g)+\mathrm{O}_{2}(g)
$$

is given in the following table. Determine graphically the activation energy for the reaction.

| $\boldsymbol{T}(\mathbf{K})$ | $\boldsymbol{k}\left(\mathbf{s}^{\mathbf{- 1}}\right)$ |
| :---: | :---: |
| 298 | $1.74 \times 10^{-5}$ |
| 308 | $6.61 \times 10^{-5}$ |
| 318 | $2.51 \times 10^{-4}$ |
| 328 | $7.59 \times 10^{-4}$ |
| 338 | $2.40 \times 10^{-3}$ |

G14.42 Given the same reactant concentrations, the reaction

$$
\mathrm{CO}(g)+\mathrm{Cl}_{2}(g) \longrightarrow \mathrm{COCl}_{2}(g)
$$

at $250^{\circ} \mathrm{C}$ is $1.50 \times 10^{3}$ times as fast as the same reaction at $150^{\circ} \mathrm{C}$. Calculate the activation energy for this reaction. Assume that the frequency factor is constant.
E14.43 For the reaction

$$
\mathrm{NO}(g)+\mathrm{O}_{3}(g) \longrightarrow \mathrm{NO}_{2}(g)+\mathrm{O}_{2}(g)
$$

the frequency factor $A$ is $8.7 \times 10^{12} \mathrm{~s}^{-1}$ and the activation energy is $63 \mathrm{~kJ} / \mathrm{mol}$. What is the rate constant for the reaction at $75^{\circ} \mathrm{C}$ ?

E14.44 The rate constant of a first-order reaction is $4.60 \times 10^{-4} \mathrm{~s}^{-1}$ at $350^{\circ} \mathrm{C}$. If the activation energy is $104 \mathrm{~kJ} / \mathrm{mol}$, calculate the temperature at which its rate constant is $8.80 \times 10^{-4} \mathrm{~s}^{-1}$.
14.45 The rate constants of some reactions double with every $10^{\circ}$ rise in temperature. Assume that a reaction takes place at 295 K and 305 K . What must the activation energy be for the rate constant to double as described?
14.46 The rate at which tree crickets chirp is $2.0 \times 10^{2}$ per minute at $27^{\circ} \mathrm{C}$ but only 39.6 per minute at $5^{\circ} \mathrm{C}$. From these data, calculate the "activation energy" for the chirping process. (Hint: The ratio of rates is equal to the ratio of rate constants.)
14.47 The rate of bacterial hydrolysis of fish muscle is twice as great at $2.2^{\circ} \mathrm{C}$ as at $-1.1^{\circ} \mathrm{C}$. Estimate an $E_{\mathrm{a}}$ value for this reaction. Is there any relation to the problem of storing fish for food?

E14.48 The activation energy for the denaturation of a protein is $396 \mathrm{~kJ} / \mathrm{mol}$. At what temperature will the rate of denaturation be 20 percent greater than its rate at $25^{\circ} \mathrm{C}$ ?

E14.49 Diagram A describes the initial state of reaction

## Diagram A

Suppose the reaction is carried out at two different temperatures as shown in diagram B. Which picture represents the result at the higher temperature? (The reaction proceeds for the same amount of time at both temperatures.)

(a)

(b)

Diagram B

## Section 14.5: Reaction Mechanisms

## Review Questions

14.50 What do we mean by the mechanism of a reaction?
14.51 What is an elementary step? What is the molecularity of a reaction?

H14.52 Classify the following elementary reactions as unimolecular, bimolecular, or termolecular:
(a) $2 \mathrm{NO}+\mathrm{Br}_{2} \longrightarrow 2 \mathrm{NOBr}$
(b) $\mathrm{CH}_{3} \mathrm{NC} \longrightarrow \mathrm{CH}_{3} \mathrm{CN}$
(c) $\mathrm{SO}+\mathrm{O}_{2} \longrightarrow \mathrm{SO}_{2}+\mathrm{O}$
14.53 Reactions can be classified as unimolecular, bimolecular, and so on. Why are there no zero-molecular reactions? Explain why termolecular reactions are rare.
fl 14.54 Determine the molecularity, and write the rate law for each of the following elementary steps:
(a) $\mathrm{X} \longrightarrow$ products
(b) $\mathrm{X}+\mathrm{Y} \longrightarrow$ products
(c) $\mathrm{X}+\mathrm{Y}+\mathrm{Z} \longrightarrow$ products
(d) $\mathrm{X}+\mathrm{X} \longrightarrow$ products
(e) $\mathrm{X}+2 \mathrm{Y} \longrightarrow$ products
14.55 What is the rate-determining step of a reaction? Give an everyday analogy to illustrate the meaning of rate determining.
14.56 The equation for the combustion of ethane $\left(\mathrm{C}_{2} \mathrm{H}_{6}\right)$ is

$$
2 \mathrm{C}_{2} \mathrm{H}_{6}(g)+7 \mathrm{O}_{2}(g) \longrightarrow 4 \mathrm{CO}_{2}(g)+6 \mathrm{H}_{2} \mathrm{O}(l)
$$

Explain why it is unlikely that this equation also represents the elementary step for the reaction.
14.57 Specify which of the following species cannot be isolated in a reaction: activated complex, product, intermediate.

## Problems

G14.58 Classify each of the following elementary steps as unimolecular, bimolecular, or termolecular.

(a)

(b)

(c)

E14.59 The rate law for the reaction

$$
2 \mathrm{NO}(g)+\mathrm{Cl}_{2}(g) \longrightarrow 2 \mathrm{NOCl}(g)
$$

is given by rate $=k[\mathrm{NO}]\left[\mathrm{Cl}_{2}\right]$. (a) What is the order of the reaction? (b) A mechanism involving the following steps has been proposed for the reaction:

$$
\begin{aligned}
\mathrm{NO}(g)+\mathrm{Cl}_{2}(g) & \longrightarrow \mathrm{NOCl}_{2}(g) \\
\mathrm{NOCl}_{2}(g)+\mathrm{NO}(g) & \longrightarrow 2 \mathrm{NOCl}(g)
\end{aligned}
$$

If this mechanism is correct, what does it imply about the relative rates of these two steps?
14.60 For the reaction $X_{2}+Y+Z \longrightarrow X Y+X Z$, it is found that doubling the concentration of $\mathrm{X}_{2}$ doubles the reaction rate,
tripling the concentration of Y triples the rate, and doubling the concentration of $Z$ has no effect. (a) What is the rate law for this reaction? (b) Why is it that the change in the concentration of Z has no effect on the rate? (c) Suggest a mechanism for the reaction that is consistent with the rate law.
14.61 The rate law for the reaction

$$
2 \mathrm{H}_{2}(g)+2 \mathrm{NO}(g) \longrightarrow \mathrm{N}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(g)
$$

is rate $=k\left[\mathrm{H}_{2}\right][\mathrm{NO}]^{2}$. Which of the following mechanisms can be ruled out on the basis of the observed rate expression?

Mechanism I

| $\mathrm{H}_{2}+\mathrm{NO}$ | $\longrightarrow \mathrm{H}_{2} \mathrm{O}+\mathrm{N}$ |
| ---: | :--- |
| $\mathrm{N}+\mathrm{NO} \longrightarrow \mathrm{N}_{2}+\mathrm{O}$ | (slow) <br> (fast) |
| $\mathrm{O}+\mathrm{H}_{2} \longrightarrow \mathrm{H}_{2} \mathrm{O}$ | (fast) |

Mechanism II

$$
\begin{align*}
& \mathrm{H}_{2}+2 \mathrm{NO} \longrightarrow \mathrm{~N}_{2} \mathrm{O}+\mathrm{H}_{2} \mathrm{O} \\
& \mathrm{~N}_{2} \mathrm{O}+\mathrm{H}_{2} \longrightarrow \mathrm{~N}_{2}+\mathrm{H}_{2} \mathrm{O}
\end{align*}
$$

Mechanism III

| 2 NO | $\longleftrightarrow \mathrm{N}_{2} \mathrm{O}_{2}$ |
| ---: | :--- |
| $\mathrm{~N}_{2} \mathrm{O}+\mathrm{H}_{2} \mathrm{O}$ | (fast equilibrium) |
| $\mathrm{N}_{2} \mathrm{O}_{2}+\mathrm{H}_{2}$ | (slow) |
| $\mathrm{N}_{2} \mathrm{O}+\mathrm{H}_{2}$ | $\longrightarrow \mathrm{~N}_{2}+\mathrm{H}_{2} \mathrm{O}$ | | (fast) |
| :--- |

E14.62 The rate law for the decomposition of ozone to molecular oxygen

$$
2 \mathrm{O}_{3}(\mathrm{~g}) \longrightarrow 3 \mathrm{O}_{2}(\mathrm{~g})
$$

is

$$
\text { rate }=k \frac{\left[\mathrm{O}_{3}\right]^{2}}{\left[\mathrm{O}_{2}\right]}
$$

The mechanism proposed for this process is

$$
\begin{aligned}
& \mathrm{O}_{3} \underset{k_{-1}}{\stackrel{k_{1}}{\rightleftarrows}} \mathrm{O}+\mathrm{O}_{2} \\
& \mathrm{O}+\mathrm{O}_{3} \xrightarrow{k_{2}} 2 \mathrm{O}_{2}
\end{aligned}
$$

Derive the rate law from these elementary steps. Clearly state the assumptions you use in the derivation. Explain why the rate decreases with increasing $\mathrm{O}_{2}$ concentration.

## Section 14.6: Catalysis

## Review Questions

14.63 How does a catalyst increase the rate of a reaction?
14.64 What are the characteristics of a catalyst?
14.65 A certain reaction is known to proceed slowly at room temperature. Is it possible to make the reaction proceed at a faster rate without changing the temperature?
14.66 Most reactions, including enzyme-catalyzed reactions, proceed faster at higher temperatures. However, for a given enzyme, the rate drops off abruptly at a certain temperature. Account for this behavior.
14.67 Are enzyme-catalyzed reactions examples of homogeneous or heterogeneous catalysis? Explain.
14.68 The concentrations of enzymes in cells are usually quite small. What is the biological significance of this fact?
14.69 When fruits such as apples and pears are cut, the exposed areas begin to turn brown. This is the result of an enzyme-catalyzed reaction. Often the browning can be prevented or slowed by adding a few drops of lemon juice. What is the chemical basis of this treatment?
14.70 The first-order rate constant for the dehydration of carbonic acid

$$
\mathrm{H}_{2} \mathrm{CO}_{3} \longrightarrow \mathrm{CO}_{2}+\mathrm{H}_{2} \mathrm{O}
$$

is about $1 \times 10^{2} \mathrm{~s}^{-1}$. In view of this rather high rate constant, explain why it is necessary to have the enzyme carbonic anhydrase to enhance the rate of dehydration in the lungs.

## Problems

\&14.71 Which two potential-energy profiles represent the same reaction catalyzed and uncatalyzed?

(i)

(ii)

(iii)

(iv)

(v)
14.72 Consider the following mechanism for the enzyme-catalyzed reaction:

$$
\begin{aligned}
\mathrm{E}+\mathrm{S} \underset{k_{-1}}{\stackrel{k_{1}}{\leftrightarrows}} \mathrm{ES} \quad \text { (fast equilibrium) } \\
\mathrm{ES} \xrightarrow{k_{2}} \mathrm{E}+\mathrm{P} \quad \text { (slow) }
\end{aligned}
$$

Derive an expression for the rate law of the reaction in terms of the concentrations of E and S. (Hint: To solve for [ES], make use of the fact that, at equilibrium, the rate of the forward reaction is equal to the rate of the reverse reaction.)

## Additional Problems

14.73 List four factors that influence the rate of a reaction.

E1 14.74 Suggest experimental means by which the rates of the following reactions could be followed:
(a) $\mathrm{CaCO}_{3}(s) \longrightarrow \mathrm{CaO}(s)+\mathrm{CO}_{2}(g)$
(b) $\mathrm{Cl}_{2}(g)+2 \mathrm{Br}^{-}(a q) \longrightarrow \mathrm{Br}_{2}(a q)+2 \mathrm{Cl}^{-}(a q)$
(c) $\mathrm{C}_{2} \mathrm{H}_{6}(g) \longrightarrow \mathrm{C}_{2} \mathrm{H}_{4}(g)+\mathrm{H}_{2}(g)$
(d) $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{I}(g)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(a q)+\mathrm{H}^{+}(a q)+\mathrm{I}^{-}(a q)$
14.75 "The rate constant for the reaction

$$
\mathrm{NO}_{2}(g)+\mathrm{CO}(g) \longrightarrow \mathrm{NO}(g)+\mathrm{CO}_{2}(g)
$$

is $1.64 \times 10^{-6} / M \cdot \mathrm{~s}$." What is incomplete about this statement?
E 14.76 In a certain industrial process involving a heterogeneous catalyst, the volume of the catalyst (in the shape of a sphere) is $10.0 \mathrm{~cm}^{3}$. Calculate the surface area of the catalyst. If the sphere is broken down into eight smaller spheres, each having a volume of $1.25 \mathrm{~cm}^{3}$, what is the total surface area of the spheres? Which of the two geometric configurations of the catalyst is more effective? (The surface area of a sphere is $4 \pi r^{2}$, where $r$ is the radius of the sphere.) Based on your analysis here, explain why it is sometimes dangerous to work in grain elevators.
$\$$ 14.77 The following pictures represent the progress of the reaction $\mathrm{A} \longrightarrow \mathrm{B}$ where the red spheres represent A molecules and the green spheres represent $B$ molecules. Calculate the rate constant of the reaction.

14.78 The following pictures show the progress of the reaction $2 \mathrm{~A} \longrightarrow \mathrm{~A}_{2}$. Determine whether the reaction is first order or second order, and calculate the rate constant.

$t=0 \mathrm{~min}$

$t=15 \mathrm{~min}$

$t=30 \mathrm{~min}$
14.79 Use the data in Sample Problem 14.5 to determine graphically the half-life of the reaction.

E14.80 The following data were collected for the reaction between hydrogen and nitric oxide at $700^{\circ} \mathrm{C}$ :

| $2 \mathrm{H}_{2}(g)+2 \mathrm{NO}(g) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(g)+\mathrm{N}_{2}(g)$ |  |  |  |
| :---: | :---: | :---: | :---: |
| Experiment | $\left[\mathbf{H}_{\mathbf{2}}\right](\boldsymbol{M})$ | $[\mathbf{N O}](\boldsymbol{M})$ | Initial Rate $(\boldsymbol{M} / \mathbf{s})$ |
| 1 | 0.010 | 0.025 | $2.4 \times 10^{-6}$ |
| 2 | 0.0050 | 0.025 | $1.2 \times 10^{-6}$ |
| 3 | 0.010 | 0.0125 | $0.60 \times 10^{-6}$ |

(a) Determine the order of the reaction. (b) Calculate the rate constant. (c) Suggest a plausible mechanism that is consistent with the rate law. (Hint: Assume that the oxygen atom is the intermediate.)
14.81 When methyl phosphate is heated in acid solution, it reacts with water:

$$
\mathrm{CH}_{3} \mathrm{OPO}_{3} \mathrm{H}_{2}+\mathrm{H}_{2} \mathrm{O} \longrightarrow \mathrm{CH}_{3} \mathrm{OH}+\mathrm{H}_{3} \mathrm{PO}_{4}
$$

If the reaction is carried out in water enriched with ${ }^{18} \mathrm{O}$, the oxygen-18 isotope is found in the phosphoric acid product but not in the methanol. What does this tell us about the mechanism of the reaction?
14.82 The rate of the reaction
$\mathrm{CH}_{3} \mathrm{COOC}_{2} \mathrm{H}_{5}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow$

$$
\mathrm{CH}_{3} \mathrm{COOH}(a q)+\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(a q)
$$

shows first-order characteristics-that is, rate $=$
$k\left[\mathrm{CH}_{3} \mathrm{COOC}_{2} \mathrm{H}_{5}\right]$-even though this is a second-order reaction (first order in $\mathrm{CH}_{3} \mathrm{COOC}_{2} \mathrm{H}_{5}$ and first order in $\mathrm{H}_{2} \mathrm{O}$ ). Explain.
14.83 Explain why most metals used in catalysis are transition metals.
$\mathbb{G} 14.84$ The reaction $2 \mathrm{~A}+3 \mathrm{~B} \longrightarrow \mathrm{C}$ is first order with respect to A and $B$. When the initial concentrations are $[\mathrm{A}]=1.6 \times 10^{-2} \mathrm{M}$ and $[\mathrm{B}]=2.4 \times 10^{-3} \mathrm{M}$, the rate is $4.1 \times 10^{-4} \mathrm{M} / \mathrm{s}$. Calculate the rate constant of the reaction.

E14.85 The bromination of acetone is acid-catalyzed:

$$
\mathrm{CH}_{3} \mathrm{COCH}_{3}+\mathrm{Br}_{2} \xrightarrow{\substack{\text { catalyst } \\ \mathrm{H}^{+}}} \mathrm{CH}_{3} \mathrm{COCH}_{2} \mathrm{Br}+\mathrm{H}^{+}+\mathrm{Br}^{-}
$$

The rate of disappearance of bromine was measured for several different concentrations of acetone, bromine, and $\mathrm{H}^{+}$ions at a certain temperature:

|  | $\left[\mathbf{C H}_{3} \mathbf{C O C H}_{3}\right]$ <br> $(\boldsymbol{M})$ | $\left[\mathbf{B r}_{\mathbf{2}}\right]$ <br> $(\boldsymbol{M})$ | $\left[\mathbf{H}^{+}\right]$ <br> $(\boldsymbol{M})$ | Rate of Disappearance <br> of $\mathbf{B r}_{\mathbf{2}}(\boldsymbol{M} / \mathbf{s})$ |
| :---: | :---: | :---: | :---: | :---: |
| $(1)$ | 0.30 | 0.050 | 0.050 | $5.7 \times 10^{-5}$ |
| $(2)$ | 0.30 | 0.10 | 0.050 | $5.7 \times 10^{-5}$ |
| $(3)$ | 0.30 | 0.050 | 0.10 | $1.2 \times 10^{-4}$ |
| $(4)$ | 0.40 | 0.050 | 0.20 | $3.1 \times 10^{-4}$ |
| $(5)$ | 0.40 | 0.050 | 0.050 | $7.6 \times 10^{-5}$ |

(a) What is the rate law for the reaction? (b) Determine the rate constant. (c) The following mechanism has been proposed for the reaction:

(fast equilibrium)

(slow)

Show that the rate law deduced from the mechanism is consistent with that shown in part (a).

I 14.86 The decomposition of $\mathrm{N}_{2} \mathrm{O}$ to $\mathrm{N}_{2}$ and $\mathrm{O}_{2}$ is a first-order reaction. At $730^{\circ} \mathrm{C}$ the half-life of the reaction is $3.58 \times 10^{3} \mathrm{~min}$. If the initial pressure of $\mathrm{N}_{2} \mathrm{O}$ is 2.10 atm at $730^{\circ} \mathrm{C}$, calculate the total gas pressure after one half-life. Assume that the volume remains constant.
14.87 The reaction $\mathrm{S}_{2} \mathrm{O}_{8}^{2-}+2 \mathrm{I}^{-} \longrightarrow 2 \mathrm{SO}_{4}^{2-}+\mathrm{I}_{2}$ proceeds slowly in aqueous solution, but it can be catalyzed by the $\mathrm{Fe}^{3+}$ ion. Given that $\mathrm{Fe}^{3+}$ can oxidize $\mathrm{I}^{-}$and $\mathrm{Fe}^{2+}$ can reduce $\mathrm{S}_{2} \mathrm{O}_{8}^{2-}$, write a plausible two-step mechanism for this reaction. Explain why the uncatalyzed reaction is slow.
14.88 What are the units of the rate constant for a third-order reaction?
14.89 The integrated rate law for the zeroth-order reaction $A \longrightarrow B$ is $[\mathrm{A}]_{t}=[\mathrm{A}]_{0}-k t$. (a) Sketch the following plots: (i) rate versus $[\mathrm{A}]_{t}$ and (ii) $[\mathrm{A}]_{t}$ versus $t$. (b) Derive an expression for the halflife of the reaction. (c) Calculate the time in half-lives when the integrated rate law is no longer valid, that is, when $[\mathrm{A}]_{t}=0$.

E14.90 A flask contains a mixture of compounds A and B. Both compounds decompose by first-order kinetics. The half-lives are 50.0 min for A and 18.0 min for B . If the concentrations of A and $B$ are equal initially, how long will it take for the concentration of A to be four times that of B?
14.91 Referring to Sample Problem 14.5, explain how you would measure the partial pressure of azomethane experimentally as a function of time.
14.92 The rate law for the reaction $2 \mathrm{NO}_{2}(g) \longrightarrow \mathrm{N}_{2} \mathrm{O}_{4}(g)$ is rate $=$ $k\left[\mathrm{NO}_{2}\right]^{2}$. Which of the following changes will change the value of $k$ ? (a) The pressure of $\mathrm{NO}_{2}$ is doubled. (b) The reaction is run in an organic solvent. (c) The volume of the container is doubled. (d) The temperature is decreased. (e) A catalyst is added to the container.
14.93 The reaction of $\mathrm{G}_{2}$ with $\mathrm{E}_{2}$ to form 2 EG is exothermic, and the reaction of $G_{2}$ with $X_{2}$ to form 2 XG is endothermic. The activation energy of the exothermic reaction is greater than that of the endothermic reaction. Sketch the potential-energy profile diagrams for these two reactions on the same graph.

E 14.94 In the nuclear industry, workers use a rule of thumb that the radioactivity from any sample will be relatively harmless after 10 half-lives. Calculate the fraction of a radioactive sample that remains after this time period. (Hint: Radioactive decays obey first-order kinetics.)
14.95 Briefly comment on the effect of a catalyst on each of the following: (a) activation energy, (b) reaction mechanism,
(c) enthalpy of reaction, (d) rate of forward reaction, (e) rate of reverse reaction.

H14.96 When 6 g of granulated Zn is added to a solution of $2 M \mathrm{HCl}$ in a beaker at room temperature, hydrogen gas is generated. For each of the following changes (at constant volume of the acid) state whether the rate of hydrogen gas evolution will be increased, decreased, or unchanged: (a) 6 g of powdered Zn is used, (b) 4 g of granulated Zn is used, (c) $2 M$ acetic acid is used instead of $2 M \mathrm{HCl}$, (d) temperature is raised to $40^{\circ} \mathrm{C}$.
14.97 Strictly speaking, the rate law derived for the reaction in Problem 14.80 applies only to certain concentrations of $\mathrm{H}_{2}$. The general rate law for the reaction takes the form

$$
\text { rate }=\frac{k_{1}[\mathrm{NO}]^{2}\left[\mathrm{H}_{2}\right]}{1+k_{2}\left[\mathrm{H}_{2}\right]}
$$

where $k_{1}$ and $k_{2}$ are constants. Derive rate law expressions under the conditions of very high and very low hydrogen concentrations. Does the result from Problem 14.80 agree with one of the rate expressions here?

G14.98 A certain first-order reaction is 35.5 percent complete in 4.90 min at $25^{\circ} \mathrm{C}$. What is its rate constant?
14.99 The decomposition of dinitrogen pentoxide has been studied in carbon tetrachloride solvent $\left(\mathrm{CCl}_{4}\right)$ at a certain temperature:

| $2 \mathrm{~N}_{2} \mathrm{O}_{5} \longrightarrow 4 \mathrm{NO}_{2}+\mathrm{O}_{2}$ |  |
| :---: | :---: |
| $\left[\mathbf{N}_{\mathbf{2}} \mathbf{O}_{5}\right](\boldsymbol{M})$ | Initial Rate $(\boldsymbol{M} / \mathbf{s})$ |
| 0.92 | $0.95 \times 10^{-5}$ |
| 1.23 | $1.20 \times 10^{-5}$ |
| 1.79 | $1.93 \times 10^{-5}$ |
| 2.00 | $2.10 \times 10^{-5}$ |
| 2.21 | $2.26 \times 10^{-5}$ |

Determine graphically the rate law for the reaction, and calculate the rate constant.

G 14.100
The thermal decomposition of $\mathrm{N}_{2} \mathrm{O}_{5}$ obeys first-order kinetics. At $45^{\circ} \mathrm{C}$, a plot of $\ln \left[\mathrm{N}_{2} \mathrm{O}_{5}\right]$ versus $t$ gives a slope of $-6.18 \times$ $10^{-4} \mathrm{~min}^{-1}$. What is the half-life of the reaction?
14.101 When a mixture of methane and bromine is exposed to light, the following reaction occurs slowly:

$$
\mathrm{CH}_{4}(g)+\mathrm{Br}_{2}(g) \longrightarrow \mathrm{CH}_{3} \mathrm{Br}(g)+\mathrm{HBr}(g)
$$

Suggest a reasonable mechanism for this reaction. (Hint: Bromine vapor is deep red; methane is colorless.)
14.102 The rate of the reaction between $\mathrm{H}_{2}$ and $\mathrm{I}_{2}$ to form HI increases with the intensity of visible light. (a) Explain why this fact supports a two-step mechanism. ( $\mathrm{I}_{2}$ vapor is purple.) (b) Explain why the visible light has no effect on the formation of H atoms.
14.103 To prevent brain damage, a standard procedure is to lower the body temperature of someone who has been resuscitated after suffering cardiac arrest. What is the physiochemical basis for this procedure?

H14.104 A gas mixture containing $\mathrm{CH}_{3}$ fragments, $\mathrm{C}_{2} \mathrm{H}_{6}$ molecules, and an inert gas $(\mathrm{He})$ was prepared at 600 K with a total pressure of 5.42 atm . The elementary reaction

$$
\mathrm{CH}_{3}+\mathrm{C}_{2} \mathrm{H}_{6} \longrightarrow \mathrm{CH}_{4}+\mathrm{C}_{2} \mathrm{H}_{5}
$$

has a second-order rate constant of $3.0 \times 10^{4} / \mathrm{M} \cdot \mathrm{s}$. Given that the mole fractions of $\mathrm{CH}_{3}$ and $\mathrm{C}_{2} \mathrm{H}_{6}$ are 0.00093 and 0.00077 , respectively, calculate the initial rate of the reaction at this temperature.
14.105 Consider the following elementary step:

$$
\mathrm{X}+2 \mathrm{Y} \longrightarrow \mathrm{XY}_{2}
$$

(a) Write a rate law for this reaction. (b) If the initial rate of formation of $\mathrm{XY}_{2}$ is $3.8 \times 10^{-3} \mathrm{M} / \mathrm{s}$ and the initial concentrations of X and Y are $0.26 M$ and 0.88 M , respectively, what is the rate constant of the reaction?
14.106 In recent years, ozone in the stratosphere has been depleted at an alarmingly fast rate by chlorofluorocarbons (CFCs). A CFC molecule such as $\mathrm{CFCl}_{3}$ is first decomposed by UV radiation:

$$
\mathrm{CFCl}_{3} \longrightarrow \mathrm{CFCl}_{2}+\mathrm{Cl}
$$

The chlorine radical then reacts with ozone as follows:

$$
\begin{aligned}
& \mathrm{Cl}+\mathrm{O}_{3} \longrightarrow \mathrm{ClO}+\mathrm{O}_{2} \\
& \mathrm{ClO}+\mathrm{O} \longrightarrow \mathrm{Cl}+\mathrm{O}_{2}
\end{aligned}
$$

(a) Write the overall reaction for the last two steps. (b) What are the roles of Cl and ClO ? (c) Why is the fluorine radical not important in this mechanism? (d) One suggestion to reduce the concentration of chlorine radicals is to add hydrocarbons such as ethane $\left(\mathrm{C}_{2} \mathrm{H}_{6}\right)$ to the stratosphere. How will this work? (e) Draw potential energy versus reaction progress diagrams for the uncatalyzed and catalyzed (by Cl ) destruction of ozone: $\mathrm{O}_{3}+$ $\mathrm{O} \longrightarrow 2 \mathrm{O}_{2}$. Use the thermodynamic data in Appendix 2 to determine whether the reaction is exothermic or endothermic.

E14.107 Chlorine oxide ( ClO ), which plays an important role in the depletion of ozone (see Problem 14.106), decays rapidly at room temperature according to the equation

$$
2 \mathrm{ClO}(g) \longrightarrow \mathrm{Cl}_{2}(g)+\mathrm{O}_{2}(g)
$$

From the following data, determine the reaction order and calculate the rate constant of the reaction.

| Time $(\mathbf{s})$ | $[\mathbf{C l O}](\boldsymbol{M})$ |
| :--- | :---: |
| $0.12 \times 10^{-3}$ | $8.49 \times 10^{-6}$ |
| $0.96 \times 10^{-3}$ | $7.10 \times 10^{-6}$ |
| $2.24 \times 10^{-3}$ | $5.79 \times 10^{-6}$ |
| $3.20 \times 10^{-3}$ | $5.20 \times 10^{-6}$ |
| $4.00 \times 10^{-3}$ | $4.77 \times 10^{-6}$ |

E14.108 A compound X undergoes two simultaneous first-order reactions as follows: $\mathrm{X} \longrightarrow \mathrm{Y}$ with rate constant $k_{1}$ and $\mathrm{X} \longrightarrow \mathrm{Z}$ with rate constant $k_{2}$. The ratio of $k_{1} / k_{2}$ at $40^{\circ} \mathrm{C}$ is 8.0 . What is the ratio at $300^{\circ} \mathrm{C}$ ? Assume that the frequency factors of the two reactions are the same.
14.109 Consider a car fitted with a catalytic converter. The first 5 min or so after it is started are the most polluting. Why?
14.110 The following scheme in which A is converted to B , which is then converted to C , is known as a consecutive reaction.

$$
\mathrm{A} \longrightarrow \mathrm{~B} \longrightarrow \mathrm{C}
$$

Assuming that both steps are first order, sketch on the same graph the variations of $[A],[B]$, and $[C]$ with time.

E14.111 (a) Consider two reactions, A and B. If the rate constant for reaction $B$ increases by a larger factor than that of reaction $A$ when the temperature is increased from $T_{1}$ to $T_{2}$, what can you conclude about the relative values of the activation energies of the two reactions? (b) If a bimolecular reaction occurs every time an A and a B molecule collide, what can you say about the orientation factor and activation energy of the reaction?
14.112 The rate law for the following reaction

$$
\mathrm{CO}(g)+\mathrm{NO}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g)+\mathrm{NO}(g)
$$

is rate $=k\left[\mathrm{NO}_{2}\right]^{2}$. Suggest a plausible mechanism for the reaction, given that the unstable species $\mathrm{NO}_{3}$ is an intermediate.
14.113 Radioactive plutonium-239 $\left(t_{1 / 2}=2.44 \times 10^{5} \mathrm{yr}\right)$ is used in nuclear reactors and atomic bombs. If there are $5.0 \times 10^{2} \mathrm{~g}$ of the isotope in a small atomic bomb, how long will it take for the substance to decay to $1.0 \times 10^{2} \mathrm{~g}$, too small an amount for an effective bomb?
14.114 Many reactions involving heterogeneous catalysts are zeroth order; that is, rate $=k$. An example is the decomposition of phosphine $\left(\mathrm{PH}_{3}\right)$ over tungsten (W):

$$
4 \mathrm{PH}_{3}(g) \longrightarrow \mathrm{P}_{4}(g)+6 \mathrm{H}_{2}(g)
$$

It is found that the reaction is independent of $\left[\mathrm{PH}_{3}\right]$ as long as phosphine's pressure is sufficiently high ( $\geq 1 \mathrm{~atm}$ ). Explain.
14.115 Thallium(I) is oxidized by cerium(IV) as follows:

$$
\mathrm{Tl}^{+}+2 \mathrm{Ce}^{4+} \longrightarrow \mathrm{Tl}^{3+}+2 \mathrm{Ce}^{3+}
$$

The elementary steps, in the presence of Mn (II), are as follows:

$$
\begin{array}{r}
\mathrm{Ce}^{4+}+\mathrm{Mn}^{2+} \longrightarrow \mathrm{Ce}^{3+}+\mathrm{Mn}^{3+} \\
\mathrm{Ce}^{4+}+\mathrm{Mn}^{3+} \longrightarrow \mathrm{Ce}^{3+}+\mathrm{Mn}^{4+} \\
\mathrm{Tl}^{+}+\mathrm{Mn}^{4+} \longrightarrow \mathrm{Tl}^{3+}+\mathrm{Mn}^{2+}
\end{array}
$$

(a) Identify the catalyst, intermediates, and the rate-determining step if the rate law is rate $=k\left[\mathrm{Ce}^{4+}\right]\left[\mathrm{Mn}^{2+}\right]$. (b) Explain why the reaction is slow without the catalyst. (c) Classify the type of catalysis (homogeneous or heterogeneous).

H14.116 Sucrose $\left(\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}\right)$, commonly called table sugar, undergoes hydrolysis (reaction with water) to produce fructose $\left(\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}\right)$ and glucose $\left(\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}\right)$ :

$$
\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}+\mathrm{H}_{2} \mathrm{O} \longrightarrow \underset{\text { fructose }}{\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}}+\underset{\text { glucose }}{\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}}
$$

This reaction is of considerable importance in the candy industry. First, fructose is sweeter than sucrose. Second, a mixture of fructose and glucose, called invert sugar, does not crystallize, so the candy containing this sugar would be chewy rather than brittle as candy containing sucrose crystals would be.
(a) From the following data determine the order of the reaction.
(b) How long does it take to hydrolyze 95 percent of sucrose?
(c) Explain why the rate law does not include $\left[\mathrm{H}_{2} \mathrm{O}\right]$ even though water is a reactant.

| Time (min) | $\left[\mathbf{C}_{\mathbf{1 2}} \mathbf{H}_{\mathbf{2 2}} \mathbf{O}_{\mathbf{1 1}}\right](\boldsymbol{M})$ |
| :---: | :---: |
| 0 | 0.500 |
| 60.0 | 0.400 |
| 96.4 | 0.350 |
| 157.5 | 0.280 |

14.117 The first-order rate constant for the decomposition of dimethyl ether

$$
\left(\mathrm{CH}_{3}\right)_{2} \mathrm{O}(g) \longrightarrow \mathrm{CH}_{4}(g)+\mathrm{H}_{2}(g)+\mathrm{CO}(g)
$$

is $3.2 \times 10^{-4} \mathrm{~s}^{-1}$ at $450^{\circ} \mathrm{C}$. The reaction is carried out in a constant-volume flask. Initially only dimethyl ether is present and the pressure is 0.350 atm . What is the pressure of the system after 8.0 min ? Assume ideal behavior.
14.118 At $25^{\circ} \mathrm{C}$, the rate constant for the ozone-depleting reaction

$$
\mathrm{O}(g)+\mathrm{O}_{3}(g) \longrightarrow 2 \mathrm{O}_{2}(g)
$$

is $7.9 \times 10^{-15} \mathrm{~cm}^{3} /$ molecule $\cdot \mathrm{s}$. Express the rate constant in units of $1 / M \cdot \mathrm{~s}$.
14.119 Consider the following elementary steps for a consecutive reaction:

$$
\mathrm{A} \xrightarrow{k_{1}} \mathrm{~B} \xrightarrow{k_{2}} \mathrm{C}
$$

(a) Write an expression for the rate of change of B. (b) Derive an expression for the concentration of B under "steady-state"
conditions; that is, when B is decomposing to C at the same rate as it is formed from A .
14.120 Ethanol is a toxic substance that, when consumed in excess, can impair respiratory and cardiac functions by interference with the neurotransmitters of the nervous system. In the human body, ethanol is metabolized by the enzyme alcohol dehydrogenase to acetaldehyde, which causes hangovers. Based on your knowledge of enzyme kinetics, explain why binge drinking (that is, consuming too much alcohol too fast) can prove fatal.

Y 14.121 Strontium-90, a radioactive isotope, is a major product of an atomic bomb explosion. It has a half-life of 28.1 yr . (a) Calculate the first-order rate constant for the nuclear decay. (b) Calculate the fraction of ${ }^{90} \mathrm{Sr}$ that remains after 10 half-lives. (c) Calculate the number of years required for 99.0 percent of ${ }^{90} \mathrm{Sr}$ to disappear.

EI 14.122 Consider the potential energy profiles for the following three reactions (from left to right). (1) Rank the rates (slowest to fastest) of the reactions. (2) Calculate $\Delta H$ for each reaction, and determine which reaction(s) are exothermic and which reaction(s) are endothermic. Assume the reactions have roughly the same frequency factors.

14.123 Consider the following potential energy profile for the $\mathrm{A} \longrightarrow$ D reaction. (a) How many elementary steps are there? (b) How many intermediates are formed? (c) Which step is rate determining? (d) Is the overall reaction exothermic or endothermic?

14.124 A factory that specializes in the refinement of transition metals such as titanium was on fire. The firefighters were advised not to douse the fire with water. Why?

G14.125 The activation energy for the decomposition of hydrogen peroxide

$$
2 \mathrm{H}_{2} \mathrm{O}_{2}(a q) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{O}_{2}(g)
$$

is $42 \mathrm{~kJ} / \mathrm{mol}$, whereas when the reaction is catalyzed by the enzyme catalase, it is $7.0 \mathrm{~kJ} / \mathrm{mol}$. Calculate the temperature that would cause the uncatalyzed decomposition to proceed as rapidly as the enzyme-catalyzed decomposition at $20^{\circ} \mathrm{C}$. Assume the frequency factor A to be the same in both cases.

E 14.126 The activity of a radioactive sample is the number of nuclear disintegrations per second, which is equal to the first-order rate constant times the number of radioactive nuclei present. The fundamental unit of radioactivity is the curie (Ci), where 1 Ci corresponds to exactly $3.70 \times 10^{10}$ disintegrations per second.

This decay rate is equivalent to that of 1 g of radium- 226 . Calculate the rate constant and half-life for the radium decay. Starting with 1.0 g of the radium sample, what is the activity after 500 yr ? The molar mass of Ra-226 is $226.03 \mathrm{~g} / \mathrm{mol}$.
14.127 To carry out metabolism, oxygen is taken up by hemoglobin $(\mathrm{Hb})$ to form oxyhemoglobin $\left(\mathrm{HbO}_{2}\right)$ according to the simplified equation

$$
\mathrm{Hb}(a q)+\mathrm{O}_{2}(a q) \xrightarrow{k} \mathrm{HbO}_{2}(a q)
$$

where the second-order rate constant is $2.1 \times 10^{6} / \mathrm{M} \cdot \mathrm{s}$ at $37^{\circ} \mathrm{C}$. For an average adult, the concentrations of Hb and $\mathrm{O}_{2}$ in the blood at the lungs are $8.0 \times 10^{-6} \mathrm{M}$ and $1.5 \times 10^{-6}$ $M$, respectively. (a) Calculate the rate of formation of $\mathrm{HbO}_{2}$. (b) Calculate the rate of consumption of $\mathrm{O}_{2}$. (c) The rate of formation of $\mathrm{HbO}_{2}$ increases to $1.4 \times 10^{-4} \mathrm{M} / \mathrm{s}$ during exercise to meet the demand of the increased metabolism rate. Assuming the Hb concentration to remain the same, what must the oxygen concentration be to sustain this rate of $\mathrm{HbO}_{2}$ formation?
14.128 At a certain elevated temperature, ammonia decomposes on the surface of tungsten metal as follows:

$$
2 \mathrm{NH}_{3} \longrightarrow \mathrm{~N}_{2}+3 \mathrm{H}_{2}
$$

From the following plot of the rate of the reaction versus the pressure of $\mathrm{NH}_{3}$, describe the mechanism of the reaction.

14.129 The following expression shows the dependence of the half-life of a reaction $\left(t_{1 / 2}\right)$ on the initial reactant concentration $[\mathrm{A}]_{0}$ :

$$
t_{1 / 2} \propto \frac{1}{[\mathrm{~A}]_{0}^{n-1}}
$$

where $n$ is the order of the reaction. Verify this dependence for zeroth-, first-, and second-order reactions.
14.130 Polyethylene is used in many items, including water pipes, bottles, electrical insulation, toys, and mailer envelopes. It is a polymer, a molecule with a very high molar mass made by joining many ethylene molecules together. (Ethylene is the basic unit, or monomer, for polyethylene.) The initiation step is

$$
\mathrm{R}_{2} \xrightarrow{k_{1}} 2 \mathrm{R} \cdot \quad \text { (initiation) }
$$

The $\mathrm{R} \cdot$ species (called a radical) reacts with an ethylene molecule (M) to generate another radical

$$
\mathrm{R} \cdot+\mathrm{M} \longrightarrow \mathrm{M}_{1}
$$

The reaction of $M_{1} \cdot$ with another monomer leads to the growth or propagation of the polymer chain:

$$
\mathrm{M}_{1} \cdot+\mathrm{M} \xrightarrow{k_{\mathrm{p}}} \mathrm{M}_{2} \cdot \quad \text { (propagation) }
$$

This step can be repeated with hundreds of monomer units. The propagation terminates when two radicals combine

$$
\mathrm{M}^{\prime} \cdot+\mathrm{M}^{\prime \prime} \cdot \xrightarrow{k_{\mathrm{t}}} \mathrm{M}^{\prime}-\mathrm{M}^{\prime \prime} \quad \text { (termination) }
$$

The initiator frequently used in the polymerization of ethylene is benzoyl peroxide $\left[\left(\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COO}\right)_{2}\right]$ :

$$
\left(\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COO}\right)_{2} \longrightarrow 2 \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COO}
$$

This is a first-order reaction. The half-life of benzoyl peroxide at $100^{\circ} \mathrm{C}$ is 19.8 min . (a) Calculate the rate constant (in $\mathrm{min}^{-1}$ ) of the reaction. (b) If the half-life of benzoyl peroxide is 7.30 h , or 438 min , at $70^{\circ} \mathrm{C}$, what is the activation energy (in $\mathrm{kJ} / \mathrm{mol}$ ) for the decomposition of benzoyl peroxide? (c) Write the rate laws for the elementary steps in the preceding polymerization process, and identify the reactant, product, and intermediates. (d) What condition would favor the growth of long, high-molarmass polyethylenes?

E114.131 The rate constant for the gaseous reaction

$$
\mathrm{H}_{2}(g)+\mathrm{I}_{2}(g) \longrightarrow 2 \mathrm{HI}(g)
$$

is $2.42 \times 10^{-2} / \mathrm{M} \cdot \mathrm{s}$ at $400^{\circ} \mathrm{C}$. Initially an equimolar sample of $\mathrm{H}_{2}$ and $\mathrm{I}_{2}$ is placed in a vessel at $400^{\circ} \mathrm{C}$, and the total pressure is 1658 mmHg . (a) What is the initial rate $(\mathrm{M} / \mathrm{min})$ of formation of HI ? (b) Determine the rate of formation of HI and the concentration of HI (in molarity) after 10.0 min .
14.132 A protein molecule P of molar mass $\mathcal{M}$ dimerizes when it is allowed to stand in solution at room temperature. A plausible mechanism is that the protein molecule is first denatured (that is, loses its activity due to a change in overall structure) before it dimerizes:

\[

\]

where the asterisk denotes a denatured protein molecule. Derive an expression for the average molar mass (of P and $\mathrm{P}_{2}$ ), $\bar{M}$, in terms of the initial protein concentration $[\mathrm{P}]_{0}$ and the concentration at time $t,[\mathrm{P}]_{t}$, and $\mathcal{M}$. Describe how you would determine $k$ from molar mass measurements.

E14.133 When the concentration of $A$ in the reaction $A \longrightarrow B$ was changed from 1.20 M to 0.60 M , the half-life increased from 2.0 min to 4.0 min at $25^{\circ} \mathrm{C}$. Calculate the order of the reaction and the rate constant. (Hint: Use the equation in Problem 14.129.)
14.134 At a certain elevated temperature, ammonia decomposes on the surface of tungsten metal as follows:

$$
\mathrm{NH}_{3} \longrightarrow \frac{1}{2} \mathrm{~N}_{2}+\frac{3}{2} \mathrm{H}_{2}
$$

The kinetic data are expressed as the variation of the half-life with the initial pressure of $\mathrm{NH}_{3}$ :

| $\boldsymbol{P}(\mathbf{m m H g})$ | $\boldsymbol{t}_{1 / 2}(\mathbf{s})$ |
| :---: | :---: |
| 264 | 456 |
| 130 | 228 |
| 59 | 102 |
| 16 | 60 |

(a) Determine the order of the reaction. (b) How does the order depend on the initial pressure? (c) How does the mechanism of the reaction vary with pressure? (Hint: You need to use the equation in Problem 14.129 and plot $\log t_{1 / 2}$ versus $\log P$.)
14.135 The activation energy for the reaction

$$
\mathrm{N}_{2} \mathrm{O}(g) \longrightarrow \mathrm{N}_{2}(g)+\mathrm{O}(g)
$$

is $2.4 \times 10^{2} \mathrm{~kJ} / \mathrm{mol}$ at 600 K . Calculate the percentage of the increase in rate from 600 K to 606 K . Comment on your results.

E14.136 The rate of a reaction was followed by the absorption of light by the reactants and products as a function of wavelengths $\left(\lambda_{1}, \lambda_{2}\right.$, $\lambda_{3}$ ) as time progresses. Which of the following mechanisms is consistent with the experimental data?
(a) $\mathrm{A} \longrightarrow \mathrm{B}, \mathrm{A} \longrightarrow \mathrm{C}$
(b) $\mathrm{A} \longrightarrow \mathrm{B}+\mathrm{C}$
(c) $\mathrm{A} \longrightarrow \mathrm{B}, \mathrm{B} \longrightarrow \mathrm{C}+\mathrm{D}$
(d) $\mathrm{A} \longrightarrow \mathrm{B}, \mathrm{B} \longrightarrow \mathrm{C}$

14.137 $\Delta H^{\circ}$ for the reaction in Problem 14.135 is $-164 \mathrm{~kJ} / \mathrm{mol}$. What is the activation energy $\left(E_{\mathrm{a}}\right)$ for the reverse reaction?

## Pre-Professional Practice Exam Problems: Physical and Biological Sciences

Metastron, an aqueous solution of ${ }^{89} \mathrm{SrCl}_{2}$, is a drug used to alleviate severe bone pain associated with some metastatic cancers. It contains the radioactive isotope ${ }^{89} \mathrm{Sr}$, which emits $\beta$ radiation and has a constant half-life of 50.5 days. Because the strontium ion is chemically similar to the calcium ion, ${ }^{89} \mathrm{Sr}$ is incorporated into bone tissue, especially in the bone lesions caused by cancer that has spread. Treatment with Metastron typically involves intravenous injection of 4 mL over the course of about 2 min .

1. Calculate the numerical value of the rate constant $(k)$ for the decay of ${ }^{89} \mathrm{Sr}$.
a) 0.0137
b) 0.0127
c) 0.693
d) 0.0198
2. What are the units of the rate constant for the decay of ${ }^{89} \mathrm{Sr}$ ?
a) Days
b) Reciprocal days
c) Reciprocal seconds
d) The rate constant has no units.
3. What percentage of the original activity of ${ }^{89} \mathrm{Sr}$ remains 101 days after an injection of Metastron?
a) 75 percent
b) 50 percent
c) 25 percent
d) 12 percent
4. How many days must pass following an injection of Metastron for the $\beta$ emission to fall to 10 percent of its original value?
a) 182
b) 168
c) 505
d) 455

## Answers to In-Chapter Materials

## Answers to Practice Problems

14.1A (a) rate $=-\frac{\Delta\left[\mathrm{CO}_{2}\right]}{\Delta t}=-\frac{1}{2} \frac{\Delta\left[\mathrm{H}_{2} \mathrm{O}\right]}{\Delta t}=\frac{\Delta\left[\mathrm{CH}_{4}\right]}{\Delta t}=\frac{1}{2} \frac{\Delta\left[\mathrm{O}_{2}\right]}{\Delta t}$,
(b) rate $=-\frac{1}{3} \frac{\Delta\left[\mathrm{O}_{2}\right]}{\Delta t}=\frac{1}{2} \frac{\Delta\left[\mathrm{O}_{3}\right]}{\Delta t}$, (c) rate $=-\frac{1}{2} \frac{\Delta[\mathrm{NO}]}{\Delta t}=-\frac{\Delta\left[\mathrm{O}_{2}\right]}{\Delta t}=$
$\frac{1}{2} \frac{\Delta\left[\mathrm{NO}_{2}\right]}{\Delta t}$. 14.1B (a) $3 \mathrm{CH}_{4}+2 \mathrm{H}_{2} \mathrm{O}+\mathrm{CO}_{2} \longrightarrow 4 \mathrm{CH}_{3} \mathrm{OH}$,
(b) $2 \mathrm{~N}_{2} \mathrm{O}_{5} \longrightarrow 2 \mathrm{~N}_{2}+5 \mathrm{O}_{2}$, (c) $\mathrm{H}_{2}+\mathrm{CO}+\mathrm{O}_{2} \longrightarrow \mathrm{H}_{2} \mathrm{CO}_{3}$.
14.2A (a) $0.0280 \mathrm{M} / \mathrm{s}$. (b) $0.112 \mathrm{M} / \mathrm{s}$. 14.2B $2 \mathrm{~A}+3 \mathrm{~B} \longrightarrow \mathrm{C}$.
14.3A rate $=\mathrm{k}\left[\mathrm{S}_{2} \mathrm{O}_{8}^{2-}\right]\left[\mathrm{I}^{-}\right], k=8.1 \times 10^{-2} / \mathrm{M} \cdot \mathrm{s} .14 .3 \mathrm{~B} 0.013 \mathrm{M}$, $8.8 \times 10^{-6} \mathrm{M} / \mathrm{s}$. 14.4 A 75 s . 14.4B 0.91 M .
14.5A

$k=1.4 \times 10^{-2} / \mathrm{min}$. 14.5B $0.39 \mathrm{M}, 0.34 \mathrm{M}, 0.30 \mathrm{M}, 0.26 \mathrm{M}$. $\mathbf{1 4 . 6 A} t_{1 / 2}=272 \mathrm{~s} .14 .6 \mathrm{~B} k=4.71 \times 10^{-2} / \mathrm{h} .14 .7 \mathrm{~A}$ (a) 13.2 s . (b) $t_{1 / 2}=4.2 \mathrm{~s}, 13 \mathrm{~s} .14 .7 \mathrm{~B}$ (a) 0.0208 M , (b) $1.25 \times 10^{-3} \mathrm{M}$,
(c) $1.79 \times 10^{-4}$ M. 14.8A $241 \mathrm{~kJ} / \mathrm{mol}$. 14.8B Red < green < blue.
14.9A $1.0 \times 10^{2} \mathrm{~kJ} / \mathrm{mol}$. 14.9B $2.7 \times 10^{-4} / \mathrm{s}$. 14.10A $1.7 / \mathrm{s}$.
14.10B $7.6 \times 10^{-2} / \mathrm{s}$. 14.11 A (a) $\mathrm{NO}_{2}+\mathrm{CO} \longrightarrow \mathrm{NO}+\mathrm{CO}_{2}$, (b) $\mathrm{NO}_{3}$, (c) step 1 is rate determining. 14.11B $\mathrm{F}_{2}+\mathrm{ClO}_{2} \longrightarrow$ $\mathrm{FClO}_{2}+\mathrm{F}$ (slow), $\mathrm{ClO}_{2}+\mathrm{F} \longrightarrow \mathrm{FClO}_{2}$ (fast). This is one possibility. Any mechanism in which the slow step has the proper rate law and the steps add to give the correct overall equation is plausible. 14.12A The first step is a rapidly established equilibrium. Setting the rates of forward and reverse reactions equal to each other gives $k_{1}[\mathrm{NO}]\left[\mathrm{Br}_{2}\right]=k_{-1}\left[\mathrm{NOBr}_{2}\right]$. Solving for $\left[\mathrm{NOBr}_{2}\right]$ gives $k_{1}[\mathrm{NO}]\left[\mathrm{Br}_{2}\right] / k_{-1}$. Substituting this into the rate law for the rate-determining step, rate $=$ $k_{2}\left[\mathrm{NOBr}_{2}\right][\mathrm{NO}]$, gives rate $=\left(k_{1} k_{2} / k_{-1}\right)\left[\mathrm{NO}^{2}\left[\mathrm{Br}_{2}\right]\right.$ or $k\left[\mathrm{NO}^{2}\left[\mathrm{Br}_{2}\right]\right.$.
14.12B Step $1: \mathrm{I}_{2}(g) \underset{k_{-1}}{\stackrel{k_{1}}{\rightleftarrows}} 2 \mathrm{I}(g)$. Step $2: \mathrm{H}_{2}(g)+2 \mathrm{I}(g) \longrightarrow 2 \mathrm{HI}(g)$. Rate $=k\left[\mathrm{H}_{2}\right]\left[\mathrm{I}_{2}\right]$.

## How the Principles of Equilibrium Favor Athletes Who "Live High and Train Low"

In chemistry, and in biology, when a necessary ingredient for a process is in short supply, nature sometimes responds in a way that compensates for the shortage. For example, in an isolated population of certain types of fish or frogs consisting of a single sex, some of the individuals will change sexes, enabling the population to reproduce.

An important example of nature responding to a shortage is the production of extra red blood cells in individuals who reside at high elevation-where the concentration of oxygen is lower than at sea level. Extra red blood cells enable the blood to transport adequate oxygen from the lungs to the rest of the body, despite the low oxygen concentration. Enhanced oxygen-carrying capacity of the blood can give an athlete greater aerobic capacity and stamina (at normal oxygen concentrations). This has given rise to attempts by some athletes to increase their red blood count (RBC) artificially-a practice known as "blood doping."

Historically, blood doping has been done with blood infusions or with the drug erythro-poietin-both of which have been banned by the World Anti-Doping Agency (WADA). In recent years, however, the use of hypoxic sleeping tents has grown in popularity. These tents are kept filled with a mixture of nitrogen and oxygen in which the oxygen concentration is lower than that in natural air. Just as the bodies of people who reside at high elevations naturally produce additional red blood cells to compensate for the lower partial pressure of oxygen in the air, the body of an athlete who spends his or her sleeping hours in a hypoxic tent adjusts in the same way, increasing the athlete's RBC. Those who "live high and train low" are believed to have an advantage over athletes who reside and train at or near sea level. Although this is a natural phenomenon and does not really constitute blood doping, WADA has issued the opinion that the artificial inducement of this effect is "contrary to the spirit of sport." As of the 2009 edition of the WADA code, the use of hypoxic tents has not been banned, but the issue likely will be revisited in the years to come.

The increase in the RBC in people who live at high altitudes or who sleep in hypoxic tents can be explained using the principles of chemical equilibrium.

Student Annotation: In Michael Crichton's 1990 novel Jurassic Park, frog DNA was used to repair ancient dinosaur DNA to facilitate cloning of the extinct animals. In the story, the scientists believed the cloned animals could not reproduce because the population was designed to be entirely female. However, some of the dinosaurs became males-something known to occur in the frogs from which the DNA for repair had been taken-and the population of dinosaurs grew out of control.

## Hypoxic sleeping tent

At the end of this chapter, you will be able to solve a series of problems related to the detection of hypoxic RBC enhancement
[ H Page 661].

## In This Chapter, You Will Learn:

What constitutes an equilibrium, what factors influence equilibrium, and how knowledge of equilibrium can be used to solve a variety of problems.

## Before you begin, you should review

- Rate laws for elementary reactions [IK4 Section 14.5]
- The quadratic equation [ $\boldsymbol{\omega}$ Appendix 1]

Student Annotation: $\mathrm{NO}_{2}$ is the cause of the brown appearance of some polluted air.

Student Annotation: We have previously treated chemical reactions as though they only proceed as written-from left to rightwherein reactants react and products form. In a reverse reaction, however, the products actually become the reactants, and vice versa To avoid confusion, we will always refer to species on the left side of the equation as reactants and those on the right side as products-regardless of whether we are discussing the forward or reverse reaction.

### 15.1 The Concept of Equilibrium

Up until now, we have treated chemical equations as though they go to completion; that is, we start with only reactants and end up with only products. In fact, this is not the case with most chemical reactions. Instead, if we start with only reactants, the reaction will proceed, causing reactant concentrations to decrease (as reactants are consumed) and product concentrations to increase (as products are produced). Eventually, though, the concentrations of reactants and products will stop changing. The reaction will appear to have stopped, and we will be left with a mixture of reactants and products.

As an example, consider the decomposition of dinitrogen tetroxide $\left(\mathrm{N}_{2} \mathrm{O}_{4}\right)$ to yield nitrogen dioxide $\left(\mathrm{NO}_{2}\right)$ :

$$
\mathrm{N}_{2} \mathrm{O}_{4}(g) \rightleftarrows 2 \mathrm{NO}_{2}(g)
$$

$\mathrm{N}_{2} \mathrm{O}_{4}$ is a colorless gas, whereas $\mathrm{NO}_{2}$ is brown. If we begin by placing a sample of pure $\mathrm{N}_{2} \mathrm{O}_{4}$ in an evacuated flask, the contents of the flask change from colorless to brown as the decomposition produces $\mathrm{NO}_{2}$ (Figure 15.1). At first, the brown color intensifies as the concentration of $\mathrm{NO}_{2}$ increases. After some time has passed, though, the intensity of the brown color stops increasing, indicating that the concentration of $\mathrm{NO}_{2}$ has stopped increasing.

Although the concentration of the product (and of the reactant) has stopped changing, the reaction has not actually stopped. Like most chemical reactions, the decomposition of $\mathrm{N}_{2} \mathrm{O}_{4}$ is a reversible process, meaning that the products of the reaction can react to form reactants. Thus, as the decomposition of $\mathrm{N}_{2} \mathrm{O}_{4}$ continues, the reverse reaction, the combination of $\mathrm{NO}_{2}$ molecules to produce $\mathrm{N}_{2} \mathrm{O}_{4}$, is also occurring. Eventually, the concentrations of both species reach levels where they remain constant because the two processes are occurring at the same rate-and the system is said to have achieved equilibrium.

In this case, both the forward and reverse reactions are elementary reactions, so we can write their rate laws from the balanced equation:

$$
\operatorname{rate}_{\text {forward }}=k_{\mathrm{f}}\left[\mathrm{~N}_{2} \mathrm{O}_{4}\right] \quad \text { and } \quad \operatorname{rate}_{\text {reverse }}=k_{\mathrm{r}}\left[\mathrm{NO}_{2}\right]^{2}
$$

Figure 15.1 Reaction of colorless $\mathrm{N}_{2} \mathrm{O}_{4}$ to form brown $\mathrm{NO}_{2}$. Initially, only $\mathrm{N}_{2} \mathrm{O}_{4}$ is present and only the forward reaction (decomposition of $\mathrm{N}_{2} \mathrm{O}_{4}$ to give $\mathrm{NO}_{2}$ ) is occurring. As $\mathrm{NO}_{2}$ forms, the reverse reaction (recombination of $\mathrm{NO}_{2}$ to give $\mathrm{N}_{2} \mathrm{O}_{4}$ ) begins to occur. The brown color continues to intensify until the forward and reverse reactions are occurring at the same rate.

where $k_{\mathrm{f}}$ and $k_{\mathrm{r}}$ are the rate constants for the forward and reverse reactions, respectively [ kf Section 14.5]. As always, the square brackets denote molar concentration. In the experiment shown in Figure 15.1, initially:

- $\mathrm{N}_{2} \mathrm{O}_{4}$ concentration is high, and the rate of the forward reaction is high.
- $\mathrm{NO}_{2}$ concentration is zero, making the rate of the reverse reaction zero.

As the reaction proceeds:

- $\mathrm{N}_{2} \mathrm{O}_{4}$ concentration falls, decreasing the rate of the forward reaction.
- $\mathrm{NO}_{2}$ concentration rises, increasing the rate of the reverse reaction.

Figure 15.2(a) shows how the rates of these forward and reverse reactions change over time, and how they eventually become equal as equilibrium is established.

We could equally well have started the $\mathrm{N}_{2} \mathrm{O}_{4}-\mathrm{NO}_{2}$ experiment with pure $\mathrm{NO}_{2}$ in a flask. Figure 15.3 shows how the brown color, initially intense, fades as $\mathrm{NO}_{2}$ combines to form $\mathrm{N}_{2} \mathrm{O}_{4}$.

Figure $15.3 \quad \mathrm{~N}_{2} \mathrm{O}_{4} / \mathrm{NO}_{2}$ equilibrium starting with $\mathrm{NO}_{2}$. Initially, only $\mathrm{NO}_{2}$ is present and only the reverse reaction (recombination of $\mathrm{NO}_{2}$ to give $\mathrm{N}_{2} \mathrm{O}_{4}$ ) is occurring. As $\mathrm{N}_{2} \mathrm{O}_{4}$ forms, the forward reaction (decomposition of $\mathrm{N}_{2} \mathrm{O}_{4}$ ) begins to occur. The brown color continues to fade until the forward and reverse reactions are occurring at the same rate.

Student Annotation: It is a common error to think that equilibrium means equal concentrations of reactants and productsit does not. Equilibrium refers to the state in which forward and reverse reactions are occurring at the same rate.

Student Annotation: From this point on, we will no longer show the "eq" subscript for concentrations in equilibrium expressionsalthough you should know that every concentration in an equilibrium expression is the concentration at equilibrium.

As before, the intensity stops changing after a period of time. When we start the experiment with pure $\mathrm{NO}_{2}$, initially:

- $\mathrm{NO}_{2}$ concentration is high, and the rate of the reverse reaction is high.
- $\mathrm{N}_{2} \mathrm{O}_{4}$ concentration is zero, making the rate of the forward reaction zero.

As the reaction proceeds:

- $\mathrm{NO}_{2}$ concentration falls, decreasing the rate of the reverse reaction.
- $\mathrm{N}_{2} \mathrm{O}_{4}$ concentration rises, increasing the rate of the forward reaction.

Figure 15.2(b) shows how the forward and reverse rates change over time when we start with $\mathrm{NO}_{2}$ instead of $\mathrm{N}_{2} \mathrm{O}_{4}$. We could also conduct this kind of experiment starting with a mixture of $\mathrm{NO}_{2}$ and $\mathrm{N}_{2} \mathrm{O}_{4}$. Again, the forward and reverse reactions would occur, initially at rates determined by the corresponding starting concentrations, and equilibrium would be established when both reactions were occurring at the same rate.

Some important things to remember about equilibrium are:

- Equilibrium is a dynamic state-both forward and reverse reactions continue to occur, although there is no net change in reactant and product concentrations over time.
- At equilibrium, the rates of the forward and reverse reactions are equal.
- Equilibrium can be established starting with only reactants, with only products, or with any mixture of reactants and products.

Finally, it is important to understand that the principles of equilibrium apply not only to reversible chemical reactions, but also to reversible physical processes such as phase changes. In this chapter, we will limit our discussion to chemical equilibria. We explore reversible physical processes in some detail in Chapter 18.

### 15.2 The Equilibrium Constant

We have defined equilibrium as the state in which the opposing forward and reverse reactions are occurring at the same rate:

$$
\text { rate }_{\text {forward }}=\text { rate }_{\text {reverse }}
$$

Thus, using the $\mathrm{N}_{2} \mathrm{O}_{4}-\mathrm{NO}_{2}$ system as an example again,

$$
k_{\mathrm{f}}\left[\mathrm{~N}_{2} \mathrm{O}_{4}\right]_{\mathrm{eq}}=k_{\mathrm{r}}\left[\mathrm{NO}_{2}\right]_{\mathrm{eq}}^{2}
$$

where the subscripted "eq" denotes a concentration at equilibrium. Rearranging this expression gives

$$
\frac{k_{\mathrm{f}}}{k_{\mathrm{r}}}=\frac{\left[\mathrm{NO}_{2}\right]_{\mathrm{eq}}^{2}}{\left[\mathrm{~N}_{2} \mathrm{O}_{4}\right]_{\mathrm{eq}}}
$$

and because the ratio of two constants $\left(k_{\mathrm{f}} / k_{\mathrm{r}}\right)$ is also a constant, we have

$$
\begin{aligned}
& \text { equilibrium expression } \\
& \qquad K_{\mathrm{c}}=\frac{\left[\mathrm{NO}_{2}\right]_{\mathrm{eq}}^{2}}{\left[\mathrm{~N}_{2} \mathrm{O}_{4}\right]_{\mathrm{eq}}} \\
& \text { brium constant }
\end{aligned}
$$

where $K_{\mathrm{c}}$ is the equilibrium constant and the equation is known as the equilibrium expression. (The subscript "c" stands for concentration, referring to the molar concentrations in the expression.) Note the relationship between the equilibrium expression and the balanced chemical equation for the reaction: the numerator contains the product concentration raised to a power equal to its stoichiometric coefficient in the balanced chemical equation:

TABLE 15.1 Initial and Equilibrium Concentrations of $\mathrm{N}_{2} \mathrm{O}_{4}$ and $\mathrm{NO}_{2}$ at $25^{\circ} \mathrm{C}$

|  | Initial <br> Concentrations (M) |  | Equilibrium <br> Concentrations ( $M$ ) |  |  |
| :---: | :---: | :--- | :--- | :--- | :--- |
| Experiment | $\left[\mathrm{N}_{2} \mathrm{O}_{4}\right]_{\mathrm{i}}$ | $\left[\mathrm{NO}_{2}\right]_{\mathbf{i}}$ | $\left[\mathrm{N}_{2} \mathrm{O}_{4}\right]$ | $\left[\mathrm{NO}_{2}\right]$ | $\frac{\left[\mathrm{NO}_{2}\right]^{2}}{\left[\mathrm{~N}_{2} \mathrm{O}_{4}\right]}$ |
| 1 | 0.670 | 0.00 | 0.643 | 0.0547 | $4.65 \times 10^{-3}$ |
| 2 | 0.446 | 0.0500 | 0.448 | 0.0457 | $4.66 \times 10^{-3}$ |
| 3 | 0.500 | 0.0300 | 0.491 | 0.0475 | $4.60 \times 10^{-3}$ |
| 4 | 0.600 | 0.0400 | 0.594 | 0.0523 | $4.60 \times 10^{-3}$ |
| 5 | 0.000 | 0.200 | 0.0898 | 0.0204 | $4.63 \times 10^{-3}$ |

The denominator, moreover, contains the reactant concentration raised to a power equal to its stoichiometric coefficient in the balanced chemical equation. (In this equation the coefficient of $\mathrm{N}_{2} \mathrm{O}_{4}$ is 1 , which generally is not written either as a coefficient or as an exponent.) Table 15.1 lists the starting and equilibrium concentrations of $\mathrm{N}_{2} \mathrm{O}_{4}$ and $\mathrm{NO}_{2}$ in a series of experiments carried out at $25^{\circ} \mathrm{C}$. Using the equilibrium concentrations from each of the experiments in the table, the value of the expression $\left[\mathrm{NO}_{2}\right]^{2} /\left[\mathrm{N}_{2} \mathrm{O}_{4}\right]$ is indeed constant (the average is $4.63 \times 10^{-3}$ ) within the limits of experimental error.

## Calculating Equilibrium Constants

In the mid-nineteenth century, Cato Guldberg ${ }^{1}$ and Peter Waage ${ }^{2}$ studied the equilibrium mixtures of a wide variety of chemical reactions. They observed that at a constant temperature in an equilibrium mixture of reactants and products regardless of the initial concentrations, the reaction quotient has a constant value. The reaction quotient $\left(\boldsymbol{Q}_{\mathrm{c}}\right)$ is a fraction with product concentrations in the numerator and reactant concentrations in the denominator-with each concentration raised to a power equal to the corresponding stoichiometric coefficient in the balanced chemical equation. For the general reaction,

$$
a \mathrm{~A}+b \mathrm{~B} \rightleftarrows c \mathrm{C}+d \mathrm{D}
$$

at equilibrium, the reaction quotient $Q_{\mathrm{c}}$ is equal to the equilibrium constant $K_{\mathrm{c}}$.

$$
Q_{\mathrm{c}}=\frac{[\mathrm{C}]^{c}[\mathrm{D}]^{d}}{[\mathrm{~A}]^{a}[\mathrm{~B}]^{b}}=K_{\mathrm{c}} \quad \text { (at equilibrium) } \quad \text { Equation } 15.1
$$

This expression is known as the law of mass action. Like the equilibrium constant $K, Q$ is subscripted with a " $c$ " to indicate that the quotient is defined in terms of concentrations. For the $\mathrm{N}_{2} \mathrm{O}_{4}-\mathrm{NO}_{2}$ system, this approach gives the same equilibrium expression as we got from our kinetics approach: $\left[\mathrm{NO}_{2}\right]_{\mathrm{eq}}^{2} /\left[\mathrm{N}_{2} \mathrm{O}_{4}\right]_{\mathrm{eq}}$. But the law of mass action was developed empirically from countless observations of many different reactions-long before the principles of kinetics were developed. Additionally, it applies not only to elementary reactions, but also to more complex reactions that occur via a series of steps. Furthermore, the law of mass action enables us to write the equilibrium expression for any reaction for which we know the balanced equation. Knowing the equilibrium expression for a reaction, we can use equilibrium concentrations to calculate the value of the equilibrium constant.

Sample Problem 15.1 shows how to use equilibrium concentrations and the law of mass action to calculate the value of an equilibrium constant.

[^40]Student Annotation: In our first example, there was just one reactant and one product. When there are multiple species on either side of the equation, the numerator is the product of product concentrations and the denominator is the product of reactant concentrations-with each concentration raised to the appropriate power, that is, the stoichiometric coefficient.

Think About It When putting the equilibrium concentrations into the equilibrium expression, we leave out the units. It is common practice to express equilibrium constants without units. We will examine the reason why in Section 15.5.

Figure 15.4 The value of the reaction quotient, $Q$, changes as the reaction (experiment 5 from Table 15.1) progresses. When the system reaches equilibrium, $Q$ is equal to the equilibrium constant.

## Sample Problem 15.1

Carbonyl chloride $\left(\mathrm{COCl}_{2}\right)$, also called phosgene, is a highly poisonous gas that was used on the battlefield in World War I. It is produced by the reaction of carbon monoxide with chlorine gas:

$$
\mathrm{CO}(g)+\mathrm{Cl}_{2}(g) \rightleftarrows \mathrm{COCl}_{2}(g)
$$

In an experiment conducted at $74^{\circ} \mathrm{C}$, the equilibrium concentrations of the species involved in the reaction were as follows: $[\mathrm{CO}]=1.2 \times 10^{-2} \mathrm{M},\left[\mathrm{Cl}_{2}\right]=0.054 \mathrm{M}$, and $\left[\mathrm{COCl}_{2}\right]=0.14 \mathrm{M}$. (a) Write the equilibrium expression, and (b) determine the value of the equilibrium constant for this reaction at $74^{\circ} \mathrm{C}$.

Strategy Use the law of mass action to write the equilibrium expression and plug in the equilibrium concentrations of all three species to evaluate $K_{\mathrm{c}}$.

Setup The equilibrium expression has the form of concentrations of products over concentrations of reactants, each raised to the appropriate power-in the case of this reaction, all the coefficients are 1 , so all the powers will be 1 .

## Solution

(a) $K_{\mathrm{c}}=\frac{\left[\mathrm{COCl}_{2}\right]}{[\mathrm{CO}]\left[\mathrm{Cl}_{2}\right]}$
(b) $K_{\mathrm{c}}=\frac{(0.14)}{\left(1.2 \times 10^{-2}\right)(0.054)}=216$ or $2.2 \times 10^{2}$
$K_{\mathrm{c}}$ for this reaction at $74^{\circ} \mathrm{C}$ is $2.2 \times 10^{2}$.

Practice Problem A In an analysis of the following reaction at $100^{\circ} \mathrm{C}$,

$$
\mathrm{Br}_{2}(g)+\mathrm{Cl}_{2}(g) \rightleftarrows 2 \mathrm{BrCl}(g)
$$

the equilibrium concentrations were found to be $\left[\mathrm{Br}_{2}\right]=2.3 \times 10^{-3} M,\left[\mathrm{Cl}_{2}\right]=1.2 \times 10^{-2} \mathrm{M}$, and $[\mathrm{BrCl}]=1.4 \times 10^{-2} \mathrm{M}$. Write the equilibrium expression, and calculate the equilibrium constant for this reaction at $100^{\circ} \mathrm{C}$.

EPractice Problem B In another analysis at $100^{\circ} \mathrm{C}$ involving the same reaction, the equilibrium concentrations of the reactants were found to be $\left[\mathrm{Br}_{2}\right]=4.1 \times 10^{-3} \mathrm{M}$ and $\left[\mathrm{Cl}_{2}\right]=8.3 \times 10^{-3} \mathrm{M}$. Determine the value of $[\mathrm{BrCl}]$.

Guldberg and Waage's work involved calculating reaction quotients at equilibrium, but the numerical value of the reaction quotient can be determined using starting concentrations or final (equilibrium) concentrations, or concentrations at any time during the reaction (provided that the concentrations are known). The value of $Q_{\mathrm{c}}$ changes as the reaction progresses (Figure 15.4), and $Q_{\mathrm{c}}$ is equal to $K_{\mathrm{c}}$ only when a system is at equilibrium. However, we often find it useful to calculate the value of $Q_{\mathrm{c}}$ for a system that is not at equilibrium. At any point during the progress of a reaction, therefore,

$$
Q_{\mathrm{c}}=\frac{[\mathrm{C}]^{c}[\mathrm{D}]^{d}}{[\mathrm{~A}]^{a}[\mathrm{~B}]^{b}}
$$

Equation 15.2

Sample Problem 15.2 lets you practice writing reaction quotients for a variety of balanced equations.

## Sample Problem 15.2

Write reaction quotients for the following reactions:
(a) $\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \rightleftarrows 2 \mathrm{NH}_{3}(g)$
(b) $\mathrm{H}_{2}(g)+\mathrm{I}_{2}(g) \rightleftarrows 2 \mathrm{HI}(g)$
(c) $\mathrm{Ag}^{+}(a q)+2 \mathrm{NH}_{3}(a q) \rightleftarrows \mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}^{+}(a q)$
(d) $2 \mathrm{O}_{3}(\mathrm{~g}) \rightleftarrows 3 \mathrm{O}_{2}(\mathrm{~g})$
(e) $\mathrm{Cd}^{2+}(a q)+4 \mathrm{Br}^{-}(a q) \rightleftarrows \mathrm{CdBr}_{4}^{2-}(a q)$
(f) $2 \mathrm{NO}(g)+\mathrm{O}_{2}(g) \rightleftarrows 2 \mathrm{NO}_{2}(g)$

Strategy Use the law of mass action to write reaction quotients.
Setup The reaction quotient for each reaction has the form of the concentrations of products over the concentrations of reactants, each raised to a power equal to its stoichiometric coefficient in the balanced chemical equation.

## Solution

(a) $Q_{\mathrm{c}}=\frac{\left[\mathrm{NH}_{3}\right]^{2}}{\left[\mathrm{~N}_{2}\right]\left[\mathrm{H}_{2}\right]^{3}}$
(d) $Q_{\mathrm{c}}=\frac{\left[\mathrm{O}_{2}\right]^{3}}{\left[\mathrm{O}_{3}\right]^{2}}$
(b) $Q_{\mathrm{c}}=\frac{[\mathrm{HI}]^{2}}{\left[\mathrm{H}_{2}\right]\left[\mathrm{I}_{2}\right]}$
(e) $Q_{\mathrm{c}}=\frac{\left[\mathrm{CdBr}_{4}^{2-}\right]}{\left[\mathrm{Cd}^{2+}\right]\left[\mathrm{Br}^{-}\right]^{4}}$
(c) $Q_{\mathrm{c}}=\frac{\left[\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}^{+}\right]}{\left[\mathrm{Ag}^{+}\right]\left[\mathrm{NH}_{3}\right]^{2}}$
(f) $Q_{\mathrm{c}}=\frac{\left[\mathrm{NO}_{2}\right]^{2}}{[\mathrm{NO}]^{2}\left[\mathrm{O}_{2}\right]}$

Practice Problem A Write the reaction quotient for each of the following reactions:
(a) $2 \mathrm{~N}_{2} \mathrm{O}(g) \rightleftarrows 2 \mathrm{~N}_{2}(g)+\mathrm{O}_{2}(g)$
(b) $2 \mathrm{NOBr}(g) \rightleftarrows 2 \mathrm{NO}(g)+\mathrm{Br}_{2}(g)$
(c) $\mathrm{HF}(a q) \rightleftarrows \mathrm{H}^{+}(a q)+\mathrm{F}^{-}(a q)$
(d) $\mathrm{CO}(g)+\mathrm{H}_{2} \mathrm{O}(g) \rightleftarrows \mathrm{CO}_{2}(g)+\mathrm{H}_{2}(g)$
(e) $\mathrm{CH}_{4}(g)+2 \mathrm{H}_{2} \mathrm{~S}(g) \rightleftarrows \mathrm{CS}_{2}(g)+4 \mathrm{H}_{2}(g)$
(f) $\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}(a q) \rightleftarrows 2 \mathrm{H}^{+}(a q)+\mathrm{C}_{2} \mathrm{O}_{4}^{2-}(a q)$

GPractice Problem B Write the equation for the equilibrium that corresponds to each of the following reaction quotients:
(a) $Q_{\mathrm{c}}=\frac{[\mathrm{HCl}]^{2}}{\left[\mathrm{H}_{2}\right]\left[\mathrm{Cl}_{2}\right]}$
(d) $Q_{\mathrm{c}}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{ClO}^{-}\right]}{[\mathrm{HClO}]}$
(b) $Q_{\mathrm{c}}=\frac{[\mathrm{HF}]}{\left[\mathrm{H}^{+}\right]\left[\mathrm{F}^{-}\right]}$
(e) $Q_{\mathrm{c}}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{HSO}_{3}^{-}\right]}{\left[\mathrm{H}_{2} \mathrm{SO}_{3}\right]}$
(c) $Q_{\mathrm{c}}=\frac{\left[\mathrm{Cr}(\mathrm{OH})_{4}^{-}\right]}{\left[\mathrm{Cr}^{3+}\right]\left[\mathrm{OH}^{-}\right]^{4}}$
(f) $Q_{\mathrm{c}}=\frac{[\mathrm{NOBr}]^{2}}{[\mathrm{NO}]^{2}\left[\mathrm{Br}_{2}\right]}$

Student Annotation: The molar concentrations in a reaction quotient may be concentrations of gases or aqueous species.

Think About It With practice, writing reaction quotients becomes second nature. Without sufficient practice, it will seem inordinately difficult. It is important that you become proficient at this. It is very often the first step in solving equilibrium problems.

## Magnitude of the Equilibrium Constant

One of the things the equilibrium constant tells us is the extent to which a reaction proceeds at a particular temperature. If we combine stoichiometric amounts of the reactants in a reaction, three outcomes are possible:

1. The reaction will go essentially to completion, and the equilibrium mixture will consist predominantly of products.
2. The reaction will not occur to any significant degree, and the equilibrium mixture will consist predominantly of reactants.
3. The reaction will proceed to a significant degree but will not go to completion, and the equilibrium mixture will contain comparable amounts of both reactants and products.

When the magnitude of $K_{\mathrm{c}}$ is very large, we expect the first outcome. The formation of the $\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}^{+}$ion is an example of this possibility.

$$
\mathrm{Ag}^{+}(a q)+2 \mathrm{NH}_{3}(a q) \rightleftarrows \mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}^{+}(a q) \quad K_{\mathrm{c}}=1.5 \times 10^{7}\left(25^{\circ} \mathrm{C}\right)
$$

If we were to combine aqueous $\mathrm{Ag}^{+}$and aqueous $\mathrm{NH}_{3}$ in a mole ratio of $1: 2$, the resulting equilibrium mixture would contain mostly $\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}^{+}$with only very small amounts of reactants remaining. A reaction with a very large equilibrium constant is sometimes said to "lie to the right" or to "favor products."

When the magnitude of $K_{\mathrm{c}}$ is very small, we expect the second outcome. The chemical combination of nitrogen and oxygen gases to give nitrogen monoxide is an example of this possibility.

$$
\mathrm{N}_{2}(g)+\mathrm{O}_{2}(g) \rightleftarrows 2 \mathrm{NO}(g) \quad K_{\mathrm{c}}=4.3 \times 10^{-25}\left(\text { at } 25^{\circ} \mathrm{C}\right)
$$

Nitrogen and oxygen gases do not react to any significant extent at room temperature. If we were to place a mixture of $\mathrm{N}_{2}$ and $\mathrm{O}_{2}$ in an evacuated flask and allow the system to reach equilibrium, the resulting mixture would be predominantly $\mathrm{N}_{2}$ and $\mathrm{O}_{2}$ with only a very small amount of NO. A reaction with a very small equilibrium constant is said to "lie to the left" or to "favor reactants."

The terms very large and very small are somewhat arbitrary when applied to equilibrium constants. Generally speaking, an equilibrium constant with a magnitude greater than about $1 \times$ $10^{2}$ can be considered large; one with a magnitude smaller than about $1 \times 10^{-2}$ can be considered small.

An equilibrium constant that falls between $1 \times 10^{2}$ and $1 \times 10^{-2}$ indicates that neither products nor reactants are strongly favored. In this case, a system at equilibrium will contain a mixture of reactants and products, the exact composition of which will depend on the stoichiometry of the reaction.

## Checkpoint 15.2 The Equilibrium Constant

15.2.1 Select the correct equilibrium expression for the reaction

$$
2 \mathrm{CO}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) \rightleftarrows 2 \mathrm{CO}_{2}(\mathrm{~g})
$$

a) $K_{\mathrm{c}}=\frac{2\left[\mathrm{CO}_{2}\right]^{2}}{2[\mathrm{CO}]^{2}\left[\mathrm{O}_{2}\right]}$
b) $K_{\mathrm{c}}=\frac{\left(2\left[\mathrm{CO}_{2}\right]\right)^{2}}{(2[\mathrm{CO}])^{2}\left(\left[\mathrm{O}_{2}\right]\right)}$
c) $K_{\mathrm{c}}=\frac{2\left[\mathrm{CO}_{2}\right]}{2[\mathrm{CO}]\left[\mathrm{O}_{2}\right]}$
d) $K_{\mathrm{c}}=\frac{2\left[\mathrm{CO}_{2}\right]^{2}}{[2 \mathrm{CO}]^{2}\left[\mathrm{O}_{2}\right]}$
e) $K_{\mathrm{c}}=\frac{\left[\mathrm{CO}_{2}\right]^{2}}{[\mathrm{CO}]^{2}\left[\mathrm{O}_{2}\right]}$
15.2.2 Determine the value of the equilibrium constant, $K_{\mathrm{c}}$, for the reaction

$$
\mathrm{A}+2 \mathrm{~B} \rightleftarrows \mathrm{C}+\mathrm{D}
$$

if the equilibrium concentrations are
$[\mathrm{A}]=0.0115 \mathrm{M},[\mathrm{B}]=0.0253 \mathrm{M}$,
$[\mathrm{C}]=0.109 \mathrm{M}$, and $[\mathrm{D}]=0.0110 \mathrm{M}$.
a) 163
b) 4.12
c) 2.06
d) $6.14 \times 10^{-3}$
e) 0.243

### 15.3 Equilibrium Expressions

The equilibria we have discussed so far have all been homogeneous; that is, the reactants and products have all existed in the same phase-either gaseous or aqueous. In these cases, the equilibrium expression consists of writing the product of the product concentrations at equilibrium over the product of the reactant concentrations at equilibrium, with each concentration raised to a power equal to its stoichiometric coefficient in the balanced chemical equation (Equation 15.2). When the species in a reversible chemical reaction are not all in the same phase, the equilibrium is heterogeneous.

## Heterogeneous Equilibria

Writing equilibrium expressions for heterogeneous equilibria is also straightforward, but it is slightly different from what we have done so far for homogeneous equilibria. For example, carbon dioxide can combine with elemental carbon to produce carbon monoxide:

$$
\mathrm{CO}_{2}(g)+\mathrm{C}(s) \rightleftarrows 2 \mathrm{CO}(g)
$$

The two gases and one solid constitute two separate phases. If we were to write the equilibrium expression for this reaction as we have done previously for homogeneous reactions, including all product concentrations in the numerator and all reactant concentrations in the denominator, we would have

$$
K_{\mathrm{c}}^{*}=\frac{[\mathrm{CO}]^{2}}{\left[\mathrm{CO}_{2}\right][\mathrm{C}]}
$$

( $K_{\mathrm{c}}^{*}$ is superscripted with an asterisk to distinguish it from the equilibrium constant that we are about to derive.) The "concentration" of a solid, however, is a constant. If we were to double the number of moles of elemental carbon $(\mathrm{C})$ in the preceding reaction, we would also double its volume. The ratio of moles to volume, which is how we define the concentration, remains the same. Because the concentration of solid carbon is a constant, it is incorporated into the value of the equilibrium constant and does not appear explicitly in the equilibrium expression.

$$
K_{\mathrm{c}}^{*} \times[\mathrm{C}]=\frac{[\mathrm{CO}]^{2}}{\left[\mathrm{CO}_{2}\right]}
$$

The product of $K_{c}^{*}$ and $[\mathrm{C}]_{\text {eq }}$ gives the real equilibrium constant for this reaction. The corresponding equilibrium expression is

$$
K_{\mathrm{c}}=\frac{[\mathrm{CO}]^{2}}{\left[\mathrm{CO}_{2}\right]}
$$

The same argument applies to the concentrations of pure liquids in heterogeneous equilibria. Only gaseous species and aqueous species appear in equilibrium expressions.

Sample Problem 15.3 lets you practice writing equilibrium expressions for heterogeneous equilibria.

## Sample Problem 15.3

Write equilibrium expressions for each of the following reactions:
(a) $\mathrm{CaCO}_{3}(s) \rightleftarrows \mathrm{CaO}(s)+\mathrm{CO}_{2}(g)$
(b) $\mathrm{Hg}(l)+\mathrm{Hg}^{2+}(a q) \rightleftarrows \mathrm{Hg}_{2}^{2+}(a q)$
(c) $2 \mathrm{Fe}(s)+3 \mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{Fe}_{2} \mathrm{O}_{3}(s)+2 \mathrm{H}_{2}(g)$
(d) $\mathrm{O}_{2}(g)+2 \mathrm{H}_{2}(g) \rightleftarrows 2 \mathrm{H}_{2} \mathrm{O}(l)$.

Strategy Use the law of mass action to write the equilibrium expression for each reaction. Only gases and aqueous species appear in the expression.

Setup
(a) Only $\mathrm{CO}_{2}$ will appear in the expression.
(b) $\mathrm{Hg}^{2+}$ and $\mathrm{Hg}_{2}^{2+}$ will appear in the expression.
(c) Only $\mathrm{H}_{2}$ will appear in the expression.
(d) $\mathrm{O}_{2}$ and $\mathrm{H}_{2}$ will appear in the expression.

Think About It Like writing equilibrium expressions for homogeneous equilibria, writing equilibrium expressions for heterogeneous equilibria becomes second nature if you practice. The importance of developing this skill now cannot be overstated. Your ability to understand the principles and to solve many of the problems in this and Chapters 16 to 19 depends on your ability to write equilibrium expressions correctly and easily.

## Solution

(a) $K_{\mathrm{c}}=\left[\mathrm{CO}_{2}\right]$
(b) $K_{\mathrm{c}}=\frac{\left[\mathrm{Hg}_{2}^{2+}\right]}{\left[\mathrm{Hg}^{2+}\right]}$
(c) $K_{\mathrm{c}}=\left[\mathrm{H}_{2}\right]^{2}$
(d) $K_{\mathrm{c}}=\frac{1}{\left[\mathrm{O}_{2}\right]\left[\mathrm{H}_{2}\right]^{2}}$

Practice Problem A Write equilibrium expressions for each of the following reactions:
(a) $\mathrm{SiCl}_{4}(g)+2 \mathrm{H}_{2}(g) \rightleftarrows \mathrm{Si}(s)+4 \mathrm{HCl}(g)$
(b) $\mathrm{Hg}^{2+}(a q)+2 \mathrm{Cl}^{-}(a q) \rightleftarrows \mathrm{HgCl}_{2}(s)$
(c) $\mathrm{Ni}(s)+4 \mathrm{CO}(g) \rightleftarrows \mathrm{Ni}(\mathrm{CO})_{4}(g)$
(d) $\mathrm{Zn}(s)+\mathrm{Fe}^{2+}(a q) \rightleftarrows \mathrm{Zn}^{2+}(a q)+\mathrm{Fe}(s)$

GPractice Problem B Which of the following equilibrium expressions corresponds to a heterogeneous equilibrium? How can you tell?
(a) $K_{\mathrm{c}}=\left[\mathrm{NH}_{3}\right][\mathrm{HCl}]$
(b) $K_{\mathrm{c}}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}\right]}{\left[\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right]}$
(c) $K_{\mathrm{c}}=\frac{\left[\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}^{+}\right]\left[\mathrm{Cl}^{-}\right]}{\left[\mathrm{NH}_{3}\right]^{2}}$
(d) $K_{\mathrm{c}}=\left[\mathrm{Ba}^{2+}\right]\left[\mathrm{F}^{-}\right]^{2}$

## Manipulating Equilibrium Expressions

In our study of enthalpy, we learned that it is possible to manipulate chemical equations to solve thermochemistry problems [ WA Section 5.3]. Recall that when we made a change in a thermochemical equation, we had to make the corresponding change in the $\Delta H$ of the reaction. When we reversed a reaction, for example, we had to change the sign of its $\Delta H$. When we change something about how an equilibrium reaction is expressed, we must also make the appropriate changes to the equilibrium expression and the equilibrium constant. Consider the reaction of nitric oxide and oxygen to produce nitrogen dioxide:

$$
2 \mathrm{NO}(g)+\mathrm{O}_{2}(g) \rightleftarrows 2 \mathrm{NO}_{2}(g)
$$

The equilibrium expression is

$$
K_{\mathrm{c}}=\frac{\left[\mathrm{NO}_{2}\right]^{2}}{\left[\mathrm{NO}^{2}\left[\mathrm{O}_{2}\right]\right.}
$$

and the equilibrium constant at 500 K is $6.9 \times 10^{5}$. If we were to reverse this equation, writing the equation for the decomposition of $\mathrm{NO}_{2}$ to produce NO and $\mathrm{O}_{2}$,

$$
2 \mathrm{NO}_{2}(g) \rightleftarrows 2 \mathrm{NO}(g)+\mathrm{O}_{2}(g)
$$

the new equilibrium expression would be the reciprocal of the original equilibrium expression:

$$
K_{\mathrm{c}}^{\prime}=\frac{[\mathrm{NO}]^{2}\left[\mathrm{O}_{2}\right]}{\left[\mathrm{NO}_{2}\right]^{2}}
$$

Because the equilibrium expression is the reciprocal of the original, the equilibrium constant is also the reciprocal of the original. At 500 K , therefore, the equilibrium constant for the new equation is $1 /\left(6.9 \times 10^{5}\right)$ or $1.5 \times 10^{-6}$.

Alternatively, if instead of reversing the original equation, we were to multiply it by 2 ,

$$
4 \mathrm{NO}(g)+2 \mathrm{O}_{2}(g) \rightleftarrows 4 \mathrm{NO}_{2}(g)
$$

the new equilibrium expression would be

$$
K_{\mathrm{c}}^{\prime \prime}=\frac{\left[\mathrm{NO}_{2}\right]^{4}}{\left.\left[\mathrm{NO}^{4}\right]^{4} \mathrm{O}_{2}\right]^{2}}
$$

which is the original equilibrium expression squared. Again, because the new equilibrium expression is the square of the original, the new equilibrium constant is the square of the original: $K_{\mathrm{c}}=$ $\left(6.9 \times 10^{5}\right)^{2}$ or $4.8 \times 10^{11}$.

Finally, if we were to add the reverse of the original equation,

$$
2 \mathrm{NO}_{2}(g) \rightleftarrows 2 \mathrm{NO}(g)+\mathrm{O}_{2}(g)
$$

(for which $K_{\mathrm{c}}=1.6 \times 10^{-6}$ at 500 K ) to the equation

$$
2 \mathrm{H}_{2}(g)+\mathrm{O}_{2}(g) \rightleftarrows 2 \mathrm{H}_{2} \mathrm{O}(g)
$$

(for which $K_{\mathrm{c}}=2.4 \times 10^{47}$ at 500 K ), the sum of the equations and the equilibrium expression (prior to the cancellation of identical terms) would be

$$
2 \mathrm{NO}_{2}(g)+2 \mathrm{H}_{2}(g)+\mathrm{O}_{2}(g) \rightleftarrows 2 \mathrm{NO}(g)+\mathrm{O}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(g)
$$

and

$$
K_{\mathrm{c}}=\frac{[\mathrm{NO}]^{2}\left[\mathrm{O}_{2}\right]\left[\mathrm{H}_{2} \mathrm{O}\right]^{2}}{\left[\mathrm{NO}_{2}\right]^{2}\left[\mathrm{H}_{2}\right]^{2}\left[\mathrm{O}_{2}\right]}
$$

It may be easier to see before canceling identical terms that for the sum of two equations, the equilibrium expression is the product of the two corresponding equilibrium expressions.

$$
\frac{\left[\mathrm{NO}^{2}{ }^{2}\left[\mathrm{O}_{2}\right]\left[\mathrm{H}_{2} \mathrm{O}\right]^{2}\right.}{\left[\mathrm{NO}_{2}\right]^{2}\left[\mathrm{H}_{2}\right]^{2}\left[\mathrm{O}_{2}\right]}=\frac{\left[\mathrm{NO}^{2}\right]^{2}\left[\mathrm{O}_{2}\right]}{\left[\mathrm{NO}_{2}\right]^{2}} \times \frac{\left[\mathrm{H}_{2} \mathrm{O}\right]^{2}}{\left[\mathrm{H}_{2}\right]^{2}\left[\mathrm{O}_{2}\right]}
$$

Canceling identical terms on the left and right sides of the equation, and on the top and bottom of the equilibrium expression, gives

$$
2 \mathrm{NO}_{2}(g)+2 \mathrm{H}_{2}(g) \rightleftarrows 2 \mathrm{NO}(g)+2 \mathrm{H}_{2} \mathrm{O}(g) \quad \text { and } \quad K_{\mathrm{c}}=\frac{\left[\mathrm{NO}^{2}\left[\mathrm{H}_{2} \mathrm{O}\right]^{2}\right.}{\left[\mathrm{NO}_{2}\right]^{2}\left[\mathrm{H}_{2}\right]^{2}}
$$

And, because the new equilibrium expression is the product of the individual expressions, the new equilibrium constant is the product of the individual constants. Therefore, for the reaction

$$
2 \mathrm{NO}_{2}(g)+2 \mathrm{H}_{2}(g) \rightleftarrows 2 \mathrm{NO}(g)+2 \mathrm{H}_{2} \mathrm{O}(g)
$$

at $500 \mathrm{~K}, K_{\mathrm{c}}=\left(1.6 \times 10^{-6}\right)\left(2.4 \times 10^{47}\right)=3.8 \times 10^{41}$.
Using hypothetical equilibria, Table 15.2 summarizes the various ways that chemical equations can be manipulated and the corresponding changes that must be made to the equilibrium expression and equilibrium constant.

Sample Problem 15.4 shows how to manipulate chemical equations and make the corresponding changes to their equilibrium constants.

## TABLE 15.2 Manipulation of Equilibrium Constant Expressions

$$
\begin{array}{rll}
\mathrm{A}(g)+\mathrm{B}(g) & \rightleftarrows \mathrm{C}(g) & K_{\mathrm{c}_{1}}=4.39 \times 10^{-3} \\
2 \mathrm{C}(g) & \rightleftarrows \mathrm{D}(g)+\mathrm{E}(g) & K_{\mathrm{c}_{2}}=1.15 \times 10^{4}
\end{array}
$$

## Equation

$$
2 \mathrm{C}(g) \rightleftarrows \mathrm{A}(g)+\mathrm{B}(g)
$$

Original equation is reversed.
$2 \mathrm{~A}(g)+2 \mathrm{~B}(g) \rightleftarrows 4 \mathrm{C}(g)$
Original equation is multiplied by a number.
$\frac{1}{2} \mathrm{~A}(g)+\frac{1}{2} \mathrm{~B}(g) \rightleftarrows \mathrm{C}(g)$
Original equation is divided by 2 .
$\mathrm{A}(g)+\mathrm{B}(g) \rightleftarrows \mathrm{D}(g)+\mathrm{E}(g)$
Two equations are added.

## Equilibrium Expression

$K_{\mathrm{c}_{1}}^{\prime}=\frac{[\mathrm{A}][\mathrm{B}]}{[\mathrm{C}]^{2}}$
$K_{\mathrm{c}_{1}}^{\prime \prime}=\frac{[\mathrm{C}]^{4}}{[\mathrm{~A}]^{2}[\mathrm{~B}]^{2}}$
$K_{\mathrm{c}_{1}}^{\prime \prime \prime}=\frac{[\mathrm{C}]}{[\mathrm{A}]^{1 / 2}[\mathrm{~B}]^{1 / 2}}$
$K_{\mathrm{c}_{3}}=\frac{[\mathrm{D}][\mathrm{E}]}{[\mathrm{A}][\mathrm{B}]}$

Relationship to

## Original $K_{c}$

$\frac{1}{K_{\mathrm{c}_{1}}}$
$\left(K_{\mathrm{c}_{1}}\right)^{2}$
$\sqrt{K_{\mathrm{c}_{1}}}$
$K_{\mathrm{c}_{1}} \times K_{\mathrm{c}_{2}}$

Equilibrium Constant
$2.28 \times 10^{2}$
New constant is the reciprocal of the original.
$1.93 \times 10^{-5}$
New constant is the original raised to the same number.
$6.63 \times 10^{-2}$
New constant is the square root of the original.

New constant is the product of the two original constants.
*Temperature is the same for both reactions.

Think About It The magnitude of an equilibrium constant reveals whether products or reactants are favored, so the reciprocal relationship between $K_{\mathrm{c}}$ values of forward and reverse reactions should make sense. A very large $K_{\mathrm{c}}$ value means that products are favored. In the reaction of hydrogen ion and hydroxide ion to form water, the value of $K_{\mathrm{c}}$ is very large, indicating that the product, water, is favored.

$$
\begin{array}{r}
\mathrm{H}^{+}(a q)+\mathrm{OH}^{-}(a q) \rightleftarrows \mathrm{H}_{2} \mathrm{O}(l) \\
K_{\mathrm{c}}=1.0 \times 10^{14}\left(\text { at } 25^{\circ} \mathrm{C}\right)
\end{array}
$$

Simply writing the equation backward doesn't change the fact that water is the predominate species. In the reverse reaction, therefore, the favored species is on the reactant side:

$$
\begin{aligned}
& \mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{H}^{+}(a q)+\mathrm{OH}^{-}(a q) \\
& K_{\mathrm{c}}=1.0 \times 10^{-14}\left(\text { at } 25^{\circ} \mathrm{C}\right)
\end{aligned}
$$

As a result, the magnitude of $K_{\mathrm{c}}$ should correspond to reactants being favored; that is, it should be very small.

## Sample Problem 15.4

The following reactions have the indicated equilibrium constants at $100^{\circ} \mathrm{C}$ :

$$
\begin{aligned}
& \text { (1) } 2 \mathrm{NOBr}(g) \rightleftarrows 2 \mathrm{NO}(g)+\mathrm{Br}_{2}(g) \quad K_{\mathrm{c}}=0.014 \\
& \text { (2) } \quad \mathrm{Br}_{2}(g)+\mathrm{Cl}_{2}(g) \rightleftarrows 2 \mathrm{BrCl}(g) \quad K_{\mathrm{c}}=7.2
\end{aligned}
$$

Determine the value of $K_{\mathrm{c}}$ for the following reactions at $100^{\circ} \mathrm{C}$ :
(a) $2 \mathrm{NO}(g)+\mathrm{Br}_{2}(g) \rightleftarrows 2 \mathrm{NOBr}(g)$
(d) $2 \mathrm{NOBr}(g)+\mathrm{Cl}_{2}(g) \rightleftarrows 2 \mathrm{NO}(g)+2 \mathrm{BrCl}(g)$
(b) $4 \mathrm{NOBr}(g) \rightleftarrows 4 \mathrm{NO}(g)+2 \mathrm{Br}_{2}(g)$
(e) $\mathrm{NO}(g)+\mathrm{BrCl}(g) \rightleftarrows \mathrm{NOBr}(g)+\frac{1}{2} \mathrm{Cl}_{2}(g)$
(c) $\mathrm{NOBr}(g) \rightleftarrows \mathrm{NO}(g)+\frac{1}{2} \mathrm{Br}_{2}(g)$

Strategy Begin by writing the equilibrium expressions for the reactions that are given. Then, determine the relationship of each equation's equilibrium expression to the equilibrium expression of the original equations, and make the corresponding change to the equilibrium constant for each.

Setup The equilibrium expressions for the reactions that are given are

$$
K_{\mathrm{c}}=\frac{[\mathrm{NO}]^{2}\left[\mathrm{Br}_{2}\right]}{[\mathrm{NOBr}]^{2}} \quad \text { and } \quad K_{\mathrm{c}}=\frac{[\mathrm{BrCl}]^{2}}{\left[\mathrm{Br}_{2}\right]\left[\mathrm{Cl}_{2}\right]}
$$

(a) This equation is the reverse of original equation 1. Its equilibrium expression is the reciprocal of that for the original equation:

$$
2 \mathrm{NO}(g)+\mathrm{Br}_{2}(g) \rightleftarrows 2 \mathrm{NOBr}(g) \quad K_{\mathrm{c}}=\frac{[\mathrm{NOBr}]^{2}}{[\mathrm{NO}]^{2}\left[\mathrm{Br}_{2}\right]}
$$

(b) This is original equation 1 multiplied by a factor of 2 . Its equilibrium expression is the original expression squared:

$$
4 \mathrm{NOBr}(g) \rightleftarrows 4 \mathrm{NO}(g)+2 \mathrm{Br}_{2}(g) \quad K_{\mathrm{c}}=\left(\frac{[\mathrm{NO}]^{2}\left[\mathrm{Br}_{2}\right]}{[\mathrm{NOBr}]^{2}}\right)^{2}
$$

(c) This is original equation 1 multiplied by $\frac{1}{2}$. Its equilibrium expression is the square root of the original:

$$
\mathrm{NOBr}(g) \rightleftarrows \mathrm{NO}(g)+\frac{1}{2} \mathrm{Br}_{2}(g) \quad K_{\mathrm{c}}=\sqrt{\frac{\left[\mathrm{NO}^{2}\left[\mathrm{Br}_{2}\right]\right.}{[\mathrm{NOBr}]^{2}}} \quad \text { or } \quad K_{\mathrm{c}}=\left(\frac{[\mathrm{NO}]^{2}\left[\mathrm{Br}_{2}\right]}{[\mathrm{NOBr}]^{2}}\right)^{1 / 2}
$$

(d) This is the sum of original equations 1 and 2. Its equilibrium expression is the product of the two individual expressions:

$$
2 \mathrm{NOBr}(g)+\mathrm{Cl}_{2}(g) \rightleftarrows 2 \mathrm{NO}(g)+2 \mathrm{BrCl}(g) \quad K_{\mathrm{c}}=\frac{[\mathrm{NO}]^{2}[\mathrm{BrCl}]^{2}}{[\mathrm{NOBr}]^{2}\left[\mathrm{Cl}_{2}\right]}
$$

(e) Probably the simplest way to analyze this reaction is to recognize that it is the reverse of the reaction in part (d), multiplied by $\frac{1}{2}$. Its equilibrium expression is the square root of the reciprocal of the expression in part (d):

$$
\begin{gathered}
\mathrm{NO}(g)+\mathrm{BrCl}(g) \rightleftarrows \mathrm{NOBr}(g)+\frac{1}{2} \mathrm{Cl}_{2}(g) \\
K_{\mathrm{c}}=\sqrt{\frac{[\mathrm{NOBr}]^{2}\left[\mathrm{Cl}_{2}\right]}{[\mathrm{NO}]^{2}[\mathrm{BrCl}]^{2}}} \quad \text { or } \quad K_{\mathrm{c}}=\left(\frac{[\mathrm{NOBr}]^{2}\left[\mathrm{Cl}_{2}\right]}{[\mathrm{NO}]^{2}[\mathrm{BrCl}]^{2}}\right)^{1 / 2}
\end{gathered}
$$

Each equilibrium constant will bear the same relationship to the original as the equilibrium expression bears to the original.

## Solution

(a) $K_{\mathrm{c}}=1 / 0.014=71$
(c) $K_{\mathrm{c}}=(0.014)^{1 / 2}=0.12$
(e) $K_{\mathrm{c}}=(1 / 0.10)^{1 / 2}=3.2$
(b) $K_{\mathrm{c}}=(0.014)^{2}=2.0 \times 10^{-4}$
(d) $K_{\mathrm{c}}=(0.014)(7.2)=0.10$

Practice Problem A The following reactions have the indicated equilibrium constants at a particular temperature:

$$
\begin{aligned}
\mathrm{N}_{2}(g)+\mathrm{O}_{2}(g) \rightleftarrows 2 \mathrm{NO}(g) & K_{\mathrm{c}}=4.3 \times 10^{-25} \\
2 \mathrm{NO}(g)+\mathrm{O}_{2}(g) \rightleftarrows 2 \mathrm{NO}_{2}(g) & K_{\mathrm{c}}=6.4 \times 10^{9}
\end{aligned}
$$

Determine the values of the equilibrium constants for the following equations at the same temperature: $\left(\right.$ a) $2 \mathrm{NO}(g) \rightleftarrows \mathrm{N}_{2}(g)+\mathrm{O}_{2}(g)$, (b) $\frac{1}{2} \mathrm{~N}_{2}(g)+\frac{1}{2} \mathrm{O}_{2}(g) \rightleftarrows \mathrm{NO}(g)$, and (c) $\mathrm{N}_{2}(g)+2 \mathrm{O}_{2}(g) \rightleftarrows 2 \mathrm{NO}_{2}(g)$.

HPractice Problem B Using the data from Practice Problem A, determine the values of the equilibrium constants for the following equations: (a) $4 \mathrm{NO}(g) \rightleftarrows \mathrm{N}_{2}(g)+2 \mathrm{NO}_{2}(g)$, (b) $4 \mathrm{NO}_{2}(g) \rightleftarrows 2 \mathrm{~N}_{2}(g)+4 \mathrm{O}_{2}(g)$, and (c) $2 \mathrm{NO}(g)+2 \mathrm{NO}_{2}(g) \rightleftarrows 3 \mathrm{O}_{2}(g)+2 \mathrm{~N}_{2}(g)$.

## FAQ You May Be Wondering...

## What if the Equilibrium Expression Contains Only Gases?

When an equilibrium expression contains only gases, we can write an alternate form of the expression in which the concentrations of gases are expressed as partial pressures (atm). Thus, for the equilibrium

$$
\mathrm{N}_{2} \mathrm{O}_{4}(\mathrm{~g}) \rightleftarrows 2 \mathrm{NO}_{2}(\mathrm{~g})
$$

we can either write the equilibrium expression as

$$
K_{\mathrm{c}}=\frac{\left[\mathrm{NO}_{2}\right]^{2}}{\left[\mathrm{~N}_{2} \mathrm{O}_{4}\right]}
$$

or as

$$
K_{P}=\frac{\left(P_{\mathrm{NO}_{2}}\right)^{2}}{P_{\mathrm{N}_{2} \mathrm{O}_{4}}}
$$

where the subscript " $P$ " in $K_{P}$ stands for pressure, and $P_{\mathrm{NO}_{2}}$ and $P_{\mathrm{N}_{2} \mathrm{O}_{4}}$ are the equilibrium partial pressures of $\mathrm{NO}_{2}$ and $\mathrm{N}_{2} \mathrm{O}_{4}$, respectively. In general, $K_{\mathrm{c}}$ is not equal to $K_{P}$ because the partial pressures of reactants and products expressed in atmospheres are not equal to their concentrations expressed in $\mathrm{mol} / \mathrm{L}$. However, a simple relationship between $K_{P}$ and $K_{\mathrm{c}}$ can be derived using the following equilibrium:

$$
a \mathrm{~A}(g) \rightleftharpoons b \mathrm{~B}(g)
$$

where $a$ and $b$ are the stoichiometric coefficients. The equilibrium constant $K_{\mathrm{c}}$ is given by

$$
K_{\mathrm{c}}=\frac{[\mathrm{B}]^{b}}{[\mathrm{~A}]^{a}}
$$

and the expression for $K_{P}$ is

$$
K_{P}=\frac{\left(P_{\mathrm{B}}\right)^{b}}{\left(P_{\mathrm{A}}\right)^{a}}
$$

where $P_{\mathrm{A}}$ and $P_{\mathrm{B}}$ are the partial pressures of A and B . Assuming ideal gas behavior,

$$
\begin{aligned}
P_{\mathrm{A}} V & =n_{\mathrm{A}} R T \\
P_{\mathrm{A}} & =\frac{n_{\mathrm{A}} R T}{V}=\left(\frac{n_{\mathrm{A}}}{V}\right) R T
\end{aligned}
$$

and

$$
P_{\mathrm{A}}=[\mathrm{A}] R T
$$

where $[\mathrm{A}]$ is the molar concentration of A . Likewise,

$$
\begin{aligned}
P_{\mathrm{B}} V & =n_{\mathrm{B}} R T \\
P_{\mathrm{B}} & =\frac{n_{\mathrm{B}} R T}{V}=\left(\frac{n_{\mathrm{B}}}{V}\right) R T
\end{aligned}
$$

and

$$
P_{\mathrm{B}}=[\mathrm{B}] R T
$$

Substituting the expressions for $P_{\mathrm{A}}$ and $P_{\mathrm{B}}$ into the expression for $K_{P}$ gives

$$
\begin{aligned}
K_{P} & =\frac{\left(P_{\mathrm{B}}\right)^{b}}{\left(P_{\mathrm{A}}\right)^{a}} \\
& =\frac{[\mathrm{B}]^{b}}{[\mathrm{~A}]^{a}}(R T)^{b-a}
\end{aligned}
$$

Think About It It isn't necessary for every species in the reaction to be a gas-only those species that appear in the equilibrium expression.
which simplifies to

$$
K_{P}=K_{\mathrm{c}}(R T)^{\Delta n}
$$

where $\Delta n=b-a$. In general,
Equation 15.3 $\Delta n=$ moles of gaseous products - moles of gaseous reactants
Because pressures are usually expressed in atmospheres, the gas constant $R$ is expressed as $0.08206 \mathrm{~L} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{mol}$, and we can write the relationship between $K_{P}$ and $K_{\mathrm{c}}$ as

$$
\text { Equation } 15.4 \quad K_{P}=K_{\mathrm{c}}[(0.08206 \mathrm{~L} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{~mol}) \times T]^{\Delta n}
$$

$K_{P}$ is equal to $K_{\mathrm{c}}$ only in the special case where $\Delta n=0$, as in the following equilibrium reaction:

$$
\mathrm{H}_{2}(g)+\mathrm{Br}_{2}(g) \rightleftarrows 2 \mathrm{HBr}(g)
$$

In this case, Equation 15.4 can be written as

$$
\begin{aligned}
K_{P} & =K_{\mathrm{c}}[(0.08206 \mathrm{~L} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{~mol}) \times T]^{0} \\
& =K_{\mathrm{c}}
\end{aligned}
$$

Keep in mind that $K_{P}$ expressions can only be written for reactions in which every species in the equilibrium expression is a gas. (Remember that solids and pure liquids do not appear in the equilibrium expression.)

Sample Problems 15.5 and 15.6 let you practice writing $K_{P}$ expressions and illustrate the conversion between $K_{\mathrm{c}}$ and $K_{P}$.

## Sample Problem 15.5

Write $K_{P}$ expressions for (a) $\mathrm{PCl}_{3}(g)+\mathrm{Cl}_{2}(g) \rightleftarrows \mathrm{PCl}_{5}(g)$, (b) $\mathrm{O}_{2}(g)+2 \mathrm{H}_{2}(g) \rightleftarrows 2 \mathrm{H}_{2} \mathrm{O}(l)$, and $(c) \mathrm{F}_{2}(g)+\mathrm{H}_{2}(g) \rightleftarrows 2 \mathrm{HF}(g)$.

Strategy Write equilibrium expressions for each equation, expressing the concentrations of the gases in partial pressures.

Setup (a) All the species in this equation are gases, so they will all appear in the $K_{P}$ expression.
(b) Only the reactants are gases.
(c) All species are gases.
Solution (a) $K_{P}=\frac{\left(P_{\mathrm{PCl}_{5}}\right)}{\left(P_{\mathrm{PCl}_{3}}\right)\left(P_{\mathrm{Cl}_{2}}\right)}$
(b) $K_{P}=\frac{1}{\left(P_{\mathrm{O}_{2}}\right)\left(P_{\mathrm{H}_{2}}\right)^{2}}$
(c) $K_{P}=\frac{\left(P_{\mathrm{HF}}\right)^{2}}{\left(P_{\mathrm{F}_{2}}\right)\left(P_{\mathrm{H}_{2}}\right)}$

## Checkpoint 15.3 Equilibrium Expressions

15.3.1 Select the correct equilibrium expression for the reaction

$$
\mathrm{H}^{+}(a q)+\mathrm{OH}^{-}(a q) \rightleftarrows \mathrm{H}_{2} \mathrm{O}(l)
$$

a) $K_{\mathrm{c}}=\frac{\left[\mathrm{H}_{2} \mathrm{O}\right]}{\left[\mathrm{H}^{+}\right]\left[\mathrm{OH}^{-}\right]}$
b) $K_{\mathrm{c}}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{OH}^{-}\right]}{\left[\mathrm{H}_{2} \mathrm{O}\right]}$
c) $K_{\mathrm{c}}=\left[\mathrm{H}^{+}\right]\left[\mathrm{OH}^{-}\right]$
d) $K_{\mathrm{c}}=\frac{1}{\left[\mathrm{H}^{+}\right]\left[\mathrm{OH}^{-}\right]}$
e) $K_{\mathrm{c}}=\left[\mathrm{H}^{+}\right]\left[\mathrm{OH}^{-}\right]\left[\mathrm{H}_{2} \mathrm{O}\right]$
15.3.2 Select the correct equilibrium expression for the reaction

$$
\mathrm{CaO}(s)+\mathrm{CO}_{2}(g) \rightleftarrows \mathrm{CaCO}_{3}(s)
$$

a) $K_{\mathrm{c}}=\frac{1}{\left[\mathrm{CO}_{2}\right]}$
b) $K_{\mathrm{c}}=\frac{\left[\mathrm{CaCO}_{3}\right]}{[\mathrm{CaO}]\left[\mathrm{CO}_{2}\right]}$
c) $K_{\mathrm{c}}=\left[\mathrm{CO}_{2}\right]$
d) $K_{\mathrm{c}}=\frac{[\mathrm{CaO}]\left[\mathrm{CO}_{2}\right]}{\left[\mathrm{CaCO}_{3}\right]}$
e) $K_{\mathrm{c}}=\frac{\left[\mathrm{CO}_{2}\right]}{[\mathrm{CaO}]\left[\mathrm{CaCO}_{3}\right]}$

Practice Problem A Write $K_{P}$ expressions for (a) $2 \mathrm{CO}(g)+\mathrm{O}_{2}(g) \rightleftarrows 2 \mathrm{CO}_{2}(g)$,
(b) $\mathrm{CaCO}_{3}(s) \rightleftarrows \mathrm{CaO}(s)+\mathrm{CO}_{2}(g)$, and (c) $\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \rightleftarrows 2 \mathrm{NH}_{3}(g)$.

EPractice Problem B Write the equation for the gaseous equilibrium corresponding to each of the following $K_{P}$ expressions:
(a) $K_{P}=\frac{\left(P_{\mathrm{NO}_{3}}\right)^{2}}{\left(P_{\mathrm{NO}_{2}}\right)^{2}\left(P_{\mathrm{O}_{2}}\right)}$
(b) $K_{P}=\frac{\left(P_{\mathrm{CO}_{2}}\right)\left(P_{\mathrm{H}_{2}}\right)^{4}}{\left(P_{\mathrm{CH}_{4}}\right)\left(P_{\mathrm{H}_{2} \mathrm{O}}\right)^{2}}$
(c) $K_{P}=\frac{\left(P_{\mathrm{HI}}\right)^{2}}{\left(P_{\mathrm{I}_{2}}\right)\left(P_{\mathrm{H}_{2}}\right)}$

## Sample Problem 15.6

The equilibrium constant, $K_{\mathrm{c}}$, for the reaction

$$
\mathrm{N}_{2} \mathrm{O}_{4}(g) \rightleftarrows 2 \mathrm{NO}_{2}(g)
$$

is $4.63 \times 10^{-3}$ at $25^{\circ} \mathrm{C}$. What is the value of $K_{P}$ at this temperature?
Strategy Use Equation 15.4 to convert from $K_{\mathrm{c}}$ to $K_{P}$. Be sure to convert temperature in degrees Celsius to kelvins.

Setup Using Equation 15.3,

$$
\Delta n=2\left(\mathrm{NO}_{2}\right)-1\left(\mathrm{~N}_{2} \mathrm{O}_{4}\right)=1
$$

$T=298 \mathrm{~K}$.

Solution $K_{P}=\left[K_{\mathrm{c}}\left(\frac{0.08206 \mathrm{~L} \cdot \mathrm{~atm}}{\mathrm{~K} \cdot \mathrm{~mol}}\right) \times T\right]$

$$
\begin{aligned}
& =\left(4.63 \times 10^{-3}\right)(0.08206 \times 298) \\
& =0.113
\end{aligned}
$$

Think About It Note that we have essentially disregarded the units of $R$ and $T$ so that the resulting equilibrium constant, $K_{P}$, is unitless. Equilibrium constants commonly are treated as unitless quantities.

Practice Problem A For the reaction

$$
\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \rightleftarrows 2 \mathrm{NH}_{3}(g)
$$

$K_{\mathrm{c}}$ is $2.3 \times 10^{-2}$ at $375^{\circ} \mathrm{C}$. Calculate $K_{P}$ for the reaction at this temperature.
$\leftrightarrows$ Practice Problem B $K_{P}=2.79 \times 10^{-5}$ for the reaction in Practice Problem A at $472^{\circ} \mathrm{C}$. What is $K_{\mathrm{c}}$ for this reaction at $472^{\circ} \mathrm{C}$ ?
15.3.3 Given the following information,

$$
\begin{aligned}
& \mathrm{HF}(a q) \rightleftarrows \mathrm{H}^{+}(a q)+\mathrm{F}^{-}(a q) \\
& \quad K_{\mathrm{c}}=6.8 \times 10^{-4}\left(\text { at } 25^{\circ} \mathrm{C}\right) \\
& \mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}(a q) \rightleftarrows 2 \mathrm{H}^{+}(a q)+\mathrm{C}_{2} \mathrm{O}_{4}^{2-}(a q) \\
& \\
& \\
& \\
& K_{\mathrm{c}}=3.8 \times 10^{-6}\left(\text { at } 25^{\circ} \mathrm{C}\right)
\end{aligned}
$$

determine the value of $K_{\mathrm{c}}$ for the following reaction at $25^{\circ} \mathrm{C}$ :

$$
\mathrm{C}_{2} \mathrm{O}_{4}^{2-}+2 \mathrm{HF} \rightleftarrows 2 \mathrm{~F}^{-}+\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}
$$

a) $2.6 \times 10^{-9}$
b) $1.8 \times 10^{-12}$
c) $1.2 \times 10^{-1}$
d) $2.6 \times 10^{5}$
e) $6.8 \times 10^{-4}$
15.3.4 $K_{\mathrm{c}}$ for the reaction

$$
\operatorname{Br}_{2}(g) \rightleftarrows 2 \operatorname{Br}(g)
$$

is $1.1 \times 10^{-3}$ at $1280^{\circ} \mathrm{C}$. Calculate the value of $K_{P}$ for this reaction at this temperature.
a) $1.1 \times 10^{-3}$
b) 18
c) 0.14
d) $9.1 \times 10^{2}$
e) $8.3 \times 10^{-6}$

Student Annotation: $Q_{c}$ is calculated using the initial concentrations of reactants and products. Similarly, $Q_{p}$ can be calculated using the initial partial pressures of reactants and products.

Student Annotation: Remember that calculating $Q_{c}$ is just like calculating $K_{c}$ : products over reactants, each raised to the appropriate power-except that the concentrations we use to calculate $Q_{c}$ are the starting concentrations. To calculate $K_{c}$ we must use equilibrium concentrations.

Student Annotation: The comparison of $Q$ with $K$ can refer either to $Q_{c}$ and $K_{c}$ or $Q_{P}$ and $K_{p}$.

### 15.4 Using Equilibrium Expressions to Solve Problems

We have already used equilibrium expressions to determine the value of an equilibrium constant using equilibrium concentrations. In this section, we will learn how to use equilibrium expressions to predict the direction of a reaction and to calculate equilibrium concentrations.

## Predicting the Direction of a Reaction

If we start an experiment with only reactants, we know that the reactant concentrations will decrease and the product concentrations will increase; that is, the reaction must proceed in the forward direction for equilibrium to be established. Likewise, if we start an experiment with only products, we know that the product concentrations will decrease and the reactant concentrations will increase. In this case, the reaction must proceed in the reverse direction to achieve equilibrium. But often we must predict the direction in which a reaction will proceed when we start with a mixture of reactants and products. For this situation, we calculate the value of the reaction quotient, $Q_{\mathrm{c}}$, and compare it to the value of the equilibrium constant, $K_{\mathrm{c}}$.

The equilibrium constant, $K_{\mathrm{c}}$, for the gaseous formation of hydrogen iodide from molecular hydrogen and molecular iodine,

$$
\mathrm{H}_{2}(g)+\mathrm{I}_{2}(g) \rightleftarrows 2 \mathrm{HI}(g)
$$

is 54.3 at $430^{\circ} \mathrm{C}$. If we were to conduct an experiment starting with a mixture of 0.243 mole of $\mathrm{H}_{2}, 0.146$ mole of $\mathrm{I}_{2}$, and 1.98 moles of HI in a $1.00-\mathrm{L}$ container at $430^{\circ} \mathrm{C}$, would more HI form or would HI be consumed and more $\mathrm{H}_{2}$ and $\mathrm{I}_{2}$ form? Using the starting concentrations, we can calculate the reaction quotient as follows:

$$
Q_{\mathrm{c}}=\frac{[\mathrm{HI}]_{\mathrm{i}}^{2}}{\left.\left[\mathrm{H}_{2}\right]_{\mathrm{i}} \mathrm{I}_{2}\right]_{\mathrm{i}}}=\frac{(1.98)^{2}}{(0.243)(0.146)}=111
$$

where the subscript "i" indicates initial concentration. Because the reaction quotient does not equal $K_{\mathrm{c}}\left(Q_{\mathrm{c}}=111, K_{\mathrm{c}}=54.3\right)$, the reaction is not at equilibrium. To establish equilibrium, the reaction will proceed to the left, consuming HI and producing $\mathrm{H}_{2}$ and $\mathrm{I}_{2}$, decreasing the value of the numerator and increasing the value in the denominator until the value of the reaction quotient equals that of the equilibrium constant. Thus, the reaction proceeds in the reverse direction (from right to left) to reach equilibrium.

There are three possibilities when we compare $Q$ with $K$ :

$$
\begin{array}{ll}
Q<K & \begin{array}{l}
\text { The ratio of initial concentrations of products to reactants is too small. To reach } \\
\text { equilibrium, reactants must be converted to products. The system proceeds in } \\
\text { the forward direction (from left to right). }
\end{array} \\
Q=K & \begin{array}{l}
\text { The initial concentrations are equilibrium concentrations. The system is already } \\
\text { at equilibrium, and there will be no net reaction in either direction. }
\end{array} \\
Q>K & \begin{array}{l}
\text { The ratio of initial concentrations of products to reactants is too large. To reach } \\
\text { equilibrium, products must be converted to reactants. The system proceeds in } \\
\text { the reverse direction (from right to left). }
\end{array}
\end{array}
$$

Sample Problem 15.7 shows how the value of $Q$ is used to determine the direction of a reaction that is not at equilibrium.

## Sample Problem 15.7

At $375^{\circ} \mathrm{C}$, the equilibrium constant for the reaction

$$
\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \rightleftarrows 2 \mathrm{NH}_{3}(g)
$$

is 1.2. At the start of a reaction, the concentrations of $\mathrm{N}_{2}, \mathrm{H}_{2}$, and $\mathrm{NH}_{3}$ are $0.071 \mathrm{M}, 9.2 \times 10^{-3} \mathrm{M}$, and $1.83 \times 10^{-4} \mathrm{M}$, respectively. Determine whether this system is at equilibrium, and if not, determine in which direction it must proceed to establish equilibrium.

Strategy Use the initial concentrations to calculate $Q_{\mathrm{c}}$, and then compare $Q_{\mathrm{c}}$ with $K_{\mathrm{c}}$.

Setup

$$
Q_{\mathrm{c}}=\frac{\left[\mathrm{NH}_{3}\right]_{\mathrm{i}}^{2}}{\left[\mathrm{~N}_{2}\right]_{\mathrm{i}}\left[\mathrm{H}_{2}\right]_{\mathrm{i}}^{3}}=\frac{\left(1.83 \times 10^{-4}\right)^{2}}{(0.071)\left(9.2 \times 10^{-3}\right)^{3}}=0.61
$$

Solution The calculated value of $Q_{\mathrm{c}}$ is less than $K_{\mathrm{c}}$. Therefore, the reaction is not at equilibrium and must proceed to the right to establish equilibrium.

Practice Problem A The equilibrium constant, $K_{\mathrm{c}}$, for the formation of nitrosyl chloride from nitric oxide and chlorine,

$$
2 \mathrm{NO}(g)+\mathrm{Cl}_{2}(g) \rightleftarrows 2 \mathrm{NOCl}(g)
$$

is $6.5 \times 10^{4}$ at $35^{\circ} \mathrm{C}$. In which direction will the reaction proceed to reach equilibrium if the starting concentrations of $\mathrm{NO}, \mathrm{Cl}_{2}$, and NOCl are $1.1 \times 10^{-3} M, 3.5 \times 10^{-4} M$, and 1.9 M , respectively?

EPractice Problem B Calculate $K_{P}$ for the formation of nitrosyl chloride from nitric oxide and chlorine at $35^{\circ} \mathrm{C}$, and determine whether the reaction will proceed to the right or the left to achieve equilibrium when the starting pressures are $P_{\mathrm{NO}}=1.01 \mathrm{~atm}, P_{\mathrm{Cl}_{2}}=0.42 \mathrm{~atm}$, and $P_{\mathrm{NOCl}}=1.76 \mathrm{~atm}$.

## Calculating Equilibrium Concentrations

If we know the equilibrium constant for a reaction, we can calculate the concentrations in the equilibrium mixture from the initial reactant concentrations. Consider the following system involving two organic compounds, cis- and trans-stilbene:

cis-Stilbene

trans-Stilbene

The equilibrium constant $\left(K_{\mathrm{c}}\right)$ for this system is 24.0 at $200^{\circ} \mathrm{C}$. If we know that the starting concentration of cis-stilbene is 0.850 M , we can use the equilibrium expression to determine the equilibrium concentrations of both species. The stoichiometry of the reaction tells us that for every mole of cis-stilbene converted, 1 mole of trans-stilbene is produced. We will let $x$ be the equilibrium concentration of trans-stilbene in $\mathrm{mol} / \mathrm{L}$; therefore, the equilibrium concentration of cis-stilbene must be $(0.850-x) \mathrm{mol} / \mathrm{L}$. It is useful to summarize these changes in concentrations in an equilibrium table:

$$
\text { cis-stilbene } \rightleftarrows \text { trans-stilbene }
$$

## Initial concentration ( $M$ ):

Change in concentration ( $M$ ):
Equilibrium concentration (M):

| 0.850 | 0 |
| :---: | :---: |
| $-x$ | $+x$ |
| $0.850-x$ | $x$ |

We then use the equilibrium concentrations, defined in terms of $x$, in the equilibrium expression:

$$
\begin{aligned}
K_{\mathrm{c}} & =\frac{[\text { trans }- \text { stilbene }]}{[\text { cis-stilbene }]} \\
24.0 & =\frac{x}{0.850-x} \\
x & =0.816 \mathrm{M}
\end{aligned}
$$

Think About It In proceeding to the right, a reaction consumes reactants and produces more products. This increases the numerator in the reaction quotient and decreases the denominator. The result is an increase in $Q_{\mathrm{c}}$ until it is equal to $K_{\mathrm{c}}$, at which point equilibrium will be established.

Having solved for $x$, we calculate the equilibrium concentrations of cis- and trans-stilbene as follows:

$$
\begin{aligned}
{[\text { cis-stilbene }] } & =(0.850-x) M=0.034 M \\
{[\text { trans-stilbene }] } & =x M=0.816 M
\end{aligned}
$$

A good way to check the answer to a problem such as this is to use the calculated equilibrium concentrations in the equilibrium expression and make sure that we get the correct $K_{\mathrm{c}}$ value.

$$
K_{\mathrm{c}}=\frac{0.816}{0.034}=24
$$

Sample Problems 15.8 and 15.9 provide additional examples of this kind of problem.

## Sample Problem 15.8

$K_{\mathrm{c}}$ for the reaction of hydrogen and iodine to produce hydrogen iodide,

$$
\mathrm{H}_{2}(g)+\mathrm{I}_{2}(g) \rightleftarrows 2 \mathrm{HI}(g)
$$

is 54.3 at $430^{\circ} \mathrm{C}$. What will the concentrations be at equilibrium if we start with 0.240 M concentrations of both $\mathrm{H}_{2}$ and $\mathrm{I}_{2}$ ?

Strategy Construct an equilibrium table to determine the equilibrium concentration of each species in terms of an unknown $(x)$; solve for $x$, and use it to calculate the equilibrium molar concentrations.

Setup Insert the starting concentrations that we know into the equilibrium table:

Initial concentration ( $M$ ):
Change in concentration ( $M$ ):
Equilibrium concentration ( $M$ ):

Solution We define the change in concentration of one of the reactants as $x$. Because there is no product at the start of the reaction, the reactant concentration must decrease; that is, this reaction must proceed in the forward direction to reach equilibrium. According to the stoichiometry of the chemical reaction, the reactant concentrations will both decrease by the same amount $(x)$, and the product concentration will increase by twice that amount $(2 x)$. Combining the initial concentration and the change in concentration for each species, we get expressions (in terms of $x$ ) for the equilibrium concentrations:

|  | $\mathrm{H}_{2}(g)$ |  | $\mathrm{I}_{2}(g)$ |
| :--- | :--- | :--- | ---: |
| Initial concentration $(M):$ | 0.240 | 0.240 | $2 \mathrm{HI}(g)$ |
| Change in concentration $(M):$ | $-x$ | $-x$ | 0 |
| Equilibrium concentration $(M):$ | $0.240-x$ | $0.240-x$ | $+2 x$ |

Next, we insert these expressions for the equilibrium concentrations into the equilibrium expression and solve for $x$.

$$
\begin{aligned}
K_{\mathrm{c}} & =\frac{[\mathrm{HI}]^{2}}{\left[\mathrm{H}_{2}\right]\left[\mathrm{I}_{2}\right]} \\
54.3 & =\frac{(2 x)^{2}}{(0.240-x)(0.240-x)}=\frac{(2 x)^{2}}{(0.240-x)^{2}} \\
\sqrt{54.3} & =\frac{2 x}{0.240-x} \\
x & =0.189
\end{aligned}
$$

Using the calculated value of $x$, we can determine the equilibrium concentration of each species as follows:

$$
\begin{aligned}
{\left[\mathrm{H}_{2}\right] } & =(0.240-x) M=0.051 \mathrm{M} \\
{\left[\mathrm{I}_{2}\right] } & =(0.240-x) M=0.051 \mathrm{M} \\
{[\mathrm{HI}] } & =2 x=0.378 \mathrm{M}
\end{aligned}
$$

Practice Problem A Calculate the equilibrium concentrations of $\mathrm{H}_{2}, \mathrm{I}_{2}$, and HI at $430^{\circ} \mathrm{C}$ if the initial concentrations are $\left[\mathrm{H}_{2}\right]=\left[\mathrm{I}_{2}\right]=0 \mathrm{M}$, and $[\mathrm{HI}]=0.525 \mathrm{M}$.

FPractice Problem B Determine the initial concentration of HI if the initial concentrations of $\mathrm{H}_{2}$ and $\mathrm{I}_{2}$ are both 0.10 M and their equilibrium concentrations are both 0.043 M at $430^{\circ} \mathrm{C}$.

## Sample Problem 15.9

For the same reaction and temperature as in Sample Problem 15.8, calculate the equilibrium concentrations of all three species if the starting concentrations are as follows: $\left[\mathrm{H}_{2}\right]=0.00623 \mathrm{M}$, $\left[\mathrm{I}_{2}\right]=0.00414 \mathrm{M}$, and $[\mathrm{HI}]=0.0424 \mathrm{M}$.

Strategy Using the initial concentrations, calculate the reaction quotient, $Q_{\mathrm{c}}$, and compare it to the value of $K_{\mathrm{c}}$ (given in the problem statement of Sample Problem 15.8) to determine which direction the reaction will proceed to establish equilibrium. Then, construct an equilibrium table to determine the equilibrium concentrations.

## Setup

$$
\frac{[\mathrm{HI}]^{2}}{\left[\mathrm{H}_{2}\right]\left[\mathrm{I}_{2}\right]}=\frac{(0.0424)^{2}}{(0.00623)(0.00414)}=69.7
$$

Therefore, $Q_{\mathrm{c}}>K_{\mathrm{c}}$, so the system will have to proceed to the left (reverse) to reach equilibrium. The equilibrium table is

Initial concentration ( $M$ ):
Change in concentration (M):
Equilibrium concentration ( $M$ ):

$$
\mathrm{H}_{2}(g)+\mathrm{I}_{2}(g) \rightleftarrows 2 \mathrm{HI}(g)
$$

Solution Because we know the reaction must proceed from right to left, we know that the concentration of HI will decrease and the concentrations of $\mathrm{H}_{2}$ and $\mathrm{I}_{2}$ will increase. Therefore, the table should be filled in as follows:

|  | $\mathrm{H}_{2}(g)$ |  | $\mathrm{I}_{2}(g)$ |
| :--- | :---: | :---: | :---: |
| Initial concentration $(M):$ | 0.00623 | 0.00414 | $2 \mathrm{HI}(g)$ |
| Change in concentration $(M):$ | $+x$ | $+x$ | 0.0424 |
| Equilibrium concentration $(M):$ | $0.00623+x$ | $0.00414+x$ | $-2 x$ |

Next, we insert these expressions for the equilibrium concentrations into the equilibrium expression and solve for $x$.

$$
\begin{gathered}
K_{\mathrm{c}}=\frac{[\mathrm{HI}]^{2}}{\left[\mathrm{H}_{2}\right]\left[\mathrm{I}_{2}\right]} \\
54.3=\frac{(0.0424-2 x)^{2}}{(0.00623+x)(0.00414+x)}
\end{gathered}
$$

It isn't possible to solve this equation the way we did in Sample Problem 15.8 (by taking the square root of both sides) because the concentrations of $\mathrm{H}_{2}$ and $\mathrm{I}_{2}$ are unequal. Instead, we have to carry out the multiplications,

$$
54.3\left(2.58 \times 10^{-5}+1.04 \times 10^{-2} x+x^{2}\right)=1.80 \times 10^{-3}-1.70 \times 10^{-1} x+4 x^{2}
$$

Collecting terms we get

$$
50.3 x^{2}+0.735 x-4.00 \times 10^{-4}=0
$$

This is a quadratic equation of the form $a x^{2}+b x+c=0$. The solution for the quadratic equation (see Appendix 1) is

$$
x=\frac{-b \pm \sqrt{b^{2}-4 a c}}{2 a}
$$

Think About It Checking this result gives

$$
\begin{aligned}
K_{\mathrm{c}} & =\frac{[\mathrm{HI}]^{2}}{\left[\mathrm{H}_{2}\right]\left[\mathrm{I}_{2}\right]} \\
& =\frac{(0.0414)^{2}}{(0.00676)(0.00467)}=54.3
\end{aligned}
$$

Student Annotation: If $Q<K$, the reaction will occur as written. If $Q>K$, the reverse reaction will occur.

Student Annotation: For this reaction,
$\Delta n=0$; therefore, $K_{c}$ is equal to $K_{p}$.

Here we have $a=50.3, b=0.735$, and $c=-4.00 \times 10^{-4}$, so

$$
\begin{gathered}
x=\frac{-0.735 \pm \sqrt{(0.735)^{2}-4(50.3)\left(-4.00 \times 10^{-4}\right)}}{2(50.3)} \\
x=5.25 \times 10^{-4} \quad \text { or } \quad x=-0.0151
\end{gathered}
$$

Only the first of these values, $5.25 \times 10^{-4}$, makes sense because concentration cannot be a negative number. Using the calculated value of $x$, we can determine the equilibrium concentration of each species as follows:

$$
\begin{aligned}
{\left[\mathrm{H}_{2}\right] } & =(0.00623+x) M=0.00676 M \\
{\left[\mathrm{I}_{2}\right] } & =(0.00414+x) M=0.00467 M \\
{[\mathrm{HI}] } & =(0.0424-2 x) M
\end{aligned}
$$

Practice Problem A At $1280^{\circ} \mathrm{C}$ the equilibrium constant $K_{\mathrm{c}}$ for the reaction

$$
\mathrm{Br}_{2}(g) \rightleftarrows 2 \mathrm{Br}(g)
$$

is $1.1 \times 10^{-3}$. If the initial concentrations are $\left[\mathrm{Br}_{2}\right]=6.3 \times 10^{-2} \mathrm{M}$ and $[\mathrm{Br}]=1.2 \times 10^{-2} \mathrm{M}$, calculate the concentrations of these two species at equilibrium.

Practice Problem B Determine the initial and equilibrium concentrations of Br if the initial and equilibrium concentrations of $\mathrm{Br}_{2}$ are $5.7 \times 10^{-3} M$ and $5.3 \times 10^{-3} M$, respectively.

Here is a summary of the use of initial reactant concentrations to determine equilibrium concentrations:

1. Construct an equilibrium table, and fill in the initial concentrations (including any that are zero).
2. Use initial concentrations to calculate the reaction quotient, $Q$, and compare $Q$ to $K$ to determine the direction in which the reaction will proceed.
3. Define $x$ as the amount of a particular species consumed, and use the stoichiometry of the reaction to define (in terms of $x$ ) the amount of other species consumed or produced.
4. For each species in the equilibrium, add the change in concentration to the initial concentration to get the equilibrium concentration.
5. Use the equilibrium concentrations and the equilibrium expression to solve for $x$.
6. Using the calculated value of $x$, determine the concentrations of all species at equilibrium.
7. Check your work by plugging the calculated equilibrium concentrations into the equilibrium expression. The result should be very close to the $K_{\mathrm{c}}$ stated in the problem.

The same procedure applies to $K_{P}$.
Sample Problem 15.10 shows how to solve an equilibrium problem using partial pressures.

## Sample Problem 15.10

A mixture of 5.75 atm of $\mathrm{H}_{2}$ and 5.75 atm of $\mathrm{I}_{2}$ is contained in a 1.0-L vessel at $430^{\circ} \mathrm{C}$. The equilibrium constant $\left(K_{P}\right)$ for the reaction

$$
\mathrm{H}_{2}(g)+\mathrm{I}_{2}(g) \rightleftarrows 2 \mathrm{HI}(g)
$$

at this temperature is 54.3. Determine the equilibrium partial pressures of $\mathrm{H}_{2}, \mathrm{I}_{2}$, and HI .
Strategy Construct an equilibrium table to determine the equilibrium partial pressures.
Setup The equilibrium table is

Initial partial pressure (atm):
Change in partial pressure (atm):
Equilibrium partial pressure (atm):

| $\mathrm{H}_{2}(g)+\mathrm{I}_{2}(g)$ | $2 \mathrm{HI}(g)$ |  |
| :---: | :---: | :---: |
| 5.75 | 5.75 | 0 |
| $-x$ | $-x$ | $+2 x$ |
| $5.75-x$ | $5.75-x$ | $2 x$ |

Solution Setting the equilibrium expression equal to $K_{P}$,

$$
54.3=\frac{(2 x)^{2}}{(5.75-x)^{2}}
$$

Taking the square root of both sides of the equation gives

$$
\begin{aligned}
\sqrt{54.3} & =\frac{2 x}{5.75-x} \\
7.369 & =\frac{2 x}{5.75-x} \\
7.369(5.75-x) & =2 x \\
42.37-7.369 x & =2 x \\
42.37 & =9.369 x \\
x & =4.52
\end{aligned}
$$

The equilibrium partial pressures are $P_{\mathrm{H}_{2}}=P_{\mathrm{I}_{2}}=5.75-4.52=1.23 \mathrm{~atm}$, and $P_{\mathrm{HI}}=9.04 \mathrm{~atm}$.

Practice Problem A Determine the equilibrium partial pressures of $\mathrm{H}_{2}, \mathrm{I}_{2}$, and HI if we begin the experiment with 1.75 atm each of $\mathrm{H}_{2}$ and $\mathrm{I}_{2}$ at $430^{\circ} \mathrm{C}$.

HPractice Problem B Determine the equilibrium partial pressures of $\mathrm{H}_{2}, \mathrm{I}_{2}$, and HI if we begin the experiment with 2.75 atm HI at $430^{\circ} \mathrm{C}$.

Think About It Plugging the calculated partial pressures into the equilibrium expression gives

$$
\frac{\left(P_{\mathrm{HI}}\right)^{2}}{\left(P_{\mathrm{H}_{2}}\right)\left(P_{\mathrm{I}_{2}}\right)}=\frac{(9.04)^{2}}{(1.23)^{2}}=54.0
$$

The small difference between this result and the equilibrium constant given in the problem statement is due to rounding.

Student Annotation: When a reaction starts with reactants and products, be sure to calculate $Q$ and compare it to $K$ to determine which direction the reaction will proceed to reach equilibrium.

## Checkpoint 15.4 Using Equilibrium Expressions to Solve Problems

Use the following information to answer questions 15.4.1 and 15.4.2: $K_{\mathrm{c}}$ for the reaction

$$
\mathrm{A}+\mathrm{B} \rightleftarrows 2 \mathrm{C}
$$

is $1.7 \times 10^{-2}$ at $250^{\circ} \mathrm{C}$.
15.4.1 What will the equilibrium concentrations of $A, B$, and $C$ be at this temperature if $[\mathrm{A}]_{\mathrm{i}}=[\mathrm{B}]_{\mathrm{i}}=0.750 M\left([\mathrm{C}]_{\mathrm{i}}=0\right)$ ?
a) $6.1 \times 10^{-3} \mathrm{M}, 6.1 \times 10^{-3} \mathrm{M}, 0.092 \mathrm{M}$
b) $0.046 M, 0.046 M, 0.092 M$
c) $0.70 \mathrm{M}, 0.70 \mathrm{M}, 0.046 \mathrm{M}$
d) $0.70 \mathrm{M}, 0.70 \mathrm{M}, 0.092 \mathrm{M}$
e) $0.087 \mathrm{M}, 0.087 \mathrm{M}, 0.66 \mathrm{M}$
15.4.2 What will the equilibrium concentrations of $A, B$, and $C$ be at this temperature if $[\mathrm{C}]_{\mathrm{i}}=0.875 M\left([\mathrm{~A}]_{\mathrm{i}}=[\mathrm{B}]_{\mathrm{i}}=0\right)$ ?
a) $0.41 \mathrm{M}, 0.41 \mathrm{M}, 0.82 \mathrm{M}$
b) $0.41 \mathrm{M}, 0.41 \mathrm{M}, 0.054 \mathrm{M}$
c) $0.43 \mathrm{M}, 0.43 \mathrm{M}, 0.0074 \mathrm{M}$
d) $0.43 \mathrm{M}, 0.43 \mathrm{M}, 0.44 \mathrm{M}$
e) $0.43 \mathrm{M}, 0.43 \mathrm{M}, 0.43 \mathrm{M}$
15.4.3 If $K_{\mathrm{c}}=2$ for the reaction $\mathrm{A}_{2}+\mathrm{B}_{2} \rightleftarrows 2 \mathrm{AB}$ at a certain temperature, which of the following diagrams represents an equilibrium mixture of $\mathrm{A}_{2}, \mathrm{~B}_{2}$, and AB ? (Select all that apply.)

15.4.4 If $K_{\mathrm{c}}=3$ for the reaction $\mathrm{X}+2 \mathrm{Y} \rightleftarrows \mathrm{Z}$ at a certain temperature, then for each of the mixtures of $\mathrm{X}, \mathrm{Y}$, and Z shown here, in what direction must the reaction proceed to achieve equilibrium?

a) Right, right
b) Neither, left
c) Neither, right
d) Left, neither
e) Right, neither

Student Annotation: Remember that at equilibrium, the reaction quotient, $Q_{c}$, is equal to the equilibrium constant, $K_{c}$.

Student Annotation: While reestablishing equilibrium causes a decrease in the $\mathrm{N}_{2}$ concentration, the final concentration will still be higher than that in the original equilibrium mixture. The system responds to the stress of the added reactant by consuming part of it.

### 15.5 Factors That Affect Chemical Equilibrium

One of the interesting and useful features of chemical equilibria is that they can be manipulated in specific ways to maximize production of a desired substance. Consider, for example, the industrial production of ammonia from its constituent elements by the Haber process:

$$
\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \rightleftarrows 2 \mathrm{NH}_{3}(g)
$$

More than 100 million tons of ammonia is produced annually by this reaction, with most of the resulting ammonia being used for fertilizers to enhance crop production. Clearly it would be in the best interest of industry to maximize the yield of $\mathrm{NH}_{3}$. In this section, we will learn about the various ways in which an equilibrium can be manipulated to accomplish this goal.

Le Châtelier's principle states that when a stress is applied to a system at equilibrium, the system will respond by shifting in the direction that minimizes the effect of the stress. In this context, "stress" refers to a disturbance of the system at equilibrium by any of the following means:

- The addition of a reactant or product
- The removal of a reactant or product
- A change in volume of the system, resulting in a change in concentration or partial pressure of the reactants and products
- A change in temperature
"Shifting" refers to the occurrence of either the forward or reverse reaction such that the effect of the stress is partially offset as the system reestablishes equilibrium. An equilibrium that shifts to the right is one in which more products are produced by the forward reaction. An equilibrium that shifts to the left is one in which more reactants are produced by the reverse reaction. Using Le Châtelier's principle, we can predict the direction in which an equilibrium will shift, given the specific stress that is applied.

## Addition or Removal of a Substance

Again using the Haber process as an example,

$$
\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \rightleftarrows 2 \mathrm{NH}_{3}(g)
$$

consider a system at 700 K , in which the equilibrium concentrations are as follows:

$$
\left[\mathrm{N}_{2}\right]=2.05 \mathrm{M} \quad\left[\mathrm{H}_{2}\right]=1.56 \mathrm{M} \quad\left[\mathrm{NH}_{3}\right]=1.52 \mathrm{M}
$$

Using these concentrations in the reaction quotient expression, we can calculate the value of $K_{\mathrm{c}}$ for the reaction at this temperature as follows:

$$
Q_{\mathrm{c}}=\frac{\left[\mathrm{NH}_{3}\right]^{2}}{\left[\mathrm{~N}_{2}\right]\left[\mathrm{H}_{2}\right]^{3}}=\frac{(1.52)^{2}}{(2.05)(1.56)^{3}}=0.297=K_{\mathrm{c}}
$$

If we were to apply stress to this system by adding more $\mathrm{N}_{2}$, increasing its concentration from $2.05 M$ to $3.51 M$, the system would no longer be at equilibrium. To see that this is true, use the new concentration of nitrogen in the reaction quotient expression. The new calculated value of $Q_{\mathrm{c}}$ $(0.173)$ is no longer equal to the value of $K_{\mathrm{c}}(0.297)$.

$$
Q_{\mathrm{c}}=\frac{\left[\mathrm{NH}_{3}\right]^{2}}{\left[\mathrm{~N}_{2}\right]\left[\mathrm{H}_{2}\right]^{3}}=\frac{(1.52)^{2}}{(3.51)(1.56)^{3}}=0.173 \neq K_{\mathrm{c}}
$$

For this system to reestablish equilibrium, the net reaction will have to shift in such a way that $Q_{\text {c }}$ is again equal to $K_{\mathrm{c}}$, which is constant at a given temperature. Recall from Section 15.4 that when $Q$ is less than $K$, the reaction proceeds to the right to achieve equilibrium. Likewise, an equilibrium that is stressed in such a way that $Q$ becomes less than $K$ will shift to the right to reestablish equilibrium. This means that the forward reaction, the consumption of $\mathrm{N}_{2}$ and $\mathrm{H}_{2}$ to produce $\mathrm{NH}_{3}$, will occur. The result will be a net decrease in the concentrations of $\mathrm{N}_{2}$ and $\mathrm{H}_{2}$ (thus making the denominator of the reaction quotient smaller), and a net increase in the concentration of $\mathrm{NH}_{3}$ (thus making the numerator larger). When the concentrations of all species are such that $Q_{\mathrm{c}}$ is again equal to $K_{\mathrm{c}}$, the system will have established a new equilibrium position, meaning that it will have shifted in one direction or the other, resulting in a new equilibrium concentration for each species. Figure 15.5 shows how the concentrations of $\mathrm{N}_{2}, \mathrm{H}_{2}$, and $\mathrm{NH}_{3}$ change when $\mathrm{N}_{2}$ is added to the original equilibrium mixture.

(a)

(b)

Conversely, if we were to remove $\mathrm{N}_{2}$ from the original equilibrium mixture, the lower concentration in the denominator of the reaction quotient would result in $Q_{\mathrm{c}}$ being greater than $K_{\mathrm{c}}$. In this case the reaction will shift to the left. That is, the reverse reaction will take place, thereby increasing the concentrations of $\mathrm{N}_{2}$ and $\mathrm{H}_{2}$ and decreasing the concentration of $\mathrm{NH}_{3}$ until $Q_{\mathrm{c}}$ is once again equal to $K_{\mathrm{c}}$.

The addition or removal of $\mathrm{NH}_{3}$ will cause a shift in the equilibrium, too. The addition of $\mathrm{NH}_{3}$ will cause a shift to the left; the removal of $\mathrm{NH}_{3}$ will cause a shift to the right. Figure 15.6(a) shows the additions and removals that cause this equilibrium to shift to the right. Figure 15.6(b) shows those that cause it to shift to the left.

In essence, a system at equilibrium will respond to the addition of a species by consuming some of that species, and it will respond to the removal of a species by producing more of that species. It is important to remember that the addition or removal of a species from an equilibrium mixture does not change the value of the equilibrium constant, $K$. Rather, it changes temporarily the value of the reaction quotient, $Q$. Furthermore, to cause a shift in the equilibrium, the species added or removed must be one that appears in the reaction quotient expression. In the case of a heterogeneous equilibrium, altering the amount of a solid or liquid species does not change the position of the equilibrium because doing so does not change the value of $Q$.

Sample Problem 15.11 shows the effects of stress on a system at equilibrium.

## Sample Problem 15.11

Hydrogen sulfide $\left(\mathrm{H}_{2} \mathrm{~S}\right)$ is a contaminant commonly found in natural gas. It is removed by reaction with oxygen to produce elemental sulfur.

$$
2 \mathrm{H}_{2} \mathrm{~S}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) \rightleftarrows 2 \mathrm{~S}(\mathrm{~s})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{~g})
$$

For each of the following scenarios, determine whether the equilibrium will shift to the right, shift to the left, or neither: (a) addition of $\mathrm{O}_{2}(\mathrm{~g})$, (b) removal of $\mathrm{H}_{2} \mathrm{~S}(\mathrm{~g})$, (c) removal of $\mathrm{H}_{2} \mathrm{O}(\mathrm{g})$, and (d) addition of $\mathrm{S}(s)$.

Strategy Use Le Châtelier's principle to predict the direction of shift for each case. Remember that the position of the equilibrium is only changed by the addition or removal of a species that appears in the reaction quotient expression.

Figure 15.5 Adding more of a reactant to a system at equilibrium causes the equilibrium position to shift toward product. The system responds to the addition of $\mathrm{N}_{2}$ by consuming some of the added $\mathrm{N}_{2}$ (and some of the other reactant, $\mathrm{H}_{2}$ ) to produce more $\mathrm{NH}_{3}$.

Figure 15.6 (a) Addition of a reactant or removal of a product will cause an equilibrium to shift to the right. (b) Addition of a product or removal of a reactant will cause an equilibrium to shift to the left.

Think About It In each case, analyze the effect the change will have on the value of $Q_{c}$. In part (a), for example, $\mathrm{O}_{2}$ is added, so its concentration increases. Looking at the reaction quotient expression, we can see that a larger concentration of oxygen corresponds to a larger overall denominator-giving the overall fraction a smaller value. Thus, $Q$ will temporarily be smaller than $K$ and the reaction will have to shift to the right, consuming some of the added $\mathrm{O}_{2}$ (along with some of the $\mathrm{H}_{2} \mathrm{~S}$ in the mixture) to reestablish equilibrium.

Setup Begin by writing the reaction quotient expression:

$$
Q_{\mathrm{c}}=\frac{\left[\mathrm{H}_{2} \mathrm{O}\right]^{2}}{\left[\mathrm{H}_{2} \mathrm{~S}\right]^{2}\left[\mathrm{O}_{2}\right]}
$$

Because sulfur is a solid, it does not appear in the expression. Changes in the concentration of any of the other species will cause a change in the equilibrium position. Addition of a reactant or removal of a product that appears in the expression for $Q_{\mathrm{c}}$ will shift the equilibrium to the right:

Removal of a reactant or addition of a product that appears in the expression for $Q_{\mathrm{c}}$ will shift the equilibrium to the left:

$$
\stackrel{\downarrow}{3} \stackrel{+}{\mathrm{N}_{2}}(g) \quad 2 \mathrm{NH}_{3}(g)
$$

Solution
(a) Shift to the right
(b) Shift to the left
(c) Shift to the right
(d) No change

Practice Problem A For each change indicated, determine whether the equilibrium

$$
\mathrm{PCl}_{3}(g)+\mathrm{Cl}_{2}(g) \rightleftarrows \mathrm{PCl}_{5}(g)
$$

will shift to the right, shift to the left, or neither: (a) addition of $\mathrm{PCl}_{3}(\mathrm{~g})$, (b) removal of $\mathrm{PCl}_{3}(\mathrm{~g})$, (c) removal of $\mathrm{PCl}_{5}(g)$, and (d) removal of $\mathrm{Cl}_{2}(g)$.

EPractice Problem B What can be added to the equilibrium that will (a) shift it to the left, (b) shift it to the right, (c) not shift it in either direction?

$$
\mathrm{AgCl}(s)+2 \mathrm{NH}_{3}(a q) \rightleftarrows \mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}^{+}(a q)+\mathrm{Cl}^{-}(a q)
$$

## Changes in Volume and Pressure

If we were to start with a gaseous system at equilibrium in a cylinder with a movable piston, we could change the volume of the system, thereby changing the concentrations of the reactants and products.

Consider again the equilibrium between $\mathrm{N}_{2} \mathrm{O}_{4}$ and $\mathrm{NO}_{2}$ :

$$
\mathrm{N}_{2} \mathrm{O}_{4}(g) \rightleftarrows 2 \mathrm{NO}_{2}(g)
$$

At $25^{\circ} \mathrm{C}$ the equilibrium constant for this reaction is $4.63 \times 10^{-3}$. Suppose we have an equilibrium mixture of $0.643 M \mathrm{~N}_{2} \mathrm{O}_{4}$ and $0.0547 \mathrm{M} \mathrm{N}_{2}$ in a cylinder fitted with a movable piston. If we push down on the piston, the equilibrium will be disturbed and will shift in the direction that minimizes the effect of this disturbance. Consider what happens to the concentrations of both species if we decrease the volume of the cylinder by half. Both concentrations are initially doubled: $\left[\mathrm{N}_{2} \mathrm{O}_{4}\right]=$ 1.286 M and $\left[\mathrm{NO}_{2}\right]=0.1094 M$. If we plug the new concentrations into the reaction quotient expression, we get

$$
Q_{\mathrm{c}}=\frac{\left[\mathrm{NO}_{2}\right]_{\mathrm{eq}}^{2}}{\left[\mathrm{~N}_{2} \mathrm{O}_{4}\right]_{\mathrm{eq}}}=\frac{(0.1094)^{2}}{1.286}=9.31 \times 10^{-3}
$$

which is not equal to $K_{\mathrm{c}}$, so the system is no longer at equilibrium. Because $Q_{\mathrm{c}}$ is greater than $K_{\mathrm{c}}$, the equilibrium will have to shift to the left for equilibrium to be reestablished (Figure 15.7).

Figure 15.7 The effect of a volume decrease (pressure increase) on the $\mathrm{N}_{2} \mathrm{O}_{4}(\mathrm{~g}) \rightleftarrows 2 \mathrm{NO}_{2}(\mathrm{~g})$ equilibrium. When volume is decreased, the equilibrium is driven toward the side with the smallest number of moles of gas.

In general, a decrease in volume of a reaction vessel will cause a shift in the equilibrium in the direction that minimizes the total number of moles of gas. Conversely, an increase in volume will cause a shift in the direction that maximizes the total number of moles of gas.

Sample Problem 15.12 shows how to predict the equilibrium shift that will be caused by a volume change.

## Sample Problem 15.12

For each reaction, predict in what direction the equilibrium will shift when the volume of the reaction vessel is decreased.
(a) $\mathrm{PCl}_{5}(\mathrm{~g}) \rightleftarrows \mathrm{PCl}_{3}(\mathrm{~g})+\mathrm{Cl}_{2}(\mathrm{~g})$
(b) $2 \mathrm{PbS}(s)+3 \mathrm{O}_{2}(g) \rightleftarrows 2 \mathrm{PbO}(s)+2 \mathrm{SO}_{2}(g)$
(c) $\mathrm{H}_{2}(g)+\mathrm{I}_{2}(g) \rightleftarrows 2 \mathrm{HI}(g)$

Strategy Determine which direction minimized the number of moles of gas in the reaction. Count only moles of gas.

Setup We have (a) 1 mole of gas on the reactant side and 2 moles of gas on the product side,
(b) 3 moles of gas on the reactant side and 2 moles of gas on the product side, and (c) 2 moles of gas on each side.

## Solution

(a) Shift to the left
(b) Shift to the right
(c) No shift

Practice Problem A For each reaction, predict the direction of shift caused by increasing the volume of the reaction vessel.
(a) $2 \mathrm{NOCl}(\mathrm{g}) \rightleftarrows 2 \mathrm{NO}(\mathrm{g})+\mathrm{Cl}_{2}(\mathrm{~g})$
(b) $\mathrm{CaCO}_{3}(\mathrm{~s}) \rightleftarrows \mathrm{CaO}(\mathrm{s})+\mathrm{CO}_{2}(\mathrm{~g})$
(c) $\mathrm{Zn}(s)+2 \mathrm{H}^{+}(a q) \rightleftarrows \mathrm{Zn}^{2+}(a q)+\mathrm{H}_{2}(g)$
\&Practice Problem B For the following equilibrium, give an example of a stress that will cause a shift to the right, a stress that will cause a shift to the left, and one that will cause no shift:

$$
\mathrm{H}_{2}(g)+\mathrm{F}_{2}(g) \rightleftarrows 2 \mathrm{HF}(g)
$$

It is possible to change the total pressure of a system without changing its volume-by adding an inert gas such as helium to the reaction vessel. Because the total volume remains the same, the concentrations of reactant and product gases do not change. Therefore, the equilibrium is not disturbed and no shift will occur.

Student Annotation: It is a common error to count all the species in a reaction to determine which side has fewer moles. To determine what direction shift a volume change will cause, it is only the number of moles of gas that matters.

Think About It When there is no difference in the number of moles of gas, changing the volume of the reaction vessel will change the concentrations of reactant(s) and product(s)—but the system will remain at equilibrium. ( $Q$ will remain equal to $K$.)

(a)

(b)

Figure 15.8 (a) $\mathrm{N}_{2} \mathrm{O}_{4}-\mathrm{NO}_{2}$ equilibrium. (b) Because the reaction is endothermic, at higher temperature, the $\mathrm{N}_{2} \mathrm{O}_{4}(g) \rightleftarrows 2 \mathrm{NO}_{2}(g)$ equilibrium shifts toward product, making the reaction mixture darker.

Figure 15.9 (a) An equilibrium mixture of $\mathrm{CoCl}_{4}^{2-}$ ions and $\mathrm{Co}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}^{2+}$ ions appears violet. (b) Heating favors the formation of $\mathrm{CoCl}_{4}^{2-}$, making the solution look more blue. (c) Cooling favors the formation of $\mathrm{Co}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}^{2+}$, making the solution look more pink.

## Changes in Temperature

A change in concentration or volume may alter the position of an equilibrium (i.e., the relative amounts of reactants and products), but it does not change the value of the equilibrium constant. Only a change in temperature can alter the value of the equilibrium constant. To understand why, consider the following reaction:

$$
\mathrm{N}_{2} \mathrm{O}_{4}(g) \rightleftarrows 2 \mathrm{NO}_{2}(g)
$$

The forward reaction is endothermic (absorbs heat, $\Delta H>0$ ):

$$
\text { Heat }+\mathrm{N}_{2} \mathrm{O}_{4}(g) \rightleftarrows 2 \mathrm{NO}_{2}(g) \quad \Delta H^{\circ}=58.0 \mathrm{~kJ} / \mathrm{mol}
$$

If we treat heat as though it were a reactant, we can use Le Châtelier's principle to predict what will happen if we add or remove heat. Increasing the temperature (adding heat) will shift the reaction in the forward direction because heat appears on the reactant side. Lowering the temperature (removing heat) will shift the reaction in the reverse direction. Consequently, the equilibrium constant, given by

$$
K_{\mathrm{c}}=\frac{\left[\mathrm{NO}_{2}\right]^{2}}{\left[\mathrm{~N}_{2} \mathrm{O}_{4}\right]}
$$

increases when the system is heated and decreases when the system is cooled (Figure 15.8). A similar argument can be made in the case of an exothermic reaction, where heat can be considered to be a product. Increasing the temperature of an exothermic reaction causes the equilibrium constant to decrease, shifting the equilibrium toward reactants.

Another example of this phenomenon is the equilibrium between the following ions:

$$
\underset{\text { blue }}{\mathrm{CoCl}_{4}^{2-}}+\underset{\text { pink }}{6 \mathrm{H}_{2} \mathrm{O}} \rightleftarrows \underset{6}{\mathrm{Co}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}^{2+}}+4 \mathrm{Cl}^{-}+\text {heat }
$$

The reaction as written, the formation of $\mathrm{Co}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}^{2+}$, is exothermic. Thus, the reverse reaction, the formation of $\mathrm{CoCl}_{4}^{2-}$, is endothermic. On heating, the equilibrium shifts to the left and the solution turns blue. Cooling favors the exothermic reaction [the formation of $\mathrm{Co}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}^{2+}$ ] and the solution turns pink (Figure 15.9).

In summary, a temperature increase favors an endothermic reaction, and a temperature decrease favors an exothermic process. Temperature affects the position of an equilibrium by changing the value of the equilibrium constant. Figures 15.10 and 15.11 illustrate the effects of various stresses on systems at equilibrium.

## Catalysis

A catalyst speeds up a reaction by lowering the reaction's activation energy [ 14 Section 14.6]. However, a catalyst lowers the activation energy of the forward and reverse reactions to the same extent (see Figure 14.15). The presence of a catalyst, therefore, does not alter the equilibrium constant, nor does it shift the position of an equilibrium system. Adding a catalyst to a reaction mixture that is not at equilibrium will simply cause the mixture to reach equilibrium sooner. The same equilibrium mixture could be obtained without the catalyst, but it might take a much longer time.

## Bringing Chemistry to Life

## Hemoglobin Production at High Altitude

As we learned at the end of Chapter 11, rapid ascent to a high altitude can cause altitude sickness. The symptoms of altitude sickness, including dizziness, headache, and nausea, are caused by hypoxia, an insufficient oxygen supply to body tissues. In severe cases, without prompt treatment, a victim may slip into a coma and die. And yet a person staying at a high altitude for weeks or months can recover gradually from altitude sickness, adjust to the low oxygen content in the atmosphere, and live and function normally.

The combination of oxygen with the hemoglobin $(\mathrm{Hb})$ molecule, which carries oxygen through the blood, is a complex reaction, but for our purposes it can be represented by the following simplified equation:*

$$
\mathrm{Hb}(a q)+\mathrm{O}_{2}(a q) \rightleftarrows \mathrm{HbO}_{2}(a q)
$$

where $\mathrm{HbO}_{2}$ is oxyhemoglobin, the hemoglobin-oxygen complex that actually transports oxygen to tissues. The equilibrium expression for this process is

$$
K_{\mathrm{c}}=\frac{\left[\mathrm{HbO}_{2}\right]}{[\mathrm{Hb}]\left[\mathrm{O}_{2}\right]}
$$

At an altitude of 3 km , the partial pressure of oxygen is only about 0.14 atm , compared with 0.20 atm at sea level. According to Le Châtelier's principle, a decrease in oxygen concentration will shift the hemoglobin-oxyhemoglobin equilibrium from right to left. This change depletes the supply of oxyhemoglobin, causing hypoxia. Over time, the body copes with this problem by producing more hemoglobin molecules. As the concentration of Hb increases, the equilibrium gradually shifts back toward the right (toward the formation of oxyhemoglobin). It can take several weeks for the increase in hemoglobin production to meet the body's oxygen needs adequately. A return to full capacity may require several years to occur. Studies show that longtime residents of high-altitude areas have high hemoglobin levels in their blood-sometimes as much as 50 percent more than individuals living at sea level. The production of more hemoglobin and the resulting increased capacity of the blood to deliver oxygen to the body have made high-altitude training and hypoxic tents popular among some athletes.

Media Player/MPEG Animation: Figures 15.10 and 15.11, Le Châtelier's Principle, pp. 656-659.
*Biological processes such as this are not true equilibria, but rather they are steady-state situations. In a steady state, the constant concentrations of reactants and products are not the result of forward and reverse reactions occurring at the same rate. Instead, reactant concentration is replenished by a previous reaction and product concentration is maintained by a subsequent reaction. Nevertheless, many of the principles of equilibrium, including Le Châtelier's principle, still apply.

## Checkpoint 15.5 Factors That Affect Chemical Equilibrium

15.5.1 Which of the following equilibria will shift to the right when $\mathrm{H}_{2}$ is added? (Select all that apply.)
a) $2 \mathrm{H}_{2}+\mathrm{O}_{2} \rightleftarrows 2 \mathrm{H}_{2} \mathrm{O}$
b) $2 \mathrm{HI} \rightleftarrows \mathrm{H}_{2}+\mathrm{I}_{2}$
c) $\mathrm{H}_{2}+\mathrm{CO}_{2} \rightleftarrows \mathrm{H}_{2} \mathrm{O}+\mathrm{CO}$
d) $2 \mathrm{NaHCO}_{3} \rightleftarrows \mathrm{Na}_{2} \mathrm{CO}_{3}+\mathrm{H}_{2} \mathrm{O}+\mathrm{CO}_{2}$
e) $2 \mathrm{CO}+\mathrm{O}_{2} \rightleftarrows 2 \mathrm{CO}_{2}$
15.5.2 Which of the following will cause the equilibrium

$$
\mathrm{C} \text { (graphite) }+\mathrm{CO}_{2}(\mathrm{~g}) \rightleftarrows 2 \mathrm{CO}(\mathrm{~g})
$$

to shift to the right? (Select all that apply.)
a) Decreasing the volume
b) Increasing the volume
c) Adding more C (graphite)
d) Adding more $\mathrm{CO}_{2}(\mathrm{~g})$
e) Removing $\mathrm{CO}(\mathrm{g})$ as it forms
15.5.3 Which of the following equilibria will shift to the left when the temperature is increased? $[\Delta H(\mathrm{~kJ} / \mathrm{mol})$ values are given in parentheses.] (Select all that apply.)
a) $\mathrm{S}+\mathrm{H}_{2} \rightleftarrows \mathrm{H}_{2} \mathrm{~S}$
$\Delta H(-20)$
b) $\mathrm{C}+\mathrm{H}_{2} \mathrm{O} \rightleftarrows \mathrm{CO}+\mathrm{H}_{2}$
$\Delta H$ (131)
c) $\mathrm{H}_{2}+\mathrm{CO}_{2} \rightleftarrows \mathrm{H}_{2} \mathrm{O}+\mathrm{CO}$
$\Delta H$ (41)
d) $\mathrm{MgO}+\mathrm{CO}_{2} \rightleftarrows \mathrm{MgCO}_{3}$
$\Delta H(-117)$
e) $2 \mathrm{CO}+\mathrm{O}_{2} \rightleftarrows 2 \mathrm{CO}_{2}$
$\Delta H(-566)$
15.5.4 For which of the following reactions will a change in volume not affect the position of the equilibrium? (Select all that apply.)
a) $\mathrm{MgO}(\mathrm{s})+\mathrm{CO}_{2}(\mathrm{~g}) \rightleftarrows \mathrm{MgCO}_{3}(\mathrm{~s})$
b) $\mathrm{H}_{2}(g)+\mathrm{Cl}_{2}(g) \rightleftarrows 2 \mathrm{HCl}(g)$
c) $\mathrm{BaCO}_{3}(s) \rightleftarrows \mathrm{BaO}(s)+\mathrm{CO}_{2}(g)$
d) $\mathrm{Br}_{2}(l)+\mathrm{H}_{2}(g) \rightleftarrows 2 \mathrm{HBr}(g)$
e) C (graphite) $+\mathrm{CO}_{2}(g) \rightleftarrows 2 \mathrm{CO}(g)$
(Continued on page 660)

Q_{\mathrm{c}}=K_{\mathrm{c}}
\end{gathered}
$$

$$
Q_{\mathrm{c}}=\frac{[\mathrm{HI}]^{2}}{\left[\mathrm{H}_{2}\right]\left[\mathrm{I}_{2}\right]}=\frac{(0.825)^{2}}{(0.112)(0.112)}=54.3
$$

$$
Q_{\mathrm{c}}=K_{\mathrm{c}}
$$

## What's the point?

Adding a reactant to an equilibrium mixture shifts the equilibrium toward the product side of the equation. Adding a product shifts the equilibrium toward the reactant side. Adding a species that is neither a reactant nor a product does not cause a shift in the equilibrium.

## Effect of Temperature Change

## $\mathrm{N}_{2} \mathrm{O}_{4}(\mathrm{~g}) \rightleftarrows 2 \mathrm{NO}_{2}(\mathrm{~g}) \quad \Delta H^{\circ}=58.04 \mathrm{~kJ} / \mathrm{mol}$

Temperature decrease drives an endothermic equilibrium toward reactants.

Temperature increase drives an endothermic equilibrium toward products.

$$
\mathrm{H}_{2}(\mathrm{~g})+\mathrm{I}_{2}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{HI}(\mathrm{~g}) \quad \Delta H^{\circ}=-9.4 \mathrm{~kJ} / \mathrm{mol}
$$

Temperature increase drives an
exothermic equilibrium toward reactants.

Temperature decrease drives an
exothermic equilibrium toward products.

What's the point?
Increasing the temperature of an equilibrium mixture causes a shift toward the product side for an endothermic reaction, and a shift toward the reactant side for an exothermic reaction.

Figure 15.11 Le Châtelier's principle.

## Effect of Volume Change

$$
\begin{aligned}
{\left[\mathrm{N}_{2} \mathrm{O}_{4}\right] } & =0.533 \mathrm{M} \\
{\left[\mathrm{NO}_{2}\right]=} & 0.0497 \mathrm{M} \\
Q_{\mathrm{c}}=\frac{(0.0497)^{2}}{0.533} & =4.6 \times 10^{-3} \\
Q_{\mathrm{c}} & =K_{\mathrm{c}}
\end{aligned}
$$

## What's the point?

Increasing the volume causes a shift toward the side with the larger number of moles of gas. Decreasing the volume of an equilibrium mixture causes a shift toward the side of the equation with the smaller number of moles of gas.

$$
\begin{aligned}
{\left[\mathrm{N}_{2} \mathrm{O}_{4}\right] } & =2.18 \mathrm{M} \\
{\left[\mathrm{NO}_{2}\right] } & =0.100 \mathrm{M} \\
Q_{\mathrm{c}}=\frac{(0.100)^{2}}{2.18} & =4.6 \times 10^{-3} \\
Q_{\mathrm{c}} & =K_{\mathrm{c}}
\end{aligned}
$$

## What's the point?

For an equilibrium with equal numbers of gaseous moles on both sides, a change in volume does not cause the equilibrium to shift in either direction.

## FAQ

You May Be Wondering...

## What Happens to the Units in Equilibrium Constants?

We have said that it is common to disregard units and write equilibrium constants as dimensionless quantities. The reason is as follows: Prior to being used in an equilibrium expression, each molar concentration is divided by a reference concentration of $1 M$, and each partial pressure is divided by a reference pressure of 1 atm . The reference concentration ( 1 M ) and reference pressure ( 1 atm ) are known as the standard states for aqueous and gaseous species, respectively. This cancels the units without changing the value of the concentration or pressure in question. The dimensionless result of dividing a concentration by a reference value is called the activity. Activities commonly are used by chemists in place of concentrations, but a detailed discussion of activities is beyond the scope of this book. Using as an example the equilibrium between $\mathrm{N}_{2} \mathrm{O}_{4}$ and $\mathrm{NO}_{2}$,

$$
\mathrm{N}_{2} \mathrm{O}_{4}(g) \rightleftarrows 2 \mathrm{NO}_{2}(g)
$$

and data from experiment 3 in Table 15.1, the equilibrium concentrations of $\mathrm{N}_{2} \mathrm{O}_{4}$ and $\mathrm{NO}_{2}\left(\right.$ at $\left.25^{\circ} \mathrm{C}\right)$ are 0.491 M and 0.0475 M , respectively. We can calculate the value of $K_{\mathrm{c}}$ as follows:

$$
K_{\mathrm{c}}=\frac{\left(\frac{0.0475 M}{1 M}\right)^{2}}{\frac{0.491 M}{1 M}}=4.60 \times 10^{-3}
$$

We can then convert the molar concentrations to partial pressures using the ideal gas equation:

$$
\begin{gathered}
P_{\mathrm{N}_{2} \mathrm{O}_{4}}=\frac{n_{\mathrm{N}_{2} \mathrm{O}_{4}}}{V} R T=\left[\mathrm{N}_{2} \mathrm{O}_{4}\right](0.08206)(298)=12.0 \mathrm{~atm} \\
P_{\mathrm{NO}_{2}}=\frac{n_{\mathrm{NO}_{2}}}{V} R T=\left[\mathrm{NO}_{2}\right](0.08206)(298)=1.16 \mathrm{~atm}
\end{gathered}
$$

Finally, we can calculate the value of $K_{P}$ as

$$
K_{P}=\frac{\left(\frac{1.16 \mathrm{~atm}}{1 \mathrm{~atm}}\right)^{2}}{\frac{12.0 \mathrm{~atm}}{1 \mathrm{~atm}}}=0.112
$$

In each case, dividing by the reference value eliminates the units without changing the numerical value of the result. We will not show the division by reference values explicitly, but you should realize that this is the reason why there are no units associated with equilibrium constants.

Division of each entry in an equilibrium expression by a reference value actually enables us to use molar concentrations and partial pressures in the same equilibrium expression. For example, we can write the equilibrium expression for the reaction

$$
\mathrm{Zn}(s)+2 \mathrm{H}^{+}(a q) \rightleftarrows \mathrm{Zn}^{2+}(a q)+\mathrm{H}_{2}(g)
$$

as

$$
K=\frac{\left(\frac{\left[\mathrm{Zn}^{2+}\right]}{1 M}\right)\left(\frac{P_{\mathrm{H}_{2}}}{1 \mathrm{~atm}}\right)}{\left(\frac{\left[\mathrm{H}^{+}\right]}{1 M}\right)^{2}}
$$

Each of the entries in the expression is divided by the appropriate reference value, making the result dimensionless. Note that this equilibrium constant is neither a $K_{\mathrm{c}}$ nor a $K_{P}$. It is referred to simply as $K$ or as $K_{\text {eq }}$, where the subscripted eq denotes equilibrium. We will encounter the use of "mixed" equilibrium constants such as this in Chapters 19 and 20.

## Checkpoint 15.5 Factors That Affect Chemical Equilibrium (continued)

15.5.5 The diagram shows the gaseous reaction $2 \mathrm{~A} \rightleftarrows \mathrm{~A}_{2}$ at equilibrium. How will the numbers of $A$ and $A_{2}$ change if the volume of the container is increased at constant temperature?

a) $A_{2}$ will increase and $A$ will decrease.
b) A will increase and $A_{2}$ will decrease.
c) $\mathrm{A}_{2}$ and A will both decrease.
d) $\mathrm{A}_{2}$ and A will both increase.
e) Neither $\mathrm{A}_{2}$ nor A will change.
15.5.6 The diagrams show equilibrium mixtures of $\mathrm{A}_{2}, \mathrm{~B}_{2}$, and AB at two different temperatures $\left(T_{2}>T_{1}\right)$. Is the reaction $\mathrm{A}_{2}+\mathrm{B}_{2} \rightleftarrows 2 \mathrm{AB}$ endothermic or exothermic?

a) Endothermic
b) Exothermic
c) Neither
d) There is not enough information to determine.

## Applying What You've Learned

At present, the World Anti-Doping Agency has no way to detect the use of hypoxic sleeping tents, other than inspection of an athlete's home. Imagine, however, that a biochemical analysis company is developing a way to determine whether an elevated red blood cell count in an athlete's blood is the result of such a practice. A key substance in the detection process is the proprietary compound OD17X, which is produced by the combination of two other proprietary compounds, OD1A and OF2A. The aqueous reaction is represented by the equation

$$
\text { OD1A }(a q)+\mathrm{OF} 2 \mathrm{~A}(a q) \rightleftarrows \text { OD17X }(a q) \quad \Delta H=29 \mathrm{~kJ} / \mathrm{mol}
$$

## Problems:

a) Write the equilibrium expression for the given reaction. [\$4 Sample Problem 15.3]
b) Given the equilibrium concentrations at room temperature of $[\mathrm{OD} 1 \mathrm{~A}]=2.12 \mathrm{M},[\mathrm{OF} 2 \mathrm{~A}]=$ 1.56 M , and $[\mathrm{OD} 17 \mathrm{X}]=1.01 \times 10^{-4} \mathrm{M}$, calculate the value of the equilibrium constant $\left(K_{\mathrm{c}}\right)$ at room temperature. [14 Sample Problem 15.2]
c) The OD17X produced is precipitated with another proprietary substance according to the equation

$$
\mathrm{OD} 17 \mathrm{X}(a q)+\mathrm{A} 771 \mathrm{~A}(a q) \rightleftarrows \text { OD17X-A77 }(s)
$$

$K_{\mathrm{c}}$ for the precipitation equilibrium is $1.00 \times 10^{6}$ at room temperature. Write the equilibrium expression for the sum of the two reactions, and determine the value of the overall equilibrium constant. [ 14 Sample Problem 15.4]
d) Determine whether a mixture with [OD1A] $=3.00 \mathrm{M}$, $[\mathrm{OF} 2 \mathrm{~A}]=2.50 \mathrm{M}$, and [OD17X] $=2.7 \times 10^{-4} M$ is at equilibrium and, if not, in which direction it will have to proceed to achieve equilibrium. [ 14 Sample Problem 15.7]
e) Because the production of OD17X is endothermic, it can be enhanced by increasing the temperature. At $250^{\circ} \mathrm{C}$, the equilibrium constant for the reaction

$$
\mathrm{OD} 1 \mathrm{~A}(a q)+\mathrm{OF} 2 \mathrm{~A}(a q) \rightleftarrows \mathrm{OD} 17 \mathrm{X}(a q)
$$

is $3.8 \times 10^{2}$. If a synthesis at $250^{\circ} \mathrm{C}$ begins with 1.00 M of each reactant, what will be the equilibrium concentrations of reactants and products? [14 Sample Problem 15.8]

## Chapter Summary

## Section 15.1

- By our definition of a chemical reaction, reactants are consumed and products are produced. This is known as the forward reaction. A reversible process is one in which the products can also be consumed to produce reactants, a process known as the reverse reaction.
- Equilibrium is the condition where the forward and reverse reactions are occurring at the same rate and there is no net change in the reactant and product concentrations over time.
- In theory, equilibrium can be established starting with just reactants, with just products, or with a combination of reactants and products.

## Section 15.2

- The reaction quotient $\left(\boldsymbol{Q}_{c}\right)$ is the product of the product concentrations over the product of the reactant concentrations, with each concentration raised to a power equal to the corresponding stoichiometric coefficient in the balanced chemical equation. This is known as the law of mass action.
- At equilibrium, the reaction quotient is equal to a constant value, the equilibrium constant $\left(K_{c}\right)$.
- At equilibrium, concentrations in the reaction quotient are equilibrium concentrations and the quotient is called the equilibrium expression.
- $K_{\mathrm{c}}$ is constant at constant temperature. The value of $K_{\mathrm{c}}$ can be calculated by plugging equilibrium concentrations into the equilibrium expression.
- A large equilibrium constant $\left(K_{\mathrm{c}}>10^{3}\right)$ indicates that products are favored at equilibrium. A small equilibrium constant $\left(K_{\mathrm{c}}<10^{-3}\right)$ indicates that reactants are favored at equilibrium.

## Section 15.3

- Solids and liquids do not appear in the equilibrium expression for a heterogeneous reaction.
- When chemical equations that represent equilibria are reversed, multiplied, combined with other equations, or any combination of these processes, the corresponding changes must be made to the equilibrium constants.
- Equilibrium expressions that contain only gases can be written either as $K_{\mathrm{c}}$ expressions or as $K_{P}$ expressions. $K_{P}$ expressions have the same form as $K_{\mathrm{c}}$ expressions but contain partial pressures rather than molar concentrations. The reaction quotient, $Q$, can also be expressed in terms of the pressures of products and reactants. In this case it is labeled $Q_{P}$.
- $\quad K_{\mathrm{c}}$ and $K_{P}$ are not usually equal. The values are the same only when the reaction results in no net change in the number of moles of gas.

## Section 15.4

- We can predict in which direction a reaction must proceed to achieve equilibrium by comparing the values of $Q_{\mathrm{c}}$ and $K_{\mathrm{c}}$ (or of $Q_{P}$ and $K_{P}$ ).
- Starting concentrations can be used, along with the equilibrium expression and equilibrium constant, to determine equilibrium concentrations.

## Section 15.5

- According to Le Châtelier's principle, a system at equilibrium will react to stress by shifting in the direction that will partially offset the effect of the stress.
- The stresses that can be applied to a system at equilibrium include the addition or removal of a substance, changes in the volume of the reaction vessel, and changes in the temperature.
- The addition of a catalyst does not shift the equilibrium in either direction.

## Key Words

Equilibrium, 630
Equilibrium constant ( $K_{\mathrm{c}}$ ) or $\left(K_{P}\right), 632$

Equilibrium expression, 632
Law of mass action, 633

Le Châtelier's principle, 650
Reversible process, 630

## Key Equations

$15.1 Q_{\mathrm{c}}=\frac{[\mathrm{C}]^{c}[\mathrm{D}]^{d}}{[\mathrm{~A}]^{a}[\mathrm{~B}]^{b}}=K_{\mathrm{c}}$ (at equilibrium)
$15.2 Q_{\mathrm{c}}=\frac{[\mathrm{C}]^{c}[\mathrm{D}]^{d}}{[\mathrm{~A}]^{a}[\mathrm{~B}]^{b}}$
$15.3 \quad \Delta n=$ moles of gaseous products - moles of gaseous reactants
$15.4 K_{P}=K_{\mathrm{c}}[(0.08206 \mathrm{~L} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{mol}) \times T]^{\Delta n}$

## Questions and Problems

## Section 15.1: The Concept of Equilibrium

## Review Questions

15.1 Define equilibrium. Give two examples of a dynamic equilibrium.
15.2 Which of the following statements is correct about a reacting system at equilibrium: (a) the concentrations of reactants are equal to the concentrations of products, (b) the rate of the forward reaction is equal to the rate of the reverse reaction.
15.3 Consider the reversible reaction $\mathrm{A} \rightleftarrows \mathrm{B}$. Explain how equilibrium can be reached by starting with only $A$, only $B$, or a mixture of A and B .

## Section 15.2: The Equilibrium Constant

## Review Questions

15.4 What is the law of mass action?
15.5 Briefly describe the importance of equilibrium in the study of chemical reactions.
15.6 Define reaction quotient. How does it differ from the equilibrium constant?
15.7 Write reaction quotients for the following reactions: (a) $2 \mathrm{NO}(g)$
$+\mathrm{O}_{2}(g) \rightleftarrows \mathrm{N}_{2} \mathrm{O}_{4}(g),(b) \mathrm{S}(s)+3 \mathrm{~F}_{2}(g) \rightleftarrows \mathrm{SF}_{6}(g)$,
(c) $\mathrm{Co}^{3+}(a q)+6 \mathrm{NH}_{3}(a q) \rightleftarrows \mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}^{3+}(a q)$,
(d) $\mathrm{HCOOH}(a q) \rightleftarrows \mathrm{HCOO}^{-}(a q)+\mathrm{H}^{+}(a q)$.
15.8 Write the equation for the reaction that corresponds to each of the following reaction quotients:
(a) $Q_{\mathrm{c}}=\frac{\left[\mathrm{H}_{2}\right]^{2}\left[\mathrm{~S}_{2}\right]}{\left[\mathrm{H}_{2} \mathrm{~S}\right]^{2}}$
(b) $Q_{\mathrm{c}}=\frac{\left[\mathrm{NO}_{2}\right]^{2}\left[\mathrm{Cl}_{2}\right]}{\left[\mathrm{NClO}_{2}\right]^{2}}$
(c) $Q_{\mathrm{c}}=\frac{\left[\mathrm{HgI}_{4}^{2-}\right]}{\left[\mathrm{Hg}^{2+}\right]\left[\mathrm{I}^{-}\right]^{4}}$
(d) $Q_{\mathrm{c}}=\frac{[\mathrm{NO}]^{2}\left[\mathrm{Br}_{2}\right]}{[\mathrm{NOBr}]^{2}}$

## Problems

15.9 Consider the reaction

$$
2 \mathrm{NO}(g)+2 \mathrm{H}_{2}(g) \rightleftarrows \mathrm{N}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(g)
$$

At a certain temperature, the equilibrium concentrations are $[\mathrm{NO}]=0.31 \mathrm{M},\left[\mathrm{H}_{2}\right]=0.16 \mathrm{M},\left[\mathrm{N}_{2}\right]=0.082 \mathrm{M}$, and $\left[\mathrm{H}_{2} \mathrm{O}\right]=$ 4.64 $M$. (a) Write the equilibrium expression for the reaction. (b) Determine the value of the equilibrium constant.

G15.10 The equilibrium constant for the reaction

$$
2 \mathrm{SO}_{2}(g)+\mathrm{O}_{2}(g) \rightleftarrows 2 \mathrm{SO}_{3}(g)
$$

is $2.8 \times 10^{2}$ at a certain temperature. If $\left[\mathrm{SO}_{2}\right]=0.0124 \mathrm{M}$ and $\left[\mathrm{O}_{2}\right]=0.031 \mathrm{M}$, what is $\left[\mathrm{SO}_{3}\right]$ ?
15.11 Consider the following equilibrium process at $700^{\circ} \mathrm{C}$ :

$$
2 \mathrm{H}_{2}(g)+\mathrm{S}_{2}(g) \rightleftarrows 2 \mathrm{H}_{2} \mathrm{~S}(g)
$$

Analysis shows that there are 2.50 moles of $\mathrm{H}_{2}, 1.35 \times 10^{-5}$ mole of $\mathrm{S}_{2}$, and 8.70 moles of $\mathrm{H}_{2} \mathrm{~S}$ present in a 12.0-L flask. Calculate the equilibrium constant $K_{\mathrm{c}}$ for the reaction.
15.12 The equilibrium constant for the reaction

$$
2 \mathrm{H}_{2}(g)+\mathrm{CO}(g) \rightleftarrows \mathrm{CH}_{3} \mathrm{OH}(g)
$$

is $1.6 \times 10^{-2}$ at a certain temperature. If there are $1.17 \times 10^{-2}$ mole of $\mathrm{H}_{2}$ and $3.46 \times 10^{-3}$ mole of $\mathrm{CH}_{3} \mathrm{OH}$ at equilibrium in a $5.60-\mathrm{L}$ flask, what is the concentration of CO ?

## Section 15.3: Equilibrium Expressions

## Review Questions

15.13 Define homogeneous equilibrium and heterogeneous equilibrium. Give two examples of each.
15.14 What do the symbols $K_{\mathrm{c}}$ and $K_{P}$ represent?
15.15 Write the expressions for the equilibrium constants $K_{P}$ of the following thermal decomposition reactions:
(a) $2 \mathrm{NaHCO}_{3}(s) \rightleftarrows \mathrm{Na}_{2} \mathrm{CO}_{3}(s)+\mathrm{CO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(g)$
(b) $2 \mathrm{CaSO}_{4}(s) \rightleftarrows 2 \mathrm{CaO}(s)+2 \mathrm{SO}_{2}(g)+\mathrm{O}_{2}(g)$

E 15.16 Write equilibrium constant expressions for $K_{\mathrm{c}}$, and for $K_{P}$, if applicable, for the following processes:
(a) $2 \mathrm{CO}_{2}(g) \rightleftarrows 2 \mathrm{CO}(g)+\mathrm{O}_{2}(g)$
(b) $3 \mathrm{O}_{2}(\mathrm{~g}) \rightleftarrows 2 \mathrm{O}_{3}(\mathrm{~g})$
(c) $\mathrm{CO}(g)+\mathrm{Cl}_{2}(g) \rightleftarrows \mathrm{COCl}_{2}(g)$
(d) $\mathrm{H}_{2} \mathrm{O}(g)+\mathrm{C}(s) \rightleftarrows \mathrm{CO}(g)+\mathrm{H}_{2}(g)$
(e) $\mathrm{HCOOH}(a q) \rightleftarrows \mathrm{H}^{+}(a q)+\mathrm{HCOO}^{-}(a q)$
(f) $2 \mathrm{HgO}(s) \rightleftarrows 2 \mathrm{Hg}(l)+\mathrm{O}_{2}(g)$
15.17 Write the equilibrium constant expressions for $K_{\mathrm{c}}$ and for $K_{P}$, if applicable, for the following reactions:
(a) $2 \mathrm{NO}_{2}(g)+7 \mathrm{H}_{2}(g) \rightleftarrows 2 \mathrm{NH}_{3}(g)+4 \mathrm{H}_{2} \mathrm{O}(l)$
(b) $2 \mathrm{ZnS}(s)+3 \mathrm{O}_{2}(g) \rightleftarrows 2 \mathrm{ZnO}(s)+2 \mathrm{SO}_{2}(g)$
(c) $\mathrm{C}(s)+\mathrm{CO}_{2}(g) \rightleftarrows 2 \mathrm{CO}(g)$
(d) $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COOH}(a q) \rightleftarrows \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COO}^{-}(a q)+\mathrm{H}^{+}(a q)$
15.18 Write the equation relating $K_{\mathrm{c}}$ to $K_{P}$, and define all the terms.
15.19 What is the rule for writing the equilibrium constant for the overall reaction that is the sum of two or more reactions?
15.20 Give an example of a multiple equilibria reaction.

## Problems

$\boldsymbol{H}$ 15.21 The equilibrium constant for the reaction $\mathrm{A} \rightleftarrows \mathrm{B}$ is $K_{\mathrm{c}}=$ 10 at a certain temperature. (1) Starting with only reactant A, which of the diagrams shown here best represents the system at equilibrium? (2) Which of the diagrams best represents the system at equilibrium if $K_{\mathrm{c}}=0.10$ ? Explain why you can calculate $K_{\mathrm{c}}$ in each case without knowing the volume of the container. The grey spheres represent the A molecules, and the green spheres represent the B molecules.

(a)

(b)

(c)

(d)

G 15.22 The following diagrams represent the equilibrium state for three different reactions of the type

$$
\mathrm{A}+\mathrm{X} \rightleftarrows \mathrm{AX}(\mathrm{X}=\mathrm{B}, \mathrm{C}, \text { or } \mathrm{D})
$$

$\mathrm{A}+\mathrm{B} \rightleftarrows \mathrm{AB}$

$\mathrm{A}+\mathrm{C} \rightleftarrows \mathrm{AC}$

$\mathrm{A}+\mathrm{D} \rightleftarrows \mathrm{AD}$
(a) Which reaction has the largest equilibrium constant?
(b) Which reaction has the smallest equilibrium constant?

E15.23 The equilibrium constant $\left(K_{\mathrm{c}}\right)$ for the reaction

$$
2 \mathrm{HCl}(g) \rightleftarrows \mathrm{H}_{2}(g)+\mathrm{Cl}_{2}(g)
$$

is $4.17 \times 10^{-34}$ at $25^{\circ} \mathrm{C}$. What is the equilibrium constant for the reaction

$$
\mathrm{H}_{2}(g)+\mathrm{Cl}_{2}(g) \rightleftarrows 2 \mathrm{HCl}(g)
$$

at the same temperature?
15.24 What is $K_{P}$ at $1273^{\circ} \mathrm{C}$ for the reaction

$$
2 \mathrm{CO}(g)+\mathrm{O}_{2}(g) \rightleftarrows 2 \mathrm{CO}_{2}(g)
$$

if $K_{\mathrm{c}}$ is $2.24 \times 10^{22}$ at the same temperature?
E15.25 The equilibrium constant $K_{P}$ for the reaction

$$
2 \mathrm{SO}_{3}(g) \rightleftarrows 2 \mathrm{SO}_{2}(g)+\mathrm{O}_{2}(g)
$$

is $1.8 \times 10^{-5}$ at $350^{\circ} \mathrm{C}$. What is $K_{\mathrm{c}}$ for this reaction?
E 15.26 Consider the reaction

$$
\mathrm{N}_{2}(g)+\mathrm{O}_{2}(g) \rightleftarrows 2 \mathrm{NO}(g)
$$

If the equilibrium partial pressures of $\mathrm{N}_{2}, \mathrm{O}_{2}$, and NO are 0.15 , 0.33 , and 0.050 atm , respectively, at $2200^{\circ} \mathrm{C}$, what is $K_{P}$ ?

H15.27 A reaction vessel contains $\mathrm{NH}_{3}, \mathrm{~N}_{2}$, and $\mathrm{H}_{2}$ at equilibrium at a certain temperature. The equilibrium concentrations are $\left[\mathrm{NH}_{3}\right]=0.25 \mathrm{M},\left[\mathrm{N}_{2}\right]=0.11 \mathrm{M}$, and $\left[\mathrm{H}_{2}\right]=1.91 \mathrm{M}$. Calculate the equilibrium constant $K_{\mathrm{c}}$ for the synthesis of ammonia if the reaction is represented as
(a) $\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \rightleftarrows 2 \mathrm{NH}_{3}(g)$
(b) $\frac{1}{2} \mathrm{~N}_{2}(g)+\frac{3}{2} \mathrm{H}_{2}(g) \rightleftarrows \mathrm{NH}_{3}(g)$
$\pm$ 15.28 The equilibrium constant $K_{\mathrm{c}}$ for the reaction

$$
\mathrm{I}_{2}(\mathrm{~g}) \rightleftarrows 2 \mathrm{I}(g)
$$

is $3.8 \times 10^{-5}$ at $727^{\circ} \mathrm{C}$. Calculate $K_{\mathrm{c}}$ and $K_{P}$ for the equilibrium

$$
2 \mathrm{I}(\mathrm{~g}) \rightleftarrows \mathrm{I}_{2}(\mathrm{~g})
$$

at the same temperature.
15.29 At equilibrium, the pressure of the reacting mixture

$$
\mathrm{CaCO}_{3}(s) \rightleftarrows \mathrm{CaO}(s)+\mathrm{CO}_{2}(g)
$$

is 0.105 atm at $350^{\circ} \mathrm{C}$. Calculate $K_{P}$ and $K_{\mathrm{c}}$ for this reaction.
EI 15.30 The equilibrium constant $K_{P}$ for the reaction

$$
\mathrm{PCl}_{5}(g) \rightleftarrows \mathrm{PCl}_{3}(g)+\mathrm{Cl}_{2}(g)
$$

is 1.05 at $250^{\circ} \mathrm{C}$. The reaction starts with a mixture of $\mathrm{PCl}_{5}, \mathrm{PCl}_{3}$, and $\mathrm{Cl}_{2}$ at pressures of $0.177,0.223$, and 0.111 atm , respectively, at $250^{\circ} \mathrm{C}$. When the mixture comes to equilibrium at that temperature, which pressures will have decreased and which will have increased? Explain why.

E15.31 Ammonium carbamate $\left(\mathrm{NH}_{4} \mathrm{CO}_{2} \mathrm{NH}_{2}\right)$ decomposes as follows:

$$
\mathrm{NH}_{4} \mathrm{CO}_{2} \mathrm{NH}_{2}(s) \rightleftarrows 2 \mathrm{NH}_{3}(g)+\mathrm{CO}_{2}(g)
$$

Starting with only the solid, it is found that when the system reaches equilibrium at $40^{\circ} \mathrm{C}$, the total gas pressure $\left(\mathrm{NH}_{3}\right.$ and $\left.\mathrm{CO}_{2}\right)$ is 0.363 atm . Calculate the equilibrium constant $K_{P}$.

G 15.32 Pure phosgene gas $\left(\mathrm{COCl}_{2}\right), 3.00 \times 10^{-2} \mathrm{~mol}$, was placed in a $1.50-\mathrm{L}$ container. It was heated to 800 K , and at equilibrium the pressure of CO was found to be 0.497 atm . Calculate the equilibrium constant $K_{P}$ for the reaction

$$
\mathrm{CO}(g)+\mathrm{Cl}_{2}(g) \rightleftarrows \mathrm{COCl}_{2}(g)
$$

G15.33 Consider the equilibrium

$$
2 \mathrm{NOBr}(g) \rightleftarrows 2 \mathrm{NO}(g)+\mathrm{Br}_{2}(g)
$$

If nitrosyl bromide ( NOBr ) is 34 percent dissociated at $25^{\circ} \mathrm{C}$ and the total pressure is 0.25 atm , calculate $K_{P}$ and $K_{\mathrm{c}}$ for the dissociation at this temperature.
15.34 The following equilibrium constants have been determined for hydrosulfuric acid at $25^{\circ} \mathrm{C}$ :

$$
\begin{aligned}
\mathrm{H}_{2} \mathrm{~S}(a q) & \rightleftarrows \mathrm{H}^{+}(a q)+\mathrm{HS}^{-}(a q)
\end{aligned} \quad \begin{aligned}
& K_{\mathrm{c}}^{\prime}=9.5 \times 10^{-8} \\
& \mathrm{HS}^{-}(a q)
\end{aligned} \mathrm{H}^{+}(a q)+\mathrm{S}^{2-}(a q) \quad 10 \times 10^{-19}=1.0 \times 1
$$

Calculate the equilibrium constant for the following reaction at the same temperature:

$$
\mathrm{H}_{2} \mathrm{~S}(a q) \rightleftarrows 2 \mathrm{H}^{+}(a q)+\mathrm{S}^{2-}(a q)
$$

15.35 The following equilibrium constants have been determined for oxalic acid at $25^{\circ} \mathrm{C}$ :

$$
\begin{array}{ll}
\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}(a q) \rightleftarrows \mathrm{H}^{+}(a q)+\mathrm{HC}_{2} \mathrm{O}_{4}^{-}(a q) & K_{\mathrm{c}}^{\prime}=6.5 \times 10^{-2} \\
\mathrm{HC}_{2} \mathrm{O}_{4}^{-}(a q) \rightleftarrows \mathrm{H}^{+}(a q)+\mathrm{C}_{2} \mathrm{O}_{4}^{2-}(a q) & K_{\mathrm{c}}^{\prime \prime}=6.1 \times 10^{-5}
\end{array}
$$

Calculate the equilibrium constant for the following reaction at the same temperature:

$$
\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}(a q) \rightleftarrows 2 \mathrm{H}^{+}(a q)+\mathrm{C}_{2} \mathrm{O}_{4}^{2-}(a q)
$$

E15.36 The following equilibrium constants were determined at 1123 K :

$$
\begin{aligned}
\mathrm{C}(s)+\mathrm{CO}_{2}(g) \rightleftarrows 2 \mathrm{CO}(g) & K_{P}^{\prime}=1.3 \times 10^{14} \\
\mathrm{CO}(g)+\mathrm{Cl}_{2}(g) \rightleftarrows \mathrm{COCl}_{2}(g) & K_{P}^{\prime \prime}=6.0 \times 10^{-3}
\end{aligned}
$$

Write the equilibrium constant expression $K_{P}$, and calculate the equilibrium constant at 1123 K for

$$
\mathrm{C}(s)+\mathrm{CO}_{2}(g)+2 \mathrm{Cl}_{2}(g) \rightleftarrows 2 \mathrm{COCl}_{2}(g)
$$

15.37 At a certain temperature, the following reactions have the constants shown:

$$
\begin{aligned}
\mathrm{S}(s)+\mathrm{O}_{2}(g) & \rightleftarrows \mathrm{SO}_{2}(g) \\
2 \mathrm{~S}(s)+3 \mathrm{O}_{2}(g) & K_{\mathrm{c}}^{\prime}=4.2 \times 10^{52} \\
2 \mathrm{SO}_{3}(g) & K_{\mathrm{c}}^{\prime \prime}=9.8 \times 10^{128}
\end{aligned}
$$

Calculate the equilibrium constant $K_{\mathrm{c}}$ for the following reaction at that temperature:

$$
2 \mathrm{SO}_{2}(g)+\mathrm{O}_{2}(g) \rightleftarrows 2 \mathrm{SO}_{3}(g)
$$

## Section 15.4: Using Equilibrium Expressions to Solve Problems

## Review Questions

15.38 Outline the steps for calculating the concentrations of reacting species in an equilibrium reaction.

## Problems

15.39 The equilibrium constant $K_{P}$ for the reaction

$$
2 \mathrm{SO}_{2}(g)+\mathrm{O}_{2}(g) \rightleftarrows 2 \mathrm{SO}_{3}(g)
$$

is $5.60 \times 10^{4}$ at $350^{\circ} \mathrm{C}$. The initial pressures of $\mathrm{SO}_{2}, \mathrm{O}_{2}$, and $\mathrm{SO}_{3}$ in a mixture are $0.350,0.762$, and 0 atm , respectively, at $350^{\circ} \mathrm{C}$. When the mixture reaches equilibrium, is the total pressure less than or greater than the sum of the initial pressures?

EI 15.40 For the synthesis of ammonia

$$
\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \rightleftarrows 2 \mathrm{NH}_{3}(g)
$$

the equilibrium constant $K_{\mathrm{c}}$ at $375^{\circ} \mathrm{C}$ is 1.2. Starting with $\left[\mathrm{H}_{2}\right]_{0}=$ $0.76 \mathrm{M},\left[\mathrm{N}_{2}\right]_{0}=0.60 \mathrm{M}$, and $\left[\mathrm{NH}_{3}\right]_{0}=0.48 \mathrm{M}$, which gases will
have increased in concentration and which will have decreased in concentration when the mixture comes to equilibrium?

G15.41 For the reaction

$$
\mathrm{H}_{2}(g)+\mathrm{CO}_{2}(g) \rightleftarrows \mathrm{H}_{2} \mathrm{O}(g)+\mathrm{CO}(g)
$$

at $700^{\circ} \mathrm{C}, K_{\mathrm{c}}=0.534$. Calculate the number of moles of $\mathrm{H}_{2}$ that are present at equilibrium if a mixture of 0.300 mole of CO and 0.300 mole of $\mathrm{H}_{2} \mathrm{O}$ is heated to $700^{\circ} \mathrm{C}$ in a $10.0-\mathrm{L}$ container.

E15.42 At 1000 K , a sample of pure $\mathrm{NO}_{2}$ gas decomposes:

$$
2 \mathrm{NO}_{2}(g) \rightleftarrows 2 \mathrm{NO}(g)+\mathrm{O}_{2}(g)
$$

The equilibrium constant $K_{P}$ is 158 . Analysis shows that the partial pressure of $\mathrm{O}_{2}$ is 0.25 atm at equilibrium. Calculate the pressure of NO and $\mathrm{NO}_{2}$ in the mixture.

G15.43 The equilibrium constant $K_{\mathrm{c}}$ for the reaction

$$
\mathrm{H}_{2}(g)+\mathrm{Br}_{2}(g) \rightleftarrows 2 \mathrm{HBr}(g)
$$

is $2.18 \times 10^{6}$ at $730^{\circ} \mathrm{C}$. Starting with 3.20 moles of HBr in a 12.0-L reaction vessel, calculate the concentrations of $\mathrm{H}_{2}, \mathrm{Br}_{2}$, and HBr at equilibrium.

E 15.44 The dissociation of molecular iodine into iodine atoms is represented as

$$
\mathrm{I}_{2}(\mathrm{~g}) \rightleftarrows 2 \mathrm{I}(g)
$$

At 1000 K , the equilibrium constant $K_{\mathrm{c}}$ for the reaction is $3.80 \times$ $10^{-5}$. Suppose you start with 0.0456 mole of $\mathrm{I}_{2}$ in a 2.30 -L flask at 1000 K . What are the concentrations of the gases at equilibrium?

E 15.45 The equilibrium constant $K_{\mathrm{c}}$ for the decomposition of phosgene $\left(\mathrm{COCl}_{2}\right)$ is $4.63 \times 10^{-3}$ at $527^{\circ} \mathrm{C}$ :

$$
\mathrm{COCl}_{2}(g) \rightleftarrows \mathrm{CO}(g)+\mathrm{Cl}_{2}(g)
$$

Calculate the equilibrium partial pressures of all the components, starting with pure phosgene at 0.760 atm .
$\leftrightarrows$ 15.46 Consider the following equilibrium process at $686^{\circ} \mathrm{C}$ :

$$
\mathrm{CO}_{2}(g)+\mathrm{H}_{2}(g) \rightleftarrows \mathrm{CO}(g)+\mathrm{H}_{2} \mathrm{O}(g)
$$

The equilibrium concentrations of the reacting species are $[\mathrm{CO}]=0.050 \mathrm{M},\left[\mathrm{H}_{2}\right]=0.045 \mathrm{M},\left[\mathrm{CO}_{2}\right]=0.086 \mathrm{M}$, and $\left[\mathrm{H}_{2} \mathrm{O}\right]=0.040 M$. (a) Calculate $K_{\mathrm{c}}$ for the reaction at $686^{\circ} \mathrm{C}$. (b) If we add $\mathrm{CO}_{2}$ to increase its concentration to $0.50 \mathrm{~mol} / \mathrm{L}$, what will the concentrations of all the gases be when equilibrium is reestablished?

E15.47 Consider the heterogeneous equilibrium process:

$$
\mathrm{C}(s)+\mathrm{CO}_{2}(g) \rightleftarrows 2 \mathrm{CO}(g)
$$

At $700^{\circ} \mathrm{C}$, the total pressure of the system is found to be 4.50 atm . If the equilibrium constant $K_{P}$ is 1.52 , calculate the equilibrium partial pressures of $\mathrm{CO}_{2}$ and CO .
$\boldsymbol{\Psi}$ 15.48 The equilibrium constant $K_{\mathrm{c}}$ for the reaction

$$
\mathrm{H}_{2}(g)+\mathrm{CO}_{2}(g) \rightleftarrows \mathrm{H}_{2} \mathrm{O}(g)+\mathrm{CO}(g)
$$

is 4.2 at $1650^{\circ} \mathrm{C}$. Initially $0.80 \mathrm{~mol} \mathrm{H}_{2}$ and $0.80 \mathrm{~mol} \mathrm{CO}_{2}$ are injected into a $5.0-\mathrm{L}$ flask. Calculate the concentration of each species at equilibrium.
15.49 The aqueous reaction

$$
\text { L-glutamate }+ \text { pyruvate } \rightleftarrows \alpha \text {-ketoglutarate }+ \text { L-alanine }
$$ is catalyzed by the enzyme L-glutamate-pyruvate aminotransferase. At 300 K , the equilibrium constant for the reaction is 1.11. Predict whether the forward reaction will occur if the concentrations of the reactants and products are [L-glutamate] $=3.0 \times 10^{-5} \mathrm{M}$, [pyruvate $]=3.3 \times 10^{-4} \mathrm{M},[\alpha$-ketoglutarate $]=1.6 \times 10^{-2} \mathrm{M}$, and [L-alanine] $=6.25 \times 10^{-3} \mathrm{M}$.

## Section 15.5: Factors That Affect Chemical Equilibrium

## Visualizing Chemistry

Figure 15.10 and Figure 15.11
Solid calcium carbonate decomposes to form solid calcium oxide and carbon dioxide gas.

$$
\mathrm{CaCO}_{3}(s) \rightleftarrows \mathrm{CaO}(s)+\mathrm{CO}_{2}(g) \quad \Delta H^{\circ}=177.8 \mathrm{~kJ} / \mathrm{mol}
$$

Consider an equilibrium mixture of calcium carbonate and its decomposition products in a container.

VC 15.1 Which of the following changes will result in the formation of more $\mathrm{CaO}(s)$ ?
a) Addition of more $\mathrm{CaCO}_{3}(s)$
b) Addition of more $\mathrm{CO}_{2}(\mathrm{~g})$
c) Removal of some of the $\mathrm{CO}_{2}(g)$

VC 15.2 Which of the following changes will result in the formation of more $\mathrm{CaCO}_{3}(s)$ ?
a) Addition of more $\mathrm{CaO}(s)$
b) Addition of more $\mathrm{CO}_{2}(\mathrm{~g})$
c) Removal of some of the $\mathrm{CaCO}_{3}(s)$

VC 15.3 Which of the following changes will not cause the equilibrium to shift in either direction? (Select all that apply.)
a) Removal of some of the $\mathrm{CaCO}_{3}(s)$
b) Removal of some of the $\mathrm{CO}_{2}(g)$
c) Addition of more $\mathrm{CaO}(s)$

VC 15.4 Which of the following will be affected by a change in the system's temperature? (Select all that apply.)
a) The amount of $\mathrm{CaCO}_{3}(s)$
b) The amount of $\mathrm{CaO}(s)$
c) The amount of $\mathrm{CO}_{2}(g)$

A sample of calcium carbonate is in equilibrium with its decomposition products in a closed system: $\mathrm{CaCO}_{3}(s) \rightleftarrows \mathrm{CaO}(s)+\mathrm{CO}_{2}(g)$.
VC 15.5 If the volume of the system is increased at constant temperature, relative to the original equilibrium mixture, which of the following will be true when equilibrium is reestablished? (Select all that apply.)
a) There will be a higher concentration of $\mathrm{CO}_{2}(g)$.
b) There will be a lower concentration of $\mathrm{CO}_{2}(g)$.
c) There will be more $\mathrm{CO}_{2}(g)$.

VC 15.6 If the volume of the system is decreased at constant temperature, relative to the original equilibrium mixture, which of the following will be true when equilibrium is reestablished? (Select all that apply.)
a) There will be more $\mathrm{CaCO}_{3}(s)$.
b) There will be more $\mathrm{CaO}(s)$.
c) There will be more $\mathrm{CO}_{2}(g)$.

A sample of gaseous hydrogen iodide is in equilibrium with its decomposition products in a closed system: $2 \mathrm{HI}(g) \rightleftarrows \mathrm{H}_{2}(g)+\mathrm{I}_{2}(g)$.

VC 15.7 If the volume of the system is increased at constant temperature, relative to the original equilibrium mixture, which of the following will be true when equilibrium is reestablished?
a) The concentration of HI will increase and the concentrations of $\mathrm{H}_{2}$ and $\mathrm{I}_{2}$ will decrease.
b) The concentration of all three species will be lower.
c) The concentration of all three species will be unchanged.

VC 15.8 If the volume of the system is decreased at constant temperature, relative to the original equilibrium mixture, which of the following will be true when equilibrium is reestablished?
a) There will be more HI.
b) There will be less HI.
c) The amount of HI will be unchanged.

## Review Questions

15.50 Explain Le Châtelier's principle. How does this principle enable us to maximize the yields of desirable reactions and minimize the effect of undesirable ones?
15.51 Use Le Châtelier's principle to explain why the equilibrium vapor pressure of a liquid increases with increasing temperature.
15.52 List four factors that can shift the position of an equilibrium. Only one of these factors can alter the value of the equilibrium constant. Which one is it?
15.53 Does the addition of a catalyst have any effects on the position of an equilibrium?

## Problems

15.54 Consider the following equilibrium system involving $\mathrm{SO}_{2}, \mathrm{Cl}_{2}$, and $\mathrm{SO}_{2} \mathrm{Cl}_{2}$ (sulfuryl dichloride):

$$
\mathrm{SO}_{2}(g)+\mathrm{Cl}_{2}(g) \rightleftarrows \mathrm{SO}_{2} \mathrm{Cl}_{2}(g)
$$

Predict how the equilibrium position would change if (a) $\mathrm{Cl}_{2}$ gas were added to the system, (b) $\mathrm{SO}_{2} \mathrm{Cl}_{2}$ were removed from the system, (c) $\mathrm{SO}_{2}$ were removed from the system. The temperature remains constant in each case.
$\leftrightarrows$ 15.55 Heating solid sodium bicarbonate in a closed vessel establishes the following equilibrium:

$$
2 \mathrm{NaHCO}_{3}(s) \rightleftarrows \mathrm{Na}_{2} \mathrm{CO}_{3}(s)+\mathrm{H}_{2} \mathrm{O}(g)+\mathrm{CO}_{2}(g)
$$

What would happen to the equilibrium position if (a) some of the $\mathrm{CO}_{2}$ were removed from the system, (b) some solid $\mathrm{Na}_{2} \mathrm{CO}_{3}$ were added to the system, (c) some of the solid $\mathrm{NaHCO}_{3}$ were removed from the system? The temperature remains constant.

EI 15.56 Consider the following equilibrium systems:
(a) $\mathrm{A} \rightleftarrows 2 \mathrm{~B}$
$\Delta H^{\circ}=20.0 \mathrm{~kJ} / \mathrm{mol}$
(b) $\mathrm{A}+\mathrm{B} \rightleftarrows \mathrm{C}$
$\Delta H^{\circ}=-5.4 \mathrm{~kJ} / \mathrm{mol}$
(c) $\mathrm{A} \rightleftarrows \mathrm{B}$
$\Delta H^{\circ}=0.0 \mathrm{~kJ} / \mathrm{mol}$

Predict the change in the equilibrium constant $K_{\mathrm{c}}$ that would occur in each case if the temperature of the reacting system were raised.
15.57 What effect does an increase in pressure have on each of the following systems at equilibrium? The temperature is kept constant, and, in each case, the reactants are in a cylinder fitted with a movable piston.
(a) $\mathrm{A}(s) \rightleftarrows 2 \mathrm{~B}(s)$
(b) $2 \mathrm{~A}(l) \rightleftarrows \mathrm{B}(l)$
(c) $\mathrm{A}(s) \rightleftarrows \mathrm{B}(g)$
(d) $\mathrm{A}(g) \rightleftarrows \mathrm{B}(g)$
(e) $\mathrm{A}(g) \rightleftarrows 2 \mathrm{~B}(g)$
15.58 Consider the equilibrium

$$
2 \mathrm{I}(g) \rightleftarrows \mathrm{I}_{2}(g)
$$

What would be the effect on the position of equilibrium of (a) increasing the total pressure on the system by decreasing its
volume, (b) adding $\mathrm{I}_{2}$ to the reaction mixture, and (c) decreasing the temperature?
15.59 Consider the following equilibrium process:

$$
\mathrm{PCl}_{5}(g) \rightleftarrows \mathrm{PCl}_{3}(g)+\mathrm{Cl}_{2}(g) \quad \Delta H^{\circ}=92.5 \mathrm{~kJ} / \mathrm{mol}
$$

Predict the direction of the shift in equilibrium when (a) the temperature is raised, (b) more chlorine gas is added to the reaction mixture, (c) some $\mathrm{PCl}_{3}$ is removed from the mixture, (d) the pressure on the gases is increased, (e) a catalyst is added to the reaction mixture.

H15.60 Consider the reaction

$$
2 \mathrm{SO}_{2}(g)+\mathrm{O}_{2}(g) \rightleftarrows 2 \mathrm{SO}_{3}(g) \quad \Delta H^{\circ}=-198.2 \mathrm{~kJ} / \mathrm{mol}
$$

Comment on the changes in the concentrations of $\mathrm{SO}_{2}, \mathrm{O}_{2}$, and $\mathrm{SO}_{3}$ at equilibrium if we were to (a) increase the temperature,
(b) increase the pressure, (c) increase $\mathrm{SO}_{2}$, (d) add a catalyst,
(e) add helium at constant volume.
15.61 In the uncatalyzed reaction

$$
\mathrm{N}_{2} \mathrm{O}_{4}(g) \rightleftarrows 2 \mathrm{NO}_{2}(g)
$$

the pressure of the gases at equilibrium are $P_{\mathrm{N}_{2} \mathrm{O}_{4}}=0.377 \mathrm{~atm}$ and $P_{\mathrm{NO}_{2}}=1.56 \mathrm{~atm}$ at $100^{\circ} \mathrm{C}$. What would happen to these pressures if a catalyst were added to the mixture?
15.62 Consider the gas-phase reaction

$$
2 \mathrm{CO}(g)+\mathrm{O}_{2}(g) \rightleftarrows 2 \mathrm{CO}_{2}(g)
$$

Predict the shift in the equilibrium position when helium gas is added to the equilibrium mixture (a) at constant pressure and (b) at constant volume.
115.63 Consider the following equilibrium reaction in a closed container:

$$
\mathrm{CaCO}_{3}(s) \rightleftarrows \mathrm{CaO}(s)+\mathrm{CO}_{2}(g)
$$

What will happen if (a) the volume is increased, (b) some CaO is added to the mixture, (c) some $\mathrm{CaCO}_{3}$ is removed, (d) some $\mathrm{CO}_{2}$ is added to the mixture, (e) a few drops of an NaOH solution are added to the mixture, (f) a few drops of an HCl solution are added to the mixture (ignore the reaction between $\mathrm{CO}_{2}$ and water), ( g ) temperature is increased?
15.64 The following diagrams show the reaction $\mathrm{A}+\mathrm{B} \rightleftarrows \mathrm{AB}$ at two different temperatures. Is the forward reaction endothermic or exothermic?

15.65 The following diagrams show an equilibrium mixture of $\mathrm{O}_{2}$ and $\mathrm{O}_{3}$ at temperatures $T_{1}$ and $T_{2}\left(T_{2}>T_{1}\right)$. (a) Write an equilibrium equation showing the forward reaction to be exothermic.
(b) Predict how the number of $\mathrm{O}_{2}$ and $\mathrm{O}_{3}$ molecules would change if the volume were decreased at constant temperature.

$T_{1}$
,
$T_{2}$

## Additional Problems

15.66 Consider the statement: "The equilibrium constant of a reacting mixture of solid $\mathrm{NH}_{4} \mathrm{Cl}$ and gaseous $\mathrm{NH}_{3}$ and HCl is 0.316 ." List three important pieces of information that are missing from this statement.

E15.67 Pure nitrosyl chloride ( NOCl ) gas was heated to $240^{\circ} \mathrm{C}$ in a $1.00-\mathrm{L}$ container. At equilibrium, the total pressure was 1.00 atm and the NOCl pressure was 0.64 atm .

$$
2 \mathrm{NOCl}(g) \rightleftarrows 2 \mathrm{NO}(g)+\mathrm{Cl}_{2}(g)
$$

(a) Calculate the partial pressures of NO and $\mathrm{Cl}_{2}$ in the system.
(b) Calculate the equilibrium constant $K_{P}$.

E15.68 The equilibrium constant $\left(K_{P}\right)$ for the formation of the air pollutant nitric oxide (NO) in an automobile engine at $530^{\circ} \mathrm{C}$ is $2.9 \times 10^{-11}$.

$$
\mathrm{N}_{2}(g)+\mathrm{O}_{2}(g) \rightleftarrows 2 \mathrm{NO}(g)
$$

(a) Calculate the partial pressure of NO under these conditions if the partial pressures of nitrogen and oxygen are 3.0 and 0.012 atm , respectively. (b) Repeat the calculation for atmospheric conditions where the partial pressures of nitrogen and oxygen are 0.78 and 0.21 atm and the temperature is $25^{\circ} \mathrm{C}$. (The $K_{P}$ for the reaction is $4.0 \times 10^{-31}$ at this temperature.) (c) Is the formation of NO endothermic or exothermic? (d) What natural phenomenon promotes the formation of NO? Why?
15.69 Baking soda (sodium bicarbonate) undergoes thermal decomposition as follows:

$$
2 \mathrm{NaHCO}_{3}(s) \rightleftarrows \mathrm{Na}_{2} \mathrm{CO}_{3}(s)+\mathrm{CO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(g)
$$

Would we obtain more $\mathrm{CO}_{2}$ and $\mathrm{H}_{2} \mathrm{O}$ by adding extra baking soda to the reaction mixture in (a) a closed vessel or (b) an open vessel?

E15.70 Consider the following reaction at equilibrium:

$$
\mathrm{A}(g) \rightleftarrows 2 \mathrm{~B}(g)
$$

From the data shown here, calculate the equilibrium constant (both $K_{P}$ and $K_{\mathrm{c}}$ ) at each temperature. Is the reaction endothermic or exothermic?

| Temperature $\left({ }^{\circ} \mathbf{C}\right)$ | $[\mathbf{A}](\boldsymbol{M})$ | $[\mathbf{B}](\boldsymbol{M})$ |
| :---: | :---: | :---: |
| 200 | 0.0125 | 0.843 |
| 300 | 0.171 | 0.764 |
| 400 | 0.250 | 0.724 |

E 15.71 The equilibrium constant $K_{P}$ for the reaction

$$
2 \mathrm{H}_{2} \mathrm{O}(\mathrm{~g}) \rightleftarrows 2 \mathrm{H}_{2}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g})
$$

is $2 \times 10^{-42}$ at $25^{\circ} \mathrm{C}$. (a) What is $K_{\mathrm{c}}$ for the reaction at the same temperature? (b) The very small value of $K_{P}$ (and $K_{\mathrm{c}}$ ) indicates that the reaction overwhelmingly favors the formation of water molecules. Explain why, despite this fact, a mixture of hydrogen and oxygen gases can be kept at room temperature without any change.
15.72 Consider the following reacting system:

$$
2 \mathrm{NO}(g)+\mathrm{Cl}_{2}(g) \rightleftarrows 2 \mathrm{NOCl}(g)
$$

What combination of temperature and pressure would maximize the yield of nitrosyl chloride $(\mathrm{NOCl})$ ? [Hint: $\Delta H_{\mathrm{f}}^{\circ}(\mathrm{NOCl})=$ $51.7 \mathrm{~kJ} / \mathrm{mol}$.]
$\mathbb{G 1 5 . 7 3}$ At a certain temperature and a total pressure of 1.2 atm , the partial pressures of an equilibrium mixture

$$
2 \mathrm{~A}(g) \rightleftarrows \mathrm{B}(g)
$$

are $P_{\mathrm{A}}=0.60 \mathrm{~atm}$ and $P_{\mathrm{B}}=0.60 \mathrm{~atm}$. (a) Calculate the $K_{P}$ for the reaction at this temperature. (b) If the total pressure were increased to 1.5 atm , what would be the partial pressures of A and B at equilibrium?
$\mathbb{Y}$ 15.74 The decomposition of ammonium hydrogen sulfide

$$
\mathrm{NH}_{4} \mathrm{HS}(s) \rightleftarrows \mathrm{NH}_{3}(g)+\mathrm{H}_{2} \mathrm{~S}(g)
$$

is an endothermic process. A $6.1589-\mathrm{g}$ sample of the solid is placed in an evacuated $4.000-\mathrm{L}$ vessel at exactly $24^{\circ} \mathrm{C}$. After equilibrium has been established, the total pressure inside is 0.709 atm . Some solid $\mathrm{NH}_{4} \mathrm{HS}$ remains in the vessel. (a) What is the $K_{P}$ for the reaction? (b) What percentage of the solid has decomposed? (c) If the volume of the vessel were doubled at constant temperature, what would happen to the amount of solid in the vessel?
15.75 Consider the reaction

$$
2 \mathrm{NO}(g)+\mathrm{O}_{2}(g) \rightleftarrows 2 \mathrm{NO}_{2}(g)
$$

At $430^{\circ} \mathrm{C}$, an equilibrium mixture consists of 0.020 mole of $\mathrm{O}_{2}$, 0.040 mole of NO , and 0.96 mole of $\mathrm{NO}_{2}$. Calculate $K_{P}$ for the reaction, given that the total pressure is 0.20 atm .
15.76 When heated, ammonium carbamate decomposes as follows:

$$
\mathrm{NH}_{4} \mathrm{CO}_{2} \mathrm{NH}_{2}(s) \rightleftarrows 2 \mathrm{NH}_{3}(g)+\mathrm{CO}_{2}(g)
$$

At a certain temperature, the equilibrium pressure of the system is 0.318 atm . Calculate $K_{P}$ for the reaction.
15.77 A mixture of 0.47 mole of $\mathrm{H}_{2}$ and 3.59 moles of HCl is heated to $2800^{\circ} \mathrm{C}$. Calculate the equilibrium partial pressures of $\mathrm{H}_{2}, \mathrm{Cl}_{2}$, and HCl if the total pressure is 2.00 atm . For the reaction

$$
\mathrm{H}_{2}(g)+\mathrm{Cl}_{2}(g) \rightleftarrows 2 \mathrm{HCl}(g)
$$

$K_{P}$ is 193 at $2800^{\circ} \mathrm{C}$.
 follows:

$$
\mathrm{I}_{2}(\mathrm{~g}) \rightleftarrows 2 \mathrm{I}(\mathrm{~g})
$$

In one experiment, a chemist finds that when 0.054 mole of $\mathrm{I}_{2}$ was placed in a flask of volume 0.48 L at 587 K , the degree of dissociation (that is, the fraction of $\mathrm{I}_{2}$ dissociated) was 0.0252 . Calculate $K_{\mathrm{c}}$ and $K_{P}$ for the reaction at this temperature.
15.79 One mole of $\mathrm{N}_{2}$ and three moles of $\mathrm{H}_{2}$ are placed in a flask at $375^{\circ} \mathrm{C}$. Calculate the total pressure of the system at equilibrium if the mole fraction of $\mathrm{NH}_{3}$ is 0.21 . The $K_{P}$ for the reaction is $4.31 \times 10^{-4}$.

E15.80 At $1130^{\circ} \mathrm{C}$, the equilibrium constant $\left(K_{c}\right)$ for the reaction

$$
\begin{aligned}
& \qquad 2 \mathrm{H}_{2} \mathrm{~S}(g) \rightleftarrows 2 \mathrm{H}_{2}(g)+\mathrm{S}_{2}(g) \\
& \text { is } 2.25 \times 10^{-4} . \text { If }\left[\mathrm{H}_{2} \mathrm{~S}\right]=4.84 \times 10^{-3} M \text { and }\left[\mathrm{H}_{2}\right]=1.50 \times \\
& 10^{-3} M \text {, calculate }\left[\mathrm{S}_{2}\right]
\end{aligned}
$$

$\boldsymbol{\oiiint}$ 15.81 A quantity of 6.75 g of $\mathrm{SO}_{2} \mathrm{Cl}_{2}$ was placed in a 2.00-L flask. At 648 K , there is 0.0345 mole of $\mathrm{SO}_{2}$ present. Calculate $K_{\mathrm{c}}$ for the reaction

$$
\mathrm{SO}_{2} \mathrm{Cl}_{2}(g) \rightleftarrows \mathrm{SO}_{2}(g)+\mathrm{Cl}_{2}(g)
$$

EI 15.82 The following diagram represents a gas-phase equilibrium mixture for the reaction $\mathrm{AB} \rightleftarrows \mathrm{A}+\mathrm{B}$ at a certain temperature. Describe what would happen to the system after each of the following changes: (a) the temperature is decreased, (b) the volume is increased, (c) He atoms are added to the mixture at constant volume, (d) a catalyst is added to the mixture.

I 15.83 The formation of $\mathrm{SO}_{3}$ from $\mathrm{SO}_{2}$ and $\mathrm{O}_{2}$ is an intermediate step in the manufacture of sulfuric acid, and it is also responsible for the acid rain phenomenon. The equilibrium constant $K_{P}$ for the reaction

$$
2 \mathrm{SO}_{2}(g)+\mathrm{O}_{2}(g) \rightleftarrows 2 \mathrm{SO}_{3}(g)
$$

is 0.13 at $830^{\circ} \mathrm{C}$. In one experiment, $2.00 \mathrm{~mol} \mathrm{SO}_{2}$ and 2.00 mol $\mathrm{O}_{2}$ were initially present in a flask. What must the total pressure at equilibrium be to have an 80.0 percent yield of $\mathrm{SO}_{3}$ ?

E 15.84 Consider the dissociation of iodine:

$$
\mathrm{I}_{2}(g) \rightleftarrows 2 \mathrm{I}(g)
$$

A $1.00-\mathrm{g}$ sample of $\mathrm{I}_{2}$ is heated to $1200^{\circ} \mathrm{C}$ in a $500-\mathrm{mL}$ flask. At equilibrium, the total pressure is 1.51 atm . Calculate $K_{P}$ for the reaction at this temperature.

H15.85 Consider the following reaction at $1600^{\circ} \mathrm{C}$ :

$$
\operatorname{Br}_{2}(g) \rightleftarrows 2 \operatorname{Br}(g)
$$

When 1.05 moles of $\mathrm{Br}_{2}$ are put in a 0.980 -L flask, 1.20 percent of the $\mathrm{Br}_{2}$ undergoes dissociation. Calculate the equilibrium constant $K_{\mathrm{c}}$ for the reaction.
15.86 Eggshells are composed mostly of calcium carbonate $\left(\mathrm{CaCO}_{3}\right)$ formed by the reaction

$$
\mathrm{Ca}^{2+}(a q)+\mathrm{CO}_{3}^{2-}(a q) \rightleftarrows \mathrm{CaCO}_{3}(s)
$$

The carbonate ions are supplied by carbon dioxide produced as a result of metabolism. Explain why eggshells are thinner in the summer when the rate of panting by chickens is greater. Suggest a remedy for this situation.
15.87 The equilibrium constant $K_{P}$ for the following reaction is $4.31 \times$ $10^{-4}$ at $375^{\circ} \mathrm{C}$ :

$$
\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \rightleftarrows 2 \mathrm{NH}_{3}(g)
$$

In a certain experiment a student starts with 0.862 atm of $\mathrm{N}_{2}$ and 0.373 atm of $\mathrm{H}_{2}$ in a constant-volume vessel at $375^{\circ} \mathrm{C}$. Calculate the partial pressures of all species when equilibrium is reached.
\$15.88 A quantity of 0.20 mole of carbon dioxide was heated to a certain temperature with an excess of graphite in a closed container until the following equilibrium was reached:

$$
\mathrm{C}(s)+\mathrm{CO}_{2}(g) \rightleftarrows 2 \mathrm{CO}(g)
$$

Under these conditions, the average molar mass of the gases was $35 \mathrm{~g} / \mathrm{mol}$. (a) Calculate the mole fractions of CO and $\mathrm{CO}_{2}$. (b) What is $K_{P}$ if the total pressure is 11 atm ? (Hint: The average molar mass is the sum of the products of the mole fraction of each gas and its molar mass.)

E15.89 When dissolved in water, glucose (corn sugar) and fructose (fruit sugar) exist in equilibrium as follows:

$$
\text { fructose } \rightleftarrows \text { glucose }
$$

A chemist prepared a 0.244 M fructose solution at $25^{\circ} \mathrm{C}$. At equilibrium, it was found that its concentration had decreased to $0.113 M$. (a) Calculate the equilibrium constant for the reaction. (b) At equilibrium, what percentage of fructose was converted to glucose?
15.90 At room temperature, solid iodine is in equilibrium with its vapor through sublimation and deposition. Describe how you would use radioactive iodine, in either solid or vapor form, to show that there is a dynamic equilibrium between these two phases.
15.91 At $1024^{\circ} \mathrm{C}$, the pressure of oxygen gas from the decomposition of copper(II) oxide $(\mathrm{CuO})$ is 0.49 atm :

$$
4 \mathrm{CuO}(s) \rightleftarrows 2 \mathrm{Cu}_{2} \mathrm{O}(s)+\mathrm{O}_{2}(g)
$$

(a) What is $K_{P}$ for the reaction? (b) Calculate the fraction of CuO that will decompose if 0.16 mole of it is placed in a $2.0-\mathrm{L}$ flask at $1024^{\circ} \mathrm{C}$. (c) What would the fraction be if a 1.0 -mole sample of CuO were used? (d) What is the smallest amount of CuO (in moles) that would establish the equilibrium?
15.92 A mixture containing 3.9 moles of NO and 0.88 mole of $\mathrm{CO}_{2}$ was allowed to react in a flask at a certain temperature according to the equation

$$
\mathrm{NO}(g)+\mathrm{CO}_{2}(g) \rightleftarrows \mathrm{NO}_{2}(g)+\mathrm{CO}(g)
$$

At equilibrium, 0.11 mole of $\mathrm{CO}_{2}$ was present. Calculate the equilibrium constant $K_{\mathrm{c}}$ of this reaction.
15.93 The equilibrium constant $K_{\mathrm{c}}$ for the reaction

$$
\mathrm{H}_{2}(g)+\mathrm{I}_{2}(g) \rightleftarrows 2 \mathrm{HI}(g)
$$

is 54.3 at $430^{\circ} \mathrm{C}$. At the start of the reaction, there are 0.714 mole of $\mathrm{H}_{2}, 0.984$ mole of $\mathrm{I}_{2}$, and 0.886 mole of HI in a 2.40-L reaction chamber. Calculate the concentrations of the gases at equilibrium.

E15.94 When heated, a gaseous compound A dissociates as follows:

$$
\mathrm{A}(g) \rightleftarrows \mathrm{B}(g)+\mathrm{C}(g)
$$

In an experiment, $A$ was heated at a certain temperature until its equilibrium pressure reached $0.14 P$, where $P$ is the total pressure. Calculate the equilibrium constant $K_{P}$ of this reaction.

E15.95 When a gas was heated under atmospheric conditions, its color deepened. Heating above $150^{\circ} \mathrm{C}$ caused the color to fade, and at $550^{\circ} \mathrm{C}$ the color was barely detectable. However, at $550^{\circ} \mathrm{C}$, the color was partially restored by increasing the pressure of the system. Which of the following best fits the preceding description: (a) a mixture of hydrogen and bromine, (b) pure bromine, (c) a mixture of nitrogen dioxide and dinitrogen tetroxide. (Hint: Bromine has a reddish color, and nitrogen dioxide is a brown gas. The other gases are colorless.) Justify your choice.
15.96 Both $\mathrm{Mg}^{2+}$ and $\mathrm{Ca}^{2+}$ are important biological ions. One of their functions is to bind to the phosphate group of ATP molecules or amino acids of proteins. For Group 2A metals in general, the equilibrium constant for binding to the anions increases in the order $\mathrm{Ba}^{2+}<\mathrm{Sr}^{2+}<\mathrm{Ca}^{2+}<\mathrm{Mg}^{2+}$. What property of the Group 2A metal cations might account for this trend?
15.97 The equilibrium constant $K_{\mathrm{c}}$ for the following reaction is 1.2 at $375^{\circ} \mathrm{C}$.

$$
\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \rightleftarrows 2 \mathrm{NH}_{3}(g)
$$

(a) What is the value of $K_{P}$ for this reaction? (b) What is the value of the equilibrium constant $K_{\mathrm{c}}$ for $2 \mathrm{NH}_{3}(g) \rightleftarrows \mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g)$ ? (c) What is $K_{\text {c }}$ for $\frac{1}{2} \mathrm{~N}_{2}(g)+\frac{3}{2} \mathrm{H}_{2}(g) \rightleftarrows \mathrm{NH}_{3}(g)$ ? (d) What are the values of $K_{P}$ for the reactions described in parts (b) and (c)?
15.98 In this chapter we learned that a catalyst has no effect on the position of an equilibrium because it speeds up both the forward and reverse rates to the same extent. To test this statement, consider a situation in which an equilibrium of the type

$$
2 \mathrm{~A}(g) \rightleftarrows \mathrm{B}(g)
$$

is established inside a cylinder fitted with a weightless piston. The piston is attached by a string to the cover of a box containing a catalyst. When the piston moves upward (expanding against atmospheric pressure), the cover is lifted and the catalyst is exposed to the gases. When the piston moves downward, the box is closed. Assume that the catalyst speeds up the forward reaction $(2 \mathrm{~A} \longrightarrow \mathrm{~B})$ but does not affect the reverse process $(\mathrm{B} \longrightarrow 2 \mathrm{~A})$. Suppose the catalyst is suddenly exposed to the equilibrium system as shown on the next page. Describe what would happen
subsequently. How does this "thought experiment" convince you that no such catalyst can exist?

§15.99 A sealed glass bulb contains a mixture of $\mathrm{NO}_{2}$ and $\mathrm{N}_{2} \mathrm{O}_{4}$ gases. Describe what happens to the following properties of the gases when the bulb is heated from $20^{\circ} \mathrm{C}$ to $40^{\circ} \mathrm{C}$ : (a) color, (b) pressure, (c) average molar mass, (d) degree of dissociation (from $\mathrm{N}_{2} \mathrm{O}_{4}$ to $\mathrm{NO}_{2}$ ), (e) density. Assume that volume remains constant. (Hint: $\mathrm{NO}_{2}$ is a brown gas; $\mathrm{N}_{2} \mathrm{O}_{4}$ is colorless.)
15.100 At $20^{\circ} \mathrm{C}$, the vapor pressure of water is 0.0231 atm . Calculate $K_{P}$ and $K_{\mathrm{c}}$ for the process

$$
\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{H}_{2} \mathrm{O}(g)
$$

15.101 Industrially, sodium metal is obtained by electrolyzing molten sodium chloride. The reaction at the cathode is $\mathrm{Na}^{+}+e^{-} \longrightarrow \mathrm{Na}$. We might expect that potassium metal would also be prepared by electrolyzing molten potassium chloride. However, potassium metal is soluble in molten potassium chloride and therefore is hard to recover. Furthermore, potassium vaporizes readily at the operating temperature, creating hazardous conditions. Instead, potassium is prepared by the distillation of molten potassium chloride in the presence of sodium vapor at $892^{\circ} \mathrm{C}$ :

$$
\mathrm{Na}(g)+\mathrm{KCl}(l) \rightleftarrows \mathrm{NaCl}(l)+\mathrm{K}(g)
$$

In view of the fact that potassium is a stronger reducing agent than sodium, explain why this approach works. (The boiling points of sodium and potassium are $892^{\circ} \mathrm{C}$ and $770^{\circ} \mathrm{C}$, respectively.)

H15.102 In the gas phase, nitrogen dioxide is actually a mixture of nitrogen dioxide $\left(\mathrm{NO}_{2}\right)$ and dinitrogen tetroxide $\left(\mathrm{N}_{2} \mathrm{O}_{4}\right)$. If the density of such a mixture is $2.3 \mathrm{~g} / \mathrm{L}$ at $74^{\circ} \mathrm{C}$ and 1.3 atm , calculate the partial pressures of the gases and $K_{P}$ for the dissociation of $\mathrm{N}_{2} \mathrm{O}_{4}$.
15.103 A 2.50-mole sample of NOCl was initially in a 1.50-L reaction chamber at $400^{\circ} \mathrm{C}$. After equilibrium was established, it was found that 28.0 percent of the NOCl had dissociated:

$$
2 \mathrm{NOCl}(g) \rightleftarrows 2 \mathrm{NO}(g)+\mathrm{Cl}_{2}(g)
$$

Calculate the equilibrium constant $K_{\mathrm{c}}$ for the reaction.
15.104 About 75 percent of hydrogen for industrial use is produced by the steam-reforming process. This process is carried out in two stages called primary and secondary reforming. In the primary stage, a mixture of steam and methane at about 30 atm is heated over a nickel catalyst at $800^{\circ} \mathrm{C}$ to give hydrogen and carbon monoxide:

$$
\mathrm{CH}_{4}(g)+\mathrm{H}_{2} \mathrm{O}(g) \rightleftarrows \mathrm{CO}(g)+3 \mathrm{H}_{2}(g) \quad \Delta H^{\circ}=206 \mathrm{~kJ} / \mathrm{mol}
$$

The secondary stage is carried out at about $1000^{\circ} \mathrm{C}$, in the presence of air, to convert the remaining methane to hydrogen:

$$
\mathrm{CH}_{4}(g)+\frac{1}{2} \mathrm{O}_{2}(g) \rightleftarrows \mathrm{CO}(g)+2 \mathrm{H}_{2}(g) \quad \Delta H^{\circ}=35.7 \mathrm{~kJ} / \mathrm{mol}
$$

(a) What conditions of temperature and pressure would favor the formation of products in both the primary and secondary stages? (b) The equilibrium constant $K_{\mathrm{c}}$ for the primary stage is 18 at $800^{\circ} \mathrm{C}$. (i) Calculate $K_{P}$ for the reaction. (ii) If the partial pressures of methane and steam were both 15 atm at the start, what are the pressures of all the gases at equilibrium?
15.105 Photosynthesis can be represented by

$$
\begin{array}{r}
6 \mathrm{CO}_{2}(g)+6 \mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}(s)+6 \mathrm{O}_{2}(g) \\
\Delta H^{\circ}=2801 \mathrm{~kJ} / \mathrm{mol}
\end{array}
$$

Explain how the equilibrium would be affected by the following changes: (a) partial pressure of $\mathrm{CO}_{2}$ is increased, (b) $\mathrm{O}_{2}$ is removed from the mixture, (c) $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}$ (glucose) is removed from the mixture, (d) more water is added, (e) a catalyst is added, (f) temperature is decreased.
15.106 Consider the decomposition of ammonium chloride at a certain temperature:

$$
\mathrm{NH}_{4} \mathrm{Cl}(s) \rightleftarrows \mathrm{NH}_{3}(g)+\mathrm{HCl}(g)
$$

Calculate the equilibrium constant $K_{P}$ if the total pressure is 2.2 atm at that temperature.
15.107 Water is a very weak electrolyte that undergoes the following ionization (called autoionization):

$$
\mathrm{H}_{2} \mathrm{O}(l) \underset{k_{-1}}{\stackrel{k_{1}}{\rightleftarrows}} \mathrm{H}^{+}(a q)+\mathrm{OH}^{-}(a q)
$$

(a) If $k_{1}=2.4 \times 10^{-5} \mathrm{~s}^{-1}$ and $k_{-1}=1.3 \times 10^{11} / \mathrm{M} \cdot \mathrm{s}$, calculate the equilibrium constant $K$ where $K=\left[\mathrm{H}^{+}\right]\left[\mathrm{OH}^{-}\right] /\left[\mathrm{H}_{2} \mathrm{O}\right]$. (b) Calculate the product $\left[\mathrm{H}^{+}\right]\left[\mathrm{OH}^{-}\right],\left[\mathrm{H}^{+}\right]$, and $\left[\mathrm{OH}^{-}\right]$. (Hint: Calculate the concentration of liquid water using its density, $1.0 \mathrm{~g} / \mathrm{mL}$.)

E15.108 Consider the following reaction, which takes place in a single elementary step:

$$
2 \mathrm{~A}+\mathrm{B} \underset{k_{-1}}{\stackrel{k_{1}}{\rightleftarrows}} \mathrm{~A}_{2} \mathrm{~B}
$$

If the equilibrium constant $K_{\mathrm{c}}$ is 12.6 at a certain temperature and if $k_{1}=5.1 \times 10^{-2} \mathrm{~s}^{-1}$, calculate the value of $k_{-1}$.
15.109 At $25^{\circ} \mathrm{C}$, the equilibrium partial pressures of $\mathrm{NO}_{2}$ and $\mathrm{N}_{2} \mathrm{O}_{4}$ are 0.15 atm and 0.20 atm , respectively. If the volume is doubled at constant temperature, calculate the partial pressures of the gases when a new equilibrium is established.
15.110 In 1899 the German chemist Ludwig Mond developed a process for purifying nickel by converting it to the volatile nickel tetracarbonyl $\left[\mathrm{Ni}(\mathrm{CO})_{4}\right]$ (b.p. $\left.=42.2^{\circ} \mathrm{C}\right)$ :

$$
\mathrm{Ni}(s)+4 \mathrm{CO}(g) \rightleftarrows \mathrm{Ni}(\mathrm{CO})_{4}(g)
$$

(a) Describe how you can separate nickel and its solid impurities.
(b) How would you recover nickel? [ $\Delta H_{\mathrm{f}}^{\circ}$ for $\mathrm{Ni}(\mathrm{CO})_{4}$ is $-602.9 \mathrm{~kJ} / \mathrm{mol}$.]

E15.111 Consider the equilibrium reaction described in Problem 15.30. A quantity of 2.50 g of $\mathrm{PCl}_{5}$ is placed in an evacuated 0.500 -L flask and heated to $250^{\circ} \mathrm{C}$. (a) Calculate the pressure of $\mathrm{PCl}_{5}$, assuming it does not dissociate. (b) Calculate the partial pressure of $\mathrm{PCl}_{5}$ at equilibrium. (c) What is the total pressure at equilibrium? (d) What is the degree of dissociation of $\mathrm{PCl}_{5}$ ? (The degree of dissociation is given by the fraction of $\mathrm{PCl}_{5}$ that has undergone dissociation.)
15.112 Consider the equilibrium system $3 \mathrm{~A} \rightleftarrows \mathrm{~B}$. Sketch the changes in the concentrations of $A$ and $B$ over time for the following situations: (a) initially only A is present, (b) initially only B is present, (c) initially both A and B are present (with $A$ in higher concentration). In each case, assume that the concentration of B is higher than that of A at equilibrium.
15.113 The vapor pressure of mercury is 0.0020 mmHg at $26^{\circ} \mathrm{C}$. (a) Calculate $K_{\text {c }}$ and $K_{P}$ for the process $\mathrm{Hg}(l) \rightleftarrows \mathrm{Hg}(g)$. (b) A chemist breaks a thermometer and spills mercury onto the floor of a laboratory measuring 6.1 m long, 5.3 m wide, and 3.1 m high. Calculate the mass of mercury (in grams) vaporized at equilibrium and the concentration of mercury vapor (in $\mathrm{mg} / \mathrm{m}^{3}$ ). Does this concentration exceed the safety limit of $0.05 \mathrm{mg} / \mathrm{m}^{3}$ ? (Ignore the volume of furniture and other objects in the laboratory.)
15.114 At $25^{\circ} \mathrm{C}$, a mixture of $\mathrm{NO}_{2}$ and $\mathrm{N}_{2} \mathrm{O}_{4}$ gases are in equilibrium in a cylinder fitted with a movable piston. The concentrations are $\left[\mathrm{NO}_{2}\right]=0.0475 \mathrm{M}$ and $\left[\mathrm{N}_{2} \mathrm{O}_{4}\right]=0.487 \mathrm{M}$. The volume of the gas mixture is halved by pushing down on the piston at constant temperature. Calculate the concentrations of the gases when equilibrium is reestablished. Will the color become darker or lighter after the change? [Hint: $K_{\mathrm{c}}$ for the dissociation of $\mathrm{N}_{2} \mathrm{O}_{4}$ is $4.63 \times 10^{-3} . \mathrm{N}_{2} \mathrm{O}_{4}(g)$ is colorless, and $\mathrm{NO}_{2}(g)$ has a brown color.]
15.115 A student placed a few ice cubes in a drinking glass with water. A few minutes later she noticed that some of the ice cubes were fused together. Explain what happened.
15.116 Consider the potential-energy diagrams for two types of reactions $A \rightleftarrows B$. In each case, answer the following questions for the system at equilibrium. (a) How would a catalyst affect the forward and reverse rates of the reaction? (b) How would a catalyst affect the energies of the reactant and product? (c) How would an increase in temperature affect the equilibrium constant? (d) If the only effect of a catalyst is to lower the activation energies for the forward and reverse reactions, show that the equilibrium constant remains unchanged if a catalyst is added to the reacting mixture.

15.117 The equilibrium constant $K_{\mathrm{c}}$ for the reaction

$$
2 \mathrm{NH}_{3}(g) \rightleftarrows \mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g)
$$

is 0.83 at $375^{\circ} \mathrm{C}$. A $14.6-\mathrm{g}$ sample of ammonia is placed in a $4.00-\mathrm{L}$ flask and heated to $375^{\circ} \mathrm{C}$. Calculate the concentrations of all the gases when equilibrium is reached.
15.118 The dependence of the equilibrium constant of a reaction on temperature is given by the van't Hoff equation:

$$
\ln K=\frac{-\Delta H^{\circ}}{R T}+C
$$

where $C$ is a constant. The following table gives the equilibrium constant $\left(K_{P}\right)$ for the reaction at various temperatures.

| $2 \mathrm{NO}(g)+\mathrm{O}_{2}(g) \rightleftarrows 2 \mathrm{NO}_{2}(g)$ |  |  |  |  |  |
| :--- | ---: | ---: | ---: | ---: | ---: |
| $K_{P}$ | 138 | 5.12 | 0.436 | 0.0626 | 0.0130 |
| $T(\mathrm{~K})$ | 600 | 700 | 800 | 900 | 1000 |

Determine graphically the $\Delta H^{\circ}$ for the reaction.
15.119 Consider the reaction between $\mathrm{NO}_{2}$ and $\mathrm{N}_{2} \mathrm{O}_{4}$ in a closed container:

$$
\mathrm{N}_{2} \mathrm{O}_{4}(g) \rightleftarrows 2 \mathrm{NO}_{2}(g)
$$

Initially, 1 mole of $\mathrm{N}_{2} \mathrm{O}_{4}$ is present. At equilibrium, $x$ mole of $\mathrm{N}_{2} \mathrm{O}_{4}$ has dissociated to form $\mathrm{NO}_{2}$. (a) Derive an expression for $K_{P}$ in terms of $x$ and $P$, the total pressure. (b) How does the expression in part (a) help you predict the shift in equilibrium due to an increase in $P$ ? Does your prediction agree with Le Châtelier's principle?
15.120 (a) Use the van't Hoff equation in Problem 15.118 to derive the following expression, which relates the equilibrium constants at two different temperatures:

$$
\ln \frac{K_{1}}{K_{2}}=\frac{\Delta H^{\circ}}{R}\left(\frac{1}{T_{2}}-\frac{1}{T_{1}}\right)
$$

How does this equation support the prediction based on Le Châtelier's principle about the shift in equilibrium with temperature? (b) The vapor pressures of water are 31.82 mmHg at $30^{\circ} \mathrm{C}$ and 92.51 mmHg at $50^{\circ} \mathrm{C}$. Calculate the molar heat of vaporization of water.
15.121 The $K_{P}$ for the reaction

$$
\mathrm{SO}_{2} \mathrm{Cl}_{2}(g) \rightleftarrows \mathrm{SO}_{2}(g)+\mathrm{Cl}_{2}(g)
$$

is 2.05 at 648 K . A sample of $\mathrm{SO}_{2} \mathrm{Cl}_{2}$ is placed in a container and heated to 648 K , while the total pressure is kept constant at 9.00 atm . Calculate the partial pressures of the gases at equilibrium.

G 15.122 The "boat" form and the "chair" form of cyclohexane $\left(\mathrm{C}_{6} \mathrm{H}_{12}\right)$ interconvert as shown here:

In this representation, the H atoms are omitted and a C atom is assumed to be at each intersection of two lines (bonds). The conversion is first order in each direction. The activation energy for the chair $\longrightarrow$ boat conversion is $41 \mathrm{~kJ} / \mathrm{mol}$. If the frequency factor is $1.0 \times 10^{12} \mathrm{~s}^{-1}$, what is $k_{1}$ at 298 K ? The equilibrium constant $K_{\mathrm{c}}$ for the reaction is $9.83 \times 10^{3}$ at 298 K .
15.123 Consider the following reaction at a certain temperature

$$
\mathrm{A}_{2}+\mathrm{B}_{2} \rightleftarrows 2 \mathrm{AB}
$$

The mixing of 1 mole of $A_{2}$ with 3 moles of $B_{2}$ gives rise to $x$ mole of AB at equilibrium. The addition of 2 more moles of $\mathrm{A}_{2}$ produces another $x$ mole of AB . What is the equilibrium constant for the reaction?
15.124 Iodine is sparingly soluble in water but much more so in carbon tetrachloride $\left(\mathrm{CCl}_{4}\right)$. The equilibrium constant, also called the partition coefficient, for the distribution of $\mathrm{I}_{2}$ between these two phases

$$
\mathrm{I}_{2}(\mathrm{aq}) \rightleftarrows \mathrm{I}_{2}\left(\mathrm{CCl}_{4}\right)
$$

is 83 at $20^{\circ} \mathrm{C}$. (a) A student adds 0.030 L of $\mathrm{CC1}_{4}$ to 0.200 L of an aqueous solution containing 0.032 g of $\mathrm{I}_{2}$. The mixture at $20^{\circ} \mathrm{C}$ is shaken, and the two phases are then allowed to separate. Calculate the fraction of $\mathrm{I}_{2}$ remaining in the aqueous phase. (b) The student now repeats the extraction of $\mathrm{I}_{2}$ with another 0.030 L of $\mathrm{CC1}_{4}$. Calculate the fraction of the $\mathrm{I}_{2}$ from the original solution that remains in the aqueous phase. (c) Compare the result in part (b) with a single extraction using $0.060 \mathrm{~L} \mathrm{of}_{\mathrm{CC1}}^{4}$. Comment on the difference.
$\leftrightarrows 15.125$ For the purpose of determining $K_{P}$ using Equation 15.4, what is $\Delta n$ for the following equation?

$$
\mathrm{C}_{3} \mathrm{H}_{8}(g)+5 \mathrm{O}_{2}(g) \rightleftarrows 3 \mathrm{CO}_{2}(g)+4 \mathrm{H}_{2} \mathrm{O}(l)
$$

15.126 Industrial production of ammonia from hydrogen and nitrogen gases is done using the Haber process.

$$
\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \rightleftarrows 2 \mathrm{NH}_{3}(g) \quad \Delta H^{\circ}=-92.6 \mathrm{~kJ} / \mathrm{mol}
$$

Based on your knowledge of the principles of equilibrium, what would the optimal temperature and pressure conditions be for production of ammonia on a large scale? Are the same conditions also optimal from the standpoint of kinetics? Explain.
15.127 For which of the following reactions is $K_{\mathrm{c}}$ equal to $K_{P}$ ? For which can we not write a $K_{P}$ expression?
(a) $4 \mathrm{NH}_{3}(g)+5 \mathrm{O}_{2}(g) \rightleftarrows 4 \mathrm{NO}(g)+6 \mathrm{H}_{2} \mathrm{O}(g)$
(b) $\mathrm{CaCO}_{3}(s) \rightleftarrows \mathrm{CaO}(s)+\mathrm{CO}_{2}(g)$
(c) $\mathrm{Zn}(s)+2 \mathrm{H}^{+}(a q) \rightleftarrows \mathrm{Zn}^{2+}(a q)+\mathrm{H}_{2}(g)$
(d) $\mathrm{PCl}_{3}(g)+3 \mathrm{NH}_{3}(g) \rightleftarrows 3 \mathrm{HCl}(g)+\mathrm{P}\left(\mathrm{NH}_{2}\right)_{3}(g)$
(e) $\mathrm{NH}_{3}(g)+\mathrm{HCl}(g) \rightleftarrows \mathrm{NH}_{4} \mathrm{Cl}(s)$
(f) $\mathrm{NaHCO}_{3}(s)+\mathrm{H}^{+}(a q) \rightleftarrows \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{CO}_{2}(g)+\mathrm{Na}^{+}(a q)$
(g) $\mathrm{H}_{2}(g)+\mathrm{F}_{2}(g) \rightleftarrows 2 \mathrm{HF}(g)$
(h) C (graphite) $+\mathrm{CO}_{2}(g) \rightleftarrows 2 \mathrm{CO}(g)$

## Pre-Professional Practice Exam Problems: Physical and Biological Sciences

Lime $(\mathrm{CaO})$ is used to prevent $\mathrm{SO}_{2}$ from escaping from the smokestacks of coal-burning power plants via the formation of solid $\mathrm{CaSO}_{4} \cdot 2 \mathrm{H}_{2} \mathrm{O}$ (gypsum). One of the important reactions in the overall process is the decomposition of $\mathrm{CaCO}_{3}$ :

$$
\mathrm{CaCO}_{3}(s) \rightleftarrows \mathrm{CaO}(s)+\mathrm{CO}_{2}(\mathrm{~g})
$$

which has an equilibrium constant $\left(K_{\mathrm{c}}\right)$ of $3.0 \times 10^{-6}$ at $725^{\circ} \mathrm{C}$.

1. Calculate the value of $K_{P}$ for the decomposition of $\mathrm{CaCO}_{3}$ at $725^{\circ} \mathrm{C}$.
a) $3.0 \times 10^{-6}$
b) $2.5 \times 10^{-4}$
c) $2.0 \times 10^{-2}$
d) $3.7 \times 10^{-8}$
2. If a $12.0-\mathrm{g}$ sample of solid $\mathrm{CaCO}_{3}$ is placed in an evacuated vessel at $725^{\circ} \mathrm{C}$, what will the pressure of $\mathrm{CO}_{2}$ be when the system reaches equilibrium?
a) $3.0 \times 10^{-6} \mathrm{~atm}$
b) $3.3 \times 10^{5} \mathrm{~atm}$
c) $1.7 \times 10^{-3} \mathrm{~atm}$
d) 1.0 atm
3. Which of the following actions will cause an increase in the pressure of $\mathrm{CO}_{2}$ in the vessel described in Question 2?
a) Addition of He gas
b) Addition of $\mathrm{SO}_{2}$ gas
c) Addition of more $\mathrm{CaCO}_{3}$ solid
d) Increasing the volume of the vessel
4. If a $12.0-\mathrm{g}$ sample of solid $\mathrm{CaCO}_{3}$ is placed in a vessel at $725^{\circ} \mathrm{C}$ in which the pressure of $\mathrm{CO}_{2}$ is 2.5 atm , what mass of CaO will form?
a) 6.72 g
c) 6.00 g
b) 12.0 g
d) None

## Answers to In-Chapter Materials

## Answers to Practice Problems

15.1A $K_{\mathrm{c}}=\frac{\left[\mathrm{BrCl}^{2}\right.}{\left[\mathrm{Br}_{2}\right]\left[\mathrm{Cl}_{2}\right]}, K_{\mathrm{c}}=7.1$. 15.1B 0.016 M .
15.2A (a) $Q_{\mathrm{c}}=\frac{\left[\mathrm{N}_{2}\right]^{2}\left[\mathrm{O}_{2}\right]}{\left[\mathrm{N}_{2} \mathrm{O}\right]^{2}}$, (b) $Q_{\mathrm{c}}=\frac{\left[\mathrm{NO}^{2}\left[\mathrm{Br}_{2}\right]\right.}{[\mathrm{NOBr}]^{2}}$, (c) $Q_{\mathrm{c}}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{F}^{-}\right]}{[\mathrm{HF}]}$,
(d) $Q_{\mathrm{c}}=\frac{\left[\mathrm{CO}_{2}\right]\left[\mathrm{H}_{2}\right]}{[\mathrm{CO}]\left[\mathrm{H}_{2} \mathrm{O}\right]}$, (e) $Q_{\mathrm{c}}=\frac{\left[\mathrm{CS}_{2}\right]\left[\mathrm{H}_{2}\right]^{4}}{\left[\mathrm{CH}_{4}\right]\left[\mathrm{H}_{2} \mathrm{~S}\right]^{2}}$, (f) $Q_{\mathrm{c}}=\frac{\left[\mathrm{H}^{+}\right]^{2}\left[\mathrm{C}_{2} \mathrm{O}_{4}^{2-}\right]}{\left[\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}\right]}$.
15.2B (a) $\mathrm{H}_{2}+\mathrm{Cl}_{2} \rightleftarrows 2 \mathrm{HCl}$, (b) $\mathrm{H}^{+}+\mathrm{F}^{-} \rightleftarrows \mathrm{HF}$,
(c) $\mathrm{Cr}^{3+}+4 \mathrm{OH}^{-} \rightleftarrows \mathrm{Cr}(\mathrm{OH})_{4}^{-}$, (d) $\mathrm{HClO} \rightleftarrows \mathrm{H}^{+}+\mathrm{ClO}^{-}$,

## How Human Activity Has Impacted the Acidity of Rain

Rainwater in unpolluted areas is slightly acidic. The cause is carbon dioxide in the air, which dissolves in raindrops and reacts to form the weak acid, carbonic acid $\left(\mathrm{H}_{2} \mathrm{CO}_{3}\right)$. In areas where the air is polluted by the burning of fossil fuels, rain can be very acidic. This phenomenon, known as acid rain, was first discovered in 1852 by Scottish chemist Robert Angus Smith (1817-1884) in Manchester, England. At that time, the industrial revolution was well under way and the British economy relied heavily on the use of coal to generate steam. The two main atmospheric contributors to the acidity of acid rain are sulfur dioxide $\left(\mathrm{SO}_{2}\right)$ and oxides of nitrogen $\left(\mathrm{NO}_{x}\right)$, which react to produce, respectively, sulfuric acid $\left(\mathrm{H}_{2} \mathrm{SO}_{4}\right)$ and nitric acid $\left(\mathrm{HNO}_{3}\right)$-both strong acids. $\mathrm{SO}_{2}$ and $\mathrm{NO}_{x}$ are both produced by the burning of sulfur-bearing coal.

Although acid rain was first discovered in 1852, scientific and societal efforts to understand and remedy its causes did not emerge for another century. U.S. scientists only began to study the causes and effects of acid rain extensively in the late 1960s. Public awareness of the phenomenon was heightened in the 1970s when results of studies at the Hubbard Brook Experimental Forest in New Hampshire were published, detailing the devastating impact of acid rain on the ecology of the region.

Despite the dire circumstance described by atmospheric scientists and ecologists in the last half of the twentieth century, there appears to be reason for optimism with regard to acid rain. The Acid Rain Program, part of the 1990 amendment to the Clean Air Act (originally enacted in 1963), has contributed to reducing the acidity of rainwater in industrial areas of the United States to levels below those seen in the 1960s. Reducing sulfur emissions from coal-burning power plants has involved using coal containing less sulfur, fitting smokestacks with chemical scrubbers to remove $\mathrm{SO}_{2}$, and developing alternative sources of energy. Significant reductions in $\mathrm{NO}_{x}$ emissions have been achieved through the use of catalytic converters, which have been standard equipment on automobiles in the United States since the mid-1970s.

Understanding the causes of acid rain and working on prevention and remediation requires an understanding of the properties of acids and bases.

Student Annotation: a) " $\mathrm{NO}_{x}$ " is a collective term used to mean NO and $\mathrm{NO}_{2}$.

At the end of this chapter, you will be able to solve a series of problems related to the acidity of rainwater [ $W$ Page 715].

## In This Chapter, You Will Learn:

More about the properties of acids and bases and how those properties are related to molecular structure.

## Before you begin, you should review

- The list of strong acids and the list of strong bases [ KH Section 4.3, Table 4.4]
- How to solve equilibrium problems [I4 Section 15.4]

### 16.1 Brønsted Acids and Bases

| TABLE 16.1 | Conjugate <br> Bases <br> of Some <br> Common <br> Species |
| :--- | :--- |
| Species | Conjugate <br> Base |
| $\mathrm{CH}_{3} \mathrm{COOH}$ | $\mathrm{CH}_{3} \mathrm{COO}^{-}$ |
| $\mathrm{H}_{2} \mathrm{O}$ | $\mathrm{OH}^{-}$ <br> $\mathrm{NH}_{2}^{-}$ |
| $\mathrm{H}_{2} \mathrm{SO}_{4}$ | $\mathrm{HSO}_{4}^{-}$ |
| $\mathrm{TABLE} \mathrm{16.2}^{\text {Conjugate }}$ |  |
| Acids |  |
| of Some |  |
| Common |  |
| Species |  |

Think About It A species does not need to be what we think of as an acid for it to have a conjugate base. For example, we would not refer to the hydroxide ion $\left(\mathrm{OH}^{-}\right)$as an acid-but it does have a conjugate base, the oxide ion $\left(\mathrm{O}^{2-}\right)$. Furthermore, a species that can either lose or gain a proton, such as $\mathrm{HCO}_{3}^{-}$, has both a conjugate base $\left(\mathrm{CO}_{3}^{2-}\right)$ and a conjugate acid $\left(\mathrm{H}_{2} \mathrm{CO}_{3}\right)$.

In Chapter 4 we learned that a Brønsted acid is a substance that can donate a proton and a Brønsted base is a substance that can accept a proton [144 Section 4.3]. In this chapter we extend our discussion of Brønsted acid-base theory to include conjugate acids and conjugate bases.

When a Brønsted acid donates a proton, what remains of the acid is known as a conjugate base. For example, in the ionization of HCl in water,

$$
\underset{\text { acid }}{\mathrm{HCl}(a q)}+\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\underset{\text { conjugate base }}{\mathrm{Cl}^{-}(a q)}
$$

HCl donates a proton to water, producing the hydronium ion $\left(\mathrm{H}_{3} \mathrm{O}^{+}\right)$and the chloride ion $\left(\mathrm{Cl}^{-}\right)$, which is the conjugate base of HCl . The two species, HCl and $\mathrm{Cl}^{-}$, are known as a conjugate acid-base pair or simply a conjugate pair. Table 16.1 lists the conjugate bases of several familiar species.

Conversely, when a Brønsted base accepts a proton, the newly formed protonated species is known as a conjugate acid. When ammonia $\left(\mathrm{NH}_{3}\right)$ ionizes in water,

$$
\underset{\text { base }}{\mathrm{NH}_{3}(a q)}+\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{NH}_{4}^{+}(a q)+\mathrm{OH}^{-}(a q)
$$

$\mathrm{NH}_{3}$ accepts a proton from water to become the ammonium ion $(\mathrm{NH})_{4}^{+}$. The ammonium ion is the conjugate acid of ammonia. Table 16.2 lists the conjugate acids of several common species.

Any reaction that we describe using Brønsted acid-base theory involves an acid and a base. The acid donates the proton, and the base accepts it. Furthermore, the products of such a reaction are always a conjugate base and a conjugate acid. It is useful to identify and label each species in a Brønsted acid-base reaction. For the ionization of HCl in water, the species are labeled as follows:

And for the ionization of $\mathrm{NH}_{3}$ in water,

Sample Problems 16.1 and 16.2 let you practice identifying conjugate pairs and the species in a Brønsted acid-base reaction.

## Sample Problem 16.1

What is (a) the conjugate base of $\mathrm{HNO}_{3}$, (b) the conjugate acid of $\mathrm{O}^{2-}$, (c) the conjugate base of $\mathrm{HSO}_{4}^{-}$, and (d) the conjugate acid of $\mathrm{HCO}_{3}^{-}$?

Strategy To find the conjugate base of a species, remove a proton from the formula. To find the conjugate acid of a species, add a proton to the formula.

Setup The word proton, in this context, refers to $\mathrm{H}^{+}$. Thus, the formula and the charge will both be affected by the addition or removal of $\mathrm{H}^{+}$.

## Solution

(a) $\mathrm{NO}_{3}^{-}$
(c) $\mathrm{SO}_{4}^{2-}$
(b) $\mathrm{OH}^{-}$
(d) $\mathrm{H}_{2} \mathrm{CO}_{3}$

Practice Problem A What is (a) the conjugate acid of $\mathrm{ClO}_{4}^{-}$, (b) the conjugate acid of $\mathrm{S}^{2-}$, (c) the conjugate base of $\mathrm{H}_{2} \mathrm{~S}$, and (d) the conjugate base of $\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}$ ?

Practice Problem $\mathrm{B} \mathrm{HSO}_{3}^{-}$is the conjugate acid of what species? $\mathrm{HSO}_{3}^{-}$is the conjugate base of what species?

## Sample Problem 16.2

Label each of the species in the following equations as an acid, base, conjugate base, or conjugate acid:
(a) $\mathrm{HF}(a q)+\mathrm{NH}_{3}(a q) \rightleftarrows \mathrm{F}^{-}(a q)+\mathrm{NH}_{4}^{+}(a q)$
(b) $\mathrm{CH}_{3} \mathrm{COO}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{CH}_{3} \mathrm{COOH}(a q)+\mathrm{OH}^{-}(a q)$

Strategy In each equation, the reactant that loses a proton is the acid and the reactant that gains a proton is the base. Each product is the conjugate of one of the reactants. Two species that differ only by a proton constitute a conjugate pair.

Setup (a) HF loses a proton and becomes $\mathrm{F}^{-} ; \mathrm{NH}_{3}$ gains a proton and becomes $\mathrm{NH}_{4}^{+}$.
(b) $\mathrm{CH}_{3} \mathrm{COO}^{-}$gains a proton to become $\mathrm{CH}_{3} \mathrm{COOH} ; \mathrm{H}_{2} \mathrm{O}$ loses a proton to become $\mathrm{OH}^{-}$.

## Solution

$\underset{\text { acid }}{\mathrm{HF}(a q)}+\underset{\text { base }}{\mathrm{NH}_{3}(a q)} \rightleftarrows \underset{\text { conjugate }}{\mathrm{F}^{-}(a q)}+\underset{\text { conjugate }}{\mathrm{NH}_{4}^{+}(a q)}$
(b) $\mathrm{CH}_{3} \mathrm{COO}_{\text {base }}^{-}(a q)+\underset{\text { acid }}{\mathrm{H}_{2} \mathrm{O}(l)} \rightleftarrows \underset{\text { conjugate acid }}{\mathrm{CH}_{3} \mathrm{COOH}(a q)}+\underset{\text { conjugate base }}{\mathrm{OH}^{-}(a q)}$

Think About It In a Brønsted acid-base reaction, there is always an acid and a base, and whether a substance behaves as an acid or a base depends on what it is combined with. Water, for example, behaves as a base when combined with HCl but behaves as an acid when combined with $\mathrm{NH}_{3}$.

Practice Problem A Identify and label the species in each reaction.
(a) $\mathrm{NH}_{4}^{+}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{NH}_{3}(a q)+\mathrm{H}_{3} \mathrm{O}^{+}(a q)$
(b) $\mathrm{CN}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{HCN}(a q)+\mathrm{OH}^{-}(a q)$

HPractice Problem B (a) Write an equation in which $\mathrm{HSO}_{4}^{-}$reacts (with water) to form its conjugate base. (b) Write an equation in which $\mathrm{HSO}_{4}^{-}$reacts (with water) to form its conjugate acid.

## Checkpoint 16.1 Brønsted Acids and Bases

16.1.1 Which of the following pairs of species are conjugate pairs? (Select all that apply.)
a) $\mathrm{H}_{2} \mathrm{~S}$ and $\mathrm{S}^{2-}$
b) $\mathrm{NH}_{2}^{-}$and $\mathrm{NH}_{3}$
c) $\mathrm{O}_{2}$ and $\mathrm{H}_{2} \mathrm{O}_{2}$
d) HBr and $\mathrm{Br}^{-}$
e) HCl and $\mathrm{OH}^{-}$
16.1.2 Which of the following species does not have a conjugate base? (Select all that apply.)
a) $\mathrm{HC}_{2} \mathrm{O}_{4}^{-}$
b) $\mathrm{OH}^{-}$
c) $\mathrm{O}^{2-}$
d) $\mathrm{CO}_{3}^{2-}$
e) HClO

### 16.2 The Acid-Base Properties of Water

Water is often referred to as the "universal solvent," because it is so common and so important to life on Earth. In addition, most of the acid-base chemistry that you will encounter takes place in aqueous solution. In this section, we take a closer look at water's ability to act as either a Brønsted acid (as in the ionization of $\mathrm{NH}_{3}$ ) or a Brønsted base (as in the ionization of HCl ). A species that can behave either as a Brønsted acid or a Brønsted base is called amphoteric.

Water is a very weak electrolyte, but it does undergo ionization to a small extent:

$$
\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{H}^{+}(a q)+\mathrm{OH}^{-}(a q)
$$

Student Annotation: Recall that in a heterogeneous equilibrium such as this, liquids and solids do not appear in the equilibrium expression [1/4 Section 15.3].

Student Annotation: The constant $K_{w}$ is sometimes referred to as the ion-product constant.

Student Annotation: Recall that we disregard the units when we substitute concentrations into an equilibrium expression [ 14 Section 15.5].

Student Annotation: Because the product of $\mathrm{H}_{3} \mathrm{O}^{+}$and $\mathrm{OH}^{-}$concentrations is a constant, we cannot alter the concentrations independently. Any change in one also affects the other.

This reaction is known as the autoionization of water. Because we can represent the aqueous proton as either $\mathrm{H}^{+}$or $\mathrm{H}_{3} \mathrm{O}^{+}$[ $/ 4$ Section 4.3], we can also write the autoionization of water as

where one water molecule acts as an acid and the other acts as a base.
As indicated by the double arrow in the equation, the reaction is an equilibrium. The equilibrium expression for the autoionization of water is

$$
K_{\mathrm{w}}=\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{OH}^{-}\right] \quad \text { or } \quad K_{\mathrm{w}}=\left[\mathrm{H}^{+}\right]\left[\mathrm{OH}^{-}\right]
$$

Because the autoionization of water is an important equilibrium that you will encounter frequently in the study of acids and bases, we use the subscript " $w$ " to indicate that the equilibrium constant is that specifically for the autoionization of water. It is important to realize, though, that $K_{\mathrm{w}}$ is simply a $K_{\mathrm{c}}$ for a specific reaction. We will frequently replace the c in $K_{\mathrm{c}}$ expressions with a letter or a series of letters to indicate the specific type of reaction to which the $K_{\mathrm{c}}$ refers. For example, $K_{\mathrm{c}}$ for the ionization of a weak acid is called $K_{\mathrm{a}}$, and $K_{\mathrm{c}}$ for the ionization of a weak base is called $K_{\mathrm{b}}$. In Chapter 17 we will encounter $K_{\text {sp }}$, where "sp" stands for "solubility product." Each specially subscripted $K$ is simply a $K_{\mathrm{c}}$ for a specific type of reaction.

In pure water, autoionization is the only source of $\mathrm{H}_{3} \mathrm{O}^{+}$and $\mathrm{OH}^{-}$, and the stoichiometry of the reaction tells us that their concentrations are equal. At $25^{\circ} \mathrm{C}$, the concentrations of hydronium and hydroxide ions in pure water are $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=\left[\mathrm{OH}^{-}\right]=1.0 \times 10^{-7} \mathrm{M}$. Using the equilibrium expression, we can calculate the value of $K_{\mathrm{w}}$ at $25^{\circ} \mathrm{C}$ as follows:

$$
K_{\mathrm{w}}=\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{OH}^{-}\right]=\left(1.0 \times 10^{-7}\right)\left(1.0 \times 10^{-7}\right)=1.0 \times 10^{-14}
$$

Furthermore, in any aqueous solution at $25^{\circ} \mathrm{C}$, the product of $\mathrm{H}_{3} \mathrm{O}^{+}$and $\mathrm{OH}^{-}$concentrations is equal to $1.0 \times 10^{-14}$.

Equation $16.1 \quad K_{\mathrm{w}}=\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{OH}^{-}\right]=1.0 \times 10^{-14}\left(\right.$ at $\left.25^{\circ} \mathrm{C}\right)$
Although their product is a constant, the individual concentrations of hydronium and hydroxide can be influenced by the addition of an acid or a base. The relative amounts of $\mathrm{H}_{3} \mathrm{O}^{+}$and $\mathrm{OH}^{-}$ determine whether a solution is neutral, acidic, or basic.

- When $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=\left[\mathrm{OH}^{-}\right]$, the solution is neutral.
- When $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]>\left[\mathrm{OH}^{-}\right]$, the solution is acidic.
- When $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]<\left[\mathrm{OH}^{-}\right]$, the solution is basic.

Sample Problem 16.3 shows how to use Equation 16.1.

## Sample Problem 16.3

The concentration of hydronium ions in stomach acid is 0.10 M . Calculate the concentration of hydroxide ions in stomach acid at $25^{\circ} \mathrm{C}$.

Strategy Use the value of $K_{\mathrm{w}}$ to determine $\left[\mathrm{OH}^{-}\right]$when $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=0.10 \mathrm{M}$.
Setup $K_{\mathrm{w}}=\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{OH}^{-}\right]=1.0 \times 10^{-14}$ at $25^{\circ} \mathrm{C}$. Rearranging Equation 16.1 to solve for $\left[\mathrm{OH}^{-}\right]$,

$$
\left[\mathrm{OH}^{-}\right]=\frac{1.0 \times 10^{-14}}{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]}
$$

Solution

$$
\left[\mathrm{OH}^{-}\right]=\frac{1.0 \times 10^{-14}}{0.10}=1.0 \times 10^{-13} \mathrm{M}
$$

Practice Problem A The concentration of hydroxide ions in the antacid milk of magnesia is $5.0 \times 10^{-4} \mathrm{M}$. Calculate the concentration of hydronium ions at $25^{\circ} \mathrm{C}$.

EfPractice Problem B The value of $K_{\mathrm{w}}$ at normal body temperature $\left(37^{\circ} \mathrm{C}\right)$ is $2.8 \times 10^{-14}$. Calculate the concentration of hydroxide ions in stomach acid at body temperature. $\left(\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=0.10 \mathrm{M}.\right)$

## Checkpoint 16.2 The Acid-Base Properties of Water

16.2.1 Calculate $\left[\mathrm{OH}^{-}\right]$in a solution in which $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=0.0012 \mathrm{M}$ at $25^{\circ} \mathrm{C}$.
a) $1.2 \times 10^{-3} \mathrm{M}$
b) $8.3 \times 10^{-17} \mathrm{M}$
c) $1.0 \times 10^{-14} \mathrm{M}$
d) $8.3 \times 10^{-12} \mathrm{M}$
e) $1.2 \times 10^{11} \mathrm{M}$
16.2.2 Calculate $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right.$] in a solution in which $\left[\mathrm{OH}^{-}\right]=0.25 \mathrm{M}$ at $25^{\circ} \mathrm{C}$.
a) $4.0 \times 10^{-14} \mathrm{M}$
b) $1.0 \times 10^{-14} \mathrm{M}$
c) $2.5 \times 10^{13} \mathrm{M}$
d) $1.0 \times 10^{-7} \mathrm{M}$
e) $4.0 \times 10^{-7} \mathrm{M}$

### 16.3 The pH Scale

The acidity of an aqueous solution depends on the concentration of hydronium ions, $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$. This concentration can range over many orders of magnitude, which can make reporting the numbers cumbersome. To describe the acidity of a solution, rather than report the molar concentration of hydronium ions, we typically use the more convenient pH scale. The $\boldsymbol{p H}$ of a solution is defined as the negative base-10 logarithm of the hydronium ion concentration (in mol/L).

$$
\mathrm{pH}=-\log \left[\mathrm{H}_{3} \mathrm{O}^{+}\right] \quad \text { or } \quad \mathrm{pH}=-\log \left[\mathrm{H}^{+}\right] \quad \text { Equation } 16.2
$$

The pH of a solution is a dimensionless quantity, so the units of concentration must be removed from $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$before taking the logarithm. Because $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=\left[\mathrm{OH}^{-}\right]=1.0 \times 10^{-7} \mathrm{M}$ in pure water at $25^{\circ} \mathrm{C}$, the pH of pure water at $25^{\circ} \mathrm{C}$ is

$$
-\log \left(1.0 \times 10^{-7}\right)=7.00
$$

Remember, too, that a solution in which $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=\left[\mathrm{OH}^{-}\right]$is neutral. At $25^{\circ} \mathrm{C}$, therefore, a neutral solution has pH 7.00 . An acidic solution, one in which $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]>\left[\mathrm{OH}^{-}\right]$, has $\mathrm{pH}<7.00$, whereas a basic solution, in which $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]<\left[\mathrm{OH}^{-}\right]$, has $\mathrm{pH}>7.00$. Table 16.3 shows the calculation of pH for solutions ranging from 0.10 M to $1.0 \times 10^{-14} \mathrm{M}$.

In the laboratory, pH is measured with a pH meter (Figure 16.1). Table 16.4 lists the pH values of a number of common fluids. Note that the pH of body fluids varies greatly, depending on the location and function of the fluid. The low pH (high acidity) of gastric juices is vital for digestion of food, whereas the higher pH of blood is required to facilitate the transport of oxygen.

TABLE 16.3 Benchmark pH Values for a Range of Hydronium Ion Concentrations at $25^{\circ} \mathrm{C}$

| $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right](M)$ | $-\log \left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$ | pH |  |
| :--- | :--- | :--- | :--- |
| 0.10 | $-\log \left(1.0 \times 10^{-1}\right)$ | 1.00 |  |
| 0.010 | $-\log \left(1.0 \times 10^{-2}\right)$ | 2.00 |  |
| $1.0 \times 10^{-3}$ | $-\log \left(1.0 \times 10^{-3}\right)$ | 3.00 |  |
| $1.0 \times 10^{-4}$ | $-\log \left(1.0 \times 10^{-4}\right)$ | 4.00 |  |
| $1.0 \times 10^{-5}$ | $-\log \left(1.0 \times 10^{-5}\right)$ | 5.00 | Acidic |
| $1.0 \times 10^{-6}$ | $-\log \left(1.0 \times 10^{-6}\right)$ | 6.00 | Neutral |
| $1.0 \times 10^{-7}$ | $-\log \left(1.0 \times 10^{-7}\right)$ | 7.00 | Basic |
| $1.0 \times 10^{-8}$ | $-\log \left(1.0 \times 10^{-8}\right)$ | 8.00 |  |
| $1.0 \times 10^{-9}$ | $-\log \left(1.0 \times 10^{-9}\right)$ | 9.00 |  |
| $1.0 \times 10^{-10}$ | $-\log \left(1.0 \times 10^{-10}\right)$ | 10.00 |  |
| $1.0 \times 10^{-11}$ | $-\log \left(1.0 \times 10^{-11}\right)$ | 12.00 |  |
| $1.0 \times 10^{-12}$ | $-\log \left(1.0 \times 10^{-12}\right)$ | 13.00 |  |
| $1.0 \times 10^{-13}$ | $-\log \left(1.0 \times 10^{-13}\right)$ | 14.00 |  |
| $1.0 \times 10^{-14}$ | $-\log \left(1.0 \times 10^{-14}\right)$ |  |  |

Student Annotation: Equation 16.2 converts numbers that can span an enormous range ( $\sim 10^{1}$ to $10^{-14}$ ) to numbers generally ranging from $\sim 1$ to 14 .

Student Annotation: A word about significant figures: When we take the log of a number with two significant figures, we report the result to two places past the decimal point. Thus, pH 7.00 has two significant figures, not three.

Figure 16.1 A pH meter is commonly used in the laboratory to determine the pH of a solution. Although many pH meters have a range of 1 to $14, \mathrm{pH}$ values can actually be less than 1 and greater than 14.

Student Annotation: $10^{\mathrm{x}}$ is the inverse function of log. (It is usually the second function on the same key.) You must be comfortable performing these operations on your calculator.

TABLE 16.4 pH Values of Some Common Fluids

| Fluid | pH | Fluid | pH |
| :--- | :--- | :--- | :--- |
| Stomach acid | 1.5 | Saliva | $6.4-6.9$ |
| Lemon juice | 2.0 | Milk | 6.5 |
| Vinegar | 3.0 | Pure water | 7.0 |
| Grapefruit juice | 3.2 | Blood | $7.35-7.45$ |
| Orange juice | 3.5 | Tears | 7.4 |
| Urine | $4.8-7.5$ | Milk of magnesia | 10.6 |
| Rainwater (in clean air) | 5.5 | Household ammonia | 11.5 |

A measured pH can be used to determine experimentally the concentration of hydronium ion in solution. Solving Equation 16.2 for $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$gives

Equation 16.3

$$
\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=10^{-\mathrm{pH}}
$$

Sample Problems 16.4 and 16.5 illustrate calculations involving pH .

## Sample Problem 16.4

Think About It When a hydronium ion concentration falls between two "benchmark" concentrations in Table 16.3, the pH falls between the two corresponding pH values. In part (c), for example, the hydronium ion concentration $\left(8.8 \times 10^{-11} M\right)$ is greater than $1.0 \times 10^{-11} \mathrm{M}$ but less than $1.0 \times 10^{-10} M$. Therefore, we expect the pH to be between 11.00 and 10.00 .

| $\left[\mathbf{H}_{\mathbf{3}} \mathbf{O}^{+}\right](M)$ | $-\log \left[\mathbf{H}_{\mathbf{3}} \mathbf{O}^{+}\right]$ | $\mathbf{p H}$ |
| :--- | :--- | :--- |
| $1.0 \times 10^{-10}$ | $-\log \left(1.0 \times 10^{-10}\right)$ | 10.00 |
| $8.8 \times 10^{-11} *$ | $-\log \left(8.8 \times 10^{-11}\right)$ | $10.06 \dagger$ |
| $1.0 \times 10^{-11}$ | $-\log \left(1.0 \times 10^{-11}\right)$ | 11.00 |

$*\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$between two benchmark values
$\dagger \mathrm{pH}$ between two benchmark values
Recognizing the benchmark concentrations and corresponding pH values is a good way to determine whether or not your calculated result is reasonable.

Determine the pH of a solution at $25^{\circ} \mathrm{C}$ in which the hydronium ion concentration is (a) $3.5 \times 10^{-4} M$, (b) $1.7 \times 10^{-7} M$, and (c) $8.8 \times 10^{-11} M$.

Strategy Given $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right.$], use Equation 16.2 to solve for pH .

## Setup

(a) $\mathrm{pH}=-\log \left(3.5 \times 10^{-4}\right)$
(b) $\mathrm{pH}=-\log \left(1.7 \times 10^{-7}\right)$
(c) $\mathrm{pH}=-\log \left(8.8 \times 10^{-11}\right)$

## Solution

(a) $\mathrm{pH}=3.46$
(b) $\mathrm{pH}=6.77$
(c) $\mathrm{pH}=10.06$

Practice Problem A Determine the pH of a solution at $25^{\circ} \mathrm{C}$ in which the hydronium ion concentration is (a) $3.2 \times 10^{-9} \mathrm{M}$, (b) $4.0 \times 10^{-8} \mathrm{M}$, and (c) $5.6 \times 10^{-2} \mathrm{M}$.

HPractice Problem B Determine the pH of a solution at $25^{\circ} \mathrm{C}$ in which the hydroxide ion concentration is (a) $8.3 \times 10^{-15} M$, (b) $3.3 \times 10^{-4} M$, and (c) $1.2 \times 10^{-3} \mathrm{M}$.

## Sample Problem 16.5

Calculate the hydronium ion concentration in a solution at $25^{\circ} \mathrm{C}$ in which the pH is (a) 4.76 , (b) 11.95, and (c) 8.01 .

Strategy Given pH , use Equation 16.3 to calculate $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$.

## Setup

(a) $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=10^{-4.76}$
(b) $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=10^{-11.95}$
(c) $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=10^{-8.01}$

## Solution

(a) $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=1.7 \times 10^{-5} \mathrm{M}$
(b) $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=1.1 \times 10^{-12} \mathrm{M}$
(c) $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=9.8 \times 10^{-9} \mathrm{M}$

Practice Problem A Calculate the hydronium ion concentration in a solution at $25^{\circ} \mathrm{C}$ in which the pH is (a) 9.90, (b) 1.45, and (c) 7.01.

HPractice Problem B Calculate the hydroxide ion concentration in a solution at $25^{\circ} \mathrm{C}$ in which the pH is (a) 11.89, (b) 2.41, and (c) 7.13.

A $\mathbf{p O H}$ scale analogous to the pH scale can be defined using the negative base- 10 logarithm of the hydroxide ion concentration of a solution, $\left[\mathrm{OH}^{-}\right]$.

$$
\mathrm{pOH}=-\log \left[\mathrm{OH}^{-}\right]
$$

Equation 16.4

Think About It If you use the calculated hydronium ion concentrations to recalculate pH , you will get numbers slightly different from those given in the problem. In part (a), for example, $-\log \left(1.7 \times 10^{-5}\right)=4.77$. The small difference between this and 4.76 (the pH given in the problem) is due to a rounding error. Remember that a concentration derived from a pH with two digits to the right of the decimal point can have only two significant figures. Note also that the benchmarks can be used equally well in this circumstance. A pH between 4 and 5 corresponds to a hydronium ion concentration between $1 \times 10^{-4} \mathrm{M}$ and $1 \times 10^{-5} \mathrm{M}$.

Rearranging Equation 16.4 to solve for hydroxide ion concentration gives

$$
\left[\mathrm{OH}^{-}\right]=10^{-\mathrm{pOH}} \quad \text { Equation } 16.5
$$

Now consider again the $K_{\mathrm{w}}$ equilibrium expression for water at $25^{\circ} \mathrm{C}$ :

$$
\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{OH}^{-}\right]=1.0 \times 10^{-14}
$$

Taking the negative logarithm of both sides, we obtain

$$
\begin{aligned}
-\log \left(\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{OH}^{-}\right]\right) & =-\log \left(1.0 \times 10^{-14}\right) \\
-\left(\log \left[\mathrm{H}_{3} \mathrm{O}^{+}\right]+\log \left[\mathrm{OH}^{-}\right]\right) & =14.00 \\
-\log \left[\mathrm{H}_{3} \mathrm{O}^{+}\right]-\log \left[\mathrm{OH}^{-}\right] & =14.00 \\
\left(-\log \left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\right)+\left(-\log \left[\mathrm{OH}^{-}\right]\right) & =14.00
\end{aligned}
$$

And from the definitions of pH and pOH , we see that at $25^{\circ} \mathrm{C}$

$$
\mathrm{pH}+\mathrm{pOH}=14.00
$$

Equation 16.6
Equation 16.6 provides another way to express the relationship between the hydronium ion concentration and the hydroxide ion concentration. On the pOH scale, 7.00 is neutral, numbers greater than 7.00 indicate that a solution is acidic, and numbers less than 7.00 indicate that a solution is basic. Table 16.5 lists pOH values for a range of hydroxide ion concentrations at $25^{\circ} \mathrm{C}$.

TABLE 16.5 $\quad$ Benchmark pOH Values for a Range of Hydroxide Ion Concentrations at $25^{\circ} \mathrm{C}$

| $\left[\mathrm{OH}^{-}\right](\mathbf{M})$ | $\mathbf{p O H}$ |
| :--- | ---: |
| 0.10 | 1.00 |
|  |  |
| $1.0 \times 10^{-3}$ | 3.00 |
| $1.0 \times 10^{-5}$ | 5.00 |
| $1.0 \times 10^{-7}$ | 7.00 |
| $1.0 \times 10^{-9}$ | 9.00 |
| $1.0 \times 10^{-11}$ | 11.00 |
| $1.0 \times 10^{-13}$ | 13.00 |

## Sample Problem 16.6

Think About It Remember that the pOH scale is, in essence, the reverse of the pH scale. On the pOH scale, numbers below 7 indicate a basic solution, whereas numbers above 7 indicate an acidic solution. The pOH benchmarks (abbreviated in Table 16.5) work the same way the pH benchmarks do. In part (a), for example, a hydroxide ion concentration between $1 \times 10^{-4} \mathrm{M}$ and $1 \times 10^{-5} \mathrm{M}$ corresponds to a pOH between 4 and 5:

| $\left[\mathbf{O H}^{-}\right](\boldsymbol{M})$ | $\mathbf{p O H}$ |
| :--- | :---: |
| $1.0 \times 10^{-4}$ | 4.00 |
| $3.7 \times 10^{-5} *$ | $4.43 \dagger$ |
| $1.0 \times 10^{-5}$ | 5.00 |
| $*\left[\mathrm{OH}^{-}\right]$between two benchmark values |  |
| $\dagger$ pOH between two benchmark values |  |

Think About It Use the benchmark pOH values to determine whether these solutions are reasonable. In part (a), for example, the pOH between 4 and 5 corresponds to $\left[\mathrm{OH}^{-}\right]$between $1 \times 10^{-4} \mathrm{M}$ and $1 \times 10^{-5} \mathrm{M}$.

Determine the pOH of a solution at $25^{\circ} \mathrm{C}$ in which the hydroxide ion concentration is (a) $3.7 \times 10^{-5} \mathrm{M}$, (b) $4.1 \times 10^{-7} M$, and (c) $8.3 \times 10^{-2} M$.

Strategy Given $\left[\mathrm{OH}^{-}\right]$, use Equation 16.4 to calculate pOH .

## Setup

(a) $\mathrm{pOH}=-\log \left(3.7 \times 10^{-5}\right)$
(b) $\mathrm{pOH}=-\log \left(4.1 \times 10^{-7}\right)$
(c) $\mathrm{pOH}=-\log \left(8.3 \times 10^{-2}\right)$

## Solution

(a) $\mathrm{pOH}=4.43$
(b) $\mathrm{pOH}=6.39$
(c) $\mathrm{pOH}=1.08$

Practice Problem A Determine the pOH of a solution at $25^{\circ} \mathrm{C}$ in which the hydroxide ion concentration is (a) $5.7 \times 10^{-12} M$, (b) $7.3 \times 10^{-3} M$, and (c) $8.5 \times 10^{-6} M$.

EPractice Problem B Determine the pH of a solution at $25^{\circ} \mathrm{C}$ in which the hydroxide ion concentration is (a) $2.8 \times 10^{-8} \mathrm{M}$, (b) $9.9 \times 10^{-9} \mathrm{M}$, and (c) $1.0 \times 10^{-11} \mathrm{M}$.

## Sample Problem 16.7

Calculate the hydroxide ion concentration in a solution at $25^{\circ} \mathrm{C}$ in which the pOH is (a) 4.91 , (b) 9.03, and (c) 10.55.

Strategy Given pOH, use Equation 16.5 to calculate $\left[\mathrm{OH}^{-}\right]$.

## Setup

(a) $\left[\mathrm{OH}^{-}\right]=10^{-4.91}$
(b) $\left[\mathrm{OH}^{-}\right]=10^{-9.03}$
(c) $\left[\mathrm{OH}^{-}\right]=10^{-10.55}$

## Solution

(a) $\left[\mathrm{OH}^{-}\right]=1.2 \times 10^{-5} \mathrm{M}$
(b) $\left[\mathrm{OH}^{-}\right]=9.3 \times 10^{-10} \mathrm{M}$
(c) $\left[\mathrm{OH}^{-}\right]=2.8 \times 10^{-11} \mathrm{M}$

Practice Problem A Calculate the hydroxide ion concentration in a solution at $25^{\circ} \mathrm{C}$ in which the pOH is (a) 13.02, (b) 5.14, and (c) 6.98 .

EPractice Problem B Calculate the hydronium ion concentration in a solution at $25^{\circ} \mathrm{C}$ in which the pOH is (a) 2.74, (b) 10.31, and (c) 12.40.

## Bringing Chemistry to Life

## Antacids and the pH Balance in Your Stomach

An average adult produces between 2 and 3 L of gastric juice daily. Gastric juice is an acidic digestive fluid secreted by glands in the mucous membrane that lines the stomach. It contains hydrochloric acid $(\mathrm{HCl})$, among other substances. The pH of gastric juice is about 1.5 , which corresponds to a hydrochloric acid concentration of 0.03 M -a concentration strong enough to dissolve zinc metal!

The inside lining of the stomach is made up of parietal cells, which are fused together to form tight junctions. The interiors of the cells are protected from the surroundings by cell membranes. These membranes allow water and neutral molecules to pass in and out of the stomach, but they usually block the movement of ions such as $\mathrm{H}^{+}, \mathrm{Na}^{+}, \mathrm{K}^{+}$, and $\mathrm{Cl}^{-}$. The $\mathrm{H}^{+}$ions come from carbonic acid $\left(\mathrm{H}_{2} \mathrm{CO}_{3}\right)$ formed as a result of the hydration of $\mathrm{CO}_{2}$, an end product of metabolism:

$$
\begin{aligned}
\mathrm{CO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l) & \rightleftarrows \mathrm{H}_{2} \mathrm{CO}_{3}(a q) \\
\mathrm{H}_{2} \mathrm{CO}_{3}(a q) & \rightleftarrows \mathrm{H}^{+}(a q)+\mathrm{HCO}_{3}^{-}(a q)
\end{aligned}
$$

These reactions take place in the blood plasma bathing the cells in the mucosa. By a process known as active transport, $\mathrm{H}^{+}$ions move across the membrane into the stomach interior. (Active transport processes are aided by enzymes.) To maintain electrical balance, an equal number of $\mathrm{Cl}^{-}$ions also move from the blood plasma into the stomach. Once in the stomach, most of these ions are prevented by cell membranes from diffusing back into the blood plasma.

The purpose of the highly acidic medium within the stomach is to digest food and to activate certain digestive enzymes. Eating stimulates $\mathrm{H}^{+}$ion secretion. A small fraction of these ions normally are reabsorbed by the mucosa, causing a number of tiny hemorrhages. About half a million cells are shed by the lining every minute, and a healthy stomach is completely relined every few days. However, if the acid content is excessively high, the constant influx of $\mathrm{H}^{+}$ions through the membrane back to the blood plasma can cause muscle contraction, pain, swelling, inflammation, and bleeding.

One way to temporarily reduce the $\mathrm{H}^{+}$ions concentration in the stomach is to take an antacid. The major function of antacids is to neutralize excess HCl in gastric juice. The following table lists the active ingredients of some popular antacids. The reactions by which these antacids neutralize stomach acid are as follows:

$$
\begin{aligned}
& \mathrm{NaHCO}_{3}(a q)+\mathrm{HCl}(a q) \longrightarrow \mathrm{NaCl}(a q)+\mathrm{H}_{2} \mathrm{O}(l)+\mathrm{CO}_{2}(g) \\
& \mathrm{CaCO}_{3}(a q)+2 \mathrm{HCl}(a q) \longrightarrow \mathrm{CaCl}_{2}(a q)+\mathrm{H}_{2} \mathrm{O}(l)+\mathrm{CO}_{2}(g) \\
& \mathrm{MgCO}_{3}(a q)+2 \mathrm{HCl}(a q) \longrightarrow \mathrm{MgCl}_{2}(a q)+\mathrm{H}_{2} \mathrm{O}(l)+\mathrm{CO}_{2}(g) \\
& \mathrm{Mg}(\mathrm{OH})_{2}(s)+2 \mathrm{HCl}(a q) \longrightarrow \mathrm{MgCl}_{2}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l) \\
& \mathrm{Al}(\mathrm{OH})_{2} \mathrm{NaCO}_{3}(s)+4 \mathrm{HCl}(a q) \longrightarrow \mathrm{AlCl}_{3}(a q)+\mathrm{NaCl}(a q)+3 \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{CO}_{2}(g)
\end{aligned}
$$

## Active Ingredients in Some Common Antacids

| Commercial Name | Active Ingredients |
| :--- | :--- |
| Alka-Seltzer | Aspirin, sodium bicarbonate, citric acid |
| Milk of magnesia | Magnesium hydroxide |
| Rolaids | Dihydroxy aluminum sodium carbonate |
| TUMS | Calcium carbonate |
| Maalox | Sodium bicarbonate, magnesium carbonate |

The $\mathrm{CO}_{2}$ released by most of these reactions increases gas pressure in the stomach, causing the person to belch. The fizzing that takes place when Alka-Seltzer dissolves in water is caused by carbon dioxide, which is released by the reaction between citric acid and sodium bicarbonate:

$$
3 \mathrm{NaHCO}_{3}(\mathrm{aq})+\mathrm{H}_{3} \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}_{7}(\mathrm{aq}) \longrightarrow 3 \mathrm{CO}_{2}(g)+3 \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{Na}_{3} \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}_{7}(a q)
$$

This effervescence helps to disperse the ingredients and enhances the palatability of the solution.

## Checkpoint 16.3 The pH Scale

16.3.1 Determine the pH of a solution at $25^{\circ} \mathrm{C}$ in which $\left[\mathrm{H}^{+}\right]=6.35 \times 10^{-8} \mathrm{M}$.
a) 7.65
b) 6.80
c) 7.20
d) 6.35
e) 8.00
16.3.2 Determine $\left[\mathrm{H}^{+}\right]$in a solution at $25^{\circ} \mathrm{C}$ if $\mathrm{pH}=5.75$.
a) $1.8 \times 10^{-6} \mathrm{M}$
b) $5.6 \times 10^{-9} \mathrm{M}$
c) $5.8 \times 10^{-6} \mathrm{M}$
d) $2.4 \times 10^{-9} \mathrm{M}$
e) $1.0 \times 10^{-6} \mathrm{M}$

Student Annotation: We indicate that ionization of a strong acid is complete by using a single arrow $(\longrightarrow)$ instead of the double, equilibrium arrow $(\rightleftarrows)$ in the equation.

## Multimedia

Acids and Bases-the dissociation of strong and weak acids (interactive).

Student Annotation: Remember that although sulfuric acid has two ionizable protons, only the first ionization is complete

Student Annotation: As we will see in Section 16.5, a solution of equal concentration but containing a weak acid has a higher pH .

## Checkpoint 16.3 The pH Scale (continued)

16.3.3 Determine the pOH of a solution at $25^{\circ} \mathrm{C}$ in which $\left[\mathrm{OH}^{-}\right]=4.65 \times 10^{-3} \mathrm{M}$.
a) 11.67
b) 13.68
c) 0.32
d) 4.65
e) 2.33
16.3.4 Determine $\left[\mathrm{OH}^{-}\right]$in a solution at $25^{\circ} \mathrm{C}$ if $\mathrm{pH}=10.50$.
a) $3.2 \times 10^{-11} \mathrm{M}$
b) $3.2 \times 10^{-4} \mathrm{M}$
c) $1.1 \times 10^{-2} \mathrm{M}$
d) $7.1 \times 10^{-8} \mathrm{M}$
e) $8.5 \times 10^{-7} \mathrm{M}$

### 16.4 Strong Acids and Bases

Most of this chapter and Chapter 17 deal with equilibrium and the application of the principles of equilibrium to a variety of reaction types. In the context of our discussion of acids and bases, however, it is necessary to review the ionization of strong acids and the dissociation of strong bases. These reactions generally are not treated as equilibria but rather as processes that go to completion. This makes the determination of pH for a solution of strong acid or strong base relatively simple.

## Strong Acids

There are many different acids, but as we learned in Chapter 4, relatively few qualify as strong.

| Strong Acid | Ionization Reaction |
| :--- | ---: |
| Hydrochloric acid | $\mathrm{HCl}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{Cl}^{-}(a q)$ |
| Hydrobromic acid | $\mathrm{HBr}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{Br}^{-}(a q)$ |
| Hydroiodic acid | $\mathrm{HI}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{I}^{-}(a q)$ |
| Nitric acid | $\mathrm{HNO}_{3}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{NO}_{3}^{-}(a q)$ |
| Chloric acid | $\mathrm{HClO}_{3}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{ClO}_{3}^{-}(a q)$ |
| Perchloric acid | $\mathrm{HClO}_{4}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{ClO}_{4}^{-}(a q)$ |
| Sulfuric acid | $\mathrm{H}_{2} \mathrm{SO}_{4}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{HSO}_{4}^{-}(a q)$ |

It is a good idea to commit this short list of strong acids to memory.
Because the ionization of a strong acid is complete, the concentration of hydronium ion at equilibrium is equal to the starting concentration of the strong acid. For instance, if we prepare a 0.10 M solution of HCl , the concentration of hydronium ion in the solution is 0.10 M . All the HCl ionizes, and no HCl molecules remain. Thus, at equilibrium (when the ionization is complete), $[\mathrm{HCl}]=0 \mathrm{M}$ and $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=\left[\mathrm{Cl}^{-}\right]=0.10 \mathrm{M}$. Therefore, the pH of the solution $\left(\right.$ at $25^{\circ} \mathrm{C}$ ) is

$$
\mathrm{pH}=-\log (0.10)=1.00
$$

This is a very low pH , which is consistent with a relatively concentrated solution of a strong acid.
Sample Problems 16.8 and 16.9 let you practice relating the concentration of a strong acid to the pH of an aqueous solution.

## Sample Problem 16.8

Calculate the pH of an aqueous solution at $25^{\circ} \mathrm{C}$ that is (a) 0.035 M in HI , (b) $1.2 \times 10^{-4} \mathrm{M}$ in $\mathrm{HNO}_{3}$, and (c) $6.7 \times 10^{-5} \mathrm{M}$ in $\mathrm{HClO}_{4}$.

Strategy $\mathrm{HI}, \mathrm{HNO}_{3}$, and $\mathrm{HClO}_{4}$ are all strong acids, so the concentration of hydronium ion in each solution is the same as the stated concentration of the acid. Use Equation 16.2 to calculate pH .
Setup (a) $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=0.035 \mathrm{M}$
(b) $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=1.2 \times 10^{-4} \mathrm{M}$
(c) $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=6.7 \times 10^{-5} \mathrm{M}$

Solution (a) $\mathrm{pH}=-\log (0.035)=1.46$
(b) $\mathrm{pH}=-\log \left(1.2 \times 10^{-4}\right)=3.92$
(c) $\mathrm{pH}=-\log \left(6.7 \times 10^{-5}\right)=4.17$

Practice Problem A Calculate the pH of an aqueous solution at $25^{\circ} \mathrm{C}$ that is (a) 0.081 M in HI, (b) $8.2 \times 10^{-6} \mathrm{M}$ in $\mathrm{HNO}_{3}$, and (c) $5.4 \times 10^{-3} \mathrm{M}$ in $\mathrm{HClO}_{4}$.

HPractice Problem B Calculate the pOH of an aqueous solution at $25^{\circ} \mathrm{C}$ that is (a) $0.011 M$ in $\mathrm{HNO}_{3}$, (b) $3.5 \times 10^{-3} M$ in HBr , and (c) $9.3 \times 10^{-10} M$ in HCl .

## Sample Problem 16.9

Calculate the concentration of HCl in a solution at $25^{\circ} \mathrm{C}$ that has pH (a) 4.95 , (b) 3.45, and (c) 2.78 .

Strategy Use Equation 16.3 to convert from pH to the molar concentration of hydronium ion. In a strong acid solution, the molar concentration of hydronium ion is equal to the acid concentration.

Setup (a) $[\mathrm{HCl}]=\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=10^{-4.95}$
(b) $[\mathrm{HCl}]=\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=10^{-3.45}$
(c) $[\mathrm{HCl}]=\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=10^{-2.78}$

Solution (a) $1.1 \times 10^{-5} \mathrm{M}$
(b) $3.5 \times 10^{-4} \mathrm{M}$
(c) $1.7 \times 10^{-3} \mathrm{M}$

Practice Problem A Calculate the concentration of $\mathrm{HNO}_{3}$ in a solution at $25^{\circ} \mathrm{C}$ that has pH (a) 2.06, (b) 1.77, and (c) 6.01.

EPractice Problem B Calculate the concentration of HBr in a solution at $25^{\circ} \mathrm{C}$ that has pOH
(a) 9.19, (b) 12.18, and (c) 10.96.

## Strong Bases

The list of strong bases is also fairly short. It consists of the hydroxides of alkali metals (Group 1 A ) and the hydroxides of the heaviest alkaline earth metals (Group 2A). The dissociation of a strong base is, for practical purposes, complete. Equations representing dissociations of the strong bases are as follows:

## Group 1A hydroxides

| $\mathrm{LiOH}(a q)$ | $\longrightarrow \mathrm{Li}^{+}(a q)+\mathrm{OH}^{-}(a q)$ |
| :--- | :--- |
| $\mathrm{NaOH}(a q)$ | $\longrightarrow \mathrm{Na}^{+}(a q)+\mathrm{OH}^{-}(a q)$ |
| $\mathrm{KOH}(a q)$ | $\longrightarrow \mathrm{K}^{+}(a q)+\mathrm{OH}^{-}(a q)$ |
| $\mathrm{RbOH}(a q)$ | $\longrightarrow \mathrm{Rb}^{+}(a q)+\mathrm{OH}^{-}(a q)$ |
| $\mathrm{CsOH}(a q)$ | $\longrightarrow \mathrm{Cs}^{+}(a q)+\mathrm{OH}^{-}(a q)$ |

Group 2A hydroxides
$\mathrm{Ca}(\mathrm{OH})_{2}(a q) \longrightarrow \mathrm{Ca}^{2+}(a q)+2 \mathrm{OH}^{-}(a q)$
$\mathrm{Sr}(\mathrm{OH})_{2}(a q) \longrightarrow \mathrm{Sr}^{2+}(a q)+2 \mathrm{OH}^{-}(a q)$
$\mathrm{Ba}(\mathrm{OH})_{2}(a q) \longrightarrow \mathrm{Ba}^{2+}(a q)+2 \mathrm{OH}^{-}(a q)$
Again, because the reaction goes to completion, the pH of such a solution is relatively easy to calculate. In the case of a Group 1A hydroxide, the hydroxide ion concentration is simply the starting concentration of the strong base. In a solution that is 0.018 M in NaOH , for example,

Think About It Again, note that when a hydronium ion concentration falls between two of the benchmark concentrations in Table 16.3, the pH falls between the two corresponding pH values. In part (b), for example, the hydronium ion concentration of $1.2 \times 10^{-4} M$ is greater than $1.0 \times$ $10^{-4} M$ and less than $1.0 \times 10^{-3} M$. Therefore, we expect the pH to be between 4.00 and 3.00.

| $\left[\mathbf{H}_{\mathbf{3}} \mathbf{O}^{+}\right](\boldsymbol{M})$ | $-\log \left[\mathbf{H}_{\mathbf{3}} \mathbf{O}^{+}\right]$ | $\mathbf{p H}$ |
| :--- | :--- | :--- |
| $1.0 \times 10^{-3}$ | $-\log \left(1.0 \times 10^{-3}\right)$ | 3.00 |

* $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$between two benchmark values $\dagger \mathrm{pH}$ between two benchmark values
Being comfortable with the benchmark hydronium ion concentrations and the corresponding pH values will help you avoid some of the common errors in pH calculations.

Student Annotation: When we take the inverse log of a number with two digits to the right of the decimal point, the result has two significant figures.

Think About It As pH decreases, acid concentration increases.

## Multimedia

Acids and Bases-ionization of a strong base and weak base (interactive).

Student Annotation: Recall that $\mathrm{Ca}(\mathrm{OH})_{2}$ and $\mathrm{Sr}(\mathrm{OH})_{2}$ are not very soluble, but what does dissolve dissociates completely [ 14 Section 4.3, Table 4.4].
$\left[\mathrm{OH}^{-}\right]=0.018 \mathrm{M}$. Its pH can be calculated in two ways. We can either use Equation 16.1 to determine hydronium ion concentration,

$$
\begin{aligned}
{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{OH}^{-}\right] } & =1.0 \times 10^{-14} \\
{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right] } & =\frac{1.0 \times 10^{-14}}{\left[\mathrm{OH}^{-}\right]}=\frac{1.0 \times 10^{-14}}{0.018}=5.56 \times 10^{-13} \mathrm{M}
\end{aligned}
$$

and then Equation 16.2 to determine pH :

$$
\mathrm{pH}=-\log \left(5.56 \times 10^{-13} M\right)=12.25
$$

or we can calculate the pOH with Equation 16.3,

$$
\mathrm{pOH}=-\log (0.018)=1.75
$$

and use Equation 16.6 to convert to pH :

$$
\begin{aligned}
\mathrm{pH}+\mathrm{pOH} & =14.00 \\
\mathrm{pH} & =14.00-1.75=12.25
\end{aligned}
$$

Both methods give the same result.
In the case of a Group 2A metal hydroxide, we must be careful to account for the reaction stoichiometry. For instance, if we prepare a solution that is $1.9 \times 10^{-4} M$ in barium hydroxide, the concentration of hydroxide ion at equilibrium (after complete dissociation) is $2\left(1.9 \times 10^{-4} \mathrm{M}\right)$ or $3.8 \times 10^{-4} M$-twice the original concentration of $\mathrm{Ba}(\mathrm{OH})_{2}$. Once we have determined the hydroxide ion concentration, we can determine pH as before:

$$
\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=\frac{1.0 \times 10^{-14}}{\left[\mathrm{OH}^{-}\right]}=\frac{1.0 \times 10^{-14}}{3.8 \times 10^{-4}}=2.63 \times 10^{-11} \mathrm{M}
$$

and

$$
\mathrm{pH}=-\log \left(2.63 \times 10^{-11} M\right)=10.58
$$

or

$$
\begin{aligned}
\mathrm{pOH} & =-\log \left(3.8 \times 10^{-4}\right)=3.42 \\
\mathrm{pH}+\mathrm{pOH} & =14.00 \\
\mathrm{pH} & =14.00-3.42=10.58
\end{aligned}
$$

Sample Problems 16.10 and 16.11 illustrate calculations involving hydroxide ion concentration, pOH , and pH .

## Sample Problem 16.10

Calculate the pOH of the following aqueous solutions at $25^{\circ} \mathrm{C}$ : (a) 0.013 M LiOH ,
(b) $0.013 \mathrm{M} \mathrm{Ba}(\mathrm{OH})_{2}$, (c) $9.2 \times 10^{-5} \mathrm{M} \mathrm{KOH}$.

Strategy $\mathrm{LiOH}, \mathrm{Ba}(\mathrm{OH})_{2}$, and KOH are all strong bases. Use reaction stoichiometry to determine hydroxide ion concentration and Equation 16.4 to determine pOH.

Setup (a) The hydroxide ion concentration is simply equal to the concentration of the base. Therefore, $\left[\mathrm{OH}^{-}\right]=[\mathrm{LiOH}]=0.013 \mathrm{M}$.
(b) The hydroxide ion concentration is twice that of the base:

$$
\mathrm{Ba}(\mathrm{OH})_{2}(a q) \longrightarrow \mathrm{Ba}^{2+}(a q)+2 \mathrm{OH}^{-}(a q)
$$

Therefore, $\left[\mathrm{OH}^{-}\right]=2 \times\left[\mathrm{Ba}(\mathrm{OH})_{2}\right]=2(0.013 \mathrm{M})=0.026 \mathrm{M}$.
(c) The hydroxide ion concentration is equal to the concentration of the base. Therefore, $\left[\mathrm{OH}^{-}\right]=[\mathrm{KOH}]=9.2 \times 10^{-5} \mathrm{M}$.

Solution (a) $\mathrm{pOH}=-\log (0.013)=1.89$
(b) $\mathrm{pOH}=-\log (0.026)=1.59$
(c) $\mathrm{pOH}=-\log \left(9.2 \times 10^{-5}\right)=4.04$

Practice Problem A Calculate the pOH of the following aqueous solutions at $25^{\circ} \mathrm{C}$ :
(a) 0.15 M NaOH , (b) $8.4 \times 10^{-3} M \mathrm{RbOH}$, (c) $1.7 \times 10^{-5} M \mathrm{CsOH}$.

FPractice Problem B Calculate the pH of the following aqueous solutions at $25^{\circ} \mathrm{C}$ :
(a) $9.5 \times 10^{-8} M \mathrm{NaOH}$, (b) $6.1 \times 10^{-2} \mathrm{MLiOH}$, (c) $6.1 \times 10^{-2} M \mathrm{Ba}(\mathrm{OH})_{2}$.

## Sample Problem 16.11

An aqueous solution of a strong base has pH 8.15 at $25^{\circ} \mathrm{C}$. Calculate the original concentration of base in the solution (a) if the base is NaOH and (b) if the base is $\mathrm{Ba}(\mathrm{OH})_{2}$.

Strategy Use Equation 16.6 to convert from pH to pOH and Equation 16.5 to determine the hydroxide ion concentration. Consider the stoichiometry of dissociation in each case to determine the concentration of the base itself.

Setup

$$
\mathrm{pOH}=14.00-8.15=5.85
$$

(a) The dissociation of 1 mole of NaOH produces 1 mole of $\mathrm{OH}^{-}$. Therefore, the concentration of the base is equal to the concentration of hydroxide ion.
(b) The dissociation of 1 mole of $\mathrm{Ba}(\mathrm{OH})_{2}$ produces 2 moles of $\mathrm{OH}^{-}$. Therefore, the concentration of the base is only one-half the concentration of hydroxide ion.

## Solution

$$
\left[\mathrm{OH}^{-}\right]=10^{-5.85}=1.41 \times 10^{-6} \mathrm{M}
$$

(a) $[\mathrm{NaOH}]=\left[\mathrm{OH}^{-}\right]=1.4 \times 10^{-6} \mathrm{M}$
(b) $\left[\mathrm{Ba}(\mathrm{OH})_{2}\right]=\frac{1}{2}\left[\mathrm{OH}^{-}\right]=7.1 \times 10^{-7} \mathrm{M}$

Practice Problem A An aqueous solution of a strong base has pH 8.98 at $25^{\circ} \mathrm{C}$. Calculate the concentration of base in the solution (a) if the base is LiOH and (b) if the base is $\mathrm{Ba}(\mathrm{OH})_{2}$.

Student Annotation: Remember to keep an additional significant figure or two until the end of the problem-to avoid rounding error [14 Section 1.5].

Think About It Alternatively, we could determine the hydroxide ion concentration using Equation 16.3, $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=10^{-8.15}=7.1 \times 10^{-9} \mathrm{M}$ and Equation 16.1,

$$
\begin{aligned}
{\left[\mathrm{OH}^{-}\right] } & =\frac{1.0 \times 10^{-14}}{7.1 \times 10^{-9} \mathrm{M}} \\
& =1.4 \times 10^{-6} \mathrm{M}
\end{aligned}
$$

Once $\left[\mathrm{OH}^{-}\right.$] is known, the solution is the same as shown previously.

Practice Problem B An aqueous solution of a strong base has pOH 1.76 at $25^{\circ} \mathrm{C}$. Calculate the concentration of base in the solution (a) if the base is NaOH and (b) if the base is $\mathrm{Ba}(\mathrm{OH})_{2}$.

## Checkpoint 16.4 $\quad$ Strong Acids and Bases

16.4.1 Calculate the pH of a $0.075 M$ solution of perchloric acid $\left(\mathrm{HClO}_{4}\right)$ at $25^{\circ} \mathrm{C}$.
a) 12.88
b) 7.75
c) 6.25
d) 1.12
e) 7.00
16.4.2 What is the concentration of HBr in a solution with pH 5.89 at $25^{\circ} \mathrm{C}$ ?
a) $7.8 \times 10^{-9} \mathrm{M}$
b) $1.3 \times 10^{-6} \mathrm{M}$
c) $5.9 \times 10^{-14} \mathrm{M}$
d) $8.1 \times 10^{-7} \mathrm{M}$
e) $1.0 \times 10^{-7} \mathrm{M}$
16.4.3 What is the pOH of a solution at $25^{\circ} \mathrm{C}$ that is $1.3 \times 10^{-3} \mathrm{M}$ in $\mathrm{Ba}(\mathrm{OH})_{2}$ ?
a) 2.89
b) 2.59
c) 3.19
d) 11.11
e) 11.41
16.4.4 What is the concentration of KOH in a solution at $25^{\circ} \mathrm{C}$ that has pOH 3.31?
a) $2.0 \times 10^{-11} \mathrm{M}$
b) $3.3 \times 10^{-1} \mathrm{M}$
c) $3.3 \times 10^{-7} \mathrm{M}$
d) $4.5 \times 10^{-4} \mathrm{M}$
e) $4.9 \times 10^{-4} \mathrm{M}$

## Checkpoint 16.4 Strong Acids and Bases (continued)

16.4.5 What is the pH of a solution at $25^{\circ} \mathrm{C}$ that is 0.0095 M in LiOH ?
a) 11.68
b) 2.02
c) 11.98
d) 1.72
e) 12.28
16.4.6 What is the concentration of $\mathrm{Ca}(\mathrm{OH})_{2}$ in a solution at $25^{\circ} \mathrm{C}$ if the pH is 9.01 ?
a) $1.0 \times 10^{-5} \mathrm{M}$
b) $5.1 \times 10^{-6} \mathrm{M}$
c) $2.0 \times 10^{-5} \mathrm{M}$
d) $9.8 \times 10^{-9} \mathrm{M}$
e) $4.9 \times 10^{-9} \mathrm{M}$

Student Annotation: Remember that $\mathrm{H}_{3} \mathrm{O}^{+}$ and $\mathrm{H}^{+}$are used interchangeably.

Student Annotation: Remember that a $K_{\mathrm{a}}$ is a $K_{c}$. The subscript "a" simply stands for "acid."

Student Annotation: For comparison, the pH of a 0.1 M solution of a strong acid such as HCl or $\mathrm{HNO}_{3}$ is 1.0 .

Media Player/MPEG Animation: Figure 16.2, Using Equilibrium Tables to Solve Problems, pp. 688-689.

### 16.5 Weak Acids and Acid Ionization Constants

Most acids are weak acids, which ionize only to a limited extent in water. At equilibrium, an aqueous solution of a weak acid contains a mixture of aqueous acid molecules, hydronium ions, and the corresponding conjugate base. The degree to which a weak acid ionizes depends on the concentration of the acid and the equilibrium constant for the ionization.

## The Ionization Constant, $K_{\text {а }}$

Consider a weak monoprotic acid HA. Its ionization in water is represented by

$$
\mathrm{HA}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{A}^{-}(a q)
$$

or by

$$
\mathrm{HA}(a q) \rightleftarrows \mathrm{H}^{+}(a q)+\mathrm{A}^{-}(a q)
$$

The equilibrium expression for this reaction is

$$
K_{\mathrm{a}}=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{A}^{-}\right]}{[\mathrm{HA}]} \quad \text { or } \quad K_{\mathrm{a}}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{A}^{-}\right]}{[\mathrm{HA}]}
$$

where $K_{\mathrm{a}}$ is the equilibrium constant for the reaction. More specifically, $K_{\mathrm{a}}$ is called the acid ionization constant. Although all weak acids ionize less than 100 percent, they vary in strength. The magnitude of $K_{\mathrm{a}}$ indicates how strong a weak acid is. A large $K_{\mathrm{a}}$ value indicates a stronger acid, whereas a small $K_{\mathrm{a}}$ value indicates a weaker acid. For example, acetic acid $\left(\mathrm{CH}_{3} \mathrm{COOH}\right)$ and hydrofluoric acid (HF) are both weak acids, but HF is the stronger acid of the two, as evidenced by its larger $K_{\mathrm{a}}$ value. Solutions of equal concentration of the two acids do not have the same pH . The pH of the HF solution is lower.

| Solution $\left(\mathbf{a t ~}^{\mathbf{2 5}}{ }^{\circ} \mathbf{C}\right)$ | $\boldsymbol{K}_{\mathrm{a}}$ | $\mathbf{p H}$ |
| :--- | :---: | :--- |
| $0.10 M \mathrm{HF}$ | $7.1 \times 10^{-4}$ | 2.09 |
| $0.10 M \mathrm{CH}_{3} \mathrm{COOH}$ | $1.8 \times 10^{-5}$ | 2.87 |

Table 16.6 lists a number of weak acids and their $K_{\mathrm{a}}$ values at $25^{\circ} \mathrm{C}$ in order of decreasing acid strength.

## Calculating pH from $K_{\mathrm{a}}$

Calculating the pH of a weak acid solution is an equilibrium problem, which we solve using the methods introduced in Chapter 15. Figure 16.2 on pages 688 and 689 shows in detail how an

| TABLE 16.6 | Ionization Constants of Some Weak Acids at $25^{\circ} \mathrm{C}$ |  |  |
| :---: | :---: | :---: | :---: |
| Name of Acid | Formula | Structure | $K_{\text {a }}$ |
| Hydrofluoric acid | HF | H-F | $7.1 \times 10^{-4}$ |
| Nitrous acid | $\mathrm{HNO}_{2}$ | $\mathrm{O}=\mathrm{N}-\mathrm{O}-\mathrm{H}$ | $4.5 \times 10^{-4}$ |
| Formic acid | HCOOH |  | $1.7 \times 10^{-4}$ |
| Benzoic acid | $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COOH}$ |  | $6.5 \times 10^{-5}$ |
| Acetic acid | $\mathrm{CH}_{3} \mathrm{COOH}$ |  | $1.8 \times 10^{-5}$ |
| Hydrocyanic acid | HCN | $\mathrm{H}-\mathrm{C} \equiv \mathrm{N}$ | $4.9 \times 10^{-10}$ |
| Phenol | $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{OH}$ |  | $1.3 \times 10^{-10}$ |

equilibrium table is used to determine the pH of a weak acid. Suppose we want to determine the pH of a 0.50 M HF solution at $25^{\circ} \mathrm{C}$. The ionization of HF is represented by

$$
\mathrm{HF}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{F}^{-}(a q)
$$

The equilibrium expression for this reaction is

$$
K_{\mathrm{a}}=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{F}^{-}\right]}{[\mathrm{HF}]}=7.1 \times 10^{-4}
$$

We construct an equilibrium table and enter the starting concentrations of all species in the equilibrium expression.

Initial concentration ( $M$ ):
Change in concentration ( $M$ ):
Equilibrium concentration (M).

Using the reaction stoichiometry, we determine the changes in all species:

Initial concentration ( $M$ ):
Change in concentration ( $M$ ):
Equilibrium concentration ( $M$ ):

| $\mathrm{HF}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{F}^{-}(a q)$ |  |  |
| :---: | :---: | :---: |
| 0.50 |  | 0 |
| $-x$ |  | $+x$ |
|  |  |  |

Finally, we express the equilibrium concentration of each species in terms of $x$.

Initial concentration ( $M$ ):
Change in concentration ( $M$ ):
Equilibrium concentration (M).

| $\mathrm{HF}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{F}^{-}(a q)$ |  |  |
| :---: | :---: | :---: |
| 0.50 |  | 0 |
| $-x$ |  | $+x$ |
| $0.50-x$ |  | $x$ |

These equilibrium concentrations are then entered into the equilibrium expression to give

$$
K_{\mathrm{a}}=\frac{(x)(x)}{0.50-x}=7.1 \times 10^{-4}
$$

## Using Equilibrium Tables to Solve Problems

## Using $K_{\mathrm{a}}$ and Concentration to Determine pH of a Weak Acid

Determine the pH of a weak acid with a concentration of 0.10 M and a $K_{\mathrm{a}}$ of $2.5 \times 10^{-5}$.

The concentrations will change by an unknown amount, $x$.

- [HA] will decrease by $x$
- $\left[\mathrm{H}^{+}\right]$and $\left[\mathrm{A}^{-}\right]$will increase by $x$ We enter the anticipated changes in concentrations in the middle row of the table.

## Using pH and Concentration to Determine $K_{\text {a }}$ of a Weak Acid

Many equilibrium problems can be solved using an equilibrium table. The table is constructed with a column under each species in the equilibrium equation, and three rows labeled i (initial), c (change), and e (equilibrium).
(This is why such a table is sometimes
referred to as an "ice" table.)

We use pH to determine the equilibrium concentration of $\mathrm{H}^{+}$:

$$
\left[\mathrm{H}^{+}\right]=10^{-\mathrm{pH}}=10^{-3.82}=1.5 \times 10^{-4} M
$$

Because the ionization of HA produces equal amounts of $\mathrm{H}^{+}$and $\mathrm{A}^{-}$, the equilibrium concentration of $\mathrm{A}^{-}$is also $1.5 \times 10^{-4} M$. We enter these concentrations in the bottom row of the table.

Determine the $K_{\mathrm{a}}$ of a weak acid if a 0.12 M solution has a pH of 3.82 .

The equilibrium concentrations, which we enter in the last row of the table, are expressed in terms of the unknown $x$. We write the equilibrium expression for the reaction,

$$
K_{\mathrm{a}}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{A}^{-}\right]}{[\mathrm{HA}]}
$$

and enter the $K_{\mathrm{a}}$ value and the equilibrium concentrations from the last row in the table:

Because the magnitude of $K_{\mathrm{a}}$ is small, we expect the amount of HA ionized $(x)$ to be small compared to 0.10 . Therefore, we can assume that $0.10-x \approx 0.10$. This simplifies the solution to

$$
2.5 \times 10^{-5}=\frac{x^{2}}{0.10}
$$

Solving for $x$ gives

$$
\begin{gathered}
\left(2.5 \times 10^{-5}\right)(0.10)=x^{2} \\
2.5 \times 10^{-6}=x^{2} \\
\sqrt{2.5 \times 10^{-6}}=x \\
x=1.6 \times 10^{-3} \mathrm{M}
\end{gathered}
$$

We used $x$ to represent $\left[\mathrm{H}^{+}\right]$at equilibrium. ( $x$ is also equal to $\left[\mathrm{A}^{-}\right]$ at equilibrium and to the change in [HA].) Therefore, we determine pH by taking the negative $\log$ of $x$.

$$
\mathrm{pH}=-\log \left[\mathrm{H}^{+}\right]=-\log \left(1.6 \times 10^{-3}\right)=2.80
$$

Verify that $\frac{1.6 \times 10^{-3} \mathrm{M}}{0.10 \mathrm{M}} \times 100 \%<5 \%$
and that $\frac{\left(1.6 \times 10^{-3}\right)^{2}}{\left(0.10-1.6 \times 10^{-3}\right)} \approx K_{\mathrm{a}}$

To complete the last row of the table, we also need the equilibrium value of [HA]. The amount of weak acid that ionized is equal to the amount of $\mathrm{H}^{+}$produced by the ionization. Therefore, at equilibrium,

With the bottom row of the table complete, we can use these equilibrium concentrations to calculate the value of $K_{\mathrm{a}}$.
$K_{\mathrm{a}}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{A}^{-}\right]}{[\mathrm{HA}]}=\frac{\left(1.5 \times 10^{-4}\right)\left(1.5 \times 10^{-4}\right)}{(0.12)}=1.9 \times 10^{-7}$

Verify that when $[\mathrm{HA}]=0.12 \mathrm{M}$ and $K_{\mathrm{a}}=1.9 \times 10^{-7}$, $\left[\mathrm{H}^{+}\right]=\sqrt{\left(1.9 \times 10^{-7}\right)(0.12)}=1.5 \times 10^{-4} \mathrm{M}$ and $\mathrm{pH}=3.82$.

## What's the point?

- Starting with the molar concentration and $K_{\mathrm{a}}$ of a weak monoprotic acid, we can use an equilibrium table to determine pH .
- Starting with pH and molar concentration, we can use an equilibrium table to determine the $K_{\mathrm{a}}$ of a weak monoprotic acid.

Student Annotation: In many cases, use of the quadratic equation can be avoided with a method called successive approximation, which is presented in Appendix 1.

Rearranging this expression, we get

$$
x^{2}+7.1 \times 10^{-4} x-3.55 \times 10^{-4}=0
$$

This is a quadratic equation, which we can solve using the quadratic formula given in Appendix 1. In the case of a weak acid, however, often we can use a shortcut to simplify the calculation. Because HF is a weak acid, and weak acids ionize only to a slight extent, $x$ must be small compared to 0.50 . Therefore, we can make the following approximation:

$$
0.50-x \approx 0.50
$$

Now the equilibrium expression becomes

$$
\frac{x^{2}}{0.50-x} \approx \frac{x^{2}}{0.50}=7.1 \times 10^{-4}
$$

Rearranging, we get

$$
\begin{aligned}
x^{2} & =(0.50)\left(7.1 \times 10^{-4}\right)=3.55 \times 10^{-4} \\
x & =\sqrt{3.55 \times 10^{-4}}=1.9 \times 10^{-2} M
\end{aligned}
$$

Thus, we have solved for $x$ without having to use the quadratic equation. At equilibrium we have

$$
\begin{aligned}
{[\mathrm{HF}] } & =(0.50-0.019) M=0.48 \mathrm{M} \\
{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right] } & =0.019 \mathrm{M} \\
{\left[\mathrm{~F}^{-}\right] } & =0.019 \mathrm{M}
\end{aligned}
$$

and the pH of the solution is

$$
\mathrm{pH}=-\log (0.019)=1.72
$$

This shortcut gives a good approximation as long as the magnitude of $x$ is significantly smaller than the initial acid concentration. As a rule, it is acceptable to use this shortcut if the calculated value of $x$ is less than 5 percent of the initial acid concentration. In this case, the approximation is acceptable because

$$
\frac{0.019 M}{0.50 M} \times 100 \%=3.8 \%
$$

This is the formula for the percent ionization of the acid [ 14 Section 13.6]. Recall that the percent ionization of a weak electrolyte, such as a weak acid, depends on concentration. Consider a more dilute solution of HF , one that is 0.050 M . Using the preceding procedure to solve for $x$, we would get $6.0 \times 10^{-3} \mathrm{M}$. The following test shows, however, that this answer is not a valid approximation because it is greater than 5 percent of 0.050 M :

$$
\frac{6.0 \times 10^{-3} M}{0.050 M} \times 100 \%=12 \%
$$

In this case, we must solve for $x$ using the quadratic equation [1/4 Sample Problem 15.9].
Sample Problem 16.12 shows how to use $K_{\mathrm{a}}$ to determine the pH of a weak acid solution.

## Sample Problem 16.12

The $K_{\mathrm{a}}$ of hypochlorous acid $(\mathrm{HClO})$ is $3.5 \times 10^{-8}$. Calculate the pH of a solution at $25^{\circ} \mathrm{C}$ that is 0.0075 M in HClO .

Strategy Construct an equilibrium table, and express the equilibrium concentration of each species in terms of $x$. Solve for $x$ using the approximation shortcut, and evaluate whether or not the approximation is valid. Use Equation 16.2 to determine pH .

## Setup

Initial concentration ( $M$ ):
Change in concentration ( $M$ ):
Equilibrium concentration ( $M$ ):

| $\mathrm{HClO}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{ClO}^{-}(a q)$ |  |  |  |
| :---: | :---: | :---: | :---: |
| 0.0075 |  | 0 | 0 |
| $-x$ |  | $+x$ | $+x$ |
| $0.0075-x$ |  | $x$ | $x$ |

Solution These equilibrium concentrations are then substituted into the equilibrium expression to give

$$
K_{\mathrm{a}}=\frac{(x)(x)}{0.0075-x}=3.5 \times 10^{-8}
$$

Assuming that $0.0075-x \approx 0.0075$,

$$
\begin{aligned}
\frac{x^{2}}{0.0075} & =3.5 \times 10^{-8} \\
x^{2} & =\left(3.5 \times 10^{-8}\right)(0.0075)
\end{aligned}
$$

Solving for $x$, we get

$$
x=\sqrt{2.625 \times 10^{-10}}=1.62 \times 10^{-5} M
$$

According to the equilibrium table, $x=\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$. Therefore,

$$
\mathrm{pH}=-\log \left(1.62 \times 10^{-5}\right)=4.79
$$

Practice Problem A Calculate the pH at $25^{\circ} \mathrm{C}$ of a 0.18 M solution of a weak acid that has $K_{\mathrm{a}}=9.2 \times 10^{-6}$.

HPractice Problem B Calculate the pH at $25^{\circ} \mathrm{C}$ of a $0.065 M$ solution of a weak acid that has $K_{\mathrm{a}}=1.2 \times 10^{-5}$.

Student Annotation: Applying the 5 percent test indicates that the approximation shortcut is valid in this case: $\left(1.62 \times 10^{-5} / 0.0075\right) \times$ $100 \%<5 \%$.

Think About It We learned in Section 16.2 that the concentration of hydronium ion in pure water at $25^{\circ} \mathrm{C}$ is $1.0 \times 10^{-7} \mathrm{M}$, yet we use 0 M as the starting concentration to solve for the pH of a solution of weak acid:

## Initial concentration ( $M$ ):

Change in concentration (M):
Equilibrium concentration (M):

The reason for this is that the actual concentration of hydronium ion in pure water is insignificant compared to the amount produced by the ionization of the weak acid. We could use the actual concentration of hydronium as the initial concentration, but doing so would not change the result because $\left(x+1.0 \times 10^{-7}\right) M \approx x M$. In solving problems of this type, we neglect the small concentration of $\mathrm{H}^{+}$due to the autoionization of water.

## Percent Ionization

When we first encountered acids [ 14 Section 4.1], we learned that a strong acid is one that ionizes completely. Weak acids ionize only partially. The degree to which a weak acid ionizes is a measure of its strength, just as the magnitude of its ionization constant $\left(K_{\mathrm{a}}\right)$ is a measure of its strength. A quantitative measure of the degree of ionization is percent ionization, which, for a weak, monoprotic acid (HA) is calculated as follows:

$$
\text { percent ionization }=\frac{\left[\mathrm{H}^{+}\right]_{\mathrm{eq}}}{[\mathrm{HA}]_{0}} \times 100 \%
$$

Equation 16.7
in which the hydrogen ion concentration, $\left[\mathrm{H}^{+}\right]_{\mathrm{eq}}$, is the concentration at equilibrium and the weak acid concentration, $[\mathrm{HA}]_{0}$, is the original concentration of the acid, which is not necessarily the same as the concentration at equilibrium.

We have learned previously how to use colligative properties to determine the percent ionization of a weak electrolyte, such as a weak acid [ 14 Section 13.6]. Now that we have an understanding of equilibrium and of ionization constants, we can predict the percent ionization of a weak acid. Moreover, we will discover that the percent ionization is not constant for a given weak acid, but in fact depends on the acid's concentration.

Consider a 0.10 M solution of benzoic acid, for which the ionization constant $\left(K_{\mathrm{a}}\right)$ is $6.5 \times$ $10^{-5}$. Using the procedure described in Sample Problem 16.12, we can determine the equilibrium concentrations of benzoic acid, $\mathrm{H}^{+}$, and the benzoate ion.

## Initial concentration (M):

Change in concentration ( $M$ ):
Equilibrium concentration (M):

| $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COOH}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COO}^{-}(a q)$ |  |  |  |
| :---: | :---: | :---: | :---: |
| 0.100 |  | 0 | 0 |
| $-x$ |  | $+x$ | $+x$ |
| $0.100-x$ |  | $x$ | $x$ |

Solving for $x$ gives $0.0025 M$. Therefore, at equilibrium, $\left[\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COOH}\right]=0.097 \mathrm{M}$ and $\left[\mathrm{H}^{+}\right]=$ $\left[\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COO}^{-}\right]=0.0025 \mathrm{M}$. The percent ionization of benzoic acid at this concentration is

$$
\frac{0.0025 M}{0.100 M} \times 100 \%=2.5 \%
$$

Now consider what happens when we dilute this equilibrium mixture by adding enough water to double the volume. The concentrations of all three species are cut in half: $\left[\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COOH}\right]=$ $0.049 \mathrm{M},\left[\mathrm{H}^{+}\right]=0.0013 \mathrm{M}$, and $\left[\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COO}^{-}\right]=0.0013 \mathrm{M}$. If we plug these new concentrations

Student Annotation: In fact, a weak acid's original concentration is never exactly equal to its equilibrium concentration. However, sometimes the amount that ionizes is so small compared to the original concentration that, to an appropriate number of significant figures, the weak acid concentration does not change and $[H A]_{0} \approx[H A]_{\text {eq }}$.

Figure 16.3 Percent ionization of a weak acid depends on the original acid concentration. As concentration approaches zero, ionization approaches 100 percent. The dashed grey line represents 100 percent ionization, which is characteristic of a strong acid.

Student Annotation: According to Le Châtelier's principle [ 14 Section 15.5], the reduction in particle concentration caused by dilution stresses the equilibrium. The equilibrium shifts to minimize the effects of the stress by shifting toward the side with more dissolved particles, causing more of the weak acid to ionize.

into the equilibrium expression and calculate the reaction quotient $(Q)$, we get a number different from $K_{\mathrm{a}}$. In fact, we get $\left(0.0013^{2} / 0.049\right)=3.4 \times 10^{-5}$, which is smaller than $K_{\mathrm{a}}$. When $Q$ is smaller than $K$, the reaction must proceed to the right to reestablish equilibrium [ 14 Section 15.4]. Proceeding to the right, in the case of weak acid ionization, corresponds to more of the acid ionizing meaning that its percent ionization increases.

We can solve again for percent ionization starting with half the original concentration of benzoic acid.

Initial concentration ( $M$ ):
Change in concentration ( $M$ ): Equilibrium concentration (M):

| $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COOH}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COO}^{-}(a q)$ |  |  |  |
| :---: | :---: | :---: | :---: |
| 0.050 |  | 0 | 0 |
| $-x$ |  | $+x$ | $+x$ |
| $0.050-x$ |  | $x$ | $x$ |

This time, solving for $x$ gives 0.0018 M . Therefore, at equilibrium, $\left[\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COOH}\right]=0.048 \mathrm{M}$, and $\left[\mathrm{H}^{+}\right]=\left[\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COO}^{-}\right]=0.0018 \mathrm{M}$. The percent ionization of benzoic acid at this concentration is

$$
\frac{0.0018 M}{0.0050 M} \times 100 \%=3.6 \%
$$

Figure 16.3 shows the dependence of percent ionization of a weak acid on concentration. Note that as concentration approaches zero, percent ionization approaches 100.

Sample Problem 16.13 lets you practice calculating percent ionization of weak acid solutions.

## Sample Problem 16.13

Determine pH and percent ionization for acetic acid solutions at $25^{\circ} \mathrm{C}$ with concentrations (a) 0.15 M , (b) 0.015 M , and (c) 0.0015 M .

Strategy Using the procedure described in Sample Problem 16.12, we construct an equilibrium table and for each concentration of acetic acid, we solve for the equilibrium concentration of $\mathrm{H}^{+}$. We use Equation 16.2 to find pH , and Equation 16.7 to find percent ionization.

Setup From Table 16.6, the ionization constant, $K_{\mathrm{a}}$, for acetic acid is $1.8 \times 10^{-5}$.

## Setup

(a)

Initial concentration ( $M$ ):
Change in concentration ( $M$ ):
Equilibrium concentration (M):

| $\mathrm{CH}_{3} \mathrm{COOH}(a q)+\mathrm{H}_{2} \mathrm{O}(l)$ | $\mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{CH}_{3} \mathrm{COO}^{-}(a q)$ |  |  |
| :---: | :---: | :---: | :---: |
| 0.15 |  | 0 | 0 |
| $-x$ |  | $+x$ | $+x$ |
| $0.15-x$ |  | $x$ | $x$ |

Solving for $x$ gives $\left[\mathrm{H}^{+}\right]=0.0016 M$ and $\mathrm{pH}=-\log (0.0016)=2.78$.

$$
\text { percent ionization }=\frac{0.0016 M}{0.15 M} \times 100 \%=1.1 \%
$$

(b) Solving in the same way as part (a) gives: $\left[\mathrm{H}^{+}\right]=5.2 \times 10^{-4} M$ and $\mathrm{pH}=3.28$.

$$
\text { percent ionization }=\frac{5.2 \times 10^{-4} M}{0.015 M} \times 100 \%=3.5 \%
$$

(c) Solving the quadratic equation, or using successive approximation [ Appendix 1] gives
$\left[\mathrm{H}^{+}\right]=1.6 \times 10^{-4} M$ and $\mathrm{pH}=3.78$.

$$
\text { percent ionization }=\frac{1.6 \times 10^{-4} M}{0.0015 M} \times 100 \%=11 \%
$$

Practice Problem A Determine the pH and percent ionization for hydrocyanic acid $(\mathrm{HCN})$ solutions of concentration (a) 0.25 M , (b) 0.0075 M , and (c) $8.3 \times 10^{-5} \mathrm{M}$.
\& Practice Problem B At what concentration does hydrocyanic acid exhibit (a) 0.05 percent ionization, (b) 0.10 percent ionization, and (c) 0.15 percent ionization?

## Using pH to Determine $K_{\mathrm{a}}$

In Chapter 15 we learned that we can determine the value of an equilibrium constant using equilibrium concentrations [ 14 Section 15.2]. Using a similar approach, we can use the pH of a weak acid solution to determine the value of $K_{\mathrm{a}}$. Suppose we want to determine the $K_{\mathrm{a}}$ of a weak acid (HA) and we know that a 0.25 M solution of the acid has a pH of 3.47 at $25^{\circ} \mathrm{C}$. The first step is to use pH to determine the equilibrium hydronium ion concentration. Using Equation 16.3, we get

$$
\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=10^{-3.47}=3.39 \times 10^{-4} \mathrm{M}
$$

We use the starting concentration of the weak acid and the equilibrium concentration of the hydronium ion to construct an equilibrium table and determine the equilibrium concentrations of all three species.

## Initial concentration ( $M$ ):

Change in concentration ( $M$ ):
Equilibrium concentration ( $M$ ):

| $\mathrm{HA}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{H}_{3} \mathrm{O}^{+}(a q)$ |  | $+\mathrm{A}^{-}(a q)$ |  |
| :---: | :---: | :---: | :---: |
| 0.25 |  | 0 | 0 |
| $-3.39 \times 10^{-4}$ |  | $+3.39 \times 10^{-4}$ | $+3.39 \times 10^{-4}$ |
| 0.2497 |  | $3.39 \times 10^{-4}$ | $3.39 \times 10^{-4}$ |

These equilibrium concentrations are substituted into the equilibrium expression to give

$$
K_{\mathrm{a}}=\frac{\left(3.39 \times 10^{-4}\right)^{2}}{0.2497}=4.6 \times 10^{-7}
$$

Therefore, the $K_{\mathrm{a}}$ of this weak acid is $4.6 \times 10^{-7}$.
Sample Problem 16.14 shows how to determine $K_{\mathrm{a}}$ using pH .

## Sample Problem 16.14

Aspirin (acetylsalicylic acid, $\mathrm{HC}_{9} \mathrm{H}_{7} \mathrm{O}_{4}$ ) is a weak acid. It ionizes in water according to the equation

$$
\mathrm{HC}_{9} \mathrm{H}_{7} \mathrm{O}_{4}(a q)+\mathrm{H}_{2} \mathrm{O}(a q) \rightleftarrows \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{C}_{9} \mathrm{H}_{7} \mathrm{O}_{4}^{-}(a q)
$$

A 0.10 M aqueous solution of the aspirin has a pH of 2.27 at $25^{\circ} \mathrm{C}$. Determine the $K_{\mathrm{a}}$ of aspirin.
Strategy Determine the hydronium ion concentration from the pH . Use the hydronium ion concentration to determine the equilibrium concentrations of the other species, and plug the equilibrium concentrations into the equilibrium expression to evaluate $K_{\mathrm{a}}$.

Setup Using Equation 16.3, we have

$$
\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=10^{-2.27}=5.37 \times 10^{-3} \mathrm{M}
$$

To calculate $K_{\mathrm{a}}$, though, we also need the equilibrium concentrations of $\mathrm{C}_{9} \mathrm{H}_{7} \mathrm{O}_{4}^{-}$and $\mathrm{HC}_{9} \mathrm{H}_{7} \mathrm{O}_{4}$. The stoichiometry of the reaction tells us that $\left[\mathrm{C}_{9} \mathrm{H}_{7} \mathrm{O}_{4}^{-}\right]=\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$. Furthermore, the amount of aspirin that has ionized is equal to the amount of hydronium ion in solution. Therefore, the equilibrium concentration of aspirin is $\left(0.10-5.37 \times 10^{-3}\right) M=0.095 M$.

Think About It Percent ionization also increases as concentration decreases for weak bases [ 1 M Section 16.6].

Student Annotation: Remember that we keep extra significant figures until the end of a multistep problem to minimize rounding error [14 Section 1.5].

Aspirin

Think About It Check your work by using the calculated value of $K_{\mathrm{a}}$ to solve for the pH of a 0.10 M solution of aspirin.

Change in concentration ( $M$ ):
Equilibrium concentration (M):

$$
\begin{array}{l|c|c}
\mathrm{HC}_{9} \mathrm{H}_{7} \mathrm{O}_{4}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{C}_{9} \mathrm{H}_{7} \mathrm{O}_{4}^{-}(a q) \\
0.10 & & 0
\end{array}
$$

Solution Substitute the equilibrium concentrations into the equilibrium expression as follows:

$$
K_{\mathrm{a}}=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{C}_{9} \mathrm{H}_{7} \mathrm{O}_{4}^{-}\right]}{\left[\mathrm{HC}_{9} \mathrm{H}_{7} \mathrm{O}_{4}\right]}=\frac{\left(5.37 \times 10^{-3}\right)^{2}}{0.095}=3.0 \times 10^{-4}
$$

The $K_{\mathrm{a}}$ of aspirin is $3.0 \times 10^{-4}$.

Practice Problem A Calculate the $K_{\mathrm{a}}$ of a weak acid if a 0.065 M solution of the acid has a pH of 2.96 at $25^{\circ} \mathrm{C}$.
flPractice Problem B Calculate the $K_{\mathrm{a}}$ of a weak acid if a 0.015 M solution of the acid has a pH of 5.03 at $25^{\circ} \mathrm{C}$.

## Checkpoint 16.5 Weak Acids and Acid Ionization Constants

16.5.1 The $K_{\mathrm{a}}$ of a weak acid is $5.5 \times 10^{-4}$. What is the pH of a 0.63 M solution of this acid at $25^{\circ} \mathrm{C}$ ?
a) 3.26
b) $1.83 \times 10^{-2}$
c) 1.73
d) 1.63
e) 0.201
16.5.2 A 0.042 M solution of a weak acid has pH 4.01 at $25^{\circ} \mathrm{C}$. What is the $K_{\mathrm{a}}$ of this acid?
a) $9.5 \times 10^{-9}$
b) $9.8 \times 10^{-5}$
c) 0.91
d) $4.2 \times 10^{-2}$
e) $2.3 \times 10^{-7}$
16.5.3 The diagrams show solutions of three different weak acids with the general formula HA. List the acids in order of increasing $K_{\mathrm{a}}$ value.

(ii)
(iii)
a) i $<$ ii $<$ iii
b) i $<$ iii $<$ ii
c) ii $<$ i $<$ iii
d) ii $<$ iii $<$ i
e) iii $<$ ii $<$ i

### 16.6 Weak Bases and Base Ionization Constants

Just as most acids are weak, most bases are also weak. The ionization of a weak base is incomplete and is treated in the same way as the ionization of a weak acid. In this section, we will see how the ionization constant for a weak base, $K_{\mathrm{b}}$, is related to the pH of an aqueous solution.

## The Ionization Constant, $K_{b}$

The ionization of a weak base can be represented by the equation

$$
\mathrm{B}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{HB}^{+}(a q)+\mathrm{OH}^{-}(a q)
$$

where B is the weak base and $\mathrm{HB}^{+}$is its conjugate acid. The equilibrium expression for the ionization is

$$
K_{\mathrm{b}}=\frac{\left[\mathrm{HB}^{+}\right]\left[\mathrm{OH}^{-}\right]}{[\mathrm{B}]}
$$

## TABLE 16.7

## Ionization Constants of Some Weak Bases at $25^{\circ} \mathrm{C}$

| Name of Base | Formula | Structure | $K_{\text {b }}$ |
| :---: | :---: | :---: | :---: |
| Ethylamine | $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{NH}_{2}$ |  | $5.6 \times 10^{-4}$ |
| Methylamine | $\mathrm{CH}_{3} \mathrm{NH}_{2}$ |  | $4.4 \times 10^{-4}$ |
| Ammonia | $\mathrm{NH}_{3}$ |  | $1.8 \times 10^{-5}$ |
| Pyridine | $\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N}$ |  | $1.7 \times 10^{-9}$ |
| Aniline | $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{NH}_{2}$ |  | $3.8 \times 10^{-10}$ |
| Urea | $\mathrm{H}_{2} \mathrm{NCONH}_{2}$ |  | $1.5 \times 10^{-14}$ |

where $K_{\mathrm{b}}$ is the equilibrium constant—specifically known as the base ionization constant. Like weak acids, weak bases vary in strength. Table 16.7 lists a number of common weak bases and their ionization constants. The ability of any one of these substances to act as a base is the result of the lone pair of electrons on the nitrogen atom. The presence of this lone pair is what enables a compound to accept a proton, which is what makes a compound a Brønsted base.

## Calculating pH from $K_{\mathrm{b}}$

Solving problems involving weak bases requires the same approach we used for weak acids. It is important to remember, though, that solving for $x$ in a typical weak base problem gives us the hydroxide ion concentration rather than the hydronium ion concentration.

Sample Problem 16.15 shows how to use $K_{\mathrm{b}}$ to calculate the pH of a weak base solution.

## Sample Problem 16.15

What is the pH of a 0.040 M ammonia solution at $25^{\circ} \mathrm{C}$ ?
Strategy Construct an equilibrium table, and express equilibrium concentrations in terms of the unknown $x$. Plug these equilibrium concentrations into the equilibrium expression, and solve for $x$. From the value of $x$, determine the pH .

Setup

Initial concentration ( $M$ ):
Change in concentration ( $M$ ):
Equilibrium concentration (M):

| $\mathrm{NH}_{3}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{NH}_{4}^{+}(a q)+\mathrm{OH}^{-}(a q)$ |  |  |  |
| :--- | :---: | :---: | :---: |
| 0.040 |  | 0 | 0 |
| $-x$ |  | $+x$ | $+x$ |
| $0.040-x$ | $x$ | $x$ |  |

Solution The equilibrium concentrations are substituted into the equilibrium expression to give

$$
K_{\mathrm{b}}=\frac{\left[\mathrm{NH}_{4}^{+}\right]\left[\mathrm{OH}^{-}\right]}{\left[\mathrm{NH}_{3}\right]}=\frac{(x)(x)}{0.040-x}=1.8 \times 10^{-5}
$$

Student Annotation: Applying the 5 percent test indicates that the approximation shortcut is valid in this case: $\left(8.49 \times 10^{-4} / 0.040\right) \times$ $100 \%=2 \%$.

Think About It It is a common error in $K_{\mathrm{b}}$ problems to forget that $x$ is the hydroxide ion concentration rather than the hydronium ion concentration. Always make sure that the pH you calculate for a solution of base is a basic pH , that is, a pH greater than 7 .

Think About It Check your answer by using the calculated $K_{\mathrm{b}}$ to determine the pH of a 0.15 M solution.

Assuming that $0.040-x \approx 0.040$ and solving for $x$ gives

$$
\begin{aligned}
\frac{(x)(x)}{0.040-x} & \approx \frac{(x)(x)}{0.040}=1.8 \times 10^{-5} \\
x^{2} & =\left(1.8 \times 10^{-5}\right)(0.040)=7.2 \times 10^{-7} \\
x & =\sqrt{7.2 \times 10^{-7}}=8.5 \times 10^{-4} \mathrm{M}
\end{aligned}
$$

According to the equilibrium table, $x=\left[\mathrm{OH}^{-}\right]$. Therefore, $\mathrm{pOH}=-\log (x)$ :

$$
-\log \left(8.5 \times 10^{-4}\right)=3.07
$$

and $\mathrm{pH}=14.00-\mathrm{pOH}=14.00-3.07=10.93$. The pH of a 0.040 M solution of $\mathrm{NH}_{3}$ at $25^{\circ} \mathrm{C}$ is 10.93 .

Practice Problem A Calculate the pH at $25^{\circ} \mathrm{C}$ of a 0.0028 M solution of a weak base with a $K_{\mathrm{b}}$ of $6.8 \times 10^{-8}$.

EPractice Problem B Calculate the pH at $25^{\circ} \mathrm{C}$ of a 0.16 M solution of a weak base with a $K_{\mathrm{b}}$ of $2.9 \times 10^{-11}$.

## Using pH to Determine $\boldsymbol{K}_{\mathrm{b}}$

Just as we can use pH to determine the $K_{\mathrm{a}}$ of a weak acid, we can also use it to determine the $K_{\mathrm{b}}$ of a weak base. Sample Problem 16.16 demonstrates this procedure.

## Sample Problem 16.16

Caffeine, the stimulant in coffee and tea, is a weak base that ionizes in water according to the equation

$$
\mathrm{C}_{8} \mathrm{H}_{10} \mathrm{~N}_{4} \mathrm{O}_{2}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{HC}_{8} \mathrm{H}_{10} \mathrm{~N}_{4} \mathrm{O}_{2}^{+}(a q)+\mathrm{OH}^{-}(a q)
$$

A 0.15 M solution of caffeine at $25^{\circ} \mathrm{C}$ has a pH of 8.45 . Determine the $K_{\mathrm{b}}$ of caffeine.
Strategy Use pH to determine pOH , and pOH to determine the hydroxide ion concentration. From the hydroxide ion concentration, use reaction stoichiometry to determine the other equilibrium concentrations and plug those concentrations into the equilibrium expression to evaluate $K_{\mathrm{b}}$.

Setup

$$
\begin{gathered}
\mathrm{pOH}=14.00-8.45=5.55 \\
{\left[\mathrm{OH}^{-}\right]=10^{-5.55}=2.82 \times 10^{-6} \mathrm{M}}
\end{gathered}
$$

Based on the reaction stoichiometry, $\left[\mathrm{HC}_{8} \mathrm{H}_{10} \mathrm{~N}_{4} \mathrm{O}_{2}^{+}\right]=\left[\mathrm{OH}^{-}\right]$, and the amount of hydroxide ion in solution at equilibrium is equal to the amount of caffeine that has ionized. At equilibrium, therefore,

$$
\left[\mathrm{C}_{8} \mathrm{H}_{10} \mathrm{~N}_{4} \mathrm{O}_{2}\right]=\left(0.15-2.82 \times 10^{-6}\right) M \approx 0.15 \mathrm{M}
$$

Initial concentration ( $M$ ):
Change in concentration ( $M$ ):
Equilibrium concentration (M):

| $\mathrm{C}_{8} \mathrm{H}_{10} \mathrm{~N}_{4} \mathrm{O}_{2}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{HC}_{8} \mathrm{H}_{10} \mathrm{~N}_{4} \mathrm{O}_{2}^{+}(a q)+\mathrm{OH}^{-}(a q)$ |  |  |  |
| :---: | :---: | :---: | :---: |
| 0.15 |  | 0 | 0 |
| $-2.82 \times 10^{-6}$ |  | $+2.82 \times 10^{-6}$ | $+2.82 \times 10^{-6}$ |
| 0.15 |  | $2.82 \times 10^{-6}$ | $2.82 \times 10^{-6}$ |

Solution Plugging the equilibrium concentrations into the equilibrium expression gives

$$
K_{\mathrm{b}}=\frac{\left[\mathrm{HC}_{8} \mathrm{H}_{10} \mathrm{~N}_{4} \mathrm{O}_{2}^{+}\right]\left[\mathrm{OH}^{-}\right]}{\left[\mathrm{C}_{8} \mathrm{H}_{10} \mathrm{~N}_{4} \mathrm{O}_{2}\right]}=\frac{\left(2.82 \times 10^{-6}\right)^{2}}{0.15}=5.3 \times 10^{-11}
$$

Practice Problem A Determine the $K_{\mathrm{b}}$ of a weak base if a 0.50 M solution of the base has a pH of 9.59 at $25^{\circ} \mathrm{C}$.

EPractice Problem B Determine the $K_{\mathrm{b}}$ of a weak base if a 0.35 M solution of the base has a pH of 11.84 at $25^{\circ} \mathrm{C}$.

## Checkpoint 16.6 Weak Bases and Base Ionization Constants

16.6.1 What is the pH of a 0.63 M solution of weak base at $25^{\circ} \mathrm{C}$ if $K_{\mathrm{b}}=9.5 \times 10^{-7}$ ?
a) 3.11
b) 10.89
c) 7.00
d) 1.12

### 16.7 Conjugate Acid-Base Pairs

At the beginning of this chapter, we introduced the concept of conjugate acids and conjugate bases. In this section, we examine the properties of conjugate acids and bases, independent of their parent compounds.

## The Strength of a Conjugate Acid or Base

When a strong acid such as HCl dissolves in water, it ionizes completely because its conjugate base $\left(\mathrm{Cl}^{-}\right)$has essentially no affinity for the $\mathrm{H}^{+}$ion in solution.

$$
\mathrm{HCl}(a q) \longrightarrow \mathrm{H}^{+}(a q)+\mathrm{Cl}^{-}(a q)
$$

Because the chloride ion has no affinity for the $\mathrm{H}^{+}$ion, it does not act as a Brønsted base in water. If we dissolve a chloride salt such as NaCl in water, for example, the $\mathrm{Cl}^{-}$ions in solution would not accept protons from the water:

$$
\mathrm{Cl}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{HCl}(a q)+\mathrm{OH}^{-}(a q)
$$

The chloride ion, which is the conjugate base of a strong acid, is an example of a weak conjugate base.

Now consider the case of a weak acid. When HF dissolves in water, the ionization happens only to a limited degree because the conjugate base, $\mathrm{F}^{-}$, has a strong affinity for the $\mathrm{H}^{+}$ion:

$$
\mathrm{HF}(a q) \rightleftarrows \mathrm{H}^{+}(a q)+\mathrm{F}^{-}(a q)
$$

This equilibrium lies far to the left $\left(K_{\mathrm{a}}=7.1 \times 10^{-4}\right)$. Because the fluoride ion has a strong affinity for the $\mathrm{H}^{+}$ion, it acts as a Brønsted base in water. If we were to dissolve a fluoride salt, such as NaF in water, the $\mathrm{F}^{-}$ions in solution would, to some extent, accept protons from water:

$$
\mathrm{F}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{HF}(a q)+\mathrm{OH}^{-}(a q)
$$

The fluoride ion, which is the conjugate base of a weak acid, is an example of a strong conjugate base.

Conversely, a strong base has a weak conjugate acid and a weak base has a strong conjugate acid. For example, $\mathrm{H}_{2} \mathrm{O}$ is the weak conjugate acid of the strong base $\mathrm{OH}^{-}$, whereas the ammonium ion $\left(\mathrm{NH}_{4}^{+}\right)$is the strong conjugate acid of the weak base ammonia $\left(\mathrm{NH}_{3}\right)$. When an ammonium salt is dissolved in water, the ammonium ions donate protons to the water molecules:

$$
\mathrm{NH}_{4}^{+}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{NH}_{3}(a q)+\mathrm{H}_{3} \mathrm{O}^{+}(a q)
$$

Student Annotation: The products HCl and $\mathrm{OH}^{-}$do not actually form when $\mathrm{Cl}^{-}$and $\mathrm{H}_{2} \mathrm{O}$ are combined.

Student Annotation: Note that one of the products of the reaction of a conjugate base with water is always the corresponding weak acid.

Student Annotation: The Group 1A and heavy Group 2A metal hydroxides are classified as strong bases. It is the hydroxide ion itself, however, that accepts a proton and is therefore the Bronsted base. Soluble metal hydroxides are simply sources of the hydroxide ion.

Student Annotation: A strong conjugate acid is a weak Brønsted acid. A strong conjugate base is a weak Brensted base.

Student Annotation: A conjugate base such as the acetate ion is introduced into a solution by dissolving a soluble salt containing acetate. Sodium acetate, for example, can be used to supply the acetate ion. The sodium ion does not take part in the reaction-it is a spectator ion [144 Section 4.2].

Student Annotation: Remember that the hydronium ion can be expressed as either $\mathrm{H}^{+}$ or $\mathrm{H}_{3} \mathrm{O}^{+}$. These are two equivalent ways to represent the autoionization of water.

In general, there is a reciprocal relationship between the strength of an acid or base and the strength of its conjugate.

| Acid | Example | Conjugate <br> base | Formula | Base | Example | Conjugate <br> acid | Formula |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| strong | $\mathrm{HNO}_{3}$ | weak <br> conjugate | $\mathrm{NO}_{3}^{-}$ | strong | $\mathrm{OH}^{-}$ | weak <br> conjugate | $\mathrm{H}_{2} \mathrm{O}$ |
| weak | HCN | strong <br> conjugate | $\mathrm{CN}^{-}$ | weak | $\mathrm{NH}_{3}$ | strong <br> conjugate | $\mathrm{NH}_{4}^{+}$ |

It is important to recognize that the words strong and weak do not mean the same thing in the context of conjugate acids and conjugate bases as they do in the context of acids and bases in general. A strong conjugate reacts with water-either accepting a proton from it or donating a proton to it-to a small but measurable extent. A strong conjugate acid acts as a weak Brønsted acid in water; and a strong conjugate base acts as a weak Brønsted base in water. A weak conjugate does not react with water to any measurable extent.

## The Relationship Between $K_{\mathrm{a}}$ and $K_{\mathrm{b}}$ of a Conjugate Acid-Base Pair

Because it accepts a proton from water to a small extent, what we refer to as a "strong conjugate base" is actually a weak Brønsted base. Therefore, every strong conjugate base has an ionization constant, $K_{\mathrm{b}}$. Likewise, every strong conjugate acid, because it acts as a weak Brønsted base, has an ionization constant, $K_{\mathrm{a}}$.

A simple relationship between the ionization constant of a weak acid $\left(K_{\mathrm{a}}\right)$ and the ionization constant of its conjugate base ( $K_{\mathrm{b}}$ ) can be derived as follows, using acetic acid as an example:

$$
\begin{gathered}
\underset{\text { acid }}{\mathrm{CH}_{3} \mathrm{COOH}(a q)} \rightleftarrows \mathrm{H}^{+}(a q)+\mathrm{CH}_{3} \mathrm{COO}^{-}(a q) \\
\text { conjugate base }
\end{gathered}
$$

The conjugate base, $\mathrm{CH}_{3} \mathrm{COO}^{-}$, reacts with water according to the equation

$$
\mathrm{CH}_{3} \mathrm{COO}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{CH}_{3} \mathrm{COOH}(a q)+\mathrm{OH}^{-}(a q)
$$

and the base ionization equilibrium expression is written as

$$
K_{\mathrm{b}}=\frac{\left[\mathrm{CH}_{3} \mathrm{COOH}\right]\left[\mathrm{OH}^{-}\right]}{\left[\mathrm{CH}_{3} \mathrm{COO}^{-}\right]}
$$

As for any chemical equations, we can add these two equilibria and cancel identical terms:

$$
\begin{aligned}
\mathrm{CH}_{3} \mathrm{COOH}(a q) & \rightleftarrows \mathrm{H}^{+}(a q)+\mathrm{CH}_{3} \mathrm{COO}^{-}(a q) \\
+\mathrm{CH}_{3} \mathrm{COO}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) & \Longleftrightarrow \mathrm{CH}_{3} \mathrm{COOH}(a q)+\mathrm{OH}^{-}(a q) \\
\hline \mathrm{H}_{2} \mathrm{O}(l) & \rightleftarrows \mathrm{H}^{+}(a q)+\mathrm{OH}^{-}(a q)
\end{aligned}
$$

The sum is the autoionization of water. In fact, this is the case for any weak acid and its conjugate base:

$$
\begin{aligned}
\mathrm{HA} & \rightleftarrows \mathrm{H}^{+}+\mathrm{A}^{-} \\
+ \text {A }^{+}+\mathrm{H}_{2} \mathrm{O} & \rightleftarrows \mathrm{HA}^{-}+\mathrm{OH}^{-} \\
\mathrm{H}_{2} \mathrm{O} & \rightleftarrows \mathrm{H}^{+}+\mathrm{OH}^{-}
\end{aligned}
$$

or for any weak base and its conjugate acid.

$$
\begin{aligned}
\mathrm{B}^{\prime}+\mathrm{H}_{2} \mathrm{O} & \rightleftarrows \mathrm{HB}^{+}+\mathrm{OH}^{-} \\
+\mathrm{HB}^{+}+\mathrm{H}_{2} \mathrm{O} & \rightleftarrows \mathrm{~B}^{\prime}+\mathrm{H}_{3} \mathrm{O}^{+} \\
2 \mathrm{H}_{2} \mathrm{O} & \rightleftarrows \mathrm{H}_{3} \mathrm{O}^{+}+\mathrm{OH}^{-}
\end{aligned}
$$

Recall that when we add two equilibria, the equilibrium constant for the net reaction is the product of the equilibrium constants for the individual equations [ 144 Section 15.3]. Thus, for any conjugate acid-base pair,

$$
K_{\mathrm{a}} \times K_{\mathrm{b}}=K_{\mathrm{w}}
$$

Equation 16.8
Equation 16.8 gives the quantitative basis for the reciprocal relationship between the strength of an acid and that of its conjugate base (or between the strength of a base and that of its conjugate acid). Because $K_{\mathrm{w}}$ is a constant, $K_{\mathrm{b}}$ must decrease if $K_{\mathrm{a}}$ increases, and vice versa.

Sample Problem 16.17 shows how to determine ionization constants for conjugates.

## Sample Problem 16.17

Determine (a) $K_{\mathrm{b}}$ of the acetate ion $\left(\mathrm{CH}_{3} \mathrm{COO}^{-}\right)$, (b) $K_{\mathrm{a}}$ of the methylammonium ion $\left(\mathrm{CH}_{3} \mathrm{NH}_{3}^{+}\right)$, (c) $K_{\mathrm{b}}$ of the fluoride ion $\left(\mathrm{F}^{-}\right)$, and (d) $K_{\mathrm{a}}$ of the ammonium ion $\left(\mathrm{NH}_{4}^{+}\right)$.

Strategy Each species listed is either a conjugate base or a conjugate acid. Determine the identity of the acid corresponding to each conjugate base and the identity of the base corresponding to each conjugate acid; then, consult Tables 16.6 and 16.7 for their ionization constants. Use the tabulated ionization constants and Equation 16.8 to calculate each indicated $K$ value.

Setup (a) A $K_{\mathrm{b}}$ value is requested, indicating that the acetate ion is a conjugate base. To identify the corresponding $\mathrm{Br} \varnothing$ nsted acid, add a proton to the formula to get $\mathrm{CH}_{3} \mathrm{COOH}$ (acetic acid). The $K_{\mathrm{a}}$ of acetic acid (from Table 16.6) is $1.8 \times 10^{-5}$.
(b) A $K_{\mathrm{a}}$ value is requested, indicating that the methylammonium ion is a conjugate acid. Determine the identity of the corresponding Brønsted base by removing a proton from the formula to get $\mathrm{CH}_{3} \mathrm{NH}_{2}$ (methylamine). The $K_{\mathrm{b}}$ of methylamine (from Table 16.7) is $4.4 \times 10^{-4}$.
(c) $\mathrm{F}^{-}$is the conjugate base of $\mathrm{HF} ; K_{\mathrm{a}}=7.1 \times 10^{-4}$.
(d) $\mathrm{NH}_{4}^{+}$is the conjugate acid of $\mathrm{NH}_{3} ; K_{\mathrm{b}}=1.8 \times 10^{-5}$. Solving Equation 16.8 separately for $K_{\mathrm{a}}$ and $K_{\mathrm{b}}$ gives, respectively,

$$
K_{\mathrm{a}}=\frac{K_{\mathrm{w}}}{K_{\mathrm{b}}} \quad \text { and } \quad K_{\mathrm{b}}=\frac{K_{\mathrm{w}}}{K_{\mathrm{a}}}
$$

Solution (a) Conjugate base $\mathrm{CH}_{3} \mathrm{COO}^{-}: K_{\mathrm{b}}=\frac{1.0 \times 10^{-14}}{1.8 \times 10^{-5}}=5.6 \times 10^{-10}$
(b) Conjugate acid $\mathrm{CH}_{3} \mathrm{NH}_{3}^{+}: K_{\mathrm{a}}=\frac{1.0 \times 10^{-14}}{4.4 \times 10^{-4}}=2.3 \times 10^{-11}$
(c) Conjugate base $\mathrm{F}^{-}: K_{\mathrm{b}}=\frac{1.0 \times 10^{-14}}{7.1 \times 10^{-4}}=1.4 \times 10^{-11}$
(d) Conjugate acid $\mathrm{NH}_{4}^{+}: K_{\mathrm{a}}=\frac{1.0 \times 10^{-14}}{1.8 \times 10^{-5}}=5.6 \times 10^{-10}$

Practice Problem A Determine (a) $K_{\mathrm{b}}$ of the benzoate ion $\left(\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COO}^{-}\right)$, (b) $K_{\mathrm{b}}$ of the ascorbate ion $\left(\mathrm{HC}_{6} \mathrm{H}_{6} \mathrm{O}_{6}^{-}\right)$, and (c) $K_{\mathrm{a}}$ of the ethylammonium ion $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{NH}_{3}^{+}\right)$.
$\$$ Practice Problem B Determine (a) $K_{\mathrm{b}}$ of the weak base B whose conjugate acid $\mathrm{HB}^{+}$has $K_{\mathrm{a}}=8.9 \times 10^{-4}$ and (b) $K_{\mathrm{a}}$ of the weak acid HA whose conjugate base has $K_{\mathrm{b}}=2.1 \times 10^{-8}$.

Think About It Because the conjugates of weak acids and bases have ionization constants, salts containing these ions have an effect on the pH of a solution. In Section 16.10 we will use the ionization constants of conjugate acids and conjugate bases to calculate pH for solutions containing dissolved salts.

## Checkpoint 16.7 Conjugate Acid-Base Pairs

16.7.1 Calculate the $K_{\mathrm{b}}$ of the cyanide ion $\left(\mathrm{CN}^{-}\right)$.
a) $4.9 \times 10^{-10}$
b) $2.0 \times 10^{-5}$
c) $4.9 \times 10^{-24}$
d) $1.0 \times 10^{-7}$
e) $2.2 \times 10^{-5}$
16.7.2 Which of the anions listed is the strongest base? (See Table 16.6.)
a) Ascorbate ion $\left(\mathrm{HC}_{6} \mathrm{H}_{6} \mathrm{O}_{6}^{-}\right)$
b) Benzoate ion $\left(\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COO}^{-}\right)$
c) Nitrite ion $\left(\mathrm{NO}_{2}^{-}\right)$
d) Phenolate ion $\left(\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}^{-}\right)$
e) Formate ion $\left(\mathrm{HCOO}^{-}\right)$
16.7.3 The diagrams show solutions of three different weak acids with formulas HX, HY, and HZ. List the anions $\mathrm{X}^{-}, \mathrm{Y}^{-}$, and $\mathrm{Z}^{-}$in order of increasing $K_{\mathrm{b}}$ value.

a) $\mathrm{Z}^{-}<\mathrm{Y}^{-}<\mathrm{X}^{-}$
b) $\mathrm{Y}^{-}<\mathrm{Z}^{-}<\mathrm{X}^{-}$
c) $\mathrm{Z}^{-}<\mathrm{X}^{-}<\mathrm{Y}^{-}$
d) $\mathrm{X}^{-}<\mathrm{Y}^{-}<\mathrm{Z}^{-}$
e) $\mathrm{X}^{-}<\mathrm{Z}^{-}<\mathrm{Y}^{-}$

Student Annotation: A triprotic acid has $K_{\mathrm{a}_{1}}$ $K_{\mathrm{a}_{2}}$ and $K_{\mathrm{a}_{3}}$.

### 16.8 Diprotic and Polyprotic Acids

Diprotic and polyprotic acids undergo successive ionizations, losing one proton at a time [ $14 \mathrm{Sec}-$ tion 4.3 ], and each ionization has a $K_{\mathrm{a}}$ associated with it. Ionization constants for a diprotic acid are designated $K_{\mathrm{a}_{1}}$ and $K_{\mathrm{a}_{2}}$. We write a separate equilibrium expression for each ionization, and we may need two or more equilibrium expressions to calculate the concentrations of species in solution at equilibrium. For carbonic acid $\left(\mathrm{H}_{2} \mathrm{CO}_{3}\right)$, for example, we write

$$
\begin{aligned}
\mathrm{H}_{2} \mathrm{CO}_{3}(a q) \rightleftarrows \mathrm{H}^{+}(a q)+\mathrm{HCO}_{3}^{-}(a q) & K_{\mathrm{a}_{1}}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{HCO}_{3}^{-}\right]}{\left[\mathrm{H}_{2} \mathrm{CO}_{3}\right]} \\
\mathrm{HCO}_{3}^{-}(a q) \rightleftarrows \mathrm{H}^{+}(a q)+\mathrm{CO}_{3}^{2-}(a q) & K_{\mathrm{a}_{2}}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{CO}_{3}^{2-}\right]}{\left[\mathrm{HCO}_{3}^{-}\right]}
\end{aligned}
$$

Note that the conjugate base in the first ionization is the acid in the second ionization. Table 16.8 shows the ionization constants of several diprotic acids and one polyprotic acid. For a given acid, the first ionization constant is much larger than the second ionization constant, and so on. This trend makes sense because it is easier to remove a proton from a neutral species than from one that is negatively charged, and it is easier to remove a proton from a species with a single negative charge than from one with a double negative charge.

Sample Problem 16.18 shows how to calculate equilibrium concentrations of all species in solution for an aqueous solution of a diprotic acid.

## Sample Problem 16.18

Oxalic acid $\left(\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}\right)$ is a poisonous substance used mainly as a bleaching agent. Calculate the concentrations of all species present at equilibrium in a 0.10 M solution at $25^{\circ} \mathrm{C}$.

Strategy Follow the same procedure for each ionization as for the determination of equilibrium concentrations for a monoprotic acid. The conjugate base resulting from the first ionization is the acid for the second ionization, and its starting concentration is the equilibrium concentration from the first ionization.

Setup The ionizations of oxalic acid and the corresponding ionization constants are

$$
\begin{aligned}
\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}(a q) \rightleftarrows \mathrm{H}^{+}(a q)+\mathrm{HC}_{2} \mathrm{O}_{4}^{-}(a q) & K_{\mathrm{a}_{1}}=6.5 \times 10^{-2} \\
\mathrm{HC}_{2} \mathrm{O}_{4}^{-}(a q) \rightleftarrows \mathrm{H}^{+}(a q)+\mathrm{C}_{2} \mathrm{O}_{4}^{2-}(a q) & K_{\mathrm{a}_{2}}=6.1 \times 10^{-5}
\end{aligned}
$$

Construct an equilibrium table for each ionization, using $x$ as the unknown in the first ionization and $y$ as the unknown in the second ionization.

## Initial concentration ( $M$ ):

Change in concentration (M):
Equilibrium concentration (M):

$$
\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}(a q) \rightleftarrows \mathrm{H}^{+}(a q)+\mathrm{HC}_{2} \mathrm{O}_{4}^{-}(a q)
$$

The equilibrium concentration of the hydrogen oxalate ion $\left(\mathrm{HC}_{2} \mathrm{O}_{4}^{-}\right)$after the first ionization becomes the starting concentration for the second ionization. Additionally, the equilibrium concentration of $\mathrm{H}^{+}$is the starting concentration for the second ionization.

$$
\mathrm{HC}_{2} \mathrm{O}_{4}^{-}(a q) \rightleftarrows \mathrm{H}^{+}(a q)+\mathrm{C}_{2} \mathrm{O}_{4}^{2-}(a q)
$$

Initial concentration ( $M$ ):
Change in concentration (M):
Equilibrium concentration (M):

| $x$ | $x$ | 0 |
| :---: | :---: | :---: |
| $-y$ | $+y$ | $+y$ |
| $x-y$ | $x+y$ | $y$ |

## Solution

$$
\begin{aligned}
K_{\mathrm{a}_{1}} & =\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{HC}_{2} \mathrm{O}_{4}^{-}\right]}{\left[\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}\right]} \\
6.5 \times 10^{-2} & =\frac{x^{2}}{0.10-x}
\end{aligned}
$$

Applying the approximation and neglecting $x$ in the denominator of the expression gives

$$
\begin{aligned}
6.5 \times 10^{-2} & \approx \frac{x^{2}}{0.10} \\
x^{2} & =6.5 \times 10^{-3} \\
x & =8.1 \times 10^{-2} M
\end{aligned}
$$

## TABLE 16.8 Ionization Constants of Some Diprotic and Polyprotic Acids at $25^{\circ} \mathrm{C}$

| Name of Acid | Formula | Structure | $K_{\mathrm{a}_{1}}$ | $K_{\mathrm{a}_{2}}$ | $K_{\mathrm{a}_{3}}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Sulfuric acid | $\mathrm{H}_{2} \mathrm{SO}_{4}$ |  | Very large | $1.3 \times 10^{-2}$ |  |
| Oxalic acid | $\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}$ |  | $6.5 \times 10^{-2}$ | $6.1 \times 10^{-5}$ |  |
| Sulfurous acid | $\mathrm{H}_{2} \mathrm{SO}_{3}$ |  | $1.3 \times 10^{-2}$ | $6.3 \times 10^{-8}$ |  |
| Ascorbic acid (vitamin C) | $\mathrm{H}_{2} \mathrm{C}_{6} \mathrm{H}_{6} \mathrm{O}_{6}$ |  | $8.0 \times 10^{-5}$ | $1.6 \times 10^{-12}$ |  |
| Carbonic acid | $\mathrm{H}_{2} \mathrm{CO}_{3}$ |  | $4.2 \times 10^{-7}$ | $4.8 \times 10^{-11}$ |  |
| Hydrosulfuric acid* | $\mathrm{H}_{2} \mathrm{~S}$ | $\mathrm{H}-\mathrm{S}-\mathrm{H}$ | $9.5 \times 10^{-8}$ | $1 \times 10^{-19}$ |  |
| Phosphoric acid | $\mathrm{H}_{3} \mathrm{PO}_{4}$ |  | $7.5 \times 10^{-3}$ | $6.2 \times 10^{-8}$ | $4.2 \times 10^{-13}$ |

[^41]Think About It Note that the second ionization did not contribute significantly to the $\mathrm{H}^{+}$concentration. Therefore, we could determine the pH of this solution by considering only the first ionization. This is true in general for polyprotic acids where $K_{\mathrm{a}_{1}}$ is at least $1000 \times K_{\mathrm{a}_{2}}$. [It is necessary to consider the second ionization to determine the concentration of oxalate ion $\left(\mathrm{C}_{2} \mathrm{O}_{4}^{2-}\right)$.]

Testing the approximation,

$$
\frac{8.1 \times 10^{-2} M}{0.10 M} \times 100 \%=81 \%
$$

Clearly the approximation is not valid, so we must solve the following quadratic equation:

$$
x^{2}+6.5 \times 10^{-2} x-6.5 \times 10^{-3}=0
$$

The result is $x=0.054 M$. Thus, after the first ionization, the concentrations of species in solution are

$$
\begin{aligned}
{\left[\mathrm{H}^{+}\right] } & =0.054 \mathrm{M} \\
{\left[\mathrm{HC}_{2} \mathrm{O}_{4}^{-}\right] } & =0.054 \mathrm{M} \\
{\left[\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}\right] } & =(0.10-0.054) M=0.046 \mathrm{M}
\end{aligned}
$$

Rewriting the equilibrium table for the second ionization, using the calculated value of $x$, gives the following:

$$
\mathrm{HC}_{2} \mathrm{O}_{4}^{-}(a q) \rightleftarrows \mathrm{H}^{+}(a q)+\mathrm{C}_{2} \mathrm{O}_{4}^{2-}(a q)
$$

Initial concentration ( $M$ ):
Change in concentration ( $M$ ):
Equilibrium concentration ( $M$ ):

| 0.054 | 0.054 | 0 |
| :---: | :---: | :---: |
| $-y$ | $+y$ | $+y$ |
| $0.054-y$ | $0.054+y$ | $y$ |

$$
\begin{aligned}
K_{\mathrm{a}_{2}} & =\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{C}_{2} \mathrm{O}_{4}^{2-}\right]}{\left[\mathrm{HC}_{2} \mathrm{O}_{4}^{-}\right]} \\
6.1 \times 10^{-5} & =\frac{(0.054+y)(y)}{0.054-y}
\end{aligned}
$$

Assuming that $y$ is very small and applying the approximations $0.054+y \approx 0.054$ and $0.054-y \approx$ 0.054 gives

$$
\frac{(0.054)(y)}{0.054}=y=6.1 \times 10^{-5} M
$$

We must test the approximation as follows to see if it is valid:

$$
\frac{6.1 \times 10^{-5} M}{0.054 M} \times 100 \%=0.11 \%
$$

This time, because the ionization constant is much smaller, the approximation is valid. At equilibrium, the concentrations of all species are

$$
\begin{aligned}
{\left[\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}\right] } & =0.046 \mathrm{M} \\
{\left[\mathrm{HC}_{2} \mathrm{O}_{4}^{-}\right] } & =\left(0.054-6.1 \times 10^{-5}\right) M=0.054 \mathrm{M} \\
{\left[\mathrm{H}^{+}\right] } & =\left(0.054+6.1 \times 10^{-5}\right) M=0.054 \mathrm{M} \\
{\left[\mathrm{C}_{2} \mathrm{O}_{4}^{2-}\right] } & =6.1 \times 10^{-5} \mathrm{M}
\end{aligned}
$$

Practice Problem A Calculate the concentrations of $\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}, \mathrm{HC}_{2} \mathrm{O}_{4}^{-}, \mathrm{C}_{2} \mathrm{O}_{4}^{2-}$, and $\mathrm{H}^{+}$ions in a 0.20 M oxalic acid solution at $25^{\circ} \mathrm{C}$.
$\boldsymbol{H}$ Practice Problem B Calculate the concentrations of $\mathrm{H}_{2} \mathrm{SO}_{4}, \mathrm{HSO}_{4}^{-}, \mathrm{SO}_{4}^{2-}$, and $\mathrm{H}^{+}$ions in a 0.14 M sulfuric acid solution at $25^{\circ} \mathrm{C}$.

## Checkpoint 16.8 Diprotic and Polyprotic Acids

16.8.1 Calculate the equilibrium concentration of $\mathrm{CO}_{3}^{2-}$ in a 0.050 M solution of carbonic acid at $25^{\circ} \mathrm{C}$.
a) $4.2 \times 10^{-7} \mathrm{M}$
b) $4.8 \times 10^{-11} \mathrm{M}$
c) $1.5 \times 10^{-4} \mathrm{M}$
d) 0.050 M
e) 0.049 M
16.8.2 What is the pH of a 0.40 M solution of phosphoric acid at $25^{\circ} \mathrm{C}$ ?
a) 5.48
b) 1.26
c) 1.29
d) 12.74
e) 0.80
16.8.3 List the molecular and ionic species in order of increasing concentration in a solution of ascorbic acid $\left(\mathrm{H}_{2} \mathrm{C}_{6} \mathrm{H}_{6} \mathrm{O}_{6}\right)$.
a) $\left[\mathrm{H}_{2} \mathrm{C}_{6} \mathrm{H}_{6} \mathrm{O}_{6}\right]<\left[\mathrm{HC}_{6} \mathrm{H}_{6} \mathrm{O}_{6}^{-}\right]<\left[\mathrm{C}_{6} \mathrm{H}_{6} \mathrm{O}_{6}^{2-}\right]=\left[\mathrm{H}^{+}\right]$
b) $\left[\mathrm{H}_{2} \mathrm{C}_{6} \mathrm{H}_{6} \mathrm{O}_{6}\right]<\left[\mathrm{HC}_{6} \mathrm{H}_{6} \mathrm{O}_{6}^{-}\right]<\left[\mathrm{C}_{6} \mathrm{H}_{6} \mathrm{O}_{6}^{2-}\right]<\left[\mathrm{H}^{+}\right]$
c) $\left[\mathrm{C}_{6} \mathrm{H}_{6} \mathrm{O}_{6}^{2-}\right]<\left[\mathrm{HC}_{6} \mathrm{H}_{6} \mathrm{O}_{6}^{-}\right]=\left[\mathrm{H}^{+}\right]<\left[\mathrm{H}_{2} \mathrm{C}_{6} \mathrm{H}_{6} \mathrm{O}_{6}\right]$
d) $\left[\mathrm{H}^{+}\right]=\left[\mathrm{H}_{2} \mathrm{C}_{6} \mathrm{H}_{6} \mathrm{O}_{6}\right]<\left[\mathrm{HC}_{6} \mathrm{H}_{6} \mathrm{O}_{6}^{-}\right]<\left[\mathrm{C}_{6} \mathrm{H}_{6} \mathrm{O}_{6}^{2-}\right]$
e) $\left[\mathrm{C}_{6} \mathrm{H}_{6} \mathrm{O}_{6}^{2-}\right]=\left[\mathrm{H}^{+}\right]<\left[\mathrm{HC}_{6} \mathrm{H}_{6} \mathrm{O}_{6}^{-}\right]<\left[\mathrm{H}_{2} \mathrm{C}_{6} \mathrm{H}_{6} \mathrm{O}_{6}\right]$
16.8.4 Which is true for any polyprotic acid?
a) $K_{\mathrm{a}_{2}}>K_{\mathrm{a}_{1}}$
b) $K_{\mathrm{a}_{2}}<K_{\mathrm{a}_{1}}$
c) $K_{\mathrm{a}_{2}}=K_{\mathrm{a}_{1}}$
d) $K_{\mathrm{a}_{2}}=\frac{K_{\mathrm{a}_{1}}}{K_{\mathrm{w}}}$
e) $K_{\mathrm{a}_{2}}>\frac{K_{\mathrm{w}}}{K_{\mathrm{a}_{1}}}$

### 16.9 Molecular Structure and Acid Strength

The strength of an acid is measured by its tendency to ionize:

$$
\mathrm{HX} \longrightarrow \mathrm{H}^{+}+\mathrm{X}^{-}
$$

Two factors influence the extent to which the acid undergoes ionization. One is the strength of the $\mathrm{H}-\mathrm{X}$ bond. The stronger the bond, the more difficult it is for the HX molecule to break up and hence the weaker the acid. The other factor is the polarity of the $\mathrm{H}-\mathrm{X}$ bond. The difference in the electronegativities between H and X results in a polar bond like

$$
\begin{gathered}
\delta+\delta- \\
\mathrm{H}-\mathrm{X}
\end{gathered}
$$

If the bond is highly polarized (i.e., if there is a large accumulation of positive and negative charges on the H and X atoms, respectively), HX will tend to break up into $\mathrm{H}^{+}$and $\mathrm{X}^{-}$ions. A high degree of polarity, therefore, gives rise to a stronger acid. In this section, we consider the roles of bond strength and bond polarity in determining the strength of an acid.

## Hydrohalic Acids

The halogens form a series of binary acids called the hydrohalic acids ( $\mathrm{HF}, \mathrm{HCl}, \mathrm{HBr}$, and HI ). Table 16.9 shows that of this series only HF is a weak acid $\left(K_{\mathrm{a}}=7.1 \times 10^{-4}\right)$. The data in the table indicate that the predominant factor in determining the strength of the hydrohalic acids is bond strength. HF has the largest bond enthalpy, making its bond the most difficult to break. In this series of binary acids, acid strength increases as bond strength decreases. The strength of the acids increases as follows:

$$
\mathrm{HF} \ll \mathrm{HCl}<\mathrm{HBr}<\mathrm{HI}
$$

## Oxoacids

An oxoacid, as we learned in Chapter 2, contains hydrogen, oxygen, and a central, nonmetal atom [ 144 Section 2.7]. As the Lewis structures in Figure 16.4 show, oxoacids contain one or more $\mathrm{O}-\mathrm{H}$ bonds. If the central atom is an electronegative element, or is in a high oxidation state, it will attract electrons, causing the $\mathrm{O}-\mathrm{H}$ bond to be more polar. This makes it easier for the hydrogen to be lost as $\mathrm{H}^{+}$, making the acid stronger.

## TABLE 16.9

Bond Enthalpies for Hydrogen Halides and Acid Strengths for Hydrohalic Acids

| Bond | Bond Enthalpy (kJ/mol) | Acid Strength |
| :---: | :---: | :---: |
| $\mathrm{H}-\mathrm{F}$ | 562.8 | Weak |
| $\mathrm{H}-\mathrm{Cl}$ | 431.9 | Strong |
| $\mathrm{H}-\mathrm{Br}$ | 366.1 | Strong |
| $\mathrm{H}-\mathrm{I}$ | 298.3 | Strong |

Student Annotation: The polarity of the $H-X$ bond actually decreases from $H-F$ to $\mathrm{H}-\mathrm{I}$, largely because F is the most electronegative element. This would suggest that HF would be the strongest of the hydrohalic acids. Based on the data in Table 16.9, however, bond enthalpy is the more important factor in determining the strengths of these acids.

Figure 16.4 Lewis structures of some common oxoacids. Recall that there is more than one possible Lewis structure for oxoacids in which the central atom is from period 3 or below on the periodic table [ 14 Section 8.8].

Figure 16.5 Lewis structures of the oxoacids of chlorine. The oxidation number of the Cl atom is shown in parentheses. Note that although hypochlorous acid is written as HClO , the H atom is bonded to the O atom.

Student Annotation: As the number of attached oxygen atoms increases, the oxidation number of the central atom also increases [14 Section 4.4].

To compare their strengths, it is convenient to divide the oxoacids into two groups:

1. Oxoacids having different central atoms that are from the same group of the periodic table and that have the same oxidation number. Two examples are

$\mathrm{HBrO}_{3}$
Within this group, acid strength increases with increasing electronegativity of the central atom. Cl and Br have the same oxidation number in these acids, +5 . However, because Cl is more electronegative than Br , it attracts the electron pair it shares with oxygen (in the $\mathrm{Cl}-\mathrm{O}-\mathrm{H}$ group) to a greater extent than Br does (in the corresponding $\mathrm{Br}-\mathrm{O}-\mathrm{H}$ group). Consequently, the $\mathrm{O}-\mathrm{H}$ bond is more polar in chloric acid than in bromic acid and ionizes more readily. The relative acid strengths are

$$
\mathrm{HClO}_{3}>\mathrm{HBrO}_{3}
$$

2. Oxoacids having the same central atom but different numbers of oxygen atoms. Within this group, acid strength increases with increasing oxidation number of the central atom. Consider the oxoacids of chlorine shown in Figure 16.5. In this series the ability of chlorine to draw electrons away from the OH group (thus making the $\mathrm{O}-\mathrm{H}$ bond more polar) increases with the number of electronegative O atoms attached to Cl . Thus, $\mathrm{HClO}_{4}$ is the strongest acid because it has the largest number of oxygen atoms attached to Cl . The acid strength decreases as follows:

$$
\mathrm{HClO}_{4}>\mathrm{HClO}_{3}>\mathrm{HClO}_{2}>\mathrm{HClO}
$$

Sample Problem 16.19 compares acid strengths based on molecular structure.

## Sample Problem 16.19

Predict the relative strengths of the oxoacids in each of the following groups: (a) $\mathrm{HClO}, \mathrm{HBrO}$, and HIO; (b) $\mathrm{HNO}_{3}$ and $\mathrm{HNO}_{2}$.

Strategy In each group, compare the electronegativities or oxidation numbers of the central atoms to determine which $\mathrm{O}-\mathrm{H}$ bonds are the most polar. The more polar the $\mathrm{O}-\mathrm{H}$ bond, the more readily it is broken and the stronger the acid.

## Setup

(a) In a group with different central atoms, we must compare electronegativities. The electronegativities of the central atoms in this group decrease as follows: $\mathrm{Cl}>\mathrm{Br}>\mathrm{I}$.
(b) These two acids have the same central atom but differ in the number of attached oxygen atoms. In a group such as this, the greater the number of attached oxygen atoms, the higher the oxidation number of the central atom and the stronger the acid.

## Solution

(a) Acid strength decreases as follows: $\mathrm{HClO}>\mathrm{HBrO}>\mathrm{HIO}$.
(b) $\mathrm{HNO}_{3}$ is a stronger acid than $\mathrm{HNO}_{2}$.

Practice Problem A Indicate which is the stronger acid: (a) $\mathrm{HBrO}_{3}$ or $\mathrm{HBrO}_{4}$; (b) $\mathrm{H}_{2} \mathrm{SeO}_{4}$ or $\mathrm{H}_{2} \mathrm{SO}_{4}$.
EPractice Problem B Based on the information in this section, which is the predominant factor in determining the strength of an oxoacid: electronegativity of the central atom or oxidation state of the central atom?

## Carboxylic Acids

So far our discussion has focused on inorganic acids. A particularly important group of organic acids is the carboxylic acids, whose Lewis structures can be represented by

where R is part of the acid molecule and the shaded portion represents the carboxyl group, -COOH .
The conjugate base of a carboxylic acid, called a carboxylate anion, $\mathrm{RCOO}^{-}$, can be represented by more than one resonance structure:

In terms of molecular orbital theory [ $\mathrm{K4}$ Section 9.6], we attribute the stability of the anion to its ability to spread out or delocalize the electron density over several atoms. The greater the extent of electron delocalization, the more stable the anion and the greater the tendency for the acid to undergo ionization-that is, the stronger the acid.

The strength of carboxylic acids depends on the nature of the R group. Consider, for example, acetic acid and chloroacetic acid:

Acetic acid ( $K_{\mathrm{a}}=1.8 \times 10^{-5}$ )
Chloroacetic acid ( $K_{\mathrm{a}}=1.4 \times 10^{-3}$ )
The presence of the electronegative Cl atom in chloroacetic acid shifts the electron density toward the R group, thereby making the $\mathrm{O}-\mathrm{H}$ bond more polar. Consequently, there is a greater tendency for chloroacetic acid to ionize:

Chloroacetic acid is the stronger of the two acids.

Student Annotation: Another way to compare the strengths of these two is to remember that $\mathrm{HNO}_{3}$ is one of the seven strong acids. $\mathrm{HNO}_{2}$ is not.

Think About It Four of the strong acids are oxoacids: $\mathrm{HNO}_{3}$, $\mathrm{HClO}_{4}, \mathrm{HClO}_{3}$, and $\mathrm{H}_{2} \mathrm{SO}_{4}$.

Student Annotation: You learned in Chapter 4 [ 14 Section 4.1 ] that carboxylic acid formulas are often written with the ionizable H atom last, in order to keep the functional group together. You should recognize the formulas for organic acids written either way. For example, acetic acid may be written as $\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$ or as $\mathrm{CH}_{3} \mathrm{COOH}$.

Student Annotation: Recall that a salt is an ionic compound formed by the reaction between an acid and a base [ 14 Section 4.3]. Salts are strong electrolytes that dissociate completely into ions.

Student Annotation: $\mathrm{HCO}_{3}^{-}$has an ionizable proton and can also act as a Brønsted acid. However, its tendency to accept a proton is stronger than its tendency to donate a proton:
$\mathrm{HCO}_{3}^{-}+\mathrm{H}_{2} \mathrm{O} \rightleftarrows \mathrm{H}_{2} \mathrm{CO}_{3}+\mathrm{OH}^{-}$
$K_{\mathrm{b}} \approx 10^{-8}$
$\mathrm{HCO}_{3}^{-}+\mathrm{H}_{2} \mathrm{O} \rightleftarrows \mathrm{CO}_{3}^{2-}+\mathrm{H}_{3} \mathrm{O}^{+}$ $K_{\mathrm{a}} \approx 10^{-11}$

Student Annotation: Remember that for any conjugate acid-base pair (Equation 16.8):

$$
K_{\mathrm{a}} \times K_{\mathrm{b}}=K_{\mathrm{w}}
$$

### 16.10 Acid-Base Properties of Salt Solutions

In Section 16.7, we saw that the conjugate base of a weak acid acts as a weak Brønsted base in water. Consider a solution of the salt sodium fluoride ( NaF ). Because NaF is a strong electrolyte, it dissociates completely in water to give a solution of sodium cations $\left(\mathrm{Na}^{+}\right)$and fluoride anions $\left(\mathrm{F}^{-}\right)$. The fluoride ion, which is the conjugate base of hydrofluoric acid, reacts with water to produce hydrofluoric acid and hydroxide ion:

$$
\mathrm{F}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{HF}(a q)+\mathrm{OH}^{-}(a q)
$$

This is a specific example of salt hydrolysis, in which ions produced by the dissociation of a salt react with water to produce either hydroxide ions or hydronium ions-thus impacting pH . Using our knowledge of how ions from a dissolved salt interact with water, we can determine (based on the identity of the dissolved salt) whether a solution will be neutral, basic, or acidic. Note in the preceding example that sodium ions $\left(\mathrm{Na}^{+}\right)$do not hydrolyze and thus have no impact on the pH of the solution.

## Basic Salt Solutions

Sodium fluoride is a salt that dissolves to give a basic solution. In general, an anion that is the conjugate base of a weak acid reacts with water to produce hydroxide ion. Other examples include the acetate ion $\left(\mathrm{CH}_{3} \mathrm{COO}^{-}\right)$, the nitrite ion $\left(\mathrm{NO}_{2}^{-}\right)$, the sulfite ion $\left(\mathrm{SO}_{3}^{2-}\right)$, and the hydrogen carbonate ion $\left(\mathrm{HCO}_{3}^{-}\right)$. Each of these anions undergoes hydrolysis to produce the corresponding weak acid and hydroxide ion:

$$
\mathrm{A}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{HA}(a q)+\mathrm{OH}^{-}(a q)
$$

We can therefore make the qualitative prediction that a solution of a salt in which the anion is the conjugate base of a weak acid will be basic. We calculate the pH of a basic salt solution the same way we calculate the pH of any weak base solution, using the $K_{\mathrm{b}}$ value for the anion. The necessary $K_{\mathrm{b}}$ value is calculated using the tabulated $K_{\mathrm{a}}$ value of the corresponding weak acid (see Table 16.6).

Sample Problem 16.20 shows how to calculate the pH of a basic salt solution.

## Sample Problem 16.20

Calculate the pH of a 0.10 M solution of sodium fluoride $(\mathrm{NaF})$ at $25^{\circ} \mathrm{C}$.
Strategy A solution of NaF contains $\mathrm{Na}^{+}$ions and $\mathrm{F}^{-}$ions. The $\mathrm{F}^{-}$ion is the conjugate base of the weak acid, HF. Use the $K_{\mathrm{a}}$ value for HF $\left(7.1 \times 10^{-4}\right.$, from Table 16.6) and Equation 16.8 to determine $K_{\mathrm{b}}$ for $\mathrm{F}^{-}$:

$$
K_{\mathrm{b}}=\frac{K_{\mathrm{w}}}{K_{\mathrm{a}}}=\frac{1.0 \times 10^{-14}}{7.1 \times 10^{-4}}=1.4 \times 10^{-11}
$$

Then, solve this pH problem like any equilibrium problem, using an equilibrium table.
Setup It's always a good idea to write the equation corresponding to the reaction that takes place along with the equilibrium expression:

$$
\mathrm{F}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{HF}(a q)+\mathrm{OH}^{-}(a q) \quad K_{\mathrm{b}}=\frac{[\mathrm{HF}]\left[\mathrm{OH}^{-}\right]}{\left[\mathrm{F}^{-}\right]}
$$

Construct an equilibrium table, and determine, in terms of the unknown $x$, the equilibrium concentrations of the species in the equilibrium expression:

Initial concentration ( $M$ ):
Change in concentration ( $M$ ):
Equilibrium concentration ( $M$ ):

| $\mathrm{F}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{HF}(a q)+\mathrm{OH}^{-}(a q)$ |  |  |
| :--- | :---: | :---: |
| 0.10 |  | 0 |
| $-x$ |  | $+x$ |
| $0.10-x$ | $x$ | $+x$ |

Solution Substituting the equilibrium concentrations into the equilibrium expression and using the shortcut to solve for $x$, we get

$$
\begin{aligned}
1.4 \times 10^{-11} & =\frac{x^{2}}{0.10-x} \approx \frac{x^{2}}{0.10} \\
x & =\sqrt{\left(1.4 \times 10^{-11}\right)(0.10)}=1.2 \times 10^{-6} \mathrm{M}
\end{aligned}
$$

According to our equilibrium table, $x=\left[\mathrm{OH}^{-}\right]$. In this case, the autoionization of water makes a significant contribution to the hydroxide ion concentration so the total concentration will be the sum of $1.2 \times 10^{-6} M$ (from the ionization of $\mathrm{F}^{-}$) and $1.0 \times 10^{-7} M$ (from the autoionization of water). Therefore, we calculate the pOH first as

$$
\mathrm{pOH}=-\log \left(1.2 \times 10^{-6}+1.0 \times 10^{-7}\right)=5.95
$$

and then the pH ,

$$
\mathrm{pH}=14.00-\mathrm{pOH}=14.00-5.95=8.05
$$

The pH of a 0.10 M solution of NaF at $25^{\circ} \mathrm{C}$ is 8.05 .

Practice Problem A Determine the pH of a 0.15 M solution of sodium acetate $\left(\mathrm{CH}_{3} \mathrm{COONa}\right)$ at $25^{\circ} \mathrm{C}$.
FPractice Problem B Determine the concentration of a solution of sodium fluoride $(\mathrm{NaF})$ that has pH 8.51 at $25^{\circ} \mathrm{C}$.

## Acidic Salt Solutions

When the cation of a salt is the conjugate acid of a weak base, a solution of the salt will be acidic. For example, when ammonium chloride dissolves in water, it dissociates to give a solution of ammonium ions and chloride ions:

$$
\mathrm{NH}_{4} \mathrm{Cl}(s) \xrightarrow{\mathrm{H}_{2} \mathrm{O}} \mathrm{NH}_{4}^{+}(a q)+\mathrm{Cl}^{-}(a q)
$$

The ammonium ion is the conjugate acid of the weak base ammonia $\left(\mathrm{NH}_{3}\right)$. It acts as a weak Brønsted acid, reacting with water to produce hydronium ion:

$$
\mathrm{NH}_{4}^{+}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{NH}_{3}(a q)+\mathrm{H}_{3} \mathrm{O}^{+}(a q)
$$

We would therefore predict that a solution containing the ammonium ion is acidic. To calculate the pH , we must determine the $K_{\mathrm{a}}$ for $\mathrm{NH}_{4}^{+}$using the tabulated $K_{\mathrm{b}}$ value for $\mathrm{NH}_{3}$ and Equation 16.8. Because $\mathrm{Cl}^{-}$is the weak conjugate base of the strong acid $\mathrm{HCl}, \mathrm{Cl}^{-}$does not hydrolyze and therefore has no impact on the pH of the solution.

Sample Problem 16.21 shows how to calculate the pH of an acidic salt solution.

## Sample Problem 16.21

Calculate the pH of a 0.10 M solution of ammonium chloride $\left(\mathrm{NH}_{4} \mathrm{Cl}\right)$ at $25^{\circ} \mathrm{C}$.
Strategy A solution of $\mathrm{NH}_{4} \mathrm{Cl}$ contains $\mathrm{NH}_{4}^{+}$cations and $\mathrm{Cl}^{-}$anions. The $\mathrm{NH}_{4}^{+}$ion is the conjugate acid of the weak base $\mathrm{NH}_{3}$. Use the $K_{\mathrm{b}}$ value for $\mathrm{NH}_{3}\left(1.8 \times 10^{-5}\right.$ from Table 16.7) and Equation 16.8 to determine $K_{\mathrm{a}}$ for $\mathrm{NH}_{4}^{+}$.

$$
K_{\mathrm{a}}=\frac{K_{\mathrm{w}}}{K_{\mathrm{b}}}=\frac{1.0 \times 10^{-14}}{1.8 \times 10^{-5}}=5.6 \times 10^{-10}
$$

Setup Again, we write the balanced chemical equation and the equilibrium expression:

$$
\mathrm{NH}_{4}^{+}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{NH}_{3}(a q)+\mathrm{H}_{3} \mathrm{O}^{+}(a q) \quad K_{\mathrm{a}}=\frac{\left[\mathrm{NH}_{3}\right]\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]}{\left[\mathrm{NH}_{4}^{+}\right]}
$$

Think About It It's easy to mix up pH and pOH in this type of problem. Always make a qualitative prediction regarding the pH of a salt solution first, and then check to make sure that your calculated pH agrees with your prediction. In this case, we would predict a basic pH because the anion in the salt $\left(\mathrm{F}^{-}\right)$is the conjugate base of a weak acid (HF). The calculated $\mathrm{pH}, 8.05$, is indeed basic.

Think About It In this case, we would predict an acidic pH because the cation in the salt $\left(\mathrm{NH}_{4}^{+}\right)$is the conjugate acid of a weak base $\left(\mathrm{NH}_{3}\right)$. The calculated pH is acidic.

Next, construct a table to determine the equilibrium concentrations of the species in the equilibrium expression:

Initial concentration (M):
Change in concentration ( $M$ ):
Equilibrium concentration ( $M$ ):

| $\mathrm{NH}_{4}^{+}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{NH}_{3}(a q)+\mathrm{H}_{3} \mathrm{O}^{+}(a q)$ |  |  |  |
| :--- | :---: | :---: | :---: |
| 0.10 |  | 0 | 0 |
| $-x$ |  | $+x$ | $+x$ |
| $0.10-x$ |  | $x$ | $x$ |

Solution Substituting the equilibrium concentrations into the equilibrium expression and using the shortcut to solve for $x$, we get

$$
\begin{aligned}
5.6 \times 10^{-10} & =\frac{x^{2}}{0.10-x} \approx \frac{x^{2}}{0.10} \\
x & =\sqrt{\left(5.6 \times 10^{-10}\right)(0.10)}=7.5 \times 10^{-6} \mathrm{M}
\end{aligned}
$$

According to the equilibrium table, $x=\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$. The pH can be calculated as follows:

$$
\mathrm{pH}=-\log \left(7.5 \times 10^{-6}\right)=5.12
$$

The pH of a $0.10 M$ solution of ammonium chloride (at $25^{\circ} \mathrm{C}$ ) is 5.12 .

Practice Problem A Determine the pH of a 0.25 M solution of pyridinium nitrate $\left(\mathrm{C}_{5} \mathrm{H}_{6} \mathrm{NNO}_{3}\right)$ at $25^{\circ} \mathrm{C}$. [Pyridinium nitrate dissociates in water to give pyridinium ions $\left(\mathrm{C}_{5} \mathrm{H}_{6} \mathrm{~N}^{+}\right)$, the conjugate acid of pyridinium (see Table 16.7), and nitrate ions $\left(\mathrm{NO}_{3}^{-}\right)$.]

EfPractice Problem B Determine the concentration of a solution of ammonium chloride $\left(\mathrm{NH}_{4} \mathrm{Cl}\right)$ that has pH 5.37 at $25^{\circ} \mathrm{C}$.

The metal ion in a dissolved salt can also react with water to produce an acidic solution. The extent of hydrolysis is greatest for the small and highly charged metal cations such as $\mathrm{Al}^{3+}, \mathrm{Cr}^{3+}$, $\mathrm{Fe}^{3+}, \mathrm{Bi}^{3+}$, and $\mathrm{Be}^{2+}$. For example, when aluminum chloride dissolves in water, each $\mathrm{Al}^{3+}$ ion becomes associated with six water molecules (Figure 16.6).

Consider one of the bonds that forms between the metal ion and an oxygen atom from one of the six water molecules in $\mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}^{3+}$ :

The positively charged $\mathrm{Al}^{3+}$ ion draws electron density toward itself, increasing the polarity of the $\mathrm{O}-\mathrm{H}$ bonds. Consequently, the H atoms have a greater tendency to ionize than those in water molecules not associated with the $\mathrm{Al}^{3+}$ ion. The resulting ionization process can be written as

$$
\mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}^{3+}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{Al}(\mathrm{OH})\left(\mathrm{H}_{2} \mathrm{O}\right)_{5}^{2+}(a q)+\mathrm{H}_{3} \mathrm{O}^{+}(a q)
$$

or as

$$
\mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}^{3+}(a q) \rightleftarrows \mathrm{Al}(\mathrm{OH})\left(\mathrm{H}_{2} \mathrm{O}\right)_{5}^{2+}(a q)+\mathrm{H}^{+}(a q)
$$

The equilibrium constant for the metal cation hydrolysis is given by

$$
K_{\mathrm{a}}=\frac{\left[\mathrm{Al}(\mathrm{OH})\left(\mathrm{H}_{2} \mathrm{O}\right)_{5}^{2+}\right]\left[\mathrm{H}^{+}\right]}{\left[\mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}^{3+}\right]}=1.3 \times 10^{-5}
$$

$\mathrm{Al}(\mathrm{OH})\left(\mathrm{H}_{2} \mathrm{O}\right)_{5}^{2+}$ can undergo further ionization:

$$
\mathrm{Al}(\mathrm{OH})\left(\mathrm{H}_{2} \mathrm{O}\right)_{5}^{2+}(a q) \rightleftarrows \mathrm{Al}(\mathrm{OH})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}^{+}(a q)+\mathrm{H}^{+}(a q)
$$

and so on. It is generally sufficient, however, to take into account only the first stage of hydrolysis when determining the pH of a solution that contains metal ions.

## Neutral Salt Solutions

The extent of hydrolysis is greatest for the smallest and most highly charged metal ions because a compact, highly charged ion is more effective in polarizing the $\mathrm{O}-\mathrm{H}$ bond and facilitating ionization. This is why relatively large ions of low charge, including the metal cations of Groups 1A and 2 A (the cations of the strong bases), do not undergo significant hydrolysis ( $\mathrm{Be}^{2+}$ is an exception). Thus, most metal cations of Groups 1 A and 2 A do not impact the pH of a solution.

Similarly, anions that are conjugate bases of strong acids do not hydrolyze to any significant degree. Consequently, a salt composed of the cation of a strong base and the anion of a strong acid, such as NaCl , produces a neutral solution.

To summarize, the pH of a salt solution can be predicted qualitatively by identifying the ions in solution and determining which of them, if any, undergoes significant hydrolysis.

## Examples

A cation that will make a solution acidic is

- the conjugate acid of a weak base.
- a small, highly charged metal ion (other than from Group 1A or 2 A ).

An anion that will make a solution basic is

- the conjugate base of a weak acid.

A cation that will not affect the pH of a solution is

- a Group 1A or heavy Group 2A cation (except $\mathrm{Be}^{2+}$ ).

An anion that will not affect the pH of a solution is

- the conjugate base of a strong acid.
$\mathrm{NH}_{4}^{+}, \mathrm{CH}_{3} \mathrm{NH}_{3}^{+}, \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{NH}_{3}^{+}$
$\mathrm{Al}^{3+}, \mathrm{Cr}^{3+}, \mathrm{Fe}^{3+}, \mathrm{Bi}^{3+}$
$\mathrm{CN}^{-}, \mathrm{NO}_{2}^{-}, \mathrm{CH}_{3} \mathrm{COO}^{-}$
$\mathrm{Li}^{+}, \mathrm{Na}^{+}, \mathrm{Ba}^{2+}$
$\mathrm{Cl}^{-}, \mathrm{NO}_{3}^{-}, \mathrm{ClO}_{4}^{-}$

Student Annotation: The metal cations of the strong bases are those of the alkali metals: ( $\mathrm{Li}^{+}, \mathrm{Na}^{+}, \mathrm{K}^{+}, \mathrm{Rb}^{+}$, and $\mathrm{Cs}^{+}$) and those of the heavy alkaline earth metals $\left(\mathrm{Sr}^{2+}\right.$ and $\left.\mathrm{Ba}^{2+}\right)$.

Sample Problem 16.22 lets you practice predicting the pH of salt solutions.

## Sample Problem 16.22

Predict whether a 0.10 M solution of each of the following salts will be basic, acidic, or neutral: (a) LiI, (b) $\mathrm{NH}_{4} \mathrm{NO}_{3}$, (c) $\mathrm{Sr}\left(\mathrm{NO}_{3}\right)_{2}$, (d) $\mathrm{KNO}_{2}$, (e) NaCN .

Strategy Identify the ions present in each solution, and determine which, if any, will impact the pH of the solution.

Setup (a) Ions in solution: $\mathrm{Li}^{+}$and $\mathrm{I}^{-} . \mathrm{Li}^{+}$is a Group 1 A cation; $\mathrm{I}^{-}$is the conjugate base of the strong acid HI. Therefore, neither ion hydrolyzes to any significant degree.
(b) Ions in solution: $\mathrm{NH}_{4}^{+}$and $\mathrm{NO}_{3}^{-} . \mathrm{NH}_{4}^{+}$is the conjugate acid of the weak base $\mathrm{NH}_{3} ; \mathrm{NO}_{3}^{-}$is the conjugate base of the strong acid $\mathrm{HNO}_{3}$. In this case, the cation will hydrolyze, making the pH acidic:

$$
\mathrm{NH}_{4}^{+}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{NH}_{3}(a q)+\mathrm{H}_{3} \mathrm{O}^{+}(a q)
$$

(c) Ions in solution: $\mathrm{Sr}^{2+}$ and $\mathrm{NO}_{3}^{-} \cdot \mathrm{Sr}^{2+}$ is a heavy Group 2A cation; $\mathrm{NO}_{3}^{-}$is the conjugate base of the strong acid $\mathrm{HNO}_{3}$. Neither ion hydrolyzes to any significant degree.
(d) Ions in solution: $\mathrm{K}^{+}$and $\mathrm{NO}_{2}^{-} . \mathrm{K}^{+}$is a Group 1 A cation; $\mathrm{NO}_{2}^{-}$is the conjugate base of the weak acid $\mathrm{HNO}_{2}$. In this case, the anion hydrolyzes, thus making the pH basic:

$$
\mathrm{NO}_{2}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{HNO}_{2}(a q)+\mathrm{OH}^{-}(a q)
$$

(e) Ions in solution: $\mathrm{Na}^{+}$and $\mathrm{CN}^{-} . \mathrm{Na}^{+}$is a Group 1 A cation; $\mathrm{CN}^{-}$is the conjugate base of the weak acid HCN. In this case, too, the anion hydrolyzes, thus making the pH basic:

$$
\mathrm{CN}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{HCN}(a q)+\mathrm{OH}^{-}(a q)
$$

Think About It It's very important that you are able to identify the ions in solution correctly. If necessary, review the formulas and charges of the common polyatomic ions [ 14 Section 2.7, Table 2.8].

Solution
(a) Neutral
(b) Acidic
(c) Neutral
(d) Basic
(e) Basic

Practice Problem A Predict whether a 0.10 M solution of each of the following salts will be basic, acidic, or neutral: (a) $\mathrm{CH}_{3} \mathrm{COOLi}$, (b) $\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{NHCl}$, (c) KF , (d) $\mathrm{KNO}_{3}$, (e) $\mathrm{KClO}_{4}$.
flPractice Problem B In addition to those given in Sample Problem 16.22 and Practice Problem A, identify two salts that will dissolve to give (a) an acidic solution, (b) a basic solution, and (c) a neutral solution.

## Salts in Which Both the Cation and the Anion Hydrolyze

So far we have considered salts in which only one ion undergoes hydrolysis. In some salts, both the cation and the anion hydrolyze. Whether a solution of such a salt is basic, acidic, or neutral depends on the relative strengths of the weak acid and the weak base. Although the process of calculating the pH in these cases is more complex than in cases where only one ion hydrolyzes, we can make qualitative predictions regarding pH using the values of $K_{\mathrm{b}}$ (of the salt's anion) and $K_{\mathrm{a}}$ (of the salt's cation):

- When $K_{\mathrm{b}}>K_{\mathrm{a}}$, the solution is basic.
- When $K_{\mathrm{b}}<K_{\mathrm{a}}$, the solution is acidic.
- When $K_{\mathrm{b}} \approx K_{\mathrm{a}}$, the solution is neutral or nearly neutral.

The salt $\mathrm{NH}_{4} \mathrm{NO}_{2}$, for example, dissociates in solution to give $\mathrm{NH}_{4}^{+}\left(K_{\mathrm{a}}=5.6 \times 10^{-10}\right)$ and $\mathrm{NO}_{2}^{-}\left(K_{\mathrm{b}}=2.2 \times 10^{-11}\right)$. Because $K_{\mathrm{a}}$ for the ammonium ion is larger than $K_{\mathrm{b}}$ for the nitrite ion, we would expect the pH of an ammonium nitrite solution to be slightly acidic.

## Checkpoint 16.10 Acid-Base Properties of Salt Solutions

16.10.1 Calculate the pH of a 0.075 M solution of $\mathrm{NH}_{4} \mathrm{NO}_{3}$ at $25^{\circ} \mathrm{C}$.
a) 5.19
b) 8.81
c) 7.00
d) 2.93
e) 11.07
16.10.2 Calculate the pH of a 0.082 M solution of NaCN at $25^{\circ} \mathrm{C}$.
a) 5.20
b) 8.80
c) 7.00
d) 2.89
e) 11.11
16.10.3 Which of the following salts will produce a basic solution when dissolved in water? (Select all that apply.)
a) Sodium hypochlorite $(\mathrm{NaClO})$
b) Potassium fluoride (KF)
c) Lithium carbonate $\left(\mathrm{Li}_{2} \mathrm{CO}_{3}\right)$
d) Barium chloride $\left(\mathrm{BaCl}_{2}\right)$
e) Ammonium iodide $\left(\mathrm{NH}_{4} \mathrm{I}\right)$
16.10.4 Which of the following salts will produce a neutral solution when dissolved in water? (Select all that apply.)
a) Calcium chlorite $\left[\mathrm{Ca}\left(\mathrm{ClO}_{2}\right)_{2}\right]$
b) Potassium iodide (KI)
c) Lithium nitrate $\left(\mathrm{LiNO}_{3}\right)$
d) Barium cyanide $\left[\mathrm{Ba}(\mathrm{CN})_{2}\right]$
e) Ammonium iodide $\left(\mathrm{NH}_{4} \mathrm{I}\right)$
16.10.5 The diagrams represent solutions of three salts $\mathrm{NaX}(X=A, B$, or C). Arrange the three $\mathrm{X}^{-}$anions in order of increasing base strength. (The $\mathrm{Na}^{+}$ions are not shown.)

a) $\mathrm{A}^{-}<\mathrm{B}^{-}<\mathrm{C}^{-}$
b) $\mathrm{A}^{-}<\mathrm{C}^{-}<\mathrm{B}^{-}$
c) $\mathrm{B}^{-}<\mathrm{A}^{-}<\mathrm{C}^{-}$
d) $\mathrm{C}^{-}<\mathrm{B}^{-}<\mathrm{A}^{-}$
e) $\mathrm{C}^{-}<\mathrm{A}^{-}<\mathrm{B}^{-}$

### 16.11 Acid-Base Properties of Oxides and Hydroxides

As we saw in Chapter 8, oxides can be classified as acidic, basic, or amphoteric. Thus, our discussion of acid-base reactions would be incomplete if we did not examine the properties of these compounds.

## Oxides of Metals and Nonmetals

Figure 16.7 shows the formulas of a number of oxides of the main group elements in their highest oxidation states. All alkali metal oxides and all alkaline earth metal oxides except BeO are basic. Beryllium oxide and several metallic oxides in Groups 3A and 4A are amphoteric. Nonmetallic oxides in which the oxidation number of the main group element is high are acidic (e.g., $\mathrm{N}_{2} \mathrm{O}_{5}, \mathrm{SO}_{3}$, and $\mathrm{Cl}_{2} \mathrm{O}_{7}$ ), but those in which the oxidation number of the main group element is low (e.g., CO and NO ) show no measurable acidic properties. No nonmetallic oxides are known to have basic properties.

The basic metallic oxides react with water to form metal hydroxides:

$$
\begin{aligned}
\mathrm{Na}_{2} \mathrm{O}(s)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{NaOH}(a q) \\
\mathrm{BaO}(s)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{Ba}(\mathrm{OH})_{2}(a q)
\end{aligned}
$$

The reactions between acidic oxides and water are as follows:

$$
\begin{aligned}
\mathrm{CO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l) & \rightleftarrows \mathrm{H}_{2} \mathrm{CO}_{3}(a q) \\
\mathrm{SO}_{3}(g)+\mathrm{H}_{2} \mathrm{O}(l) & \rightleftarrows \mathrm{H}_{2} \mathrm{SO}_{4}(a q) \\
\mathrm{N}_{2} \mathrm{O}_{5}(g)+\mathrm{H}_{2} \mathrm{O}(l) & \rightleftarrows 2 \mathrm{HNO}_{3}(a q) \\
\mathrm{P}_{4} \mathrm{O}_{10}(g)+6 \mathrm{H}_{2} \mathrm{O}(l) & \rightleftarrows 4 \mathrm{H}_{3} \mathrm{PO}_{4}(a q) \\
\mathrm{C}_{2} \mathrm{O}_{7}(g)+\mathrm{H}_{2} \mathrm{O}(l) & \rightleftarrows 2 \mathrm{HClO}_{4}(a q)
\end{aligned}
$$

The reaction between $\mathrm{CO}_{2}$ and $\mathrm{H}_{2} \mathrm{O}$ explains why pure water gradually becomes acidic when it is exposed to air, which contains $\mathrm{CO}_{2}$. The pH of rainwater exposed only to unpolluted air is slightly acidic. The reaction between $\mathrm{SO}_{3}$ and $\mathrm{H}_{2} \mathrm{O}$ is largely responsible for acid rain.

Reactions between acidic oxides and bases and those between basic oxides and acids resemble normal acid-base reactions in that the products are a salt and water:

$$
\begin{aligned}
& \mathrm{CO}_{2}(g)+2 \mathrm{NaOH}(a q) \longrightarrow \mathrm{Na}_{2} \mathrm{CO}_{3}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \\
& \mathrm{BaO}(s)+2 \mathrm{HNO}_{3}(a q) \longrightarrow \mathrm{Ba}\left(\mathrm{NO}_{3}\right)_{2}(a q)+\mathrm{H}_{2} \mathrm{O}(l)
\end{aligned}
$$

Figure 16.7 Oxides of the main group elements in their highest oxidation states.

Aluminum oxide $\left(\mathrm{Al}_{2} \mathrm{O}_{3}\right)$ is amphoteric. Depending on the reaction conditions, it can behave either as an acidic oxide or as a basic oxide. For example, $\mathrm{Al}_{2} \mathrm{O}_{3}$ acts as a base with hydrochloric acid to produce a salt $\left(\mathrm{AlCl}_{3}\right)$ and water:

$$
\mathrm{Al}_{2} \mathrm{O}_{3}(s)+6 \mathrm{HCl}(a q) \longrightarrow 2 \mathrm{AlCl}_{3}(a q)+3 \mathrm{H}_{2} \mathrm{O}(l)
$$

and acts as an acid with sodium hydroxide:

$$
\mathrm{Al}_{2} \mathrm{O}_{3}(s)+2 \mathrm{NaOH}(a q)+3 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{NaAl}(\mathrm{OH})_{4}(a q)
$$

Only a salt, sodium aluminum hydroxide $\left[\mathrm{NaAl}(\mathrm{OH})_{4}\right.$, which contains the $\mathrm{Na}^{+}$and $\mathrm{Al}(\mathrm{OH})_{4}^{-}$ions] is formed in the reaction with sodium hydroxide-no water is produced. Nevertheless, the reaction is still classified as an acid-base reaction because $\mathrm{Al}_{2} \mathrm{O}_{3}$ neutralizes NaOH .

Some transition metal oxides in which the metal has a high oxidation number act as acidic oxides. Two examples are manganese(VII) oxide $\left(\mathrm{Mn}_{2} \mathrm{O}_{7}\right)$ and chromium(VI) oxide $\left(\mathrm{CrO}_{3}\right)$, both of which react with water to produce acids:

## Basic and Amphoteric Hydroxides

All the alkali and alkaline earth metal hydroxides, except $\mathrm{Be}(\mathrm{OH})_{2}$, are basic. $\mathrm{Be}(\mathrm{OH})_{2}, \mathrm{Al}(\mathrm{OH})_{3}$, $\mathrm{Sn}(\mathrm{OH})_{2}, \mathrm{~Pb}(\mathrm{OH})_{2}, \mathrm{Cr}(\mathrm{OH})_{3}, \mathrm{Cu}(\mathrm{OH})_{2}, \mathrm{Zn}(\mathrm{OH})_{2}$, and $\mathrm{Cd}(\mathrm{OH})_{2}$ are amphoteric. All amphoteric hydroxides are insoluble, but beryllium hydroxide reacts with both acids and bases as follows:

$$
\begin{aligned}
\mathrm{Be}(\mathrm{OH})_{2}(s)+2 \mathrm{H}^{+}(a q) & \longrightarrow \mathrm{Be}^{2+}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l) \\
\mathrm{Be}(\mathrm{OH})_{2}(s)+2 \mathrm{OH}^{-}(a q) & \longrightarrow \mathrm{Be}(\mathrm{OH})_{4}^{2-}(a q)
\end{aligned}
$$

Aluminum hydroxide reacts with both acids and bases in a similar fashion:

$$
\begin{aligned}
& \mathrm{Al}(\mathrm{OH})_{3}(s)+3 \mathrm{H}^{+}(a q) \longrightarrow \mathrm{Al}^{3+}(a q)+3 \mathrm{H}_{2} \mathrm{O}(l) \\
& \mathrm{Al}(\mathrm{OH})_{3}(s)+\mathrm{OH}^{-}(a q) \longrightarrow \mathrm{Al}(\mathrm{OH})_{4}^{-}(a q)
\end{aligned}
$$

### 16.12 Lewis Acids and Bases

So far we have discussed acid-base properties in terms of the Brønsted theory. For example, a Brønsted base is a substance that must be able to accept protons. By this definition, both the hydroxide ion and ammonia are bases:

In each case, the atom to which the proton becomes attached possesses at least one unshared pair of electrons. This characteristic property of $\mathrm{OH}^{-}, \mathrm{NH}_{3}$, and other Brønsted bases suggests a more general definition of acids and bases.

In 1932 G. N. Lewis defined what we now call a Lewis base as a substance that can donate a pair of electrons. A Lewis acid is a substance that can accept a pair of electrons. In the protonation of ammonia, for example, $\mathrm{NH}_{3}$ acts as a Lewis base because it donates a pair of electrons to the proton $\mathrm{H}^{+}$, which acts as a Lewis acid by accepting the pair of electrons. A Lewis acid-base reaction, therefore, is one that involves the donation of a pair of electrons from one species to another.

The significance of the Lewis concept is that it is more general than other definitions. Lewis acid-base reactions include many reactions that do not involve Brønsted acids. Consider, for example, the reaction between boron trifluoride $\left(\mathrm{BF}_{3}\right)$ and ammonia to form an adduct compound:

The B atom in $\mathrm{BF}_{3}$ is $s p^{2}$-hybridized [ 144 Section 9.4]. The vacant, unhybridized $2 p_{z}$ orbital accepts the pair of electrons from $\mathrm{NH}_{3}$. Thus, $\mathrm{BF}_{3}$ functions as an acid according to the Lewis definition, even though it does not contain an ionizable proton. A coordinate covalent bond [ 144 Section 8.8] is formed between the B and N atoms. In fact, every Lewis acid-base reaction results in the formation of a coordinate covalent bond.

Boric acid is another Lewis acid containing boron. Boric acid (a weak acid used in eyewash) is an oxoacid with the following structure:

Boric acid does not ionize in water to produce $\mathrm{H}^{+}$. Instead, it produces $\mathrm{H}^{+}$in solution by taking a hydroxide ion away from water.

$$
\mathrm{B}(\mathrm{OH})_{3}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{B}(\mathrm{OH})_{4}^{-}(a q)+\mathrm{H}^{+}(a q)
$$

In this Lewis acid-base reaction, boric acid accepts a pair of electrons from the hydroxide ion that is derived from the water molecule, leaving behind the hydrogen ion.

The hydration of carbon dioxide to produce carbonic acid,

$$
\mathrm{CO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{H}_{2} \mathrm{CO}_{3}(a q)
$$

can be explained in terms of Lewis acid-base theory as well. The first step involves the donation of a lone pair on the O atom in $\mathrm{H}_{2} \mathrm{O}$ to the C atom in $\mathrm{CO}_{2}$. An orbital is vacated on the C atom to accommodate the lone pair by relocation of the electron pair in one of the $\mathrm{C}-\mathrm{O}$ pi bonds, changing the hybridization of the oxygen atom from $s p^{2}$ to $s p^{3}$ :

As a result, $\mathrm{H}_{2} \mathrm{O}$ is a Lewis base and $\mathrm{CO}_{2}$ is a Lewis acid. Finally, a proton is transferred onto the O atom bearing the negative charge to form $\mathrm{H}_{2} \mathrm{CO}_{3}$ :

Other examples of Lewis acid-base reactions are

$$
\begin{aligned}
\mathrm{Ag}^{+}(a q)+2 \mathrm{NH}_{3}(a q) & \rightleftarrows \mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}^{+}(a q) \\
\mathrm{Cd}^{2+}(a q)+4 \mathrm{I}^{-}(a q) & \rightleftarrows \mathrm{CdI}_{4}^{2-}(a q) \\
\mathrm{Ni}(s)+4 \mathrm{CO}(g) & \rightleftarrows \mathrm{Ni}(\mathrm{CO})_{4}(g)
\end{aligned}
$$

The hydration of metal ions is in itself a Lewis acid-base reaction. When copper(II) sulfate $\left(\mathrm{CuSO}_{4}\right)$ dissolves in water, each $\mathrm{Cu}^{2+}$ ion becomes associated with six water molecules as $\mathrm{Cu}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}^{2+}$. In this case, $\mathrm{Cu}^{2+}$ acts as the acid, accepting electrons, whereas $\mathrm{H}_{2} \mathrm{O}$ acts as the base, donating electrons.

Student Annotation: An electron-deficient molecule is one with less than a complete octet around the central atom.

Sample Problem 16.23 shows how to classify Lewis acids and bases.

## Sample Problem 16.23

Identify the Lewis acid and Lewis base in each of the following reactions:
(a) $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OC}_{2} \mathrm{H}_{5}+\mathrm{AlCl}_{3} \rightleftarrows\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)_{2} \mathrm{OAlCl}_{3}$
(b) $\mathrm{Hg}^{2+}(a q)+4 \mathrm{CN}^{-}(a q) \rightleftarrows \mathrm{Hg}(\mathrm{CN})_{4}^{2-}(a q)$

Strategy Determine which species in each reaction accepts a pair of electrons (Lewis acid) and which species donates a pair of electrons (Lewis base).

Setup (a) It can be helpful to draw Lewis structures of the species involved:

(b) Metal ions act as Lewis acids, accepting electron pairs from anions or molecules with lone pairs.

Solution (a) The Al is $s p^{2}$-hybridized in $\mathrm{AlCl}_{3}$ with an empty $2 p_{z}$ orbital. It is electron deficient, sharing only six electrons. Therefore, the Al atom has the capacity to gain two electrons to complete its octet. This property makes $\mathrm{AlCl}_{3}$ a Lewis acid. On the other hand, the lone pairs on the oxygen atom in $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OC}_{2} \mathrm{H}_{5}$ make the compound a Lewis base:

(b) $\mathrm{Hg}^{2+}$ accepts four pairs of electrons from the $\mathrm{CN}^{-}$ions. Therefore, $\mathrm{Hg}^{2+}$ is the Lewis acid and $\mathrm{CN}^{-}$is the Lewis base.

Practice Problem A Identify the Lewis acid and Lewis base in the following reaction:

$$
\mathrm{Co}^{3+}(a q)+6 \mathrm{NH}_{3}(a q) \rightleftarrows \mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}^{3+}(a q)
$$

\&Practice Problem B Write formulas for the Lewis acid and Lewis base that react to form $\mathrm{H}_{2} \mathrm{NAlBr}_{3}$.

## Checkpoint 16.12 Lewis Acids and Bases

16.12.1 Which of the following cannot act as a Lewis base? (Select all that apply.)
a) $\mathrm{NH}_{3}$
b) $\mathrm{OH}^{-}$
c) $\mathrm{CH}_{4}$
d) $\mathrm{Fe}^{2+}$
e) $\mathrm{Al}^{3+}$
16.12.2 Which of the following is a Lewis acid but not a Brønsted acid? (Select all that apply.)
a) $\mathrm{H}_{2} \mathrm{O}$
b) $\mathrm{BCl}_{3}$
c) $\mathrm{OH}^{-}$
d) $\mathrm{Al}^{3+}$
e) $\mathrm{NH}_{3}$

## Applying What You've Learned

As was noted at the beginning of the chapter, rain in unpolluted areas is slightly acidic because it contains carbonic acid $\left(\mathrm{H}_{2} \mathrm{CO}_{3}\right)$. Carbonic acid is a weak, diprotic acid that ionizes to give $\mathrm{H}^{+}$and the hydrogen carbonate ion:

$$
\mathrm{H}_{2} \mathrm{CO}_{3}(a q) \rightleftarrows \mathrm{H}^{+}(a q)+\mathrm{HCO}_{3}^{-}(a q)
$$

a) Give the formulas for the conjugate acid and the conjugate base of the hydrogen carbonate ion (also known as the bicarbonate ion). [14 Sample Problem 16.1]
b) Determine $\left[\mathrm{H}^{+}\right]$and pH for a raindrop in which the carbonic acid concentration is $1.8 \times 10^{-5} \mathrm{M}$. Assume that carbonic acid is the only acid in the raindrop and that the second ionization is negligible. [ 14 Sample Problem 16.12]
c) Calculate $\left[\mathrm{OH}^{-}\right]$and pOH of the raindrop in part (b). [ 14 Sample Problems 16.3 and 16.6]
d) What concentration of HCl would have the same pH as the raindrop in part (b)?
[14 Sample Problem 16.9]
e) Determine $K_{\mathrm{b}}$ for the hydrogen carbonate ion $\left(\mathrm{HCO}_{3}^{-}\right)$and the pH of a 0.10 M solution of $\mathrm{NaHCO}_{3}$. [14 Sample Problems 16.17 and 16.21]
f) Carbonic acid undergoes a second ionization to produce additional $\mathrm{H}^{+}$and the carbonate ion:

$$
\mathrm{HCO}_{3}^{-}(a q) \rightleftarrows \mathrm{H}^{+}(a q)+\mathrm{CO}_{3}^{2-}(a q)
$$

Calculate the concentrations of all species $\left(\mathrm{H}_{2} \mathrm{CO}_{3}, \mathrm{H}^{+}, \mathrm{HCO}_{3}^{-}\right.$, and $\left.\mathrm{CO}_{3}^{2-}\right)$ in the raindrop. [ KA Sample Problem 16.18]
g) Sulfuric acid $\left(\mathrm{H}_{2} \mathrm{SO}_{4}\right)$ accounts for as much as 80 percent of the acid in acid rain. Its first ionization is complete, producing $\mathrm{H}^{+}$and the hydrogen sulfate ion:

$$
\mathrm{H}_{2} \mathrm{SO}_{4}(a q) \rightleftarrows \mathrm{H}^{+}(a q)+\mathrm{HSO}_{4}^{-}(a q)
$$

Its second ionization, which produces additional $\mathrm{H}^{+}$and the sulfate ion, has an ionization constant ( $K_{\mathrm{a}_{2}}$ ) of $1.3 \times 10^{-2}$.

$$
\mathrm{HSO}_{4}^{-}(a q) \rightleftarrows \mathrm{H}^{+}(a q)+\mathrm{SO}_{4}^{2-}(a q)
$$

Calculate the concentrations of all species in a raindrop in which the sulfuric acid concentration is $4.00 \times 10^{-5} \mathrm{M}$. Assume that sulfuric acid is the only acid present. [ KA Sample Problem 16.18]
h) At low concentrations, the percent ionization of a weak acid such as the hydrogen sulfate ion can be quite high. What is the percent ionization of the hydrogen sulfate ion at the concentration calculated in part (g)? [ 14 Sample Problem 16.13]

## Chapter Summary

## Section 16.1

- A Brønsted acid donates a proton; a Brønsted base accepts a proton.
- When a Brønsted acid donates a proton, the anion that remains is a conjugate base.
- When a Brønsted base accepts a proton, the resulting cation is a conjugate acid.
- The combination of a Brønsted acid and its conjugate base (or the combination of a Brønsted base and its conjugate acid) is called a conjugate pair.

## Section 16.2

- Water is amphoteric, meaning it can act both as a Brønsted acid and a Brønsted base.
- Pure water undergoes autoionization (to a very small extent), resulting in concentrations of $\mathrm{H}^{+}$and $\mathrm{OH}^{-}$of $1.0 \times 10^{-7} \mathrm{M}$ at $25^{\circ} \mathrm{C}$.
- $K_{\mathrm{w}}$ is the equilibrium constant for the autoionization of water, also called the ion-product constant. $K_{\mathrm{w}}=\left[\mathrm{H}^{+}\right]\left[\mathrm{OH}^{-}\right]=1.0 \times 10^{-14}$ at $25^{\circ} \mathrm{C}$.

## Section 16.3

- The $\boldsymbol{p} \boldsymbol{H}$ scale measures acidity: $\mathrm{pH}=-\log \left[\mathrm{H}^{+}\right]$.
- $\mathrm{pH}=7.00$ is neutral, $\mathrm{pH}<7.00$ is acidic, and $\mathrm{pH}>7.00$ is basic.
- The $\mathbf{p O H}$ scale is analogous to the pH scale, but it measures basicity: $\mathrm{pOH}=-\log \left[\mathrm{OH}^{-}\right]$.
- $\mathrm{pOH}=7.00$ is neutral, $\mathrm{pOH}<7.00$ is basic, and $\mathrm{pOH}>7.00$ is acidic.
- $\mathrm{pH}+\mathrm{pOH}=14.00\left(\right.$ at $\left.25^{\circ} \mathrm{C}\right)$.

## Section 16.4

- There are seven strong acids: $\mathrm{HCl}, \mathrm{HBr}, \mathrm{HI}, \mathrm{HNO}_{3}, \mathrm{HClO}_{3}, \mathrm{HClO}_{4}$, and $\mathrm{H}_{2} \mathrm{SO}_{4}$.
- Strong acids ionize completely in aqueous solution. (Only the first ionization of the diprotic acid $\mathrm{H}_{2} \mathrm{SO}_{4}$ is complete.)
- The strong bases are the Group 1A and the heaviest Group 2A hydroxides: $\mathrm{LiOH}, \mathrm{NaOH}, \mathrm{KOH}, \mathrm{RbOH}, \mathrm{CsOH}, \mathrm{Ca}(\mathrm{OH})_{2}, \mathrm{Sr}(\mathrm{OH})_{2}$, and $\mathrm{Ba}(\mathrm{OH})_{2}$.

## Section 16.5

- A weak acid ionizes only partially. The acid ionization constant, $\boldsymbol{K}_{a}$, is the equilibrium constant that indicates to what extent a weak acid ionizes.
- We solve for the pH of a solution of weak acid using the concentration of the acid, the $K_{\mathrm{a}}$ value, and an equilibrium table.
- We can also determine the $K_{\mathrm{a}}$ of a weak acid if we know the initial acid concentration and the pH at equilibrium.

## Section 16.6

- A weak base ionizes only partially. The base ionization constant, $\boldsymbol{K}_{b}$, is the equilibrium constant that indicates to what extent a weak base ionizes.
- We solve for the pH of a solution of weak base using the concentration of the base, the $K_{\mathrm{b}}$ value, and an equilibrium table.
- We can also determine the $K_{\mathrm{b}}$ of a weak base if we know the concentration and the pH at equilibrium.

## Section 16.7

- The conjugate base of a strong acid is a weak conjugate base, meaning that it does not react with water.
- The conjugate base of a weak acid is a strong conjugate base, meaning that it acts as a weak Brønsted base in water.
- The conjugate base of a strong base is a weak conjugate acid, meaning that it does not react with water.
- The conjugate acid of a weak base is a strong conjugate acid, meaning that it acts as a weak Brønsted acid in water.
- For any conjugate acid-base pair, $K_{\mathrm{a}} \times K_{\mathrm{b}}=K_{\mathrm{w}}$.

## Section 16.8

- Diprotic and polyprotic acids have more than one proton to donate. They undergo stepwise ionizations. Each ionization has a $K_{\mathrm{a}}$ value associated with it.
- The $K_{\mathrm{a}}$ values for stepwise ionizations become progressively smaller.
- In most cases, it is only necessary to consider the first ionization of an acid to determine pH . To determine the concentrations of other species at equilibrium, it may be necessary to consider subsequent ionizations.

## Section 16.9

- The strength of an acid is affected by molecular structure.
- Polar and weak bonds to the ionizable hydrogen lead to a stronger acid.
- Resonance stabilization of the conjugate base favors the ionization process, resulting in a stronger acid.

## Section 16.10

- Salts dissolve in water to give neutral, acidic, or basic solutions depending on their constituent ions. Salt hydrolysis is the reaction of an ion with water to produce hydronium or hydroxide ions.
- Cations that are strong conjugate acids such as $\mathrm{NH}_{4}^{+}$make a solution more acidic.
- Anions that are strong conjugate bases such as $\mathrm{F}^{-}$make a solution more basic. Anions that are conjugate bases of strong acids have no effect on pH .
- Small, highly charged metal ions hydrolyze to give acidic solutions.

## Section 16.11

- Oxides of metals generally are basic; oxides of nonmetals generally are acidic.
- Metal hydroxides may be basic or amphoteric.

## Section 16.12

- Lewis theory provides more general definitions of acids and bases.
- A Lewis acid accepts a pair of electrons; a Lewis base donates a pair of electrons.
- A Lewis acid is generally electron-poor and need not have a hydrogen atom.
- A Lewis base is an anion or a molecule with one or more lone pairs of electrons.

$$

## Questions and Problems

## Section 16.1: Brønsted Acids and Bases

## Review Questions

16.1 Define Brønsted acids and bases. Give an example of a conjugate pair in an acid-base reaction.
16.2 For a species to act as a Brønsted base, an atom in the species must possess a lone pair of electrons. Explain why this is so.

## Problems

16.3 Classify each of the following species as a Brønsted acid or base, or both: (a) $\mathrm{H}_{2} \mathrm{O}$, (b) $\mathrm{OH}^{-}$, (c) $\mathrm{H}_{3} \mathrm{O}^{+}$, (d) $\mathrm{NH}_{3}$, (e) $\mathrm{NH}_{4}^{+}$, (f) $\mathrm{NH}_{2}^{-}$, (g) $\mathrm{NO}_{3}^{-}$, (h) $\mathrm{CO}_{3}^{2-}$, (i) HBr , (j) HCN
16.4 Identify the acid-base conjugate pairs in each of the following reactions:
(a) $\mathrm{CH}_{3} \mathrm{COO}^{-}+\mathrm{HCN} \rightleftarrows \mathrm{CH}_{3} \mathrm{COOH}+\mathrm{CN}^{-}$
(b) $\mathrm{HCO}_{3}^{-}+\mathrm{HCO}_{3}^{-} \rightleftarrows \mathrm{H}_{2} \mathrm{CO}_{3}+\mathrm{CO}_{3}^{2-}$
(c) $\mathrm{H}_{2} \mathrm{PO}_{4}^{-}+\mathrm{NH}_{3} \rightleftarrows \mathrm{HPO}_{4}^{2-}+\mathrm{NH}_{4}^{+}$
(d) $\mathrm{HClO}+\mathrm{CH}_{3} \mathrm{NH}_{2} \rightleftarrows \mathrm{CH}_{3} \mathrm{NH}_{3}^{+}+\mathrm{ClO}^{-}$
(e) $\mathrm{CO}_{3}^{2-}+\mathrm{H}_{2} \mathrm{O} \rightleftarrows \mathrm{HCO}_{3}^{-}+\mathrm{OH}^{-}$

E16.5 Write the formulas of the conjugate bases of the following acids: (a) $\mathrm{HNO}_{2}$, (b) $\mathrm{H}_{2} \mathrm{SO}_{4}$, (c) $\mathrm{H}_{2} \mathrm{~S}$, (d) HCN , (e) HCOOH (formic acid).

E16.6 Write the formula for the conjugate acid of each of the following bases: (a) $\mathrm{HS}^{-}$, (b) $\mathrm{HCO}_{3}^{-}$, (c) $\mathrm{CO}_{3}^{2-}$, (d) $\mathrm{H}_{2} \mathrm{PO}_{4}^{-}$, (e) $\mathrm{HPO}_{4}^{2-}$, (f) $\mathrm{PO}_{4}^{3-}$, (g) $\mathrm{HSO}_{4}^{-}$, (h) $\mathrm{SO}_{4}^{2-}$, (i) $\mathrm{SO}_{3}^{2-}$.

H16.7 Write the formula for the conjugate base of each of the following acids: (a) $\mathrm{CH}_{2} \mathrm{ClCOOH}$, (b) $\mathrm{HIO}_{4}$, (c) $\mathrm{H}_{3} \mathrm{PO}_{4}$, (d) $\mathrm{H}_{2} \mathrm{PO}_{4}^{-}$, (e) $\mathrm{HPO}_{4}^{2-}$, (f) $\mathrm{H}_{2} \mathrm{SO}_{4}$, (g) $\mathrm{HSO}_{4}^{-}$, (h) $\mathrm{HIO}_{3}$, (i) $\mathrm{HSO}_{3}^{-}$, (j) $\mathrm{NH}_{4}^{+}$, (k) $\mathrm{H}_{2} \mathrm{~S}$, (l) $\mathrm{HS}^{-}$, (m) HClO
16.8 Oxalic acid $\left(\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}\right)$ has the following structure:

An oxalic acid solution contains the following species in varying concentrations: $\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}, \mathrm{HC}_{2} \mathrm{O}_{4}^{-}, \mathrm{C}_{2} \mathrm{O}_{4}^{2-}$, and $\mathrm{H}^{+}$. (a) Draw Lewis structures of $\mathrm{HC}_{2} \mathrm{O}_{4}^{-}$and $\mathrm{C}_{2} \mathrm{O}_{4}^{2-}$. (b) Which of the four species can act only as acids, which can act only as bases, and which can act as both acids and bases?

## Section 16.2: The Acid-Base Properties of Water

## Review Questions

16.9 Write the equilibrium expression for the autoionization of water and an equation relating $\left[\mathrm{H}^{+}\right]$and $\left[\mathrm{OH}^{-}\right]$in solution at $25^{\circ} \mathrm{C}$.
16.10 In Section 15.3 we learned that when we multiply a chemical equation by 2 , we must square its equilibrium constant. Explain why $K_{\mathrm{w}}$ is the same $\left(1.0 \times 10^{-14}\right.$ at $\left.25^{\circ} \mathrm{C}\right)$ whether we start with one water molecule or two.
16.11 The equilibrium constant for the autoionization of water

$$
\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{H}^{+}(a q)+\mathrm{OH}^{-}(a q)
$$

is $1.0 \times 10^{-14}$ at $25^{\circ} \mathrm{C}$ and $3.8 \times 10^{-14}$ at $40^{\circ} \mathrm{C}$. Is the forward process endothermic or exothermic?
16.12 Define the term amphoteric.
16.13 Compare the magnitudes of $\left[\mathrm{H}^{+}\right]$and $\left[\mathrm{OH}^{-}\right]$in aqueous solutions that are acidic, basic, and neutral.

## Problems

16.14 Calculate the $\mathrm{OH}^{-}$concentration in an aqueous solution at $25^{\circ} \mathrm{C}$ with each of the following $\mathrm{H}_{3} \mathrm{O}^{+}$concentrations:
(a) $1.13 \times 10^{-4} M$, (b) $4.55 \times 10^{-8} M$, (c) $7.05 \times 10^{-11} M$,
(d) $3.13 \times 10^{-2} \mathrm{M}$.
16.15 Calculate the $\mathrm{H}_{3} \mathrm{O}^{+}$concentration in an aqueous solution at $25^{\circ} \mathrm{C}$ with each of the following $\mathrm{OH}^{-}$concentrations:
(a) $2.50 \times 10^{-2} M$, (b) $1.67 \times 10^{-5} M$, (c) $8.62 \times 10^{-3} \mathrm{M}$,
(d) $1.75 \times 10^{-12} \mathrm{M}$.
16.16 The value of $K_{\mathrm{w}}$ at $50^{\circ} \mathrm{C}$ is $5.48 \times 10^{-14}$. Calculate the $\mathrm{OH}^{-}$ concentration in each of the aqueous solutions from Problem 16.14 at $50^{\circ} \mathrm{C}$.
16.17 The value of $K_{\mathrm{w}}$ at $100^{\circ} \mathrm{C}$ is $5.13 \times 10^{-13}$. Calculate the $\mathrm{H}_{3} \mathrm{O}^{+}$ concentration in each of the aqueous solutions from Problem 16.15 at $100^{\circ} \mathrm{C}$.

## Section 16.3: The pH Scale

## Review Questions

16.18 Define pH . Why do chemists normally choose to discuss the acidity of a solution in terms of pH rather than hydrogen ion concentration $\left[\mathrm{H}^{+}\right]$?
16.19 The pH of a solution is 6.7. From this statement alone, can you conclude that the solution is acidic? If not, what additional information would you need? Can the pH of a solution be zero or negative? If so, give examples to illustrate these values.
16.20 Define pOH . Write the equation relating pH and pOH .

## Problems

G16.21 Calculate the concentration of $\mathrm{OH}^{-}$ions in a $1.4 \times 10^{-3} M \mathrm{HCl}$ solution.
16.22 Calculate the concentration of $\mathrm{H}^{+}$ions in a 0.62 M NaOH solution.

E16.23 Calculate the pH of each of the following solutions: (a) 0.0010 M HCl , (b) 0.76 M KOH .

EI 16.24 Calculate the pH of each of the following solutions: (a) $2.8 \times 10^{-4} M \mathrm{Ba}(\mathrm{OH})_{2}$, (b) $5.2 \times 10^{-4} M \mathrm{HNO}_{3}$.

EI 16.25 Calculate the hydrogen ion concentration in mol/L for solutions with the following pH values: (a) 2.42 , (b) 11.21 , (c) 6.96 , (d) 15.00 .
16.26 Calculate the hydrogen ion concentration in $\mathrm{mol} / \mathrm{L}$ for each of the following solutions: (a) a solution whose pH is 5.20 , (b) a solution whose pH is 16.00 , (c) a solution whose hydroxide concentration is $3.7 \times 10^{-9} \mathrm{M}$.
16.27 Complete the following table for a solution:

| $\mathbf{p H}$ | $\left[\mathbf{H}^{+}\right]$ | Solution is |
| :---: | :---: | :---: |
| $<7$ |  |  |
|  | $<1.0 \times 10^{-7} M$ |  |
|  |  | Neutral |

16.28 Fill in the word acidic, basic, or neutral for the following solutions:
(a) $\mathrm{pOH}>7$; solution is $\qquad$ -
(b) $\mathrm{pOH}=7$; solution is $\qquad$
(c) $\mathrm{pOH}<7$; solution is $\qquad$
16.29 The pOH of a solution is 9.40 at $25^{\circ} \mathrm{C}$. Calculate the hydrogen ion concentration of the solution.
16.30 Calculate the number of moles of KOH in 5.50 mL of a 0.360 M KOH solution. What is the pOH of the solution at $25^{\circ} \mathrm{C}$ ?
16.31 How much NaOH (in grams) is needed to prepare 546 mL of solution with a pH of 10.00 at $25^{\circ} \mathrm{C}$ ?

E16.32 A solution is made by dissolving 18.4 g of HCl in enough water to make 662 mL of solution. Calculate the pH of the solution at $25^{\circ} \mathrm{C}$.

## Section 16.4: Strong Acids and Bases

## Review Questions

16.33 Without referring to the text, write the formulas of four strong acids and four strong bases.
16.34 Which of the following statements are true regarding a 1.0 M solution of a strong acid HA at $25^{\circ} \mathrm{C}$ ? (Choose all that apply.)
(a) $\left[\mathrm{A}^{-}\right]>\left[\mathrm{H}^{+}\right]$
(b) The pH is 0.00 .
(c) $\left[\mathrm{H}^{+}\right]=1.0 \mathrm{M}$
(d) $[\mathrm{HA}]=1.0 \mathrm{M}$
16.35 Why are ionizations of strong acids and strong bases generally not treated as equilibria?

## Problems

EI 16.36 Calculate the pH of an aqueous solution at $25^{\circ} \mathrm{C}$ that is (a) 0.12 M in HCl , (b) $2.4 ~ M$ in $\mathrm{HNO}_{3}$, and (c) $3.2 \times 10^{-4} \mathrm{M}$ in $\mathrm{HClO}_{4}$.
16.37 Calculate the pH of an aqueous solution at $25^{\circ} \mathrm{C}$ that is (a) 1.02 M in HI , (b) 0.035 M in $\mathrm{HClO}_{4}$, and (c) $1.5 \times 10^{-6} \mathrm{M}$ in HCl .
16.38 Calculate the concentration of HBr in a solution at $25^{\circ} \mathrm{C}$ that has a pH of (a) 0.12, (b) 2.46, and (c) 6.27 .
16.39 Calculate the concentration of $\mathrm{HNO}_{3}$ in a solution at $25^{\circ} \mathrm{C}$ that has a pH of (a) 4.21 , (b) 3.55 , and (c) 0.98 .

E 16.40 Calculate the pOH and pH of the following aqueous solutions at $25^{\circ} \mathrm{C}$ : (a) 0.066 M KOH , (b) 5.43 M NaOH , (c) $0.74 \mathrm{M} \mathrm{Ba}(\mathrm{OH})_{2}$.

H16.41 Calculate the pOH and pH of the following aqueous solutions at $25^{\circ} \mathrm{C}$ : (a) 1.24 MLiOH , (b) $0.22 \mathrm{M} \mathrm{Ba}(\mathrm{OH})_{2}$, (c) 0.085 M NaOH .
© 16.42 An aqueous solution of a strong base has a pH of 9.78 at $25^{\circ} \mathrm{C}$. Calculate the concentration of the base if the base is (a) LiOH and (b) $\mathrm{Ba}(\mathrm{OH})_{2}$.
16.43 An aqueous solution of a strong base has a pH of 11.04 at $25^{\circ} \mathrm{C}$. Calculate the concentration of the base if the base is (a) KOH and (b) $\mathrm{Ba}(\mathrm{OH})_{2}$.

## Section 16.5: Weak Acids and Acid Ionization Constants

## Visualizing Chemistry

Figure 16.2
Three weak acid solutions are shown here.

(i)

(ii)

(iii)

VC 16.1 Which weak acid has the largest $K_{\mathrm{a}}$ value?
a) i
b) ii
c) iii

VC 16.2 Which weak acid has the highest pH ?
a) i
b) ii
c) iii

VC 16.3 For which weak acid solution can we most likely neglect $x$ in the denominator of the equilibrium expression in the determination of pH ?
a) i
b) ii
c) iii

VC 16.4 In the event that we cannot neglect $x$ in the denominator of the equilibrium expression, $\qquad$ to solve for pH .
a) we cannot use an equilibrium table
b) we must use the quadratic equation
c) it is unnecessary

## Review Questions

16.44 Explain what is meant by the strength of an acid.
16.45 What does the ionization constant tell us about the strength of an acid?
16.46 List the factors on which the $K_{\mathrm{a}}$ of a weak acid depends.
16.47 Why do we normally not quote $K_{\mathrm{a}}$ values for strong acids such as HCl and $\mathrm{HNO}_{3}$ ? Why is it necessary to specify temperature when giving $K_{\mathrm{a}}$ values?
16.48 Which of the following solutions has the highest pH : (a) 0.40 M HCOOH , (b) 0.40 M HClO 4 , (c) $0.40 \mathrm{M} \mathrm{CH}_{3} \mathrm{COOH}$ ?
16.49 Without referring to the text, write the formulas of four weak acids.

## Problems

16.50 Classify each of the following species as a weak or strong acid:
(a) $\mathrm{HNO}_{3}$, (b) HF , (c) $\mathrm{H}_{2} \mathrm{SO}_{4}$, (d) $\mathrm{HSO}_{4}^{-}$, (e) $\mathrm{H}_{2} \mathrm{CO}_{3}$, (f) $\mathrm{HCO}_{3}^{-}$, (g) HCl , (h) HCN , (i) $\mathrm{HNO}_{2}$.
16.51 Classify each of the following species as a weak or strong base: (a) LiOH , (b) $\mathrm{CN}^{-}$, (c) $\mathrm{H}_{2} \mathrm{O}$, (d) $\mathrm{ClO}_{4}^{-}$, (e) $\mathrm{NH}_{2}^{-}$.

EI 16.52 Which of the following statements are true for a 0.10 M solution of a weak acid HA? (Choose all that apply.)
(a) The pH is 1.00 .
(b) $\left[\mathrm{H}^{+}\right] \gg\left[\mathrm{A}^{-}\right]$.
(c) $\left[\mathrm{H}^{+}\right]=\left[\mathrm{A}^{-}\right]$.
(d) The pH is less than 1 .
16.53 The $K_{\mathrm{a}}$ for benzoic acid is $6.5 \times 10^{-5}$. Calculate the pH of a 0.10 M aqueous solution of benzoic acid at $25^{\circ} \mathrm{C}$.
16.54 The $K_{\mathrm{a}}$ for hydrofluoric acid is $7.1 \times 10^{-4}$. Calculate the pH of a 0.15 M aqueous solution of hydrofluoric acid at $25^{\circ} \mathrm{C}$.
16.55 Calculate the pH of an aqueous solution at $25^{\circ} \mathrm{C}$ that is 0.095 M in hydrocyanic acid $(\mathrm{HCN})$. $\left(K_{\mathrm{a}}\right.$ for hydrocyanic acid $=$ $4.9 \times 10^{-10}$.)
16.56 Calculate the pH of an aqueous solution at $25^{\circ} \mathrm{C}$ that is 0.34 M in phenol $\left(\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{OH}\right)$. $\left(K_{\mathrm{a}}\right.$ for phenol $\left.=1.3 \times 10^{-10}.\right)$
16.57 Determine the percent ionization of the following solutions of formic acid at $25^{\circ} \mathrm{C}$ : (a) 0.016 M , (b) $5.7 \times 10^{-4} \mathrm{M}$, (c) 1.75 M .
16.58 Determine the percent ionization of the following solutions of phenol: (a) 0.56 M , (b) 0.25 M , (c) $1.8 \times 10^{-6} \mathrm{M}$.
$\leftrightarrows$ 16.59 A $0.015 M$ solution of a monoprotic acid is 0.92 percent ionized. Calculate the ionization constant for the acid.
16.60 Calculate the concentration at which a monoprotic acid with $K_{\mathrm{a}}=4.5 \times 10^{-5}$ will be 2.5 percent ionized.
16.61 Calculate the $K_{\mathrm{a}}$ of a weak acid if a 0.19 M aqueous solution of the acid has a pH of 4.52 at $25^{\circ} \mathrm{C}$.
16.62 The pH of an aqueous acid solution is 6.20 at $25^{\circ} \mathrm{C}$. Calculate the $K_{\mathrm{a}}$ for the acid. The initial acid concentration is 0.010 M .
16.63 What is the original molarity of a solution of formic acid $(\mathrm{HCOOH})$ whose pH is 3.26 at $25^{\circ} \mathrm{C} ?\left(K_{\mathrm{a}}\right.$ for formic acid $=$ $1.7 \times 10^{-4}$.)
16.64 What is the original molarity of a solution of a weak acid whose $K_{\mathrm{a}}$ is $3.5 \times 10^{-5}$ and whose pH is 5.26 at $25^{\circ} \mathrm{C}$ ?
16.65 In biological and medical applications, it is often necessary to study the autoionization of water at $37^{\circ} \mathrm{C}$ instead of $25^{\circ} \mathrm{C}$. Given that $K_{\mathrm{w}}$ for water is $2.5 \times 10^{-14}$ at $37^{\circ} \mathrm{C}$, calculate the pH of pure water at this temperature.

## Section 16.6: Weak Bases and Base Ionization Constants

## Review Questions

16.66 Compare the pH values for 0.10 M solutions of NaOH and of $\mathrm{NH}_{3}$ to illustrate the difference between a strong base and a weak base.
16.67 Which of the following has a higher pH : (a) $1.0 \mathrm{M}_{3}$, (b) $0.20 \mathrm{M} \mathrm{NaOH}\left(K_{\mathrm{b}}\right.$ for $\left.\mathrm{NH}_{3}=1.8 \times 10^{-5}\right)$ ?

## Problems

16.68 Calculate the pH for each of the following solutions at $25^{\circ} \mathrm{C}$ : (a) $0.10 \mathrm{M} \mathrm{H}_{3}$, (b) $0.050 \mathrm{M}_{5} \mathrm{H}_{5} \mathrm{~N}$ (pyridine). ( $K_{\mathrm{b}}$ for pyridine $=$ $1.7 \times 10^{-9}$.)
16.69 The pH of a 0.30 M solution of a weak base is 10.66 at $25^{\circ} \mathrm{C}$. What is the $K_{\mathrm{b}}$ of the base?

I 16.70 What is the original molarity of an aqueous solution of ammonia $\left(\mathrm{NH}_{3}\right)$ whose pH is 11.22 at $25^{\circ} \mathrm{C}$ ? (Use the $K_{\mathrm{b}}$ for ammonia provided in Problem 16.67.)

H16.71 Calculate the pH at $25^{\circ} \mathrm{C}$ of a 0.61 M aqueous solution of a weak base B with a $K_{\mathrm{b}}$ of $1.5 \times 10^{-4}$.
16.72 Determine the $K_{\mathrm{b}}$ of a weak base if a 0.19 M aqueous solution of the base at $25^{\circ} \mathrm{C}$ has a pH of 10.88 .
16.73 The following diagrams represent aqueous solutions of three different monoprotic acids: $\mathrm{HA}, \mathrm{HB}$, and HC. (a) Which conjugate base ( $\mathrm{A}^{-}, \mathrm{B}^{-}$, or $\mathrm{C}^{-}$) has the smallest $K_{\mathrm{b}}$ value? (b) Which anion is the strongest base? The water molecules have been omitted for clarity.
$D=\mathrm{HA}, \mathrm{HB}$, or HC

HB
$\bigcirc=\mathrm{A}^{-}, \mathrm{B}^{-}$, or $\mathrm{C}^{-}$
HA

HC

## Section 16.7: Conjugate Acid-Base Pairs

## Review Questions

16.74 Write the equation relating $K_{\mathrm{a}}$ for a weak acid and $K_{\mathrm{b}}$ for its conjugate base. Use $\mathrm{NH}_{3}$ and its conjugate acid $\mathrm{NH}_{4}^{+}$to derive the relationship between $K_{\mathrm{a}}$ and $K_{\mathrm{b}}$.
16.75 From the relationship $K_{\mathrm{a}} K_{\mathrm{b}}=K_{\mathrm{w}}$, what can you deduce about the relative strengths of a weak acid and its conjugate base?

## Problems

16.76 The following diagrams represent solutions of three salts NaX ( $\mathrm{X}=\mathrm{A}, \mathrm{B}$, or C ). (a) Which $\mathrm{X}^{-}$has the weakest conjugate acid? (b) Arrange the three $\mathrm{X}^{-}$anions in order of decreasing base strength. The $\mathrm{Na}^{+}$ion and water molecules have been omitted for clarity.

$=\mathrm{HA}, \mathrm{HB}$, or HC

16.77 Calculate $K_{\mathrm{b}}$ for each of the following ions: $\mathrm{CN}^{-}, \mathrm{F}^{-}, \mathrm{CH}_{3} \mathrm{COO}^{-}$, $\mathrm{HCO}_{3}^{-}$.

## Section 16.8: Diprotic and Polyprotic Acids

## Review Questions

16.78 Write all the species (except water) that are present in a phosphoric acid solution. Indicate which species can act as a Brønsted acid, which as a Brønsted base, and which as both a Brønsted acid and a Brønsted base.

## Problems

E16.79 (1) Which of the following diagrams represents a solution of a weak diprotic acid? (2) Which diagrams represent chemically implausible situations? (The hydrated proton is shown as a hydronium ion. Water molecules are omitted for clarity.)

(a)

(b)

(c)

(d)
16.80 The first and second ionization constants of a diprotic acid $\mathrm{H}_{2} \mathrm{~A}$ are $K_{\mathrm{a}_{1}}$ and $K_{\mathrm{a}_{2}}$ at a certain temperature. Under what conditions will $\left[\mathrm{A}^{2-}\right]=K_{\mathrm{a}_{1}}$ ?
16.81 Compare the pH of a 0.040 M HCl solution with that of a 0.040 M $\mathrm{H}_{2} \mathrm{SO}_{4}$ solution. (Hint: $\mathrm{H}_{2} \mathrm{SO}_{4}$ is a strong acid; $K_{\mathrm{a}}$ for $\mathrm{HSO}_{4}^{-}=$ $1.3 \times 10^{-2}$.)

E16.82 What are the concentrations of $\mathrm{HSO}_{4}^{-}, \mathrm{SO}_{4}^{2-}$, and $\mathrm{H}^{+}$in a 0.20 M $\mathrm{KHSO}_{4}$ solution? (Hint: $\mathrm{H}_{2} \mathrm{SO}_{4}$ is a strong acid; $K_{\mathrm{a}}$ for $\mathrm{HSO}_{4}^{-}=$ $1.3 \times 10^{-2}$.)
16.83 Calculate the concentrations of $\mathrm{H}^{+}, \mathrm{HCO}_{3}^{-}$, and $\mathrm{CO}_{3}^{2-}$ in a $0.025 \mathrm{M} \mathrm{H}_{2} \mathrm{CO}_{3}$ solution.

H16.84 Calculate the pH at $25^{\circ} \mathrm{C}$ of a 0.25 M aqueous solution of phosphoric acid $\left(\mathrm{H}_{3} \mathrm{PO}_{4}\right)$. $\left(K_{\mathrm{a}_{1}}, K_{\mathrm{a}_{2}}\right.$, and $K_{\mathrm{a}_{3}}$ for phosphoric acid are $7.5 \times 10^{-3}, 6.25 \times 10^{-8}$, and $4.8 \times 10^{-13}$, respectively.)
16.85 Calculate the pH at $25^{\circ} \mathrm{C}$ of a 0.25 M aqueous solution of oxalic acid $\left(\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}\right)$. $\left(K_{\mathrm{a}_{1}}\right.$ and $K_{\mathrm{a}_{2}}$ for oxalic acid are $6.5 \times 10^{-2}$ and $6.1 \times 10^{-5}$, respectively.)

## Section 16.9: Molecular Structure and Acid Strength

## Review Questions

16.86 List four factors that affect the strength of an acid.
16.87 How does the strength of an oxoacid depend on the electronegativity and oxidation number of the central atom?

## Problems

E 16.88 Predict the relative acid strengths of the following compounds: $\mathrm{H}_{2} \mathrm{O}, \mathrm{H}_{2} \mathrm{~S}$, and $\mathrm{H}_{2} \mathrm{Se}$.
16.89 Compare the strengths of the following pairs of acids: (a) $\mathrm{H}_{2} \mathrm{SO}_{4}$ and $\mathrm{H}_{2} \mathrm{SeO}_{4}$, (b) $\mathrm{H}_{3} \mathrm{PO}_{4}$ and $\mathrm{H}_{3} \mathrm{AsO}_{4}$.
16.90 Which of the following is the stronger acid: $\mathrm{CH}_{2} \mathrm{ClCOOH}$ or $\mathrm{CHCl}_{2} \mathrm{COOH}$ ? Explain your choice.
16.91 Consider the following compounds:

Phenol

$$
\mathrm{CH}_{3}-\mathrm{O}-\mathrm{H}
$$

Methanol

Experimentally, phenol is found to be a stronger acid than methanol. Explain this difference in terms of the structures of the conjugate bases. (Hint: A more stable conjugate base favors ionization. Only one of the conjugate bases can be stabilized by resonance.)

## Section 16.10: Acid-Base Properties of Salt Solutions

## Review Questions

16.92 Define salt hydrolysis. Categorize salts according to how they affect the pH of a solution.
16.93 Explain why small, highly charged metal ions are able to undergo hydrolysis.
16.94 $\mathrm{Al}^{3+}$ is not a $\mathrm{Br} \varnothing$ nsted acid, but $\mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}^{3+}$ is. Explain.
16.95 Specify which of the following salts will undergo hydrolysis: $\mathrm{KF}, \mathrm{NaNO}_{3}, \mathrm{NH}_{4} \mathrm{NO}_{2}, \mathrm{MgSO}_{4}, \mathrm{KCN}, \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COONa}, \mathrm{RbI}$, $\mathrm{Na}_{2} \mathrm{CO}_{3}, \mathrm{CaCl}_{2}, \mathrm{HCOOK}$.

## Problems

H 16.96 Predict the $\mathrm{pH}(>7,<7$, or $\approx 7)$ of aqueous solutions containing the following salts: (a) KBr , (b) $\mathrm{Al}\left(\mathrm{NO}_{3}\right)_{3}$, (c) $\mathrm{BaCl}_{2}$, (d) $\mathrm{Bi}\left(\mathrm{NO}_{3}\right)_{3}$.
\$16.97 Predict whether the following solutions are acidic, basic, or nearly neutral: (a) NaBr , (b) $\mathrm{K}_{2} \mathrm{SO}_{3}$, (c) $\mathrm{NH}_{4} \mathrm{NO}_{2}$, (d) $\mathrm{Cr}\left(\mathrm{NO}_{3}\right)_{3}$.
16.98 A certain salt, MX (containing the $\mathrm{M}^{+}$and $\mathrm{X}^{-}$ions), is dissolved in water, and the pH of the resulting solution is 7.0 . What can you say about the strengths of the acid and the base from which the salt is derived?
16.99 In a certain experiment, a student finds that the pHs of 0.10 M solutions of three potassium salts KX, KY, and KZ are 7.0, 9.0, and 11.0 , respectively. Arrange the acids HX, HY, and HZ in order of increasing acid strength.
16.100 Predict whether a solution containing the salt $\mathrm{K}_{2} \mathrm{HPO}_{4}$ will be acidic, neutral, or basic.
16.101 Predict the $\mathrm{pH}(>7,<7$, or $\approx 7)$ of a $\mathrm{NaHCO}_{3}$ solution.
16.102 Calculate the pH of a $0.36 \mathrm{M} \mathrm{CH}_{3} \mathrm{COONa}$ solution. $\left(K_{\mathrm{a}}\right.$ for acetic acid $=1.8 \times 10^{-5}$.)
16.103 Calculate the pH of a $0.42 \mathrm{M} \mathrm{NH}_{4} \mathrm{Cl}$ solution. $\left(K_{\mathrm{b}}\right.$ for ammonia $\left.=1.8 \times 10^{-5}.\right)$
16.104 Calculate the pH of a 0.082 M NaF solution. $\left(K_{\mathrm{a}}\right.$ for $\mathrm{HF}=7.1 \times 10^{-4}$.)
16.105 Calculate the pH of a $0.91 \mathrm{M}_{2} \mathrm{H}_{5} \mathrm{NH}_{3} \mathrm{I}$ solution. $\left(K_{\mathrm{b}}\right.$ for $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{NH}_{2}=5.6 \times 10^{-4}$.)

## Section 16.11: Acid-Base Properties of Oxides and Hydroxides

## Review Questions

16.106 Classify the following oxides as acidic, basic, amphoteric, or neutral: (a) $\mathrm{CO}_{2}$, (b) $\mathrm{K}_{2} \mathrm{O}$, (c) CaO , (d) $\mathrm{N}_{2} \mathrm{O}_{5}$, (e) CO , (f) NO , (g) $\mathrm{SnO}_{2}$, (h) $\mathrm{SO}_{3}$, (i) $\mathrm{Al}_{2} \mathrm{O}_{3}$, (j) BaO .
16.107 Write equations for the reactions between (a) $\mathrm{CO}_{2}$ and $\mathrm{NaOH}(a q)$, (b) $\mathrm{Na}_{2} \mathrm{O}$ and $\mathrm{HNO}_{3}(a q)$.

## Problems

16.108 Explain why metal oxides tend to be basic if the oxidation number of the metal is low and tend to be acidic if the oxidation number of the metal is high. (Hint: Metallic compounds in which the oxidation numbers of the metals are low are more ionic than those in which the oxidation numbers of the metals are high.)
16.109 Arrange the oxides in each of the following groups in order of increasing basicity: (a) $\mathrm{K}_{2} \mathrm{O}, \mathrm{Al}_{2} \mathrm{O}_{3}, \mathrm{BaO}$, (b) $\mathrm{CrO}_{3}, \mathrm{CrO}, \mathrm{Cr}_{2} \mathrm{O}_{3}$.
16.110 $\mathrm{Zn}(\mathrm{OH})_{2}$ is an amphoteric hydroxide. Write balanced ionic equations to show its reaction with (a) HCl , (b) NaOH [the product is $\mathrm{Zn}(\mathrm{OH})_{4}^{2-}$ ].
16.111 $\mathrm{Al}(\mathrm{OH})_{3}$ is insoluble in water. It dissolves in concentrated NaOH solution. Write a balanced ionic equation for this reaction. What type of reaction is this?

## Section 16.12: Lewis Acids and Bases

## Review Questions

16.112 What are the Lewis definitions of an acid and a base? In what way are they more general than the Brønsted definitions?
16.113 In terms of orbitals and electron arrangements, what must be present for a molecule or an ion to act as a Lewis acid (use $\mathrm{H}^{+}$ and $\mathrm{BF}_{3}$ as examples)? What must be present for a molecule or ion to act as a Lewis base (use $\mathrm{OH}^{-}$and $\mathrm{NH}_{3}$ as examples)?

## Problems

E 16.114 Classify each of the following species as a Lewis acid or a Lewis base: (a) $\mathrm{CO}_{2}$, (b) $\mathrm{H}_{2} \mathrm{O}$, (c) $\mathrm{I}^{-}$, (d) $\mathrm{SO}_{2}$, (e) $\mathrm{NH}_{3}$, (f) $\mathrm{OH}^{-}$, (g) $\mathrm{H}^{+}$, (h) $\mathrm{BCl}_{3}$.
16.115 Describe the following reaction in terms of the Lewis theory of acids and bases:

$$
\mathrm{AlCl}_{3}(s)+\mathrm{Cl}^{-}(a q) \longrightarrow \mathrm{AlCl}_{4}^{-}(a q)
$$

16.116 Which would be considered a stronger Lewis acid: (a) $\mathrm{BF}_{3}$ or $\mathrm{BCl}_{3}$, (b) $\mathrm{Fe}^{2+}$ or $\mathrm{Fe}^{3+}$ ? Explain.
16.117 All Brønsted acids are Lewis acids, but the reverse is not true. Give two examples of Lewis acids that are not Brønsted acids.
16.118 Identify the Lewis acid and the Lewis base in the following reactions:
(a) $5 \mathrm{CO}(g)+\mathrm{Fe}(s) \longrightarrow \mathrm{Fe}(\mathrm{CO})_{5}(l)$
(b) $\mathrm{NH}_{3}(g)+\mathrm{BCl}_{3}(g) \longrightarrow \mathrm{Cl}_{3} \mathrm{BNH}_{3}(s)$
(c) $\mathrm{Hg}^{2+}(a q)+4 \mathrm{I}^{-}(a q) \longrightarrow \mathrm{HgI}_{4}^{2-}(a q)$
16.119 Identify the Lewis acid and the Lewis base in the following reactions:
(a) $\mathrm{AlBr}_{3}(s)+\mathrm{Br}^{-}(a q) \longrightarrow \mathrm{AlBr}_{4}^{-}(a q)$
(b) $6 \mathrm{CO}(g)+\mathrm{Cr}(s) \longrightarrow \mathrm{Cr}(\mathrm{CO})_{6}(s)$
(c) $\mathrm{Cu}^{2+}(a q)+4 \mathrm{CN}^{-}(a q) \longrightarrow \mathrm{Cu}(\mathrm{CN})_{4}^{2-}(a q)$

## Additional Problems

$16.120 \mathrm{H}_{2} \mathrm{SO}_{4}$ is a strong acid, but $\mathrm{HSO}_{4}^{-}$is a weak acid. Account for the difference in strength of these two related species.
16.121 Which of the following diagrams best represents a strong acid, such as HCl , dissolved in water? Which represents a weak acid? Which represents a very weak acid? (The hydrated proton is shown as a hydronium ion. Water molecules are omitted for clarity.)

16.122 Predict the direction that predominates in this reaction:

$$
\mathrm{F}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{HF}(a q)+\mathrm{OH}^{-}(a q)
$$

16.123 Predict the products and tell whether the following reaction will occur to any measurable extent:

$$
\mathrm{CH}_{3} \mathrm{COOH}(a q)+\mathrm{Cl}^{-}(a q) \longrightarrow
$$

16.124 In a $0.080 \mathrm{M} \mathrm{H}_{3}$ solution, what percent of the $\mathrm{NH}_{3}$ is present as $\mathrm{NH}_{4}^{+}$?
16.125 Calculate the pH and percent ionization of a $0.88 \mathrm{M} \mathrm{HNO}_{2}$ solution at $25^{\circ} \mathrm{C}$.
16.126 A typical reaction between an antacid and the hydrochloric acid in gastric juice is

$$
\mathrm{NaHCO}_{3}(s)+\mathrm{HCl}(a q) \rightleftarrows \mathrm{NaCl}(a q)+\mathrm{H}_{2} \mathrm{O}(l)+\mathrm{CO}_{2}(g)
$$

Calculate the volume (in liters) of $\mathrm{CO}_{2}$ generated from 0.350 g of $\mathrm{NaHCO}_{3}$ and excess gastric juice at 1.00 atm and $37.0^{\circ} \mathrm{C}$.
$\$ 16.127$ To which of the following would the addition of an equal volume of 0.60 M NaOH lead to a solution having a lower pH : (a) water, (b) 0.30 M HCl , (c) 0.70 M KOH , (d) $0.40 \mathrm{M} \mathrm{NaNO}_{3}$ ?
16.128 The pH of a 0.0642 M solution of a monoprotic acid is 3.86 . Is this a strong acid?
16.129 Like water, liquid ammonia undergoes autoionization:

$$
\mathrm{NH}_{3}+\mathrm{NH}_{3} \rightleftarrows \mathrm{NH}_{4}^{+}+\mathrm{NH}_{2}^{-}
$$

(a) Identify the Brønsted acids and Brønsted bases in this reaction. (b) What species correspond to $\mathrm{H}^{+}$and $\mathrm{OH}^{-}$, and what is the condition for a neutral solution?
16.130 HA and HB are both weak acids although HB is the stronger of the two. Will it take a larger volume of a 0.10 M NaOH solution to neutralize 50.0 mL of 0.10 M HB than would be needed to neutralize 50.0 mL of 0.10 M HA ?
16.131 A solution contains a weak monoprotic acid HA and its sodium salt NaA both at 0.1 M concentration. Show that $\left[\mathrm{OH}^{-}\right]=K_{\mathrm{w}} / K_{\mathrm{a}}$.
16.132 The three common chromium oxides are $\mathrm{CrO}, \mathrm{Cr}_{2} \mathrm{O}_{3}$, and $\mathrm{CrO}_{3}$. If $\mathrm{Cr}_{2} \mathrm{O}_{3}$ is amphoteric, what can you say about the acid-base properties of CrO and $\mathrm{CrO}_{3}$ ?
16.133 Use the data in Table 16.6 to calculate the equilibrium constant for the following reaction:

$$
\mathrm{HCOOH}(a q)+\mathrm{OH}^{-}(a q) \rightleftarrows \mathrm{HCOO}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l)
$$

16.134 Use the data in Table 16.6 to calculate the equilibrium constant for the following reaction:

$$
\left.\mathrm{CH}_{3} \mathrm{COOH}(a q)+\mathrm{NO}_{2}^{-} a q\right) \rightleftarrows \mathrm{CH}_{3} \mathrm{COO}^{-}(a q)+\mathrm{HNO}_{2}(a q)
$$

16.135 Most of the hydrides of Group 1A and Group 2A metals are ionic (the exceptions are $\mathrm{BeH}_{2}$ and $\mathrm{MgH}_{2}$, which are covalent compounds). (a) Describe the reaction between the hydride ion $\left(\mathrm{H}^{-}\right)$and water in terms of a Brønsted acid-base reaction. (b) The same reaction can also be classified as a redox reaction. Identify the oxidizing and reducing agents.
§16.136 Calculate the pH of a 0.20 M ammonium acetate $\left(\mathrm{CH}_{3} \mathrm{COONH}_{4}\right)$ solution.
16.137 Novocaine, used as a local anesthetic by dentists, is a weak base $\left(K_{\mathrm{b}}=8.91 \times 10^{-6}\right)$. What is the ratio of the concentration of the base to that of its acid in the blood plasma ( $\mathrm{pH}=7.40$ ) of a patient? (As an approximation, use the $K_{\mathrm{a}}$ values at $25^{\circ} \mathrm{C}$.)
16.138 Which of the following is the stronger base: $\mathrm{NF}_{3}$ or $\mathrm{NH}_{3}$ ? (Hint: F is more electronegative than H .)
16.139 Which of the following is a stronger base: $\mathrm{NH}_{3}$ or $\mathrm{PH}_{3}$ ? (Hint: The $\mathrm{N}-\mathrm{H}$ bond is stronger than the $\mathrm{P}-\mathrm{H}$ bond.)

I 16.140 The ion product of $\mathrm{D}_{2} \mathrm{O}$ is $1.35 \times 10^{-15}$ at $25^{\circ} \mathrm{C}$. (a) Calculate pD where $\mathrm{pD}=-\log \left[\mathrm{D}^{+}\right]$. (b) For what values of pD will a solution be acidic in $\mathrm{D}_{2} \mathrm{O}$ ? (c) Derive a relation between pD and pOD .
16.141 Give an example of (a) a weak acid that contains oxygen atoms, (b) a weak acid that does not contain oxygen atoms, (c) a neutral molecule that acts as a Lewis acid, (d) a neutral molecule that acts as a Lewis base, (e) a weak acid that contains two ionizable H atoms, (f) a conjugate acid-base pair, both of which react with HCl to give carbon dioxide gas.
16.142 What is the pH of 250.0 mL of an aqueous solution containing 0.616 g of a strong acid?
16.143 (a) Use VSEPR to predict the geometry of the hydronium ion $\left(\mathrm{H}_{3} \mathrm{O}^{+}\right)$. (b) The O atom in $\mathrm{H}_{2} \mathrm{O}$ has two lone pairs and in principle can accept two $\mathrm{H}^{+}$ions. Explain why the species $\mathrm{H}_{4} \mathrm{O}^{2+}$ does not exist. What would be its geometry if it did exist?
16.144 HF is a weak acid, but its strength increases with concentration. Explain. (Hint: $\mathrm{F}^{-}$reacts with HF to form $\mathrm{HF}_{2}^{-}$. The equilibrium constant for this reaction is 5.2 at $25^{\circ} \mathrm{C}$.)
16.145 When chlorine reacts with water, the resulting solution is weakly acidic and reacts with $\mathrm{AgNO}_{3}$ to give a white precipitate. Write balanced equations to represent these reactions. Explain why manufacturers of household bleaches add bases such as NaOH to their products to increase their effectiveness.
16.146 When the concentration of a strong acid is not substantially higher than $1.0 \times 10^{-7} \mathrm{M}$, the ionization of water must be taken into account in the calculation of the solution's pH . (a) Derive an expression for the pH of a strong acid solution, including the contribution to $\left[\mathrm{H}^{+}\right]$from $\mathrm{H}_{2} \mathrm{O}$. (b) Calculate the pH of a $1.0 \times$ $10^{-7} M \mathrm{HCl}$ solution.

E16.147 Calculate the pH of a $2.00 \mathrm{M} \mathrm{H}_{4} \mathrm{CN}$ solution.
16.148 Calculate the concentrations of all species in a $0.100 M \mathrm{H}_{3} \mathrm{PO}_{4}$ solution.

E16.149 In the vapor phase, acetic acid molecules associate to a certain extent to form dimers:

$$
2 \mathrm{CH}_{3} \mathrm{COOH}(\mathrm{~g}) \rightleftarrows\left(\mathrm{CH}_{3} \mathrm{COOH}\right)_{2}(\mathrm{~g})
$$

At $51^{\circ} \mathrm{C}$, the pressure of a certain acetic acid vapor system is 0.0342 atm in a $360-\mathrm{mL}$ flask. The vapor is condensed and neutralized with 13.8 mL of 0.0568 M NaOH . (a) Calculate the degree of dissociation $(\alpha)$ of the dimer under these conditions:

$$
\left(\mathrm{CH}_{3} \mathrm{COOH}\right)_{2} \rightleftarrows 2 \mathrm{CH}_{3} \mathrm{COOH}
$$

(b) Calculate the equilibrium constant $K_{P}$ for the reaction in part (a).
16.150 Calculate the concentrations of all the species in a 0.100 M $\mathrm{Na}_{2} \mathrm{CO}_{3}$ solution.

G16.151 Henry's law constant for $\mathrm{CO}_{2}$ at $38^{\circ} \mathrm{C}$ is $2.28 \times 10^{-3} \mathrm{~mol} /$ $\mathrm{L} \cdot \operatorname{atm}$. Calculate the pH of a solution of $\mathrm{CO}_{2}$ at $38^{\circ} \mathrm{C}$ in equilibrium with the gas at a partial pressure of 3.20 atm .
16.152 Hydrocyanic acid $(\mathrm{HCN})$ is a weak acid and a deadly poisonous compound-in the gaseous form (hydrogen cyanide), it is used in gas chambers. Why is it dangerous to treat sodium cyanide with acids (such as HCl ) without proper ventilation?
$\$ 16.153$ How many grams of NaCN would you need to dissolve in enough water to make exactly 250 mL of solution with a pH of 10.00 ?
$\leftrightarrows 16.154$ A solution of formic acid $(\mathrm{HCOOH})$ has a pH of 2.53 . How many grams of formic acid are there in 100.0 mL of the solution?
116.155 Calculate the pH of a 1-L solution containing 0.150 mole of $\mathrm{CH}_{3} \mathrm{COOH}$ and 0.100 mole of HCl .
16.156 A 1.87-g sample of Mg reacts with 80.0 mL of a HCl solution whose pH is -0.544 . What is the pH of the solution after all the Mg has reacted? Assume constant volume.
16.157 You are given two beakers, one containing an aqueous solution of strong acid (HA) and the other an aqueous solution of weak $\operatorname{acid}(\mathrm{HB})$ of the same concentration. Describe how you would compare the strengths of these two acids by (a) measuring the pH , (b) measuring electrical conductance, and (c) studying the rate of hydrogen gas evolution when these solutions are combined with an active metal such as Mg or Zn .
16.158 Use Le Châtelier's principle to predict the effect of the following changes on the extent of hydrolysis of sodium nitrite $\left(\mathrm{NaNO}_{2}\right)$ solution: (a) HCl is added, (b) NaOH is added, (c) NaCl is added, (d) the solution is diluted.

H16.159 A $0.400 M$ formic acid $(\mathrm{HCOOH})$ solution freezes at $-0.758^{\circ} \mathrm{C}$. Calculate the $K_{\mathrm{a}}$ of the acid at that temperature. (Hint: Assume that molarity is equal to molality. Carry out your calculations to three significant figures and round off to two for $K_{\mathrm{a}}$.)
16.160 The disagreeable odor of fish is mainly due to organic compounds $\left(\mathrm{RNH}_{2}\right)$ containing an amino group, $-\mathrm{NH}_{2}$, where R is the rest of the molecule. Amines are bases just like ammonia. Explain why putting some lemon juice on fish can greatly reduce the odor.
©16.161 A solution of methylamine $\left(\mathrm{CH}_{3} \mathrm{NH}_{2}\right)$ has a pH of 10.64. How many grams of methylamine are there in 100.0 mL of the solution?
16.162 Describe the hydration of $\mathrm{SO}_{2}$ as a Lewis acid-base reaction.
16.163 Both the amide ion $\left(\mathrm{NH}_{2}^{-}\right)$and the nitride ion $\left(\mathrm{N}^{3-}\right)$ are stronger bases than the hydroxide ion and hence do not exist in aqueous solutions. (a) Write equations showing the reactions of these ions with water, and identify the Brønsted acid and base in each case. (b) Which of the two is the stronger base?
16.164 The atmospheric sulfur dioxide $\left(\mathrm{SO}_{2}\right)$ concentration over a certain region is 0.12 ppm by volume. Calculate the pH of the rainwater due to this pollutant. Assume that the dissolution of $\mathrm{SO}_{2}$ does not affect its pressure. ( $K_{\mathrm{a}}$ for $\mathrm{H}_{2} \mathrm{SO}_{3}=1.3 \times 10^{-2}$.)
16.165 Explain the action of smelling salt, which is ammonium carbonate $\left[\left(\mathrm{NH}_{4}\right)_{2} \mathrm{CO}_{3}\right]$. (Hint: The thin film of aqueous solution that lines the nasal passages is slightly basic.)
16.166 About half of the hydrochloric acid produced annually in the United States ( 3.0 billion pounds) is used in metal pickling. This process involves the removal of metal oxide layers from metal surfaces to prepare them for coating. (a) Write the overall and net ionic equations for the reaction between iron(III) oxide, which represents the rust layer over iron, and HCl . Identify the Brønsted acid and base. (b) Hydrochloric acid is also used to remove scale (which is mostly $\mathrm{CaCO}_{3}$ ) from water pipes. Hydrochloric acid reacts with calcium carbonate in two stages; the first stage forms the bicarbonate ion, which then reacts further to form carbon dioxide. Write equations for these two stages and for the overall reaction. (c) Hydrochloric acid is used to recover oil from the ground. It dissolves rocks (often $\mathrm{CaCO}_{3}$ ) so that the oil can flow more easily. In one process, a 15 percent (by mass) HCl solution is injected into an oil well to dissolve the rocks. If the density of the acid solution is $1.073 \mathrm{~g} / \mathrm{mL}$, what is the pH of the solution?
16.167 Which of the following does not represent a Lewis acid-base reaction?
(a) $\mathrm{H}_{2} \mathrm{O}+\mathrm{H}^{+} \longrightarrow \mathrm{H}_{3} \mathrm{O}^{+}$
(b) $\mathrm{NH}_{3}+\mathrm{BF}_{3} \longrightarrow \mathrm{H}_{3} \mathrm{NBF}_{3}$
(c) $\mathrm{PF}_{3}+\mathrm{F}_{2} \longrightarrow \mathrm{PF}_{5}$
(d) $\mathrm{Al}(\mathrm{OH})_{3}+\mathrm{OH}^{-} \longrightarrow \mathrm{Al}(\mathrm{OH})_{4}^{-}$
16.168 Determine whether each of the following statements is true or false. If false, explain why the statement is wrong. (a) All Lewis acids are Brønsted acids. (b) The conjugate base of an acid always carries a negative charge. (c) The percent ionization of a base increases with its concentration in solution. (d) A solution of barium fluoride is acidic.
16.169 How many milliliters of a strong monoprotic acid solution at $\mathrm{pH}=4.12$ must be added to 528 mL of the same acid solution at $\mathrm{pH}=5.76$ to change its pH to 5.34 ? Assume that the volumes are additive.
16.170 Hemoglobin $(\mathrm{Hb})$ is a blood protein that is responsible for transporting oxygen. It can exist in the protonated form as $\mathrm{HbH}^{+}$. The binding of oxygen can be represented by the simplified equation

$$
\mathrm{HbH}^{+}+\mathrm{O}_{2} \rightleftarrows \mathrm{HbO}_{2}+\mathrm{H}^{+}
$$

(a) What form of hemoglobin is favored in the lungs where oxygen concentration is highest? (b) In body tissues, where the cells release carbon dioxide produced by metabolism, the blood is more acidic due to the formation of carbonic acid. What form of hemoglobin is favored under this condition?
(c) When a person hyperventilates, the concentration of $\mathrm{CO}_{2}$ in his or her blood decreases. How does this action affect the given equilibrium? Frequently a person who is hyperventilating is advised to breathe into a paper bag. Why does this action help the individual?
16.171 A 20.27-g sample of a metal carbonate $\left(\mathrm{MCO}_{3}\right)$ is combined with 500 mL of a 1.00 M HCl solution. The excess HCl acid is then neutralized by 32.80 mL of 0.588 M NaOH . Identify M .
16.172 Calculate the pH of a solution that is 1.00 M HCN and 1.00 M HF. Compare the concentration (in molarity) of the $\mathrm{CN}^{-}$ion in this solution with that in a 1.00 MHCN solution. Comment on the difference.
16.173 Tooth enamel is largely hydroxyapatite $\left[\mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{3} \mathrm{OH}\right]$. When it dissolves in water (a process called demineralization), it dissociates as follows:

$$
\mathrm{Ca}_{5}\left(\mathrm{PO}_{4}\right)_{3} \mathrm{OH} \longrightarrow 5 \mathrm{Ca}^{2+}+3 \mathrm{PO}_{4}^{3-}+\mathrm{OH}^{-}
$$

The reverse process, called remineralization, is the body's natural defense against tooth decay. Acids produced from food remove the $\mathrm{OH}^{-}$ions and thereby weaken the enamel layer. Most toothpastes contain a fluoride compound such as NaF or $\mathrm{SnF}_{2}$. What is the function of these compounds in preventing tooth decay?
16.174 Use the van't Hoff equation (see Problem 15.118) and the data in Appendix 2 to calculate the pH of water at its normal boiling point.
16.175 At $28^{\circ}$ and 0.982 atm , gaseous compound HA has a density of $1.16 \mathrm{~g} / \mathrm{L}$. A quantity of 2.03 g of this compound is dissolved in water and diluted to exactly 1 L . If the pH of the solution at $25^{\circ} \mathrm{C}$ is 5.22 (due to ionization of HA), calculate the $K_{\mathrm{a}}$ of the acid.
16.176 A 10.0-g sample of white phosphorus was burned in an excess of oxygen. The product was dissolved in enough water to make 500.0 mL of solution. Calculate the pH of the solution at $25^{\circ} \mathrm{C}$.

## Pre-Professional Practice Exam Problems: Physical and Biological Sciences

The following questions are not based on a descriptive passage.

1. Which of the following best describes the titration of a weak acid with a strong base?
a) Low starting pH , and $\mathrm{pH} \approx 7$ at equivalence point b) High starting pH , and $\mathrm{pH} \approx 7$ at equivalence point c) High starting pH , and $\mathrm{pH}<7$ at equivalence point d) Low starting pH , and $\mathrm{pH}>7$ at equivalence point
2. What is the pH of a solution made by combining 150 mL of 0.125 M HCl and 150 mL of $0.120 \mathrm{M} \mathrm{Ba}(\mathrm{OH})_{2}$ at $25^{\circ} \mathrm{C}$ ?
a) 1.240
b) 12.760
c) 2.602
d) 11.398
3. What volume of 0.085 M NaOH is necessary to titrate to the equivalence point 25.0 mL of 0.15 M HCN at $25^{\circ} \mathrm{C}$ ?
a) 44 mL
b) 88 mL
c) 22 mL
d) 25 mL
4. Determine the pH at the equivalence point for the titration in Question 3.
a) 2.98
b) 11.02
c) 8.71
d) 5.29

Saliva becomes more acidic when highsugar foods are eaten. Brushing regularly with fluoride toothpaste helps prevent cavities by making tooth enamel less soluble in acid.

## Equilibrium and Tooth Decay

Teeth are protected by a hard enamel layer about 2 mm thick that is composed of a mineral called hydroxyapatite $\left[\mathrm{Ca}_{5}\left(\mathrm{PO}_{4}\right)_{3} \mathrm{OH}\right]$. Demineralization is the process by which hydroxyapatite dissolves in the saliva. Because phosphates of alkaline earth metals such as calcium are insoluble [ Kt Section 4.2, Table 4.3], this process happens only to a very small extent:

$$
\mathrm{Ca}_{5}\left(\mathrm{PO}_{4}\right)_{3} \mathrm{OH}(s) \longleftarrow 5 \mathrm{Ca}^{2+}(a q)+3 \mathrm{PO}_{4}^{3-}(a q)+\mathrm{OH}^{-}(a q)
$$

The reverse process, called remineralization, is the body's natural defense against tooth decay:

$$
5 \mathrm{Ca}^{2+}(a q)+3 \mathrm{PO}_{4}^{3-}(a q)+\mathrm{OH}^{-}(a q) \longleftrightarrow \mathrm{Ca}_{5}\left(\mathrm{PO}_{4}\right)_{3} \mathrm{OH}(s)
$$

Bacteria in the mouth break down some of the food we eat to produce organic acids such as acetic acid and lactic acid. Acid production is greatest from foods that are high in sugar. Thus, after a sugary snack, the $\mathrm{H}^{+}$concentration in the mouth increases, causing $\mathrm{OH}^{-}$ions in the saliva to be consumed.

$$
\mathrm{H}^{+}(a q)+\mathrm{OH}^{-}(a q) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)
$$

Removal of $\mathrm{OH}^{-}$from the saliva draws the $\mathrm{Ca}_{5}\left(\mathrm{PO}_{4}\right)_{3} \mathrm{OH}$ dissolution equilibrium to the right, promoting demineralization. Once the protective enamel layer is weakened, tooth decay begins. The best way to prevent tooth decay is to eat a diet low in sugar and brush immediately after every meal.

Student Annotation: In children, the growth of the enamel layer (mineralization) occurs faster than demineralization; in adults, demineralization and remineralization occur at roughly equal rates.

At the end of this chapter, you will be able to solve a series of problems involving the solubility of hydroxyapatite, the principal component of tooth enamel[ $M$ Page 766].

## In This Chapter, You Will Learn:

More about the behavior of acids and bases and about the factors that affect the aqueous solubility of ionic compounds.

Before you begin, you should review

- Determination of pH [ kH Section 16.3]
- Manipulating equilibrium expressions [ 14 Section 15.3]

Student Annotation: The percent ionization of acetic acid is

$$
\frac{1.34 \times 10^{-3} M}{0.10 \mathrm{M}} \times 100 \%=1.3 \%
$$

Student Annotation: By adding sodium acetate, we also add sodium ions to the solution. However, sodium ions do not interact with water or with any of the other species present [ 14 Section 16.10].

Student Annotation: Remember that prior to the ionization of a weak acid, the concentration of hydrogen ion in water at $25^{\circ} \mathrm{C}$ is $1.0 \times 10^{-7} \mathrm{M}$. However, because this concentration is insignificant compared to the concentration resulting from the ionization, we can neglect it in our equilibrium table.

### 17.1 The Common Ion Effect

Up until now, we have discussed the properties of solutions containing a single solute. In this section, we will examine how the properties of a solution change when a second solute is introduced.

Recall that a system at equilibrium will shift in response to being stressed and that stress can be applied in a variety of ways, including the addition of a reactant or a product [ 14 Section 15.5]. Consider a liter of solution containing 0.10 mole of acetic acid. Using the $K_{\mathrm{a}}$ for acetic acid $\left(1.8 \times 10^{-5}\right)$ and an equilibrium table [ 14 Section 16.5], the pH of this solution at $25^{\circ} \mathrm{C}$ can be determined:

$$
\mathrm{CH}_{3} \mathrm{COOH}(a q) \rightleftarrows \mathrm{H}^{+}(a q)+\mathrm{CH}_{3} \mathrm{COO}^{-}(a q)
$$

## Initial concentration ( $M$ ):

Change in concentration ( $M$ ):
Equilibrium concentration $(M)$ :

| 0.10 | 0 | 0 |
| :---: | :---: | :---: |
| $-x$ | $+x$ | $+x$ |
| $0.10-x$ | $x$ | $x$ |

Assuming that $(0.10-x) M \approx 0.10 M$ and solving for $x$, we get $1.34 \times 10^{-3}$. Therefore, $\left[\mathrm{CH}_{3} \mathrm{COOH}\right]=0.09866 \mathrm{M},\left[\mathrm{H}^{+}\right]=\left[\mathrm{CH}_{3} \mathrm{COO}^{-}\right]=1.34 \times 10^{-3} \mathrm{M}$ and $\mathrm{pH}=2.87$.

Now consider what happens when we add 0.050 mole of sodium acetate $\left(\mathrm{CH}_{3} \mathrm{COONa}\right)$ to the solution. Sodium acetate dissociates completely in aqueous solution to give sodium ions and acetate ions:

$$
\mathrm{CH}_{3} \mathrm{COONa}(a q) \xrightarrow{\mathrm{H}_{2} \mathrm{O}} \mathrm{Na}^{+}(a q)+\mathrm{CH}_{3} \mathrm{COO}^{-}(a q)
$$

Thus, by adding sodium acetate, we have increased the concentration of acetate ion. Because acetate ion is a product in the ionization of acetic acid, the addition of acetate ion causes the equilibrium to shift to the left. The net result is a reduction in the percent ionization of acetic acid.

Equilibrium is driven toward reactant.
Shifting the equilibrium to the left consumes not only some of the added acetate ion, but also some of the hydrogen ion. This causes the pH to change (in this case the pH increases).

Sample Problem 17.1 shows how an equilibrium table can be used to calculate the pH of a solution of acetic acid after the addition of sodium acetate.

## Sample Problem 17.1

Determine the pH at $25^{\circ} \mathrm{C}$ of a solution prepared by adding 0.050 mole of sodium acetate to 1.0 L of 0.10 M acetic acid. (Assume that the addition of sodium acetate does not change the volume of the solution.)

Strategy Construct a new equilibrium table to solve for the hydrogen ion concentration.
Setup We use the stated concentration of acetic acid, $0.10 M$, and $\left[\mathrm{H}^{+}\right] \approx 0 M$ as the initial concentrations in the table:

Initial concentration ( $M$ ):
Change in concentration $(M)$ :
Equilibrium concentration ( $M$ ):

$$
\mathrm{CH}_{3} \mathrm{COOH}(a q) \rightleftarrows \mathrm{H}^{+}(a q)+\mathrm{CH}_{3} \mathrm{COO}^{-}(a q)
$$

Solution Substituting the equilibrium concentrations, in terms of the unknown $x$, into the equilibrium expression gives

$$
1.8 \times 10^{-5}=\frac{(x)(0.050+x)}{0.10-x}
$$

Because we expect $x$ to be very small (even smaller than $1.34 \times 10^{-3} M$-see above), because the ionization of $\mathrm{CH}_{3} \mathrm{COOH}$ is suppressed by the presence of $\mathrm{CH}_{3} \mathrm{COO}^{-}$, we assume

$$
(0.10-x) M \approx 0.10 M \quad \text { and } \quad(0.050-x) M \approx 0.050 M
$$

Therefore, the equilibrium expression simplifies to

$$
1.8 \times 10^{-5}=\frac{(x)(0.050)}{0.10}
$$

and $x=3.6 \times 10^{-5} M$. According to the equilibrium table, $\left[\mathrm{H}^{+}\right]=x$, so $\mathrm{pH}=-\log \left(3.6 \times 10^{-5}\right)=4.44$.

Student Annotation: In this case, the percent ionization of acetic acid is

$$
\frac{3.6 \times 10^{-5} \mathrm{M}}{0.10 \mathrm{M}} \times 100 \%=0.036 \%
$$

This is considerably smaller than the percent ionization prior to the addition of sodium acetate.

Practice Problem A Determine the pH at $25^{\circ} \mathrm{C}$ of a solution prepared by dissolving 0.075 mole of sodium acetate in 1.0 L of 0.25 M acetic acid. (Assume that the addition of sodium acetate does not change the volume of the solution.)

HPractice Problem B Determine the pH at $25^{\circ} \mathrm{C}$ of a solution prepared by dissolving 0.35 mole of ammonium chloride in 1.0 L of 0.25 M aqueous ammonia.

Think About It The equilibrium concentrations of $\mathrm{CH}_{3} \mathrm{COOH}, \mathrm{CH}_{3} \mathrm{COO}^{-}$, and $\mathrm{H}^{+}$are the same regardless of whether we add sodium acetate to a solution of acetic acid, add acetic acid to a solution of sodium acetate, or dissolve both species at the same time. We could have constructed an equilibrium table starting with the equilibrium concentrations in the 0.10 M acetic acid solution:

Initial concentration ( $M$ ):
Change in concentration ( $M$ ):
Equilibrium concentration $(M)$ :

| $\mathrm{CH}_{3} \mathrm{COOH}(a q)$ |  |  |
| :---: | :---: | :---: |
| 0.09866 | $\rightleftarrows \mathrm{H}^{+}(a q)$ |  |$+\mathrm{CH}_{3} \mathrm{COO}^{-}(a q)$

In this case, the reaction proceeds to the left. (The acetic acid concentration increases, and the concentrations of hydrogen and acetate ions decrease.) Solving for $y$ gives $1.304 \times 10^{-3} M$. $\left[\mathrm{H}^{+}\right]=1.34 \times 10^{-3}-y=3.6 \times 10^{-5} M$ and $\mathrm{pH}=4.44$. We get the same pH either way.

An aqueous solution of a weak electrolyte contains both the weak electrolyte and its ionization products, which are ions. If a soluble salt that contains one of those ions is added, the equilibrium shifts to the left, thereby suppressing the ionization of the weak electrolyte. In general, when a compound containing an ion in common with a dissolved substance is added to a solution at equilibrium, the equilibrium shifts to the left. This phenomenon is known as the common ion effect.

## Checkpoint 17.1 The Common Ion Effect

17.1.1 Which of the following would cause a decrease in the percent ionization of nitrous acid $\left(\mathrm{HNO}_{2}\right)$ when added to a solution of nitrous acid at equilibrium? (Select all that apply.)
a) $\mathrm{NaNO}_{2}$
b) $\mathrm{H}_{2} \mathrm{O}$
c) $\mathrm{Ca}\left(\mathrm{NO}_{2}\right)_{2}$
d) $\mathrm{HNO}_{3}$
e) $\mathrm{NaNO}_{3}$
17.1.2 What is the pH of a solution prepared by adding 0.05 mole of NaF to 1.0 L of 0.1 M HF at $25^{\circ} \mathrm{C}$ ? (Assume that the addition of NaF does not change the volume of the solution.) ( $K_{\mathrm{a}}$ for $\mathrm{HF}=7.1 \times 10^{-4}$.)
a) 2.1
b) 2.8
c) 1.4
d) 4.6
e) 7.3

### 17.2 Buffer Solutions

A solution that contains a weak acid and its conjugate base (or a weak base and its conjugate acid) is a buffer solution or simply a buffer. Buffer solutions, by virtue of their composition, resist changes in pH upon addition of small amounts of either an acid or a base. The ability to resist pH change is very important to chemical and biological systems, including the human body. The pH of blood is about 7.4, whereas that of gastric juices is about 1.5 . Each of these pH values is crucial for proper enzyme function and the balance of osmotic pressure, and each is maintained within a very narrow pH range by a buffer.

## Calculating the pH of a Buffer

Consider a solution that is 1.0 M in acetic acid and 1.0 M sodium acetate. If a small amount of acid is added to this solution, it is consumed completely by the acetate ion,

$$
\mathrm{H}^{+}(a q)+\mathrm{CH}_{3} \mathrm{COO}^{-}(a q) \longrightarrow \mathrm{CH}_{3} \mathrm{COOH}(a q)
$$

Student Annotation: This is the sum of the equilibrium concentration of acetate ion in a 0.10 M solution of acetic acid $\left(1.34 \times 10^{-3} \mathrm{M}\right)$ and the added acetate ion $(0.050 \mathrm{M})$.

Student Annotation: Treating the problem as though both $\mathrm{CH}_{3} \mathrm{COOH}$ and $\mathrm{CH}_{3} \mathrm{COO}^{-}$ are added at the same time and the reaction proceeds to the right simplifies the solution.

Student Annotation: The common ion can also be $\mathrm{H}^{+}$or $\mathrm{OH}^{-}$. For example, addition of a strong acid to a solution of a weak acid suppresses ionization of the weak acid. Similarly, addition of a strong base to a solution of weak base suppresses ionization of the weak base.

Student Annotation: Any solution of a weak acid contains some conjugate base. In a buffer solution, though, the amounts of weak acid and conjugate base must be comparable, meaning that the conjugate base must be supplied by a dissolved salt.

Student Annotation: Remember that sodium acetate is a strong electrolyte [ 144 Section 4.1], so it dissociates completely in water to give sodium ions and acetate ions:
$\mathrm{CH}_{3} \mathrm{COONa} \longrightarrow \mathrm{Na}^{+}(\mathrm{aq})+\mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})$

Multimedia
Acids and Bases-effect of addition of a strong acid and a strong base on a buffer.

Student Annotation: The forward reaction is suppressed by the presence of the common ion, $\mathrm{CH}_{3} \mathrm{COO}^{-}$, and the reverse process is suppressed by the presence of $\mathrm{CH}_{3} \mathrm{COOH}$.

Student Annotation: As long as the amount of strong acid added to the buffer does not exceed the amount of conjugate base originally present, all the added acid will be consumed and converted to weak acid.
thus converting a strong acid $\left(\mathrm{H}^{+}\right)$to a weak acid $\left(\mathrm{CH}_{3} \mathrm{COOH}\right)$. Addition of a strong acid lowers the pH of a solution. However, a buffer's ability to convert a strong acid to a weak acid minimizes the effect of the addition on the pH .

Similarly, if a small amount of a base is added, it is consumed completely by the acetic acid,

$$
\mathrm{CH}_{3} \mathrm{COOH}(a q)+\mathrm{OH}^{-}(a q) \longrightarrow \mathrm{CH}_{3} \mathrm{COO}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l)
$$

thus converting a strong base $\left(\mathrm{OH}^{-}\right)$to a weak base $\left(\mathrm{CH}_{3} \mathrm{COO}^{-}\right)$. Addition of a strong base increases the pH of a solution. Again, however, a buffer's ability to convert a strong base to a weak base minimizes the effect of the addition on pH .

To illustrate the function of a buffer, suppose that we have 1 L of the acetic acid-sodium acetate solution described previously. We can calculate the pH of the buffer using the procedure in Section 17.1:

Initial concentration $(M)$ :
Change in concentration ( $M$ ):
Equilibrium concentration ( $M$ ):

The equilibrium expression is

$$
K_{\mathrm{a}}=\frac{(x)(1.0+x)}{1.0-x}
$$

Because it is reasonable to assume that $x$ will be very small,

$$
(1.0-x) M \approx 1.0 M \quad \text { and } \quad(1.0+x) M \approx 1.0 M
$$

Thus, the equilibrium expression simplifies to

$$
1.8 \times 10^{-5}=\frac{(x)(1.0)}{1.0}=x
$$

At equilibrium, therefore, $\left[\mathrm{H}^{+}\right]=1.8 \times 10^{-5} \mathrm{M}$ and $\mathrm{pH}=4.74$.
Now consider what happens when we add 0.10 mole of HCl to the buffer. (We assume that the addition of HCl causes no change in the volume of the solution.) The reaction that takes place when we add a strong acid is the conversion of $\mathrm{H}^{+}$to $\mathrm{CH}_{3} \mathrm{COOH}$. The added acid is all consumed, along with an equal amount of acetate ion. We keep track of the amounts of acetic acid and acetate ion when a strong acid (or base) is added by writing the starting amounts above the equation and the final amounts (after the added substance has been consumed) below the equation:

Upon addition of $\mathrm{H}^{+}$:

| 1.0 mol | 0.1 mol | 1.0 mol |
| :--- | :---: | :---: |
| $\mathrm{CH}_{3} \mathrm{COO}^{-}(a q)+$ |  |  |
| $\mathrm{H}^{+}(a q)$ |  |  |
| 0.9 mol | 0 mol | $\mathrm{CH}_{3} \mathrm{COOH}(a q)$ |
|  | 1.1 mol |  |

After $\mathrm{H}^{+}$has been consumed:

$$
0.9 \mathrm{~mol} \quad 0 \mathrm{~mol} \quad 1.1 \mathrm{~mol}
$$

We can use the resulting amounts of acetic acid and acetate ion to construct a new equilibrium table:

Initial concentration ( $M$ ):
Change in concentration ( $M$ ):
Equilibrium concentration (M):

$$
\mathrm{CH}_{3} \mathrm{COOH}(a q) \rightleftarrows \mathrm{H}^{+}(a q)+\mathrm{CH}_{3} \mathrm{COO}^{-}(a q)
$$

We can solve for pH as we have done before, assuming that $x$ is small enough to be neglected,

$$
\begin{aligned}
1.8 \times 10^{-5} & =\frac{(x)(0.9+x)}{1.1-x} \approx \frac{(x)(0.9)}{1.1} \\
x & =2.2 \times 10^{-5} M
\end{aligned}
$$

Thus, when equilibrium is reestablished, $\left[\mathrm{H}^{+}\right]=2.2 \times 10^{-5} \mathrm{M}$ and $\mathrm{pH}=4.66$-a change of only 0.08 pH unit.

In the determination of the pH of a buffer such as the one just described, we always neglect the small amount of weak acid that ionizes $(x)$ because ionization is suppressed by the presence of a common ion. Similarly, we ignore the hydrolysis of the acetate ion because of the presence of acetic acid. This enables us to derive an expression for determining the pH of a buffer. We begin with the equilibrium expression

$$
K_{\mathrm{a}}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{A}^{-}\right]}{[\mathrm{HA}]}
$$

Rearranging to solve for $\left[\mathrm{H}^{+}\right]$gives

$$
\left[\mathrm{H}^{+}\right]=\frac{K_{\mathrm{a}}[\mathrm{HA}]}{\left[\mathrm{A}^{-}\right]}
$$

Taking the negative logarithm of both sides, we obtain

$$
-\log \left[\mathrm{H}^{+}\right]=-\log K_{\mathrm{a}}-\log \frac{[\mathrm{HA}]}{\left[\mathrm{A}^{-}\right]}
$$

or

$$
-\log \left[\mathrm{H}^{+}\right]=-\log K_{\mathrm{a}}+\log \frac{\left[\mathrm{A}^{-}\right]}{[\mathrm{HA}]}
$$

Thus,

$$
\begin{equation*}
\mathrm{pH}=\mathrm{p} K_{\mathrm{a}}+\log \frac{\left[\mathrm{A}^{-}\right]}{[\mathrm{HA}]} \tag{Equation 17.1}
\end{equation*}
$$

where

$$
\begin{equation*}
\mathrm{p} K_{\mathrm{a}}=-\log K_{\mathrm{a}} \tag{Equation 17.2}
\end{equation*}
$$

Equation 17.1 is known as the Henderson-Hasselbalch equation. Its more general form is

$$
\mathrm{pH}=\mathrm{p} K_{\mathrm{a}}+\log \frac{\text { [conjugate base] }}{\text { [weak acid] }} \quad \text { Equation } 17.3
$$

In the case of our acetic acid $(1.0 M)$ and sodium acetate $(1.0 M)$ buffer, the concentrations of weak acid and conjugate base are equal. When this is true, the log term in the Henderson-Hasselbalch equation is zero and the pH is numerically equal to the $\mathrm{p} K_{\mathrm{a}}$. In the case of an acetic acid-acetate ion buffer, $\mathrm{p} K_{\mathrm{a}}=-\log 1.8 \times 10^{-5}=4.74$.

After the addition of 0.10 mole of HCl , we determined that the concentrations of acetic acid and acetate ion were 1.1 M and 0.9 M , respectively. Using these concentrations in the HendersonHasselbalch equation gives

$$
\begin{aligned}
\mathrm{pH} & =4.74+\log \frac{\left[\mathrm{CH}_{3} \mathrm{COO}^{-}\right]}{\left[\mathrm{CH}_{3} \mathrm{COOH}\right]} \\
& =4.74+\log \frac{0.9 \mathrm{M}}{1.1 \mathrm{M}} \\
& =4.74+(-0.087)=4.65
\end{aligned}
$$

The small difference between this pH and the 4.66 calculated using an equilibrium table is due to differences in rounding. Figure 17.1 illustrates how a buffer solution resists drastic changes in pH .

Sample Problem 17.2 shows how the Henderson-Hasselbalch equation is used to determine the pH of a buffer after the addition of a strong base.

Media Player/MPEG Animation: Figure 17.1, Buffer Solutions, pp. 732-733.

## Figure 17.1

## Buffer Solutions

We can calculate the new pH using the Henderson-Hasselbalch equation:

$$
\mathrm{pH}=4.74+\log \frac{0.009}{0.011}=4.65
$$

We can calculate the new pH using the Henderson-Hasselbalch equation:

$$
\mathrm{pH}=4.74+\log \frac{0.011}{0.009}=4.83
$$

There is nothing in pure water to consume strong acid. Therefore, its pH drops drastically

$$
\mathrm{pH}=-\log \frac{0.001 \mathrm{~mol}}{0.10 \mathrm{~L}}=2.00
$$

There is nothing in pure water to consume strong base. Therefore, its pH rises drastically.

$$
\mathrm{pOH}=-\log \frac{0.001 \mathrm{~mol}}{0.10 \mathrm{~L}}=2.00, \mathrm{pH}=12.00
$$

## What's the point?

A buffer contains both a weak acid and its conjugate base.* Small amounts of strong acid or strong base are consumed by the buffer components, thereby preventing drastic pH changes. Pure water does not contain species that can consume acid or base. Even a very small addition of either acid or base causes a large change in pH .
*A buffer could also be prepared using a weak base and its conjugate acid.

Student Annotation: The volume of the buffer is 1 L in this example, so the number of moles of a substance is equal to the molar concentration. In cases where the buffer volume is something other than 1 L , however, we can still use molar amounts in the Henderson-Hasselbalch equation because the volume would cancel in the top and bottom of the log term.

## Sample Problem 17.2

Starting with 1.00 L of a buffer that is 1.00 M in acetic acid and 1.00 M in sodium acetate, calculate the pH after the addition of 0.100 mole of NaOH . (Assume that the addition does not change the volume of the solution.)

Strategy Added base will react with the acetic acid component of the buffer, converting $\mathrm{OH}^{-}$to $\mathrm{CH}_{3} \mathrm{COO}^{-}$:

$$
\mathrm{CH}_{3} \mathrm{COOH}(a q)+\mathrm{OH}^{-}(a q) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{CH}_{3} \mathrm{COO}^{-}(a q)
$$

Write the starting amount of each species above the equation and the final amount of each species below the equation. Use the final amounts as concentrations in Equation 17.1.

## Setup

Upon addition of $\mathrm{OH}^{-}$:

After $\mathrm{OH}^{-}$has been consumed:

## Solution

$$
\begin{aligned}
\mathrm{pH} & =4.74+\log \frac{1.10 M}{0.90 M} \\
& =4.74+\log \frac{1.10 M}{0.90 M}=4.83
\end{aligned}
$$

Thus, the pH of the buffer after addition of 0.10 mole of NaOH is 4.83 .

Practice Problem A Calculate the pH of 1 L of a buffer that is 1.0 M in acetic acid and 1.0 M in sodium acetate after the addition of 0.25 mole of NaOH .
$\boldsymbol{H}$ Practice Problem B How much HCl must be added to a liter of buffer that is 1.5 M in acetic acid and $0.75 M$ in sodium acetate to result in a buffer pH of 4.10 ?

## Preparing a Buffer Solution with a Specific pH

A solution is only a buffer if it has the capacity to resist pH change when either an acid or a base is added. If the concentrations of a weak acid and conjugate base differ by more than a factor of 10 , the solution does not have this capacity. Therefore, we consider a solution a buffer, and can use Equation 17.1 to calculate its pH , only if the following condition is met:

$$
10 \geq \frac{\text { [conjugate base }]}{[\text { weak acid }]} \geq 0.1
$$

Consequently, the $\log$ term in Equation 17.1 can only have values from -1 to 1 , and the pH of a buffer cannot be more than one pH unit different from the $\mathrm{p} K_{\mathrm{a}}$ of the weak acid it contains. This is known as the range of the buffer, where $\mathrm{pH}=\mathrm{p} K_{\mathrm{a}} \pm 1$. This enables us to select the appropriate conjugate pair to prepare a buffer with a specific, desired pH .

First, we choose a weak acid whose $\mathrm{p} K_{\mathrm{a}}$ is close to the desired pH . Next, we substitute the pH and $\mathrm{p} K_{\mathrm{a}}$ values into Equation 17.1 to obtain the necessary ratio of [conjugate base]/[weak acid]. This ratio can then be converted to molar quantities for the preparation of the buffer.

Sample Problem 17.3 demonstrates this procedure.

| Weak Acid | $\boldsymbol{K}_{\mathrm{a}}$ | $\mathrm{p} \boldsymbol{K}_{\mathrm{a}}$ |
| :--- | :---: | :---: |
| HF | $7.1 \times 10^{-4}$ | 3.15 |
| $\mathrm{HNO}_{2}$ | $4.5 \times 10^{-4}$ | 3.35 |
| $\mathrm{HCOOH}^{2}$ | $1.7 \times 10^{-4}$ | 3.77 |
| $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COOH}$ | $6.5 \times 10^{-5}$ | 4.19 |
| $\mathrm{CH}_{3} \mathrm{COOH}$ | $1.8 \times 10^{-5}$ | 4.74 |
| HCN | $4.9 \times 10^{-10}$ | 9.31 |
| $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{OH}$ | $1.3 \times 10^{-10}$ | 9.89 |

## Sample Problem 17.3

Select an appropriate weak acid from the table in the margin, and describe how you would prepare a buffer with a pH of 9.50 .

Strategy Select an acid with a $\mathrm{p} K_{\mathrm{a}}$ within one pH unit of 9.50 . Use the $\mathrm{p} K_{\mathrm{a}}$ of the acid and Equation 17.1 to calculate the necessary ratio of [conjugate base]/[weak acid]. Select concentrations of the buffer components that yield the calculated ratio.

Setup Two of the acids listed in Table 16.6 have $\mathrm{p} K_{\mathrm{a}}$ values in the desired range: hydrocyanic acid $\left(\mathrm{HCN}, \mathrm{p} K_{\mathrm{a}}=9.31\right)$ and phenol $\left(\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{OH}, \mathrm{p} K_{\mathrm{a}}=9.89\right)$.

Solution Plugging the values for phenol into Equation 17.1 gives

$$
\begin{aligned}
9.50 & =9.89+\log \frac{\left[\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}^{-}\right]}{\left[\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{OH}\right]} \\
9.50-9.89 & =\log \frac{\left[\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}^{-}\right]}{\left[\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{OH}\right]}=-0.39 \\
\frac{\left[\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}^{-}\right]}{\left[\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{OH}\right]} & =10^{-0.39}=0.41
\end{aligned}
$$

Therefore, the ratio of $\left[\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}^{-}\right]$to $\left[\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{OH}\right]$ must be 0.41 to 1 . One way to achieve this would be to dissolve 0.41 mole of $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{ONa}$ and 1.00 mole of $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{OH}$ in 1 L of water.

Practice Problem A Select an appropriate acid from Table 16.6, and describe how you would prepare a buffer with $\mathrm{pH}=4.5$.

EPractice Problem B What range of pH values could be achieved with a buffer consisting of nitrous acid $\left(\mathrm{HNO}_{2}\right)$ and sodium nitrite $\left(\mathrm{NO}_{2}^{-}\right)$?

## Bringing Chemistry to Life

## Maintaining the pH of Blood

Think About lt There is an infinite number of combinations of [conjugate base] and [weak acid] that will give the necessary ratio. Note that this pH could also be achieved using HCN and a cyanide salt. For most purposes, it is best to use the least toxic compounds available.

There are about 5 L of blood in the average adult. Circulating blood keeps cells alive by providing them with oxygen and nutrients and by removing carbon dioxide and other waste materials. The efficiency of this enormously complex system relies on buffers.

The two primary components of blood are blood plasma and red blood cells, or erythrocytes. Blood plasma contains many compounds, including proteins, metal ions, and inorganic phosphates. The erythrocytes contain hemoglobin molecules, as well as the enzyme carbonic anhydrase, which catalyzes both the formation and the decomposition of carbonic acid $\left(\mathrm{H}_{2} \mathrm{CO}_{3}\right)$ :

$$
\mathrm{CO}_{2}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{H}_{2} \mathrm{CO}_{3}(a q)
$$

The substances inside the erythrocytes are protected from extracellular fluid (blood plasma) by a semipermeable cell membrane that allows only certain molecules to diffuse through it.

The pH of blood plasma is maintained at about 7.40 by several buffer systems, the most important of which is the $\mathrm{HCO}_{3}^{-} / \mathrm{H}_{2} \mathrm{CO}_{3}$ system. In the erythrocyte, where the pH is 7.25 , the principal buffer systems are $\mathrm{HCO}_{3}^{-} / \mathrm{H}_{2} \mathrm{CO}_{3}$ and hemoglobin. The hemoglobin molecule is a complex protein molecule (molar mass of $65,000 \mathrm{~g}$ ) that contains a number of ionizable protons. As a very rough approximation, we can treat it as a monoprotic acid in the form HHb :

$$
\mathrm{HHb}(a q) \rightleftarrows \mathrm{H}^{+}(a q)+\mathrm{Hb}^{-}(a q)
$$

where HHb represents the hemoglobin molecule and $\mathrm{Hb}^{-}$is the conjugate base of HHb . Oxyhemoglobin $\left(\mathrm{HHbO}_{2}\right)$, formed by the combination of oxygen with hemoglobin, is a stronger acid than HHb :

$$
\mathrm{HHbO}_{2}(a q) \rightleftarrows \mathrm{H}^{+}(a q)+\mathrm{HbO}_{2}^{-}(a q)
$$

Carbon dioxide produced by metabolic processes diffuses into the erythrocyte, where it is rapidly converted to $\mathrm{H}_{2} \mathrm{CO}_{3}$ by carbonic anhydrase:

$$
\mathrm{CO}_{2}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{H}_{2} \mathrm{CO}_{3}(a q)
$$

The ionization of the carbonic acid,

$$
\mathrm{H}_{2} \mathrm{CO}_{3}(a q) \rightleftarrows \mathrm{H}^{+}(a q)+\mathrm{HCO}_{3}^{-}(a q)
$$

has two important consequences. First, the bicarbonate ion diffuses out of the erythrocyte and is carried by the blood plasma to the lungs. This is the major mechanism for removing carbon dioxide. Second, the $\mathrm{H}^{+}$ions shift the equilibrium in favor of the un-ionized oxyhemoglobin molecules:

$$
\mathrm{H}^{+}(a q)+\mathrm{HbO}_{2}^{-}(a q) \rightleftarrows \mathrm{HHbO}_{2}(a q)
$$

Because $\mathrm{HHbO}_{2}$ releases oxygen more readily than does its conjugate base $\left(\mathrm{HbO}_{2}^{-}\right)$, the formation of the acid promotes the following reaction from left to right:

$$
\mathrm{HHbO}_{2}(a q) \rightleftarrows \mathrm{HHb}(a q)+\mathrm{O}_{2}(a q)
$$

The $\mathrm{O}_{2}$ molecules diffuse out of the erythrocyte and are taken up by other cells to carry out metabolism.

When the venous blood returns to the lungs, the preceding processes are reversed. The bicarbonate ions now diffuse into the erythrocyte, where they react with hemoglobin to form carbonic acid:

$$
\mathrm{HHb}(a q)+\mathrm{HCO}_{3}^{-}(a q) \rightleftarrows \mathrm{Hb}^{-}(a q)+\mathrm{H}_{2} \mathrm{CO}_{3}(a q)
$$

Most of the acid is then converted to $\mathrm{CO}_{2}$ by carbonic anhydrase:

$$
\mathrm{H}_{2} \mathrm{CO}_{3}(a q) \rightleftarrows \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{CO}_{2}(a q)
$$

The carbon dioxide diffuses to the lungs and is eventually exhaled. The formation of the $\mathrm{Hb}^{-}$ions (due to the reaction between HHb and $\mathrm{HCO}_{3}^{-}$) also favors the uptake of oxygen at the lungs,

$$
\mathrm{Hb}^{-}(a q)+\mathrm{O}_{2}(a q) \rightleftarrows \mathrm{HbO}_{2}^{-}(a q)
$$

because $\mathrm{Hb}^{-}$has a greater affinity for oxygen than does HHb .
When the arterial blood flows back to the body tissues, the entire cycle is repeated.

## Checkpoint 17.2 Buffer Solutions

17.2.1 Which of the following combinations can be used to prepare a buffer?
a) $\mathrm{HCl} / \mathrm{NaCl}$
b) $\mathrm{HF} / \mathrm{KF}$
c) $\mathrm{NH}_{3} / \mathrm{NH}_{4} \mathrm{Cl}$
d) $\mathrm{HNO}_{3} / \mathrm{HNO}_{2}$
e) $\mathrm{NaNO}_{2} / \mathrm{HNO}_{3}$
17.2.2 What is the pH of a buffer that is 0.76 M in HF and 0.98 M in NaF ?
a) 3.26
b) 3.04
c) 3.15
d) 10.85
e) 10.74
17.2.3 Consider 1 L of a buffer that is 0.85 M in formic acid ( HCOOH ) and 1.4 M in sodium formate $(\mathrm{HCOONa})$. Calculate the pH after the addition of 0.15 mol HCl . (Assume the addition causes no volume change.)
a) 4.11
b) 3.99
c) 3.87
d) 10.13
e) 10.01
17.2.4 Consider 1 L of a buffer that is 1.5 M in hydrocyanic acid (HCN) and 1.2 M in sodium cyanide $(\mathrm{NaCN})$. Calculate the pH after the addition of 0.25 mol NaOH . (Assume the addition causes no volume change.)
a) 9.21
b) 9.37
c) 9.04
d) 4.63
e) 4.96
17.2.5 The solutions shown contain one or more of the following compounds: $\mathrm{H}_{2} \mathrm{~A}$ (a weak diprotic acid), NaHA , and $\mathrm{Na}_{2} \mathrm{~A}$ (the sodium salts of $\mathrm{HA}^{-}$and $\mathrm{A}^{2-}$ ). (For clarity, the sodium ions and water molecules are not shown.) Which solutions are buffers? (Select all that apply.)

17.2.6 The solutions shown contain a combination of the weak acid HA and its sodium salt NaA . (For clarity, the sodium ions and water molecules are not shown.) Arrange the solutions in order of increasing pH .

a) i $<$ iii $<$ iv $<$ ii
b) iv $<$ ii $<$ iii $<$ i
c) i $<$ ii $<$ iv $<$ iii
d) iv $<$ ii $<$ i $=$ iii
e) i $=$ iii $<$ iv $<$ ii

### 17.3 Acid-Base Titrations

In Section 4.6 we introduced acid-base titrations as a form of chemical analysis. Having discussed buffer solutions, we can now look in more detail at the quantitative aspects of acid-base titrations. We will consider three types of reactions: (1) titrations involving a strong acid and a strong base, (2) titrations involving a weak acid and a strong base, and (3) titrations involving a strong acid and a weak base. Titrations involving a weak acid and a weak base are complicated by the hydrolysis of both the cation and the anion of the salt formed. These titrations will not be discussed here. Figure 17.2 shows the experimental setup for monitoring the pH over the course of an acid-base titration.

## Strong Acid-Strong Base Titrations

The reaction between the strong acid HCl and the strong base NaOH can be represented by

$$
\mathrm{NaOH}(a q)+\mathrm{HCl}(a q) \longrightarrow \mathrm{NaCl}(a q)+\mathrm{H}_{2} \mathrm{O}(l)
$$

or by the net ionic equation,

$$
\mathrm{OH}^{-}(a q)+\mathrm{H}^{+}(a q) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)
$$

Consider the addition of a 0.100 M NaOH solution (from a burette) to a vessel containing 25.0 mL of 0.100 M HCl . For convenience, we will use only three significant figures for volume and concentration and two significant figures for pH . Figure 17.3 shows the titration curve-the plot of pH as a function of titrant volume added.

Multimedia
Acids and Bases-titration of HCl with NaOH .

Student Annotation: Recall that only the digits to the right of the decimal point are significant in a pH value.

Student Annotation: The titrant is the solution that is added from the burette.

Figure 17.2 ApH meter is used to monitor an acid-base titration.

Figure 17.3 Titration curve ( pH as a function of volume titrant added) of a strong acid-strong base titration. A 0.100 M NaOH solution, the titrant, is added from a burette to 25.0 mL of a 0.100 M HCl solution in an Erlenmeyer flask.

Student Annotation: Recall that for an acid and base that combine in a 1:1 ratio, the equivalence point is where equal molar amounts of acid and base have been combined [14 Section 4.5].

Student Annotation: These calculations could also be done using moles, but using millimoles simplifies the calculations. Remember that millimoles $=M \times \mathrm{mL}$ [ 14 Section 4.5].

Before the addition of NaOH begins, the pH of the acid is given by $-\log (0.100)$, or 1.00 . When NaOH is added, the pH of the solution increases slowly at first. Near the equivalence point, the pH begins to rise steeply, and at the equivalence point, when equimolar amounts of acid and base have reacted, the curve rises almost vertically. In a strong acid-strong base titration, both the hydrogen ion and hydroxide ion concentrations are very small at the equivalence point (roughly $1 \times 10^{-7} M$; consequently, the addition of a single drop of the base causes a large increase in $\left[\mathrm{OH}^{-}\right]$and a steep rise in the pH of the solution. Beyond the equivalence point, the pH again increases slowly with the continued addition of NaOH .

It is possible to calculate the pH of the solution at every stage of titration. Here are three sample calculations.

1. Consider the addition of 10.0 mL of 0.100 M NaOH to 25.0 mL of 0.100 M HCl : The total volume of the solution is 35.0 mL . The number of millimoles of NaOH in 10.0 mL is

$$
10.0 \mathrm{~mL} \times \frac{0.100 \mathrm{mmol} \mathrm{NaOH}}{1 \mathrm{~mL}}=1.00 \mathrm{mmol}
$$

The number of millimoles of HCl originally present in 25.0 mL of solution is

$$
25.0 \mathrm{~mL} \times \frac{0.100 \mathrm{mmol} \mathrm{HCl}}{1 \mathrm{~mL}}=2.50 \mathrm{mmol}
$$

Thus, the amount of HCl left after partial neutralization is $2.50-1.00$, or 1.50 mmol . Next, we determine the resulting concentration of $\mathrm{H}^{+}$. We have 1.50 mmol in 35.0 mL :

$$
\frac{1.50 \mathrm{mmol} \mathrm{HCl}}{35.0 \mathrm{~mL}}=0.0429 \mathrm{M}
$$

Thus $\left[\mathrm{H}^{+}\right]=0.0429 \mathrm{M}$, and the pH of the solution is

$$
\mathrm{pH}=-\log (0.04289)=1.37
$$

2. Consider the addition of 25.0 mL of 0.100 M NaOH to 25.0 mL of 0.100 M HCl : This is a straightforward calculation, because it involves a complete neutralization reaction and neither ion in the salt $(\mathrm{NaCl})$ undergoes hydrolysis [ Kt Section 16.10]. At the equivalence point, $\left[\mathrm{H}^{+}\right]=\left[\mathrm{OH}^{-}\right]=1.00 \times 10^{-7} \mathrm{M}$ and the pH of the solution is 7.000 .
3. Consider the addition of 35.0 mL of 0.100 M NaOH to 25.0 mL of 0.100 M HCl : The total volume of the solution is now 60.0 mL . The number of millimoles of NaOH added is

$$
35.0 \mathrm{~mL} \times \frac{0.100 \mathrm{mmol} \mathrm{NaOH}}{1 \mathrm{~mL}}=3.50 \mathrm{mmol}
$$

There are 2.50 mmol of HCl in 25.0 mL of solution. After complete neutralization of HCl , 2.50 mmol of NaOH have been consumed, and the number of millimoles of NaOH remaining is $3.5-2.5$ or 1.00 mmol . The concentration of NaOH in 60.0 mL of solution is

$$
\frac{1.00 \mathrm{mmol} \mathrm{NaOH}}{60.0 \mathrm{~mL}}=0.0167 \mathrm{M}
$$

Thus $\left[\mathrm{OH}^{-}\right]=0.0167 \mathrm{M}$ and $\mathrm{pOH}=-\log (0.0167)=1.78$. The pH of the solution is $14.00-1.78$ or 12.22 .

Table 17.1 lists the data at nine different points during a strong acid-strong base titration along with the calculated pH at each point.

## Weak Acid-Strong Base Titrations

Consider the neutralization reaction between acetic acid (a weak acid) and sodium hydroxide (a strong base):

$$
\mathrm{CH}_{3} \mathrm{COOH}(a q)+\mathrm{NaOH}(a q) \longrightarrow \mathrm{CH}_{3} \mathrm{COONa}(a q)+\mathrm{H}_{2} \mathrm{O}(l)
$$

This equation can be simplified to

$$
\mathrm{CH}_{3} \mathrm{COOH}(a q)+\mathrm{OH}^{-}(a q) \longrightarrow \mathrm{CH}_{3} \mathrm{COO}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l)
$$

The acetate ion that results from this neutralization undergoes hydrolysis [ 14 Section 16.10] as follows:

$$
\mathrm{CH}_{3} \mathrm{COO}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{CH}_{3} \mathrm{COOH}(a q)+\mathrm{OH}^{-}(a q)
$$

TABLE 17.1 Determination of pH at Several Different Points in a Strong Acid-Strong Base Titration

| Volume $\mathrm{OH}^{-}$ <br> added (mL) | $\mathrm{OH}^{-}$ <br> added (mmol) | $\stackrel{\mathrm{H}^{+}}{\text {remaining (mmol) }}$ | Total volume (mL) | $\begin{gathered} {\left[\mathrm{H}^{+}\right]} \\ (\mathrm{mol} / \mathrm{L}) \end{gathered}$ |  | pH |

| 30.0 | 3.0 | 0.5 | 55.0 | 0.0091 | 2.04 | 11.96 |
| 35.0 | 3.5 | 1.0 | 60.0 | 0.0167 | 1.78 | 12.223 |

Figure 17.4 Titration curve of a weak acid - strong base titration. A 0.100 M NaOH solution is added from a burette to 25.0 mL of a 0.100 M $\mathrm{CH}_{3} \mathrm{COOH}$ solution in an Erlenmeyer flask. Because of the hydrolysis of the salt formed, the pH at the equivalence point is greater than 7 .

At the equivalence point, therefore, when we only have sodium acetate in solution, the pH will be greater than 7 as a result of the $\mathrm{OH}^{-}$formed by hydrolysis of the acetate ion.

The curve for titration of 25.0 mL of 0.1 M acetic acid with 0.10 M sodium hydroxide is shown in Figure 17.4. Note how the shape of the curve differs from the one in Figure 17.3. Compared to the curve for titration of a strong acid with a strong base, the curve for titration of a weak acid with a strong base has a higher initial pH , a more gradual change in pH as base is added, and a shorter vertical region near the equivalence point.

Again, it is possible to calculate the pH at every stage of the titration. Here are four sample calculations.

1. Prior to the addition of any base, the pH is determined by the ionization of acetic acid. We use its concentration $(0.10 \mathrm{M})$ and its $K_{\mathrm{a}}\left(1.8 \times 10^{-5}\right)$ to calculate the $\mathrm{H}^{+}$concentration using an equilibrium table:

$$
\mathrm{CH}_{3} \mathrm{COOH}(a q) \rightleftarrows \mathrm{H}^{+}(a q)+\mathrm{CH}_{3} \mathrm{COO}^{-}(a q)
$$

Initial concentration ( $M$ ):
Change in concentration ( $M$ ):
Equilibrium concentration $(M)$ :

| 0.10 | 0 | 0 |
| :---: | :---: | :---: |
| $-x$ | $+x$ | $+x$ |
| $0.10-x$ | $x$ | $x$ |

$$
K_{\mathrm{a}}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{CH}_{3} \mathrm{COO}^{-}\right]}{\left[\mathrm{CH}_{3} \mathrm{COOH}\right]}=\frac{x^{2}}{0.10-x}=1.8 \times 10^{-5}
$$

Student Annotation: Remember that we can use mol or mmol amounts in place of concentrations in the Henderson-Hasselbalch equation.

Student Annotation: $K_{\mathrm{a}} \times K_{\mathrm{b}}=K_{\mathrm{w}}$
[ IKA Section 16.7].

We can neglect $x$ on the bottom of the equation [144 Section 16.5]. Solving for $x$,

$$
\begin{aligned}
\frac{x^{2}}{0.10} & =1.8 \times 10^{-5} \\
x^{2} & =\left(1.8 \times 10^{-5}\right)(0.10)=1.8 \times 10^{-6} \\
x & =\sqrt{1.8 \times 10^{-6}}=1.34 \times 10^{-3} \mathrm{M}
\end{aligned}
$$

gives $\left[\mathrm{H}^{+}\right]=1.34 \times 10^{-3} \mathrm{M}$ and $\mathrm{pH}=2.87$.
2. After the first addition of base, some of the acetic acid has been converted to acetate ion via the reaction

$$
\mathrm{CH}_{3} \mathrm{COOH}(a q)+\mathrm{OH}^{-}(a q) \longrightarrow \mathrm{CH}_{3} \mathrm{COO}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l)
$$

With significant amounts of both acetic acid and acetate ion in solution, we now treat the solution as a buffer and use the Henderson-Hasselbalch equation to calculate the pH .

After the addition of 10.0 mL of base, the solution contains 1.5 mmol of acetic acid and 1.0 mmol of acetate ion (see Table 17.2).

$$
\mathrm{pH}=4.74+\log \frac{1.0 \mathrm{mmol}}{1.5 \mathrm{mmol}}=4.56
$$

Each of the points between the beginning of the titration and the equivalence point can be calculated in this way.
3. At the equivalence point, all the acetic acid has been neutralized and we are left with acetate ion in solution. (There is also sodium ion, which does not undergo hydrolysis and therefore does not impact the pH of the solution.) At this point, pH is determined by the concentration and the $K_{\mathrm{b}}$ of acetate ion. The equivalence point occurs when 25.0 mL of base has been added, making the total volume 50.0 mL . The 2.5 mmol of acetic acid (see Table 17.2) has all been converted to acetate ion. Therefore, the concentration of acetate ion is

$$
\left[\mathrm{CH}_{3} \mathrm{COO}^{-}\right]=\frac{2.5 \mathrm{mmol}}{50.0 \mathrm{~mL}}=0.050 \mathrm{M}
$$

As we did at the beginning of the titration, we construct an equilibrium table:

|  | $\mathrm{CH}_{3} \mathrm{COO}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{OH}^{-}(a q)+\mathrm{CH}_{3} \mathrm{COOH}(a q)$ |  |  |
| :---: | :---: | :---: | :---: |
| Initial concentration ( $M$ ): | 0.050 | 0 | 0 |
| Change in concentration ( $M$ ): | -x | $+x$ | $+x$ |
| Equilibrium concentration ( $M$ ): | : $0.050-x$ | $x$ | $x$ |

The $K_{\mathrm{b}}$ for acetate ion is $5.6 \times 10^{-10}$.

$$
K_{\mathrm{b}}=\frac{\left[\mathrm{OH}^{-}\right]\left[\mathrm{CH}_{3} \mathrm{COOH}\right]}{\left[\mathrm{CH}_{3} \mathrm{COO}^{-}\right]}=\frac{x^{2}}{0.050-x}=5.6 \times 10^{-10}
$$

As before, we can neglect $x$ in the denominator of the equation. Solving for $x$,

$$
\begin{aligned}
\frac{x^{2}}{0.050} & =5.6 \times 10^{-10} \\
x^{2} & =\left(5.6 \times 10^{-10}\right)(0.050)=2.8 \times 10^{-11} \\
x & =\sqrt{2.78 \times 10^{-11}}=5.3 \times 10^{-6} \mathrm{M}
\end{aligned}
$$

gives $\left[\mathrm{OH}^{-}\right]=5.3 \times 10^{-6} \mathrm{M}, \mathrm{pOH}=5.28$, and $\mathrm{pH}=8.72$.
4. After the equivalence point, the curve for titration of a weak acid with a strong base is identical to the curve for titration of a strong acid with a strong base. Because all the acetic acid has been consumed, there is nothing in solution to consume the additional added $\mathrm{OH}^{-}$, and the pH levels off between 12 and 13 .

Table 17.2 lists the data for the titration of 25.0 mL of 0.10 M acetic acid with 0.10 M NaOH .

Sample Problem 17.4 shows how to calculate the pH for the titration of a weak acid with a strong base.

$*\left[\mathrm{CH}_{3} \mathrm{COOH}\right]=0.10 \mathrm{M}, K_{\mathrm{a}}=1.8 \times 10^{-5}$.
$\dagger\left[\mathrm{CH}_{3} \mathrm{COO}^{-}\right]=0.050 \mathrm{M}, K_{\mathrm{b}}=5.6 \times 10^{-10}$.

## Sample Problem 17.4

Calculate the pH in the titration of 50.0 mL of 0.120 M acetic acid by 0.240 M sodium hydroxide after the addition of (a) 10.0 mL of base, (b) 25.0 mL of base, and (c) 35.0 mL of base.

Strategy The reaction between acetic acid and sodium hydroxide is

$$
\mathrm{CH}_{3} \mathrm{COOH}(a q)+\mathrm{OH}^{-}(a q) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{CH}_{3} \mathrm{COO}^{-}(a q)
$$

Prior to the equivalence point [part (a)], the solution contains both acetic acid and acetate ion, making the solution a buffer. We can solve part (a) using Equation 17.1, the Henderson-Hasselbalch equation. At the equivalence point [part (b)], all the acetic acid has been neutralized and we have only acetate ion in solution. We must determine the concentration of acetate ion and solve part (b) as an equilibrium problem, using the $K_{\mathrm{b}}$ for acetate ion. After the equivalence point [part (c)], all the acetic acid has been neutralized and there is nothing to consume the additional added base. We must determine the concentration of excess hydroxide ion in the solution and solve for pH using Equations 16.4 and 16.6.

Setup Remember that $M$ can be defined as either $\mathrm{mol} / \mathrm{L}$ or $\mathrm{mmol} / \mathrm{mL}$ [ $14 \operatorname{Section} 4.5$ ]. For this type of problem, it simplifies the calculations to use millimoles rather than moles. $K_{\mathrm{a}}$ for acetic acid is $1.8 \times 10^{-5}$, so $\mathrm{p} K_{\mathrm{a}}=4.74$. $K_{\mathrm{b}}$ for acetate ion is $5.6 \times 10^{-10}$.
(a) The solution originally contains $(0.120 \mathrm{mmol} / \mathrm{mL})(50.0 \mathrm{~mL})=6.00 \mathrm{mmol}$ of acetic acid. A $10.0-\mathrm{mL}$ amount of base contains $(0.240 \mathrm{mmol} / \mathrm{mL})(10.0 \mathrm{~mL})=2.40 \mathrm{mmol}$ of base. After the addition of 10.0 mL of base, 2.40 mmol of $\mathrm{OH}^{-}$has neutralized 2.40 mmol of acetic acid, leaving 3.60 mmol of acetic acid and 2.40 mmol acetate ion in solution:

| Upon addition of $\mathrm{OH}^{-}:$ | 6.00 mmol | 2.40 mmol | 0 mmol |
| :--- | :--- | :--- | :---: |
|  | $\mathrm{CH}_{3} \mathrm{COOH}(a q)+\mathrm{OH}^{-}(a q) \rightleftarrows \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{CH}_{3} \mathrm{COO}^{-}(a q)$ |  |  |
| After $\mathrm{OH}^{-}$has been consumed: | 3.60 mmol | 0 mmol | 2.40 mmol |

(b) After the addition of 25.0 mL of base, the titration is at the equivalence point. We calculate the pH using the concentration and the $K_{\mathrm{b}}$ of acetate ion.
(c) After the addition of 35.0 mL of base, the titration is past the equivalence point and we solve for pH by determining the concentration of excess hydroxide ion.

Solution (a) $\mathrm{pH}=\mathrm{p} K_{\mathrm{a}}+\log \frac{2.40}{3.60}=4.74-0.18=4.56$

Think About It For each point in a titration, decide first what species are in solution and what type of problem it is. If the solution contains only a weak acid (or weak base), as is the case before any titrant is added, or if it contains only a conjugate base (or conjugate acid), as is the case at the equivalence point, when pH is determined by salt hydrolysis, it is an equilibrium problem that requires a concentration, an ionization constant, and an equilibrium table. If the solution contains comparable concentrations of both members of a conjugate pair, which is the case at points prior to the equivalence point, it is a buffer problem and is solved using the Henderson-Hasselbalch equation. If the solution contains excess titrant, either a strong base or strong acid, it is simply a pH problem requiring only a concentration.
(b) At the equivalence point, we have 6.0 mmol of acetate ion in the total volume. We determine the total volume by calculating what volume of 0.24 M base contains 6.0 mmol :

$$
\begin{aligned}
(\text { volume })(0.240 \mathrm{mmol} / \mathrm{mL}) & =6.00 \mathrm{mmol} \\
\text { volume } & =\frac{6.00 \mathrm{mmol}}{0.240 \mathrm{mmol} / \mathrm{mL}}=25.0 \mathrm{~mL}
\end{aligned}
$$

Therefore, the equivalence point occurs when 25.0 mL of base has been added, making the total volume $50.0 \mathrm{~mL}+25.0 \mathrm{~mL}=75.0 \mathrm{~mL}$. The concentration of acetate ion at the equivalence point is therefore

$$
\frac{6.00 \mathrm{mmol} \mathrm{CH}_{3} \mathrm{COO}^{-}}{75.0 \mathrm{~mL}}=0.0800 \mathrm{M}
$$

We can construct an equilibrium table using this concentration and solve for pH using the ionization constant for $\mathrm{CH}_{3} \mathrm{COO}^{-}\left(K_{\mathrm{b}}=5.6 \times 10^{-10}\right)$ :

Initial concentration ( $M$ ):
Change in concentration ( $M$ ):
Equilibrium concentration ( $M$ ):

| $\mathrm{CH}_{3} \mathrm{COO}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{OH}^{-}(a q)+\mathrm{CH}_{3} \mathrm{COOH}(a q)$ |  |  |  |
| :---: | :---: | :---: | :---: |
| 0.0800 |  | 0 | 0 |
| $-x$ |  | $+x$ | $+x$ |
| $0.0800-x$ |  | $x$ | $x$ |

Using the equilibrium expression and assuming that $x$ is small enough to be neglected,

$$
\begin{aligned}
K_{\mathrm{b}} & =\frac{\left[\mathrm{CH}_{3} \mathrm{COOH}\right]\left[\mathrm{OH}^{-}\right]}{\left[\mathrm{CH}_{3} \mathrm{COO}^{-}\right]}=\frac{(x)(x)}{0.0800-x} \approx \frac{x^{2}}{0.0800}=5.6 \times 10^{-10} \\
x & =\sqrt{4.48 \times 10^{-11}}=6.7 \times 10^{-6} \mathrm{M}
\end{aligned}
$$

According to the equilibrium table, $x=\left[\mathrm{OH}^{-}\right]$, so $\left[\mathrm{OH}^{-}\right]=6.7 \times 10^{-6} \mathrm{M}$. At equilibrium, therefore, $\mathrm{pOH}=-\log \left(6.7 \times 10^{-6}\right)=5.17$ and $\mathrm{pH}=14.00-5.17=8.83$.
(c) After the equivalence point, we must determine the concentration of excess base and calculate pOH and pH using Equations 16.4 and 16.6. A $35.0-\mathrm{mL}$ amount of the base contains $(0.240 \mathrm{mmol} / \mathrm{mL})(35.0 \mathrm{~mL})=8.40 \mathrm{mmol}$ of $\mathrm{OH}^{-}$. After neutralizing the 6.00 mmol of acetic acid originally present in the solution, this leaves $8.40-6.00=2.40 \mathrm{mmol}$ of excess $\mathrm{OH}^{-}$. The total volume is $50.0+35.0=85.0 \mathrm{~mL}$. Therefore, $\left[\mathrm{OH}^{-}\right]=2.40 \mathrm{mmol} / 85.0 \mathrm{~mL}=0.0280 \mathrm{M}$,
$\mathrm{pOH}=-\log (0.0280)=1.553$, and $\mathrm{pH}=14.000-1.553=12.447$.
In summary, (a) $\mathrm{pH}=4.56$, (b) $\mathrm{pH}=8.83$, and (c) $\mathrm{pH}=12.447$.

Practice Problem A For the titration of 10.0 mL of 0.15 M acetic acid with 0.10 M sodium hydroxide, determine the pH when (a) 10.0 mL of base has been added, (b) 15.0 mL of base has been added, and (c) 20.0 mL of base has been added.

EPractice Problem B For the titration of 25.0 mL of 0.20 M hydrofluoric acid with 0.20 M sodium hydroxide, determine the volume of base added when pH is (a) 2.85 , (b) 3.15 , and (c) 11.89 . [To solve part c, you may want to review the approach in Sample Problem 4.10 (page 145).]

## Strong Acid-Weak Base Titrations

Consider the titration of HCl , a strong acid, with $\mathrm{NH}_{3}$, a weak base:

$$
\mathrm{HCl}(a q)+\mathrm{NH}_{3}(a q) \longrightarrow \mathrm{NH}_{4} \mathrm{Cl}(a q)
$$

or simply

$$
\mathrm{H}^{+}(a q)+\mathrm{NH}_{3}(a q) \longrightarrow \mathrm{NH}_{4}^{+}(a q)
$$

The pH at the equivalence point is less than 7 because the ammonium ion acts as a weak Brønsted acid:

$$
\mathrm{NH}_{4}^{+}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{NH}_{3}(a q)+\mathrm{H}_{3} \mathrm{O}^{+}(a q)
$$

or simply

$$
\mathrm{NH}_{4}^{+}(a q) \rightleftarrows \mathrm{NH}_{3}(a q)+\mathrm{H}^{+}(a q)
$$

Because of the volatility of an aqueous ammonia solution, it is more convenient to use hydrochloric acid as the titrant (i.e., to add HCl solution from the burette). Figure 17.5 shows the titration curve for this experiment.

Analogous to the titration of a weak acid with a strong base, the initial pH is determined by the concentration and the $K_{\mathrm{b}}$ of ammonia:

$$
\mathrm{NH}_{3}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{NH}_{4}^{+}(a q)+\mathrm{OH}^{-}(a q)
$$

Consider the titration of 25.0 mL of $0.10 \mathrm{MH}_{3}$ with 0.10 M HCl . We calculate the initial pH by constructing an equilibrium table and solving for $x$ :

## Initial concentration ( $M$ ):

Change in concentration ( $M$ ):
Equilibrium concentration ( $M$ ):

| $\mathrm{NH}_{3}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{NH}_{4}^{+}(a q)+\mathrm{OH}^{-}(a q)$ |  |  |  |
| :---: | :---: | :---: | :---: |
| 0.10 |  | 0 | 0 |
| $-x$ |  | $+x$ | $+x$ |
| $0.10-x$ |  | $x$ | $x$ |

Using the equilibrium expression and assuming that $x$ is small enough to be neglected,

$$
\begin{aligned}
K_{\mathrm{b}} & =\frac{\left[\mathrm{NH}_{4}^{+}\right]\left[\mathrm{OH}^{-}\right]}{\left[\mathrm{NH}_{3}\right]}=\frac{(x)(x)}{0.10-x} \approx \frac{x^{2}}{0.10}=1.8 \times 10^{-5} \\
x^{2} & =1.8 \times 10^{-6} \\
x & =\sqrt{1.8 \times 10^{-6}}=1.3 \times 10^{-3} \\
\mathrm{pH} & =11.11
\end{aligned}
$$

The pH at the equivalence point is calculated using the concentration and $K_{\mathrm{a}}$ of the conjugate base of $\mathrm{NH}_{3}$, the $\mathrm{NH}_{4}^{+}$ion, and an equilibrium table.

Sample Problem 17.5 shows how this is done.

## Sample Problem 17.5

Calculate the pH at the equivalence point when 25.0 mL of $0.100 \mathrm{M} \mathrm{H}_{3}$ is titrated with 0.100 M HCl .
Strategy The reaction between $\mathrm{NH}_{3}$ and HCl is

$$
\mathrm{NH}_{3}(a q)+\mathrm{H}^{+}(a q) \longrightarrow \mathrm{NH}_{4}^{+}(a q)
$$

At the equivalence point, all the $\mathrm{NH}_{3}$ has been converted to $\mathrm{NH}_{4}^{+}$. Therefore, we must determine the concentration of $\mathrm{NH}_{4}^{+}$at the equivalence point and use the $K_{\mathrm{a}}$ for $\mathrm{NH}_{4}^{+}$to solve for pH using an equilibrium table.

Figure 17.5 Titration curve of a strong acid-weak base titration. A 0.100 M HCl solution is added from a burette to 25.0 mL of a $0.100 \mathrm{M} \mathrm{NH}_{3}$ solution in an Erlenmeyer flask. As a result of salt hydrolysis, the pH at the equivalence point is lower than 7 .

Think About It In the titration of a weak base with a strong acid, the species in solution at the equivalence point is the conjugate acid. Therefore, we should expect an acidic pH . Once all the $\mathrm{NH}_{3}$ has been converted to $\mathrm{NH}_{4}^{+}$, there is no longer anything in the solution to consume added acid. Thus, the pH after the equivalence point depends on the number of millimoles of $\mathrm{H}^{+}$ added and not consumed divided by the new total volume.

Student Annotation: The endpoint is where the color changes. The equivalence point is where neutralization is complete. Experimentally, we use the endpoint to estimate the equivalence point.

Setup The solution originally contains $(0.100 \mathrm{mmol} / \mathrm{mL})(25.0 \mathrm{~mL})=2.50 \mathrm{mmol} \mathrm{NH}_{4}^{+}$. At the equivalence point, 2.50 mmol of HCl has been added. The volume of 0.100 M HCl that contains 2.50 mmol is

$$
\begin{aligned}
(\text { volume })(0.100 \mathrm{mmol} / \mathrm{mL}) & =2.50 \mathrm{mmol} \\
\text { volume } & =\frac{2.50 \mathrm{mmol}}{0.100 \mathrm{mmol} / \mathrm{mL}}=25.0 \mathrm{~mL}
\end{aligned}
$$

It takes 25.0 mL of titrant to reach the equivalence point, so the total solution volume is $25.0+$ $25.0=50.0 \mathrm{~mL}$. At the equivalence point, all the $\mathrm{NH}_{3}$ originally present has been converted to $\mathrm{NH}_{4}^{+}$. The concentration of $\mathrm{NH}_{4}^{+}$is $(2.50 \mathrm{mmol}) /(50.0 \mathrm{~mL})=0.0500 \mathrm{M}$. We must use this concentration as the starting concentration of ammonium ion in our equilibrium table.

## Solution

Initial concentration ( $M$ ):
Change in concentration ( $M$ ):
Equilibrium concentration ( $M$ ):

| $\mathrm{NH}_{4}^{+}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{NH}_{3}(a q)+\mathrm{H}_{3} \mathrm{O}(a q)$ |  |  |  |
| :--- | :---: | :---: | :---: |
| 0.0500 |  | 0 | 0 |
| $-x$ |  | $+x$ | $+x$ |
| $0.0500-x$ | $x$ | $x$ |  |

The equilibrium expression is

$$
\begin{gathered}
K_{\mathrm{a}}=\frac{\left[\mathrm{NH}_{3}\right]\left[\mathrm{H}^{+}\right]}{\left[\mathrm{NH}_{4}^{+}\right]}=\frac{(x)(x)}{0.0500}-x \approx \frac{x^{2}}{0.0500}=5.6 \times 10^{-10} \\
x^{2}=2.8 \times 10^{-11} \\
x=\sqrt{2.8 \times 10^{-11}}=5.3 \times 10^{-6} M \\
{\left[\mathrm{H}^{+}\right]=x=5.3 \times 10^{-6} M . \text { At equilibrium, therefore, } \mathrm{pH}=-\log \left(5.3 \times 10^{-6}\right)=5.28}
\end{gathered}
$$

Practice Problem A Calculate the pH at the equivalence point in the titration of 50.0 mL of 0.10 M methylamine (see Table 16.7) with 0.20 M HCl .
fl Practice Problem B A 50.0-mL quantity of a 0.20 M solution of one of the weak bases in Table 16.7 is titrated with 0.050 M HCl . At the equivalence point, the pH is 2.99 . Identify the weak base.

## Acid-Base Indicators

The equivalence point is the point at which the acid has been neutralized completely by the added base. The equivalence point in a titration can be determined by monitoring the pH over the course of the titration, or it can be determined using an acid-base indicator. An acid-base indicator is usually a weak organic acid or base for which the ionized and un-ionized forms are different colors.

Consider a weak organic acid that we will refer to as HIn. To be an effective acid-base indicator, HIn and its conjugate base, $\mathrm{In}^{-}$, must have distinctly different colors. In solution, the acid ionizes to a small extent:

$$
\mathrm{HIn}(a q) \rightleftarrows \mathrm{H}^{+}(a q)+\operatorname{In}^{-}(a q)
$$

In a sufficiently acidic medium, the ionization of HIn is suppressed according to Le Châtelier's principle, and the preceding equilibrium shifts to the left. In this case, the color of the solution will be that of HIn. In a basic medium, on the other hand, the equilibrium shifts to the right and the color of the solution will be that of the conjugate base, $\mathrm{In}^{-}$.

The endpoint of a titration is the point at which the color of the indicator changes. Not all indicators change color at the same pH , however, so the choice of indicator for a particular titration depends on the strength of the acid (and the base) used in the titration. To use the endpoint to determine the equivalence point of a titration, we must select an appropriate indicator.

The endpoint of an indicator does not occur at a specific pH ; rather, there is a range of pH over which the color change occurs. In practice, we select an indicator whose color change occurs

over a pH range that coincides with the steepest part of the titration curve. Consider the information in Figure 17.6, which shows the titration curves for hydrochloric acid and acetic acid-each being titrated with sodium hydroxide. Either of the indicators shown can be used for the titration of a strong acid with a strong base because both endpoints coincide with the steepest part of the $\mathrm{HCl}-\mathrm{NaOH}$ titration curve. However, methyl red changes from red to yellow over the pH range of 4.2 to 6.3. This endpoint occurs significantly before the equivalence point in the titration of acetic acid, which occurs at about pH 8.7. Therefore, methyl red is not a suitable indicator for use in the titration of acetic acid with sodium hydroxide. Phenolphthalein, on the other hand, is a suitable indicator for the $\mathrm{CH}_{3} \mathrm{COOH}-\mathrm{NaOH}$ titration.

Many acid-base indicators are plant pigments. For example, boiling red cabbage in water extracts pigments that exhibit a variety of colors at different pH values (Figure 17.7).

Table 17.3 lists a number of indicators commonly used in acid-base titrations. The choice of indicator for a particular titration depends on the strength of the acid and base to be titrated.

Sample Problem 17.6 illustrates this point.

Figure 17.6 Titration curve of a strong acid with a strong base (blue) and titration curve of a weak acid with a strong base (red). The indicator phenolphthalein can be used to determine the equivalence point of either titration. Methyl red can be used for the strong acid-strong base titration but cannot be used for the weak acid-strong base titration because its color change does not coincide with the steepest part of the curve.

Figure 17.7 Solutions containing extracts of red cabbage (obtained by boiling the cabbage in water) produce different colors when treated with an acid and a base. The pH of the solutions increases from left to right.

Think About It If we don't select an appropriate indicator, the endpoint (color change) will not coincide with the equivalence point.

TABLE 17.3 Some Common Acid-Base Indicators

|  | Color |  |  |
| :--- | :--- | :--- | :--- |
| Indicator | In Acid | In Base | pH Range |
| Thymol blue | Red | Yellow | $1.2-2.8$ |
| Bromophenol blue | Yellow | Bluish purple | $3.0-4.6$ |
| Methyl orange | Orange | Yellow | $3.1-4.4$ |
| Methyl red | Red | Yellow | $4.2-6.3$ |
| Chlorophenol blue | Yellow | Red | $4.8-6.4$ |
| Bromothymol blue | Yellow | Blue | $6.0-7.6$ |
| Cresol red | Yellow | Red | $7.2-8.8$ |
| Phenolphthalein | Colorless | Reddish pink | $8.3-10.0$ |

## Sample Problem 17.6

Which indicator (or indicators) listed in Table 17.3 would you use for the acid-base titrations shown in (a) Figure 17.3, (b) Figure 17.4, and (c) Figure 17.5?

Strategy Determine the pH range that corresponds to the steepest part of each titration curve and select an indicator (or indicators) that changes color within that range.

Setup (a) The titration curve in Figure 17.3 is for the titration of a strong acid with a strong base. The steep part of the curve spans a pH range of about 4 to 10 .
(b) Figure 17.4 shows the curve for the titration of a weak acid with a strong base. The steep part of the curve spans a pH range of about 7 to 10 .
(c) Figure 17.5 shows the titration of a weak base with a strong acid. The steep part of the curve spans a pH range of about 7 to 3 .

Solution (a) Most of the indicators listed in Table 17.3, with the exceptions of thymol blue, bromophenol blue, and methyl orange, would work for the titration of a strong acid with a strong base.
(b) Cresol red and phenolphthalein are suitable indicators.
(c) Bromophenol blue, methyl orange, methyl red, and chlorophenol blue are all suitable indicators.

Practice Problem A Referring to Table 17.3, specify at least one indicator that would be suitable for the following titrations: (a) $\mathrm{CH}_{3} \mathrm{NH}_{2}$ with HBr , (b) $\mathrm{HNO}_{3}$ with NaOH , (c) $\mathrm{HNO}_{2}$ with KOH .

EPractice Problem B For which of the bases in Table 16.7 could you titrate a $0.1 M$ solution of base with 0.1 M nitric acid using the indicator thymol blue?

## Checkpoint 17.3 Acid-Base Titrations

17.3.1 For which of the following titrations will the pH at the equivalence point not be neutral? (Select all that apply.)
a) HCN with NaOH
b) HBr with NaOH
c) $\mathrm{NH}_{3}$ with $\mathrm{HNO}_{3}$
d) $\mathrm{HNO}_{2}$ with KOH
e) HF with KOH
17.3.2 Calculate the pH at the equivalence point in the titration of 30 mL of 0.25 M $\mathrm{CH}_{3} \mathrm{COOH}$ with 0.25 M KOH .
a) 7.00
b) 5.08
c) 8.92
d) 2.82
e) 11.18
17.3.3 Calculate the pH after the addition of 25 mL of 0.10 M NaOH to 50 mL of 0.10 M HF .
a) 3.15
b) 9.31
c) 12.52
d) 1.48
e) 11.87
17.3.4 Calculate the pH after the addition of 35 mL of 0.10 M NaOH to 30 mL of 0.10 M HCN .
a) 11.89
b) 2.11
c) 12.22
d) 1.78
e) 13.00

For Questions 17.3 .5 to 17.3 .8 , refer to the following diagrams. The solutions shown represent various points in the titration of the weak acid HA with NaOH . (For clarity, the sodium ions and water molecules are not shown.)

17.3.5 Which diagram corresponds to the beginning of the titration, prior to the addition of any NaOH ?
17.3.6 Which diagram corresponds to the equivalence point of the titration? (Ignore salt hydrolysis.)
17.3.7 Which diagram illustrates the solution after the equivalence point, when excess NaOH has been added?
17.3.8 Which diagram corresponds to the point at which the pH is equal to the $\mathrm{p} K_{\mathrm{a}}$ of the weak acid?

### 17.4 Solubility Equilibria

The solubility of ionic compounds is important in industry, medicine, and everyday life. For example, barium sulfate $\left(\mathrm{BaSO}_{4}\right)$, an insoluble compound that is opaque to X rays, is used to diagnose ailments of the digestive tract. Tooth decay begins when tooth enamel, which is mainly made of hydroxyapatite $\left[\mathrm{Ca}_{5}\left(\mathrm{PO}_{4}\right)_{3} \mathrm{OH}\right]$, is made more soluble in saliva by the presence of acid.

The general rules for predicting the solubility of ionic compounds in water were introduced in Section 4.2. While these rules are useful, they do not allow us to make quantitative predictions about how much of a given ionic compound will dissolve in water. To develop a quantitative approach, we must start with the principles of chemical equilibrium. Unless otherwise stated, the solvent is water in the following discussion and the temperature is $25^{\circ} \mathrm{C}$.

## Solubility Product Expression and $K_{\text {sp }}$

Consider a saturated solution of silver chloride that is in contact with undissolved solid silver chloride. The equilibrium can be represented as

$$
\mathrm{AgCl}(s) \rightleftarrows \mathrm{Ag}^{+}(a q)+\mathrm{Cl}^{-}(a q)
$$

Although AgCl is not very soluble, all the AgCl that does dissolve in water dissociates completely into $\mathrm{Ag}^{+}$and $\mathrm{Cl}^{-}$ions. We can write the equilibrium expression for the dissociation of AgCl as

$$
K_{\mathrm{sp}}=\left[\mathrm{Ag}^{+}\right]\left[\mathrm{Cl}^{-}\right]
$$

where $\boldsymbol{K}_{\text {sp }}$ is called the solubility product constant. ( $K_{\text {sp }}$ is just another specially subscripted $K_{\mathrm{c}}$, where "sp" stands for "solubility product.")

Because each AgCl unit contains only one $\mathrm{Ag}^{+}$and one $\mathrm{Cl}^{-}$ion, its solubility product expression is particularly simple to write. Many ionic compounds dissociate into more than two ions. Table 17.4 lists a number of slightly soluble ionic compounds along with equations representing their dissolution equilibria and their solubility product constants. (Compounds deemed "soluble" by the solubility rules in Chapter 4 are not listed for the same reason we did not list $K_{\mathrm{a}}$ values for the strong acids in Table 16.6.) In general, the magnitude of $K_{\text {sp }}$ indicates the solubility of an ionic compound-the smaller the $K_{\text {sp }}$ value, the less soluble the compound. To make a direct comparison of $K_{\text {sp }}$ values, however, we must compare salts with similar formulas, such as AgCl with ZnS (one cation, one anion) or $\mathrm{CaF}_{2}$ with $\mathrm{Fe}(\mathrm{OH})_{2}$ (one cation, two anions).

Student Annotation: The compounds described as "insoluble" in Chapter 4 [ 14 Section 4.2, Table 4.3] are actually very slightly soluble - each to a different degree.

Student Annotation: A solubility product equilibrium expression is like any other equilibrium expression: $K$ is equal to the concentrations of products over the concentrations of reactants, each raised to its coefficient from the balanced chemical equation.

> Thus, for the process

$$
\mathrm{MX}_{n}(s) \rightleftarrows \mathrm{M}^{n+}(a q)+n \mathrm{X}^{-}(a q)
$$ the $K_{\text {sp }}$ expression is

$$
K_{\mathrm{sp}}=\left[\mathrm{M}^{n+}\right]\left[\mathrm{X}^{-}\right]^{n}
$$

$M X_{n}$ does not appear in the expression because, as for any heterogeneous equilibrium, the equilibrium expression does not include pure liquids or solids [ 14 Section 15.3].

TABLE 17.4
Solubility Products of Some Slightly Soluble Ionic Compounds at $25^{\circ} \mathrm{C}$

Compound
Aluminum hydroxide

$1.4 \times 10^{-24}$
$7.7 \times 10^{-13}$
$8.1 \times 10^{-12}$

## TABLE 17.4

## Solubility Products of Some Slightly Soluble Ionic Compounds

 at $25^{\circ} \mathrm{C}$ (continued)| Compound | Dissolution Equilibrium | $K_{\text {sp }}$ |
| :---: | :---: | :---: |
| Silver chloride | $\mathrm{AgCl}(s) \rightleftarrows \mathrm{Ag}^{+}(a q)+\mathrm{Cl}^{-}(a q)$ | $1.6 \times 10^{-10}$ |
| Silver chromate | $\mathrm{Ag}_{2} \mathrm{CrO}_{4}(s) \rightleftarrows 2 \mathrm{Ag}^{+}(a q)+\mathrm{CrO}_{4}^{2-}(a q)$ | $1.2 \times 10^{-12}$ |
| Silver iodide | $\mathrm{AgI}(s) \rightleftarrows \mathrm{Ag}^{+}(a q)+\mathrm{I}^{-}(a q)$ | $8.3 \times 10^{-17}$ |
| Silver sulfate | $\mathrm{Ag}_{2} \mathrm{SO}_{4}(s) \rightleftarrows 2 \mathrm{Ag}^{+}(a q)+\mathrm{SO}_{4}^{2-}(a q)$ | $1.5 \times 10^{-5}$ |
| Silver sulfide | $\mathrm{Ag}_{2} \mathrm{~S}(s) \rightleftarrows 2 \mathrm{Ag}^{+}(a q)+\mathrm{S}^{2-}(a q)$ | $6.0 \times 10^{-51}$ |
| Strontium carbonate | $\mathrm{SrCO}_{3}(s) \rightleftarrows \mathrm{Sr}^{2+}(a q)+\mathrm{CO}_{3}^{2-}(a q)$ | $1.6 \times 10^{-9}$ |
| Strontium(II) hydroxide | $\mathrm{Sr}(\mathrm{OH})_{2}(s) \rightleftarrows \mathrm{Sr}^{2+}(a q)+2 \mathrm{OH}^{-}(a q)$ | $3.2 \times 10^{-4}$ |
| Strontium sulfate | $\mathrm{SrSO}_{4}(s) \rightleftarrows \mathrm{Sr}^{2+}(a q)+\mathrm{SO}_{4}^{2-}(a q)$ | $3.8 \times 10^{-7}$ |
| Tin(II) sulfide | $\mathrm{SnS}(\mathrm{s}) \rightleftarrows \mathrm{Sn}^{2+}(a q)+\mathrm{S}^{2-}(a q)$ | $1.0 \times 10^{-26}$ |
| Zinc hydroxide | $\mathrm{Zn}(\mathrm{OH})_{2}(s) \rightleftarrows \mathrm{Zn}^{2+}(a q)+2 \mathrm{OH}^{-}(a q)$ | $1.8 \times 10^{-14}$ |
| Zinc sulfide | $\mathrm{ZnS}(s) \rightleftarrows \mathrm{Zn}^{2+}(a q)+\mathrm{S}^{2-}(a q)$ | $3.0 \times 10^{-23}$ |

## Calculations Involving $K_{\text {sp }}$ and Solubility

There are two ways to express the solubility of a substance: molar solubility, which is the number of moles of solute in 1 L of a saturated solution ( $\mathrm{mol} / \mathrm{L}$ ), and solubility, which is the number of grams of solute in 1 L of a saturated solution ( $\mathrm{g} / \mathrm{L}$ ). Both of these expressions refer to concentrations of saturated solutions at a particular temperature (usually $25^{\circ} \mathrm{C}$ ).

Often we know the value of $K_{\text {sp }}$ for a compound and are asked to calculate the compound's molar solubility. The procedure for solving such a problem is essentially identical to the procedure for solving weak acid or weak base equilibrium problems:

1. Construct an equilibrium table.
2. Fill in what we know.
3. Figure out what we don't know.

For example, the $K_{\text {sp }}$ of silver bromide $(\mathrm{AgBr})$ is $7.7 \times 10^{-13}$. We can construct an equilibrium table and fill in the starting concentrations of $\mathrm{Ag}^{+}$and $\mathrm{Br}^{-}$ions:

Initial concentration ( $M$ ):
Change in concentration ( $M$ ):
Equilibrium concentration ( $M$ ):

Let $s$ be the molar solubility (in mol/L) of AgBr . Because one unit of AgBr yields one $\mathrm{Ag}^{+}$cation and one $\mathrm{Br}^{-}$anion, both $\left[\mathrm{Ag}^{+}\right]$and $\left[\mathrm{Br}^{-}\right]$are equal to $s$ at equilibrium:

Initial concentration ( $M$ ):
Change in concentration ( $M$ ):
Equilibrium concentration (M):

The equilibrium expression is

$$
K_{\mathrm{sp}}=\left[\mathrm{Ag}^{+}\right]\left[\mathrm{Br}^{-}\right]
$$

Therefore,

$$
7.7 \times 10^{-13}=(s)(s)
$$

and

$$
s=\sqrt{7.7 \times 10^{-13}}=8.8 \times 10^{-7} \mathrm{M}
$$

Student Annotation: Be careful not to confuse the terms solubility and $K_{\text {sp }}$. Solubility is the concentration of a saturated solution. $K_{\text {sp }}$ is an equilibrium constant.

Student Annotation: The stoichiometry of the balanced dissociation equation indicates that the concentration of $\mathrm{OH}^{-}$increases by twice as much as that of $\mathrm{Cu}^{2+}$.

Thus, the molar solubility of AgBr is $8.8 \times 10^{-7} \mathrm{M}$. Furthermore, we can express this solubility in $\mathrm{g} / \mathrm{L}$ by multiplying the molar solubility by the molar mass of AgBr :

$$
\frac{8.8 \times 10^{-7} \underline{\mathrm{~mol} A g B r}}{1 \mathrm{~L}} \times \frac{187.8 \mathrm{~g}}{1 \mathrm{~mol} \mathrm{AgBr}}=1.7 \times 10^{-4} \mathrm{~g} / \mathrm{L}
$$

Sample Problem 17.7 demonstrates this approach.

## Sample Problem 17.7

Calculate the solubility of copper(II) hydroxide $\left[\mathrm{Cu}(\mathrm{OH})_{2}\right]$ in $\mathrm{g} / \mathrm{L}$.
Strategy Write the dissociation equation for $\mathrm{Cu}(\mathrm{OH})_{2}$, and look up its $K_{\text {sp }}$ value in Table 17.4. Solve for molar solubility using the equilibrium expression. Convert molar solubility to solubility in $\mathrm{g} / \mathrm{L}$ using the molar mass of $\mathrm{Cu}(\mathrm{OH})_{2}$.

Setup The equation for the dissociation of $\mathrm{Cu}(\mathrm{OH})_{2}$ is

$$
\mathrm{Cu}(\mathrm{OH})_{2}(s) \rightleftarrows \mathrm{Cu}^{2+}(a q)+2 \mathrm{OH}^{-}(a q)
$$

and the equilibrium expression is $K_{\text {sp }}=\left[\mathrm{Cu}^{2+}\right]\left[\mathrm{OH}^{-}\right]^{2}$. According to Table $17.4, K_{\text {sp }}$ for $\mathrm{Cu}(\mathrm{OH})_{2}$ is $2.2 \times 10^{-20}$. The molar mass of $\mathrm{Cu}(\mathrm{OH})_{2}$ is $97.57 \mathrm{~g} / \mathrm{mol}$.

## Solution

Initial concentration ( $M$ ):
Change in concentration ( $M$ ):
Equilibrium concentration $(M)$ :

| $\mathrm{Cu}(\mathrm{OH})_{2}(s) \rightleftarrows \mathrm{Cu}^{2+}(a q)+2 \mathrm{OH}^{-}(a q)$ |  |  |
| :---: | :---: | :---: |
|  | 0 | 0 |
|  | $+s$ | $+2 s$ |
|  | $s$ | $2 s$ |

Therefore,

$$
\begin{aligned}
2.2 \times 10^{-20} & =(s)(2 s)^{2}=4 s^{3} \\
s & =\sqrt[3]{\frac{2.2 \times 10^{-20}}{4}}=1.8 \times 10^{-7} \mathrm{M}
\end{aligned}
$$

The molar solubility of $\mathrm{Cu}(\mathrm{OH})_{2}$ is $1.8 \times 10^{-7} \mathrm{M}$. Multiplying by its molar mass gives

$$
\begin{aligned}
\text { solubility of } \mathrm{Cu}(\mathrm{OH})_{2} & =\frac{1.8 \times 10^{-7} \mathrm{~mol} \mathrm{Cu}(\mathrm{OH})_{2}}{1 \mathrm{~L}} \times \frac{97.57 \mathrm{~g} \mathrm{Cu}(\mathrm{OH})_{2}}{1 \mathrm{molCu}(\mathrm{OH})_{2}} \\
& =1.7 \times 10^{-5} \mathrm{~g} / \mathrm{L}
\end{aligned}
$$

Practice Problem A Calculate the molar solubility and the solubility in $\mathrm{g} / \mathrm{L}$ of each salt at $25^{\circ} \mathrm{C}$ : (a) AgCl , (b) SnS , (c) $\mathrm{SrCO}_{3}$.

EIPractice Problem B Calculate the molar solubility and the solubility in $\mathrm{g} / \mathrm{L}$ of each salt at $25^{\circ} \mathrm{C}$ : (a) $\mathrm{PbF}_{2}$, (b) $\mathrm{Ag}_{2} \mathrm{CO}_{3}$, (c) $\mathrm{Bi}_{2} \mathrm{~S}_{3}$.

We can also use molar solubility to determine the value of $K_{\mathrm{sp}}$. Sample Problem 17.8 illustrates this procedure.

## Sample Problem 17.8

The solubility of calcium sulfate $\left(\mathrm{CaSO}_{4}\right)$ is measured experimentally and found to be $0.67 \mathrm{~g} / \mathrm{L}$. Calculate the value of $K_{\text {sp }}$ for calcium sulfate.

Strategy Convert solubility to molar solubility using the molar mass of $\mathrm{CaSO}_{4}$, and substitute the molar solubility into the equilibrium expression to determine $K_{\text {sp }}$.

Setup The molar mass of $\mathrm{CaSO}_{4}$ is $136.2 \mathrm{~g} / \mathrm{mol}$. The molar solubility of $\mathrm{CaSO}_{4}$ is

$$
\begin{aligned}
\text { molar solubility of } \mathrm{CaSO}_{4} & =\frac{0.67 \mathrm{~g} \mathrm{CaSO}_{4}}{1 \mathrm{~L}} \times \frac{1 \mathrm{~mol} \mathrm{CaSO}_{4}}{136.2 \mathrm{~g} \mathrm{CaSO}_{4}} \\
s & =4.9 \times 10^{-3} \mathrm{~mol} / \mathrm{L}
\end{aligned}
$$

The equation and the equilibrium expression for the dissociation of $\mathrm{CaSO}_{4}$ are

$$
\mathrm{CaSO}_{4}(s) \rightleftarrows \mathrm{Ca}^{2+}(a q)+\mathrm{SO}_{4}^{2-}(a q) \quad \text { and } \quad K_{\text {sp }}=\left[\mathrm{Ca}^{2+}\right]\left[\mathrm{SO}_{4}^{2-}\right]
$$

Solution Substituting the molar solubility into the equilibrium expression gives

$$
K_{\mathrm{sp}}=(s)(s)=\left(4.9 \times 10^{-3}\right)^{2}=2.4 \times 10^{-5}
$$

Practice Problem A Given the solubility, calculate the solubility product constant $\left(K_{\text {sp }}\right)$ of each salt at $25^{\circ} \mathrm{C}$ : (a) $\mathrm{PbCrO}_{4}, s=4.0 \times 10^{-5} \mathrm{~g} / \mathrm{L}$; (b) $\mathrm{BaC}_{2} \mathrm{O}_{4}, s=0.29 \mathrm{~g} / \mathrm{L}$; (c) $\mathrm{MnCO}_{3}, s=4.2 \times 10^{-6} \mathrm{~g} / \mathrm{L}$.
\& Practice Problem B Given the solubility, calculate the solubility product constant ( $K_{\text {sp }}$ ) of each salt at $25^{\circ} \mathrm{C}$ : (a) $\mathrm{Ag}_{2} \mathrm{SO}_{3}, s=4.6 \times 10^{-3} \mathrm{~g} / \mathrm{L}$; (b) $\mathrm{Hg}_{2} \mathrm{I}_{2}, s=1.5 \times 10^{-7} \mathrm{~g} / \mathrm{L}$; (c) $\mathrm{Zn}_{3}\left(\mathrm{PO}_{4}\right)_{2}, s=5.9 \times 10^{-5} \mathrm{~g} / \mathrm{L}$.

## Predicting Precipitation Reactions

For the dissociation of an ionic solid in water, any one of the following conditions may exist: (1) the solution is unsaturated, (2) the solution is saturated, or (3) the solution is supersaturated. For concentrations of ions that do not correspond to equilibrium conditions, we use the reaction quotient $(Q)[$ K4 Section 15.2] to predict when a precipitate will form. Note that $Q$ has the same form as $K_{\text {sp }}$ except that the concentrations of ions are not equilibrium concentrations. For example, if we mix a solution containing $\mathrm{Ag}^{+}$ions with one containing $\mathrm{Cl}^{-}$ions, we write

$$
Q=\left[\mathrm{Ag}^{+}\right]_{\mathrm{i}}\left[\mathrm{Cl}^{-}\right]_{\mathrm{i}}
$$

The subscript " i " denotes that these are initial concentrations and do not necessarily correspond to those at equilibrium. If $Q$ is less than or equal to $K_{\text {sp }}$, no precipitate will form. If $Q$ is greater than $K_{\text {sp }}, \mathrm{AgCl}$ will precipitate out. (Precipitation will continue until the product of the ion concentrations is equal to $K_{\mathrm{sp}}$.)

The ability to predict whether precipitation will occur often has practical value. In industrial and laboratory preparations, we can adjust the concentrations of ions until the ion product exceeds $K_{\text {sp }}$ to obtain a desired ionic compound (in the form of a precipitate). The ability to predict precipitation reactions is also useful in medicine. Kidney stones, which can be extremely painful, consist largely of calcium oxalate $\left(\mathrm{CaC}_{2} \mathrm{O}_{4}, K_{\text {sp }}=2.3 \times 10^{-9}\right)$. The normal physiological concentration of calcium ions in blood plasma is about $5 \times 10^{-3} \mathrm{M}$. Oxalate ions ( $\mathrm{C}_{2} \mathrm{O}_{4}^{2-}$ ), derived from oxalic acid present in vegetables such as rhubarb and spinach, react with the calcium ions to form insoluble calcium oxalate, which can gradually build up in the kidneys. Proper adjustment of a patient's diet can help to reduce precipitate formation.

Sample Problem 17.9 demonstrates the steps involved in predicting precipitation reactions.

## Sample Problem 17.9

Predict whether a precipitate will form when each of the following is added to 650 mL of 0.0080 M $\mathrm{K}_{2} \mathrm{SO}_{4}$ : (a) 250 mL of $0.0040 \mathrm{M} \mathrm{BaCl}_{2}$; (b) 175 mL of $0.15 \mathrm{M} \mathrm{AgNO}_{3}$; (c) 325 mL of 0.25 M $\mathrm{Sr}\left(\mathrm{NO}_{3}\right)_{2}$. (Assume volumes are additive.)

Strategy For each part, identify the compound that might precipitate and look up its $K_{\text {sp }}$ value in Table 17.4 or Appendix 3. Determine the concentrations of each compound's constituent ions, and use them to determine the value of the reaction quotient, $Q_{\mathrm{sp}}$; then compare each reaction quotient with the value of the corresponding $K_{\mathrm{sp}}$. If the reaction quotient is greater than $K_{\mathrm{sp}}$, a precipitate will form.

## Think About It The $K_{\text {sp }}$

 for $\mathrm{CaSO}_{4}$ is relatively large (compared to many of the $K_{\text {sp }}$ values in Table 17.4). In fact, sulfates are listed as soluble compounds in Table 4.2, but calcium sulfate is listed as an insoluble exception. Remember that the term insoluble really refers to compounds that are slightly soluble, and that different sources may differ with regard to how soluble a compound must be to be considered "soluble."Think About It Students sometimes have difficulty deciding what compound might precipitate. Begin by writing down the constituent ions in the two solutions before they are combined. Consider the two possible combinations: the cation from the first solution and the anion from the second, or vice versa. You can consult the information in Tables 4.2 and 4.3 to determine whether one of the combinations is insoluble. Also keep in mind that only an insoluble salt will have a tabulated $K_{\text {sp }}$ value.

Setup The compounds that might precipitate and their $K_{\text {sp }}$ values are (a) $\mathrm{BaSO}_{4}, K_{\text {sp }}=1.1 \times 10^{-10}$; (b) $\mathrm{Ag}_{2} \mathrm{SO}_{4}, K_{\text {sp }}=1.5 \times 10^{-5}$; (c) $\mathrm{SrSO}_{4}, K_{\text {sp }}=3.8 \times 10^{-7}$.

Solution (a) Concentrations of the constituent ions of $\mathrm{BaSO}_{4}$ are:
$\left[\mathrm{Ba}^{2+}\right]=\frac{250 \mathrm{~mL} \times 0.0040 \mathrm{M}}{650 \mathrm{~mL}+250 \mathrm{~mL}}=0.0011 \mathrm{M} \quad$ and $\quad\left[\mathrm{SO}_{4}^{2-}\right]=\frac{650 \mathrm{~mL} \times 0.0080 \mathrm{M}}{650 \mathrm{~mL}+250 \mathrm{~mL}}=0.0058 \mathrm{M}$
Using these concentrations in the equilibrium expression, $\left[\mathrm{Ba}^{2+}\right]\left[\mathrm{SO}_{4}^{2-}\right]$, gives a reaction quotient of $(0.0011)(0.0058)=6.4 \times 10^{-6}$, which is greater than the $K_{\mathrm{sp}}$ of $\mathrm{BaSO}_{4}\left(1.1 \times 10^{-10}\right)$. Therefore, $\mathrm{BaSO}_{4}$ will precipitate.
(b) Concentrations of the constituent ions of $\mathrm{Ag}_{2} \mathrm{SO}_{4}$ are:

$$
\left[\mathrm{Ag}^{+}\right]=\frac{175 \mathrm{~mL} \times 0.15 \mathrm{M}}{650 \mathrm{~mL}+175 \mathrm{~mL}}=0.0032 \mathrm{M} \quad \text { and } \quad\left[\mathrm{SO}_{4}^{2-}\right]=\frac{650 \mathrm{~mL} \times 0.0080 \mathrm{M}}{650 \mathrm{~mL}+175 \mathrm{~mL}}=0.0063 \mathrm{M}
$$

Using these concentrations in the equilibrium expression, $\left[\mathrm{Ag}^{+}\right]^{2}\left[\mathrm{SO}_{4}^{2-}\right.$, gives a reaction quotient of $(0.032)^{2}(0.0063)=6.5 \times 10^{-6}$, which is less than the $K_{\text {sp }}$ of $\mathrm{Ag}_{2} \mathrm{SO}_{4}\left(1.5 \times 10^{-5}\right)$. Therefore, $\mathrm{Ag}_{2} \mathrm{SO}_{4}$ will not precipitate.
(c) Concentrations of the constituent ions of SrSO 4 are:

$$
\left[\mathrm{Sr}^{2+}\right]=\frac{325 \mathrm{~mL} \times 0.25 \mathrm{M}}{650 \mathrm{~mL}+325 \mathrm{~mL}}=0.083 \mathrm{M} \quad \text { and } \quad\left[\mathrm{SO}_{4}^{2-}\right]=\frac{650 \mathrm{~mL} \times 0.0080 \mathrm{M}}{650 \mathrm{~mL}+325 \mathrm{~mL}}=0.0053 \mathrm{M}
$$

Using these concentrations in the equilibrium expression, $\left[\mathrm{Sr}^{2+}\right]\left[\mathrm{SO}_{4}^{2-}\right]$, gives a reaction quotient of $(0.083)(0.0053)=4.4 \times 10^{-4}$, which is greater than the $K_{\text {sp }}$ of $\mathrm{SrSO}_{4}\left(3.8 \times 10^{-7}\right)$. Therefore, $\mathrm{SrSO}_{4}$ will precipitate.

Practice Problem A Predict whether a precipitate will form from each of the following combinations: (a) 25 mL of $1 \times 10^{-5} M \mathrm{Co}\left(\mathrm{NO}_{3}\right)_{2}$ and 75 mL of $5 \times 10^{-4} M \mathrm{Na}_{2} \mathrm{~S}$; (b) 500 mL of $7.5 \times 10^{-4} M \mathrm{AlCl}_{3}$ and 100 mL of $1.7 \times 10^{-5} M \mathrm{Hg}_{2}\left(\mathrm{NO}_{3}\right)_{2}$; (c) 1.5 L of $0.025 \mathrm{MaCl}_{2}$ and 1.25 L of $0.014 \mathrm{M} \mathrm{Pb}\left(\mathrm{NO}_{3}\right)_{2}$.

EPractice Problem B What is the maximum mass (in grams) of each of the following soluble salts that can be added to 150 mL of 0.050 M BaCl 2 without causing a precipitate to form: (a) $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{SO}_{4}$, (b) $\mathrm{Pb}\left(\mathrm{NO}_{3}\right)_{2}$, (c) NaF ? (Assume that the addition of solid causes no change in volume.)

## Checkpoint 17.4 Solubility Equilibria

17.4.1 Using the $K_{\text {sp }}$ for aluminum hydroxide $\left[\mathrm{Al}(\mathrm{OH})_{3}\right]$, calculate its molar solubility.
a) $2.9 \times 10^{-9} \mathrm{M}$
b) $7.7 \times 10^{-12} \mathrm{M}$
c) $4.2 \times 10^{-17} \mathrm{M}$
d) $8.4 \times 10^{-12} \mathrm{M}$
e) $3.8 \times 10^{-9} \mathrm{M}$
17.4.2 What precipitate will form if $0.10 M$ solutions of $\mathrm{Pb}\left(\mathrm{NO}_{3}\right)_{2}$ and NaI are mixed?
a) $\mathrm{Pb}\left(\mathrm{NO}_{3}\right)_{2}$
b) NaI
c) $\mathrm{PbI}_{2}$
d) $\mathrm{NaNO}_{3}$
e) None
17.4.3 The diagrams represent saturated solutions of MX, MY, and MZ, each in equilibrium with its solid. Each solution also contains the soluble nitrate salt of $\mathrm{M}^{n+}$. Arrange the solutions in order of increasing $K_{\text {sp }}$. (For clarity, the water molecules and nitrate ions are not shown.)

a) i $<$ iii $<$ ii
b) ii $<$ iii $<$ i
c) i $=$ ii $<$ iii
d) iii $<$ ii $=$ i
e) ii $<$ i $<$ iii
17.4.4 The diagram represents a saturated solution of the salt $\mathrm{MA}_{2}$. Which soluble salt will cause the precipitation of the greatest quantity of $\mathrm{MA}_{2}$ when 0.1 mole is dissolved in the saturated solution? (For clarity, the water molecules are not shown.)

a) NaA
b) $\mathrm{BaA}_{2}$
c) $\mathrm{AlA}_{3}$
d) $\mathrm{M}\left(\mathrm{NO}_{3}\right)_{2}$
e) $\mathrm{M}_{3}\left(\mathrm{PO}_{4}\right)_{2}$
17.4.5 Diagrams 1 and 2 represent a saturated solution of the slightly soluble salt $\mathrm{M}_{2} \mathrm{~B}$ and a solution of the soluble salt $\mathrm{MNO}_{3}$, respectively. Which of the solutions of the soluble salt $\mathrm{Na}_{2} \mathrm{~B}$ can be added to the solution of $\mathrm{MNO}_{3}$ without causing a precipitate to form? Select all that apply. Assume that the solution volumes are equal, and that they are additive when combined. (For clarity, the water molecules, nitrate ions, and sodium ions are not shown.)

### 17.5 Factors Affecting Solubility

In this section we will examine the effect of several factors on solubility including the common ion effect, pH , and the formation of complex ions.

## The Common Ion Effect

The solubility product is an equilibrium constant, and precipitation of an ionic compound from solution occurs whenever the ion product exceeds the $K_{\text {sp }}$ for that substance. In a saturated solution of AgCl , for example, the ion product $\left[\mathrm{Ag}^{+}\right]\left[\mathrm{Cl}^{-}\right]$is equal to $K_{\mathrm{sp}}$. The solubility of AgCl in water can be calculated as follows, using the procedure introduced in Section 17.4:

$$
1.6 \times 10^{-10}=\left[\mathrm{Ag}^{+}\right]\left[\mathrm{Cl}^{-}\right]
$$

In a solution in which AgCl is the only solute, $\left[\mathrm{Ag}^{+}\right]=\left[\mathrm{Cl}^{-}\right]$. Therefore,

$$
1.6 \times 10^{-10}=s^{2}
$$

and $s=1.3 \times 10^{-5} \mathrm{M}$. Thus, the solubility of AgCl in water at $25^{\circ} \mathrm{C}$ is $1.3 \times 10^{-5} \mathrm{M}$.
Now suppose we want to determine the solubility of AgCl in a solution already containing a solute that has an ion in common with AgCl . For example, consider dissolving AgCl in a 0.10 M solution of $\mathrm{AgNO}_{3}$. In this case, the $\mathrm{Ag}^{+}$and $\mathrm{Cl}^{-}$concentrations at equilibrium will not be equal. In fact, the $\mathrm{Ag}^{+}$ion concentration will be equal to 0.10 M plus the concentration contributed by AgCl . The equilibrium expression is

$$
1.6 \times 10^{-10}=\left[\mathrm{Ag}^{+}\right]\left[\mathrm{Cl}^{-}\right]=(0.10+s)(s)
$$

Because we expect $s$ to be very small, we can simplify this calculation as follows:

Student Annotation: $s$ still represents the concentration of $\mathrm{Cl}^{-}$at equilibrium and the solubility of AgCl .

$$
(0.10+s) M \approx 0.10 M
$$

Student Annotation: The common ion effect is an example of Le Châtelier's principle [ 14 Section 15.5].

Media Player/MPEG Animation: Figure 17.8, Common Ion Effect, pp. 756-757.

Think About It The molar solubility of AgCl in water is $\sqrt{1.6 \times 10^{-10}}=1.3 \times 10^{-5} \mathrm{M}$. The presence of $6.5 \times 10^{-3} \mathrm{M}$ $\mathrm{AgNO}_{3}$ reduces the solubility of AgCl by a factor of $\sim 500$.

Therefore,

$$
1.6 \times 10^{-10}=0.10 s
$$

and $s=1.6 \times 10^{-9} M$. Thus, AgCl is significantly less soluble in $0.10 \mathrm{MANO}_{3}$ than in pure water-due to the common ion effect. Figure 17.8 (pp. 756-57) illustrates the common ion effect. Sample Problem 17.10 shows how the common ion effect affects solubility.

## Sample Problem 17.10

Calculate the molar solubility of silver chloride in a solution that is $6.5 \times 10^{-3} \mathrm{M}$ in silver nitrate.
Strategy Silver nitrate is a strong electrolyte that dissociates completely in water. Therefore, the concentration of $\mathrm{Ag}^{+}$before any AgCl dissolves is $6.5 \times 10^{-3} M$. Use the equilibrium expression, the $K_{\text {sp }}$ for AgCl , and an equilibrium table to determine how much AgCl will dissolve.

Setup The dissolution equilibrium and the equilibrium expression are

$$
\mathrm{AgCl}(s) \rightleftarrows \mathrm{Ag}^{+}(a q)+\mathrm{Cl}^{-}(a q) \quad 1.6 \times 10^{-10}=\left[\mathrm{Ag}^{+}\right]\left[\mathrm{Cl}^{-}\right]
$$

## Solution

Initial concentration ( $M$ ):
Change in concentration $(M)$ :
Equilibrium concentration (M):

| $\mathrm{AgCl}(s) \rightleftarrows \mathrm{Ag}^{+}(a q)+\mathrm{Cl}^{-}(a q)$ |  |  |
| :---: | :---: | :---: |
|  | $6.5 \times 10^{-3}$ | 0 |
|  | $+s$ | $+s$ |
|  | $6.5 \times 10^{-3}+s$ | $s$ |

Substituting these concentrations into the equilibrium expression gives

$$
1.6 \times 10^{-10}=\left(6.5 \times 10^{-3}+s\right)(s)
$$

We expect $s$ to be very small, so

$$
6.5 \times 10^{-3}+s \approx 6.5 \times 10^{-3}
$$

and

$$
1.6 \times 10^{-10}=\left(6.5 \times 10^{-3}\right)(s)
$$

Thus

$$
s=\frac{1.6 \times 10^{-10}}{6.5 \times 10^{-3}}=2.5 \times 10^{-8} \mathrm{M}
$$

Therefore, the molar solubility of AgCl in $6.5 \times 10^{-3} M \mathrm{AgNO}_{3}$ is $2.5 \times 10^{-8} M$.

Practice Problem A Calculate the molar solubility of AgI in (a) pure water and (b) 0.0010 M NaI .
Practice Problem B Arrange the following salts in order of increasing molar solubility in 0.0010 M $\mathrm{AgNO}_{3}: \mathrm{AgBr}, \mathrm{Ag}_{2} \mathrm{CO}_{3}, \mathrm{AgCl}, \mathrm{AgI}, \mathrm{Ag}_{2} \mathrm{~S}$.

## pH

The solubility of a substance can also depend on the pH of the solution. Consider the solubility equilibrium of magnesium hydroxide:

$$
\mathrm{Mg}(\mathrm{OH})_{2}(s) \rightleftarrows \mathrm{Mg}^{2+}(a q)+2 \mathrm{OH}^{-}(a q)
$$

According to Le Châtelier's principle, adding $\mathrm{OH}^{-}$ions (increasing the pH ) shifts the equilibrium from right to left, thereby decreasing the solubility of $\mathrm{Mg}(\mathrm{OH})_{2}$. (This is actually another example of the common ion effect.) On the other hand, adding $\mathrm{H}^{+}$ions (decreasing the pH ) shifts the equilibrium from left to right, and the solubility of $\mathrm{Mg}(\mathrm{OH})_{2}$ increases. Thus, insoluble bases tend to dissolve in acidic solutions. Similarly, insoluble acids tend to dissolve in basic solutions.

To examine the effect of pH on the solubility of $\mathrm{Mg}(\mathrm{OH})_{2}$, we first calculate the pH of a saturated $\mathrm{Mg}(\mathrm{OH})_{2}$ solution:

$$
\begin{aligned}
K_{\mathrm{sp}} & =(s)(2 s)^{2}=4 s^{3} \\
4 s^{3} & =1.2 \times 10^{-11} \\
s^{3} & =3.0 \times 10^{-12} \\
s & =1.4 \times 10^{-4} M
\end{aligned}
$$

At equilibrium, therefore,

$$
\begin{aligned}
{\left[\mathrm{OH}^{-}\right] } & =2\left(1.4 \times 10^{-4} M\right)=2.8 \times 10^{-4} M \\
\mathrm{pOH} & =-\log \left(2.8 \times 10^{-4}\right)=3.55 \\
\mathrm{pH} & =14.00-3.55=10.45
\end{aligned}
$$

In a solution with a pH of less than 10.45 , the solubility of $\mathrm{Mg}(\mathrm{OH})_{2}$ would increase. The dissolution process and the effect of additional $\mathrm{H}^{+}$ions are summarized as follows:

$$
\begin{aligned}
\mathrm{Mg}(\mathrm{OH})_{2}(s) & \rightleftarrows \mathrm{Mg}^{2+}(a q)+2 \mathrm{OH}^{-}(a q) \\
2 \mathrm{H}^{+}(a q)+2 \mathrm{OH}^{-}(a q) & \longleftrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l) \\
\text { Overall: } \quad \mathrm{Mg}(\mathrm{OH})_{2}(s)+2 \mathrm{H}^{+}(a q) & \rightleftarrows \mathrm{Mg}^{2+}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l)
\end{aligned}
$$

If the pH of the medium were higher than $10.45,\left[\mathrm{OH}^{-}\right]$would be higher and the solubility of $\mathrm{Mg}(\mathrm{OH})_{2}$ would decrease because of the common ion $\left(\mathrm{OH}^{-}\right)$effect.

The pH also influences the solubility of salts that contain a basic anion. For example, the solubility equilibrium for $\mathrm{BaF}_{2}$ is

$$
\mathrm{BaF}_{2}(s) \rightleftarrows \mathrm{Ba}^{2+}(a q)+2 \mathrm{~F}^{-}(a q)
$$

and

$$
K_{\mathrm{sp}}=\left[\mathrm{Ba}^{2+}\right]\left[\mathrm{F}^{-}\right]^{2}
$$

In an acidic medium, the high $\left[\mathrm{H}^{+}\right]$will shift the following equilibrium to the left, consuming $\mathrm{F}^{-}$:

$$
\mathrm{HF}(a q) \rightleftarrows \mathrm{H}^{+}(a q)+\mathrm{F}^{-}(a q)
$$

As the concentration of $\mathrm{F}^{-}$decreases, the concentration of $\mathrm{Ba}^{2+}$ must increase to satisfy the equality $K_{\mathrm{sp}}=\left[\mathrm{Ba}^{2+}\right]\left[\mathrm{F}^{-}\right]^{2}$ and maintain the state of equilibrium. Thus, more $\mathrm{BaF}_{2}$ dissolves. The process and the effect of pH on the solubility of $\mathrm{BaF}_{2}$ can be summarized as follows:

$$
\begin{aligned}
\mathrm{BaF}_{2}(s) & \Longleftrightarrow \mathrm{Ba}^{2+}(a q)+2 \mathrm{~F}^{-}(a q) \\
2 \mathrm{H}^{+}(a q)+2 \mathrm{~F}^{-}(a q) & \longleftrightarrow 2 \mathrm{HF}(a q) \\
\text { Overall: } \quad \mathrm{BaF}_{2}(s)+2 \mathrm{H}^{+}(a q) & \rightleftarrows \mathrm{Ba}^{2+}(a q)+2 \mathrm{HF}(a q)
\end{aligned}
$$

The solubilities of salts containing anions that do not hydrolyze, such as $\mathrm{Cl}^{-}, \mathrm{Br}^{-}$, and $\mathrm{NO}_{3}^{-}$, are unaffected by pH .

Sample Problem 17.11 demonstrates the effect of pH on solubility.

## Sample Problem 17.11

Which of the following compounds will be more soluble in acidic solution than in water: (a) CuS , (b) AgCl , (c) $\mathrm{PbSO}_{4}$ ?

Strategy For each salt, write the dissociation equilibrium equation and determine whether it produces an anion that will react with $\mathrm{H}^{+}$. Only an anion that is the conjugate base of a weak acid will react with $\mathrm{H}^{+}$.

## Setup

(a) $\mathrm{CuS}(s) \rightleftarrows \mathrm{Cu}^{2+}(a q)+\mathrm{S}^{2-}(a q)$
$\mathrm{S}^{2-}$ is the conjugate base of the weak acid $\mathrm{HS}^{-} . \mathrm{S}^{2-}$ reacts with $\mathrm{H}^{+}$as follows:

$$
\mathrm{S}^{2-}(a q)+\mathrm{H}^{+}(a q) \longrightarrow \mathrm{HS}^{-}(a q)
$$

Figure 17.8

## Common Ion Effect

We prepare a saturated solution by adding AgCl to water and stirring.

In the resulting saturated solution, the concentrations of $\mathrm{Ag}^{+}$and $\mathrm{Cl}^{-}$are equal, and the product of their concentrations is equal to $K_{\mathrm{sp}}$.

$$
\left[\mathrm{Ag}^{+}\right]\left[\mathrm{Cl}^{-}\right]=1.6 \times 10^{-10}
$$

Therefore, the concentrations are
$\left[\mathrm{Ag}^{+}\right]=1.3 \times 10^{-5} \mathrm{M}$
and $\left[\mathrm{Cl}^{-}\right]=1.3 \times 10^{-5} \mathrm{M}$

Neither AgCl nor a saturated solution of AgCl is purple. The color has been used in this illustration to clarify the process.

After filtering off the solid AgCl , we dissolve enough NaCl to make the concentration of $\mathrm{Cl}^{-}=1.0 \mathrm{M}$.

Because the concentration of $\mathrm{Cl}^{-}$is now larger, the product of $\mathrm{Ag}^{+}$and $\mathrm{Cl}^{-}$concentrations is no longer equal to $K_{\text {sp }}$. $\left[\mathrm{Ag}^{+}\right]\left[\mathrm{Cl}^{-}\right]=\left(1.3 \times 10^{-5} \mathrm{M}\right)(1.0 \mathrm{M})>1.6 \times 10^{-10}$ In any solution saturated with AgCl at $25^{\circ} \mathrm{C}$, the product of $\left[\mathrm{Ag}^{+}\right]$and $\left[\mathrm{Cl}^{-}\right]$must equal the $K_{\text {sp }}$ of AgCl .
Therefore, AgCl will precipitate until the product of ion concentrations is again $1.6 \times 10^{-10}$.

Note that this causes nearly all the dissolved AgCl to precipitate. With a $\mathrm{Cl}^{-}$concentration of 1.0 M , the highest possible concentration of $\mathrm{Ag}^{+}$is $1.6 \times 10^{-10} \mathrm{M}$.

The amount of AgCl precipitated is exaggerated for emphasis. The actual amount of AgCl would be extremely small.

## What's the point?

When two salts contain the same ion, the ion they both contain is called the "common ion." The solubility of a slightly soluble salt such as AgCl can be decreased by the addition of a soluble salt with a common ion. In this example, AgCl is precipitated by adding $\mathrm{NaCl} . \mathrm{AgCl}$ could also be precipitated by adding a soluble salt containing the $\mathrm{Ag}^{+}$ion, such as $\mathrm{AgNO}_{3}$.

Think About It When a salt dissociates to give the conjugate base of a weak acid, $\mathrm{H}^{+}$ions in an acidic solution consume a product (base) of the dissolution. This drives the equilibrium to the right (more solid dissolves) according to Le Châtelier's principle.

Student Annotation: Lewis acid-base reactions in which a metal cation combines with a Lewis base result in the formation of complex ions.
(b) $\mathrm{AgCl}(s) \rightleftarrows \mathrm{Ag}^{+}(a q)+\mathrm{Cl}^{-}(a q)$
$\mathrm{Cl}^{-}$is the conjugate base of the strong acid $\mathrm{HCl} . \mathrm{Cl}^{-}$does not react with $\mathrm{H}^{+}$.
(c) $\mathrm{PbSO}_{4}(s) \rightleftarrows \mathrm{Pb}^{2+}(a q)+\mathrm{SO}_{4}^{2-}(a q)$
$\mathrm{SO}_{4}^{2-}$ is the conjugate base of the weak acid $\mathrm{HSO}_{4}^{-}$. It reacts with $\mathrm{H}^{+}$as follows:

$$
\mathrm{SO}_{4}^{2-}(a q)+\mathrm{H}^{+}(a q) \longrightarrow \mathrm{HSO}_{4}^{-}(a q)
$$

A salt that produces an anion that reacts with $\mathrm{H}^{+}$will be more soluble in acid than in water.
Solution CuS and $\mathrm{PbSO}_{4}$ are more soluble in acid than in water. ( AgCl is no more or less soluble in acid than in water.)

Practice Problem A Determine if the following compounds are more soluble in acidic solution than in pure water: (a) $\mathrm{Ca}(\mathrm{OH})_{2}$, (b) $\mathrm{Mg}_{3}\left(\mathrm{PO}_{4}\right)_{2}$, (c) $\mathrm{PbBr}_{2}$.

GPractice Problem B Other than those in Sample Problem 17.11 and those in Practice Problem A, list three salts that are more soluble in acidic solution than in pure water.

## Complex Ion Formation

A complex ion is an ion containing a central metal cation bonded to one or more molecules or ions. Complex ions are crucial to many chemical and biological processes. Here we will consider the effect of complex ion formation on solubility. In Chapter 22 we will discuss the chemistry of complex ions in more detail.

Transition metals have a particular tendency to form complex ions. For example, a solution of cobalt(II) chloride $\left(\mathrm{CoCl}_{2}\right)$ is pink because of the presence of the $\mathrm{Co}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}^{2+}$ ions (Figure 17.9). When HCl is added, the solution turns blue because the complex ion $\mathrm{CoCl}_{4}^{2-}$ forms:

$$
\mathrm{Co}^{2+}(a q)+4 \mathrm{Cl}^{-}(a q) \rightleftarrows \mathrm{CoCl}_{4}^{2-}(a q)
$$

Copper(II) sulfate $\left(\mathrm{CuSO}_{4}\right)$ dissolves in water to produce a blue solution. The hydrated copper(II) ions are responsible for this color; many other sulfates (e.g., $\mathrm{Na}_{2} \mathrm{SO}_{4}$ ) are colorless. Adding a few drops of concentrated ammonia solution to a $\mathrm{CuSO}_{4}$ solution causes the formation of a light-blue precipitate, copper(II) hydroxide:

$$
\mathrm{Cu}^{2+}(a q)+2 \mathrm{OH}^{-}(a q) \longrightarrow \mathrm{Cu}(\mathrm{OH})_{2}(s)
$$

The $\mathrm{OH}^{-}$ions are supplied by the ammonia solution. If more $\mathrm{NH}_{3}$ is added, the blue precipitate redissolves to produce a beautiful dark-blue solution, this time due to the formation of the complex ion $\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}^{2+}$ (Figure 17.10):

$$
\mathrm{Cu}(\mathrm{OH})_{2}(s)+4 \mathrm{NH}_{3}(a q) \rightleftarrows \mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}^{2+}(a q)+2 \mathrm{OH}^{-}(a q)
$$

Thus, the formation of the complex ion $\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}^{2+}$ increases the solubility of $\mathrm{Cu}(\mathrm{OH})_{2}$.
A measure of the tendency of a metal ion to form a particular complex ion is given by the formation constant $\left(\boldsymbol{K}_{\mathbf{f}}\right)$ (also called the stability constant), which is the equilibrium constant for the complex ion formation. The larger $K_{\mathrm{f}}$ is, the more stable the complex ion is. Table 17.5 (page 762) lists the formation constants of a number of complex ions.

The formation of the $\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}^{2+}$ ion can be expressed as

$$
\mathrm{Cu}^{2+}(a q)+4 \mathrm{NH}_{3}(a q) \rightleftarrows \mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}^{2+}(a q)
$$

The corresponding formation constant is

$$
K_{\mathrm{f}}=\frac{\left[\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}^{2+}\right]}{\left[\mathrm{Cu}^{2+}\right]\left[\mathrm{NH}_{3}\right]^{4}}=5.0 \times 10^{13}
$$

The large value of $K_{\mathrm{f}}$ in this case indicates that the complex ion is very stable in solution and accounts for the very low concentration of copper(II) ions at equilibrium.

Recall that $K$ for the sum of two reactions is the product of the individual $K$ values [ $\$ 4$ Section 15.3]. The dissolution of silver chloride is represented by the equation

$$
\mathrm{AgCl}(s) \rightleftarrows \mathrm{Ag}^{+}(a q)+\mathrm{Cl}^{-}(a q)
$$

The sum of this equation and the one representing the formation of $\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}^{+}$is

$$
\begin{array}{rll}
\mathrm{AgCl}(s) & \rightleftarrows \mathrm{Ag}^{+}(a q)+\mathrm{Cl}^{-}(a q) & K_{\mathrm{sp}}=1.6 \times 10^{-10} \\
\mathrm{Ag}^{+}(a q)+2 \mathrm{NH}_{3}(a q) \rightleftarrows \mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}^{+}(a q) & K_{\mathrm{f}}=1.5 \times 10^{7} \\
\mathrm{AgCl}(s)+2 \mathrm{NH}_{3}(a q) & \rightleftarrows \mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}^{+}(a q)+\mathrm{Cl}^{-}(a q) &
\end{array}
$$

and the corresponding equilibrium constant is $\left(1.6 \times 10^{-10}\right)\left(1.5 \times 10^{7}\right)=2.4 \times 10^{-3}$. This is significantly larger than the $K_{\text {sp }}$ value, indicating that much more AgCl will dissolve in the presence of aqueous ammonia than in pure water. In general, the effect of complex ion formation generally is to increase the solubility of a substance.

Figure 17.9 (Left) An aqueous cobalt(II) chloride solution. The pink color is due to the presence of $\mathrm{Co}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}^{2+}$ ions. (Right) After the addition of HCl solution, the solution turns blue because of the formation of the complex $\mathrm{CoCl}_{4}^{2-}$ ions.

Figure 17.10 (Left) An aqueous solution of copper(II) sulfate. (Center) After the addition of a few drops of concentrated aqueous ammonia solution, a light-blue precipitate of $\mathrm{Cu}(\mathrm{OH})_{2}$ is formed. (Right) When more concentrated aqueous ammonia solution is added, the $\mathrm{Cu}(\mathrm{OH})_{2}$ precipitate dissolves to form the dark-blue complex ion $\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}^{2+}$.

Student Annotation: Formation of a complex ion consumes the metal ion produced by the dissociation of a salt, increasing the salt's solubility simply due to Le Châtelier's principle [ $\mathrm{W4}$ Section 15.5].

## How Do I Solve Equilibrium Problems Involving Complex Ion Formation?

Student Annotation: The term free is used to refer to a metal ion that is not part of a complex ion.

Many of the equilibrium problems we encounter involve equilibrium constants, such as $K_{\mathrm{a}}, K_{\mathrm{b}}$, and $K_{\text {sp }}$, that are very small. Often, this enables us to neglect the unknown $x$ in the denominator of the equilibrium expression, which simplifies the math necessary to solve the problem [ 14 Section 16.5]. The solution of an equilibrium problem involving complex ion formation is complicated both by the magnitude of $K_{\mathrm{f}}$ and by the stoichiometry of the reaction. Consider the combination of aqueous copper(II) ions and ammonia to form the complex ion $\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}^{2+}$ :

$$
\mathrm{Cu}^{2+}(a q)+4 \mathrm{NH}_{3}(a q) \rightleftarrows \mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}^{)^{2+}}(a q) \quad K_{\mathrm{f}}=5.0 \times 10^{14}
$$

Let's say we wish to determine the molar concentration of free copper(II) ion in solution when 0.10 mole of $\mathrm{Cu}\left(\mathrm{NO}_{3}\right)_{2}$ is dissolved in a liter of $3.0 \mathrm{M} \mathrm{NH}_{3}$. We cannot solve this with the same approach we used to determine the pH of a weak acid solution. Not only can we not neglect $x$, the amount of copper(II) ion consumed in the reaction, but having to raise the ammonia concentration to the fourth power in the equilibrium expression results in an equation that is not easily solved. Another approach is needed.

Because the magnitude of $K_{\mathrm{f}}$ is so large, we begin by assuming that all the copper(II) ion is consumed to form the complex ion. Then we consider the equilibrium in terms of the reverse reaction; that is, the dissociation of $\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}^{2+}$, for which the equilibrium constant is the reciprocal of $K_{\mathrm{f}}$.

$$
\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}^{2+}(a q) \rightleftarrows \mathrm{Cu}^{2+}(a q)+4 \mathrm{NH}_{3}(a q) \quad K=2.0 \times 10^{-15}
$$

Now we construct an equilibrium table and, because this $K$ is so small, we can expect $x$ (the amount of complex ion that dissociates) to be insignificant compared to the concentration of the complex ion and the concentration of ammonia. [Note that the concentration of ammonia, which had been 3.0 M , has been diminished by $4 \times 0.10 \mathrm{M}$ due to the amount required to complex 0.10 mole of copper(II) ion.]

$$
\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}^{2+}(a q) \rightleftarrows \mathrm{Cu}^{2+}(a q)+4 \mathrm{NH}_{3}(a q)
$$

Initial concentration ( $M$ ):
Change in concentration ( $M$ ):
Equilibrium concentration ( $M$ ):

| 0.10 | 0 | 2.6 |
| :---: | :---: | :---: |
| $-x$ | $+x$ | $+4 x$ |
| $0.10-x$ | $x$ | $2.6+4 x$ |

We can neglect $x$ with respect to the concentrations of $\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}^{2+}$ and $\mathrm{NH}_{3}(0.10-x \approx 0.10$ and $2.6+4 x \approx 2.6$ ), and the solution becomes

$$
\frac{\left[\mathrm{Cu}^{2+}\right]\left[\mathrm{NH}_{3}\right]^{4}}{\left[\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}^{2+}\right]}=\frac{x(2.6)^{4}}{0.10}=2.0 \times 10^{-15}
$$

and $x=4.4 \times 10^{-18} \mathrm{M}$. Note that because the formation constant is so large, the amount of copper that remains uncomplexed is extremely small. As always, it is a good idea to check the answer by plugging it into the equilibrium expression:

$$
\frac{\left(4.4 \times 10^{-18}\right)\left[2.6+4\left(4.4 \times 10^{-18}\right)\right]^{4}}{0.10-4.4 \times 10^{-18}}=2.0 \times 10^{-15}
$$

Sample Problem 17.12 lets you practice applying this approach to a complex-ion formation equilibrium problem.

## Sample Problem 17.12

In the presence of aqueous cyanide, cadmium(II) forms the complex ion $\mathrm{Cd}(\mathrm{CN})_{4}^{2-}$. Determine the molar concentration of free (uncomplexed) cadmium(II) ion in solution when 0.20 mole of $\mathrm{Cd}\left(\mathrm{NO}_{3}\right)_{2}$ is dissolved in a liter of 2.0 M sodium cyanide $(\mathrm{NaCN})$.

Strategy Because formation constants are typically very large, we begin by assuming that all the $\mathrm{Cd}^{2+}$ ion is consumed and converted to complex ion. We then determine how much $\mathrm{Cd}^{2+}$ is produced by the subsequent dissociation of the complex ion, a process for which the equilibrium constant is the reciprocal of $K_{\mathrm{f}}$.
Setup From Table 17.5, the formation constant $\left(K_{\mathrm{f}}\right)$ for the complex ion $\mathrm{Cd}(\mathrm{CN})_{4}^{2-}$ is $7.1 \times 10^{16}$. The reverse process,

$$
\mathrm{Cd}(\mathrm{CN})_{4}^{2-}(a q) \rightleftarrows \mathrm{Cd}^{2+}(a q)+4 \mathrm{CN}^{-}(a q)
$$

has an equilibrium constant of $1 / K_{\mathrm{f}}=1.4 \times 10^{-17}$. The equilibrium expression for the dissociation is

$$
1.4 \times 10^{-17}=\frac{\left[\mathrm{Cd}^{2+}\right]\left[\mathrm{CN}^{-}\right]^{4}}{\left[\mathrm{Cd}(\mathrm{CN})_{4}^{2-}\right]}
$$

The formation of complex ion will consume some of the cyanide originally present. Stoichiometry indicates that four $\mathrm{CN}^{-}$ions are required to react with one $\mathrm{Cd}^{2+}$ ion. Therefore, the concentration of $\mathrm{CN}^{-}$that we enter in the top row of the equilibrium table will be $[2.0 \mathrm{M}-4(0.20 \mathrm{M})]=1.2 \mathrm{M}$.

Solution We construct an equilibrium table:

$$
\mathrm{Cd}(\mathrm{CN})_{4}^{2-}(a q) \rightleftarrows \mathrm{Cd}^{2+}(a q)+4 \mathrm{CN}^{-}(a q)
$$

Initial concentration ( $M$ ):
Change in concentration ( $M$ ):
Equilibrium concentration ( $M$ ):

| 0.20 | 0 | 1.2 |
| :---: | :---: | :---: |
| $-x$ | $+x$ | $+4 x$ |
| $0.20-x$ | $x$ | $1.2+4 x$ |

and, because the magnitude of $K$ is so small, we can neglect $x$ with respect to the initial concentrations of $\mathrm{Cd}(\mathrm{CN})_{4}^{2-}$ and $\mathrm{CN}^{-}(0.20-x \approx 0.20$ and $1.2+4 x \approx 1.2)$, so the solution becomes

$$
\frac{\left[\mathrm{Cd}^{2+}\right]\left[\mathrm{CN}^{-}\right]^{4}}{\left[\mathrm{Cd}(\mathrm{CN})_{4}^{2-}\right]}=\frac{x(1.2)^{4}}{0.20}=1.4 \times 10^{-17}
$$

and $x=1.4 \times 10^{-18} \mathrm{M}$.

Practice Problem A In the presence of aqueous ammonia, cobalt(III) forms the complex ion $\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}^{3+}$. Determine the molar concentration of free cobalt(III) ion in solution when 0.15 mole of $\mathrm{Co}\left(\mathrm{NO}_{3}\right)_{3}$ is dissolved in a liter of 2.5 M aqueous ammonia.
$\boldsymbol{s}$ Practice Problem B Use information from Tables 17.4 and 17.5 to determine the molar solubility of chromium(III) hydroxide in a buffered solution with $\mathrm{pH}=11.45$.

## TABLE 17.5 Formation Constants of Selected Complex Ions in Water at $25^{\circ} \mathrm{C}$

| Complex Ion | Equilibrium Expression | Formation Constant $\left(K_{\mathrm{f}}\right)$ |
| :--- | :--- | :---: |
| $\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}^{+}$ | $\mathrm{Ag}^{+}+2 \mathrm{NH}_{3} \rightleftarrows \mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}^{+}$ | $1.5 \times 10^{7}$ |
| $\mathrm{Ag}(\mathrm{CN})_{2}^{-}$ | $\mathrm{Ag}^{+}+2 \mathrm{CN}^{-} \rightleftarrows \mathrm{Ag}(\mathrm{CN})_{2}^{-}$ | $1.0 \times 10^{21}$ |
| $\mathrm{Cu}(\mathrm{CN})_{4}^{2-}$ | $\mathrm{Cu}^{2+}+4 \mathrm{CN}^{-} \rightleftarrows \mathrm{Cu}(\mathrm{CN})_{4}^{2-}$ | $1.0 \times 10^{25}$ |
| $\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}^{2+}$ | $\mathrm{Cu}^{2+}+4 \mathrm{NH}_{3} \rightleftarrows \mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}^{2+}$ | $5.0 \times 10^{13}$ |
| $\mathrm{Cd}(\mathrm{CN})_{4}^{2-}$ | $\mathrm{Cd}^{2+}+4 \mathrm{CN}^{-} \rightleftarrows \mathrm{Cd}(\mathrm{CN})_{4}^{2-}$ | $7.1 \times 10^{16}$ |
| $\mathrm{CdI}_{4}^{2-}$ | $\mathrm{Cd}^{2+}+4 \mathrm{I}^{-} \rightleftarrows \mathrm{CdI}_{4}^{2-}$ | $2.0 \times 10^{6}$ |
| $\mathrm{HgCl}_{4}^{2-}$ | $\mathrm{Hg}^{2+}+4 \mathrm{Cl}^{-} \rightleftarrows \mathrm{HgCl}_{4}^{2-}$ | $1.7 \times 10^{16}$ |
| $\mathrm{HgI}_{4}^{2-}$ | $\mathrm{Hg}^{2+}+4 \mathrm{I}^{-} \rightleftarrows \mathrm{HgI}_{4}^{2-}$ | $2.0 \times 10^{30}$ |
| $\mathrm{Hg}(\mathrm{CN})_{4}^{2-}$ | $\mathrm{Hg}^{2+}+4 \mathrm{CN}^{-} \rightleftarrows \mathrm{Hg}_{4} \rightleftarrows \mathrm{CN}_{4}^{2-}$ | $2.5 \times 10^{41}$ |
| $\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}^{3+}$ | $\mathrm{Co}^{3+}+6 \mathrm{NH}_{3} \rightleftarrows \mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}^{3+}$ | $5.0 \times 10^{31}$ |
| $\mathrm{Zn}\left(\mathrm{NH}_{3}\right)_{4}^{2+}$ | $\mathrm{Zn}^{2+}+4 \mathrm{NH}_{3} \rightleftarrows \mathrm{Zn}\left(\mathrm{NH}_{3}\right)_{4}^{2+}$ | $2.9 \times 10^{9}$ |
| $\mathrm{Cr}(\mathrm{OH})_{4}^{-}$ | $\mathrm{Cr}^{3+}+4 \mathrm{OH}^{-} \rightleftarrows \mathrm{Cr}(\mathrm{OH})_{4}^{-}$ | $8 \times 10^{29}$ |

Finally, there is a class of hydroxides, called amphoteric hydroxides, which can react with both acids and bases. Examples are $\mathrm{Al}(\mathrm{OH})_{3}, \mathrm{~Pb}(\mathrm{OH})_{2}, \mathrm{Cr}(\mathrm{OH})_{3}, \mathrm{Zn}(\mathrm{OH})_{2}$, and $\mathrm{Cd}(\mathrm{OH})_{2} \cdot \mathrm{Al}(\mathrm{OH})_{3}$ reacts with acids and bases as follows:

$$
\begin{aligned}
& \mathrm{Al}(\mathrm{OH})_{3}(s)+3 \mathrm{H}^{+}(a q) \longrightarrow \mathrm{Al}^{3+}(a q)+3 \mathrm{H}_{2} \mathrm{O}(l) \\
& \mathrm{Al}(\mathrm{OH})_{3}(s)+\mathrm{OH}^{-}(a q) \rightleftarrows \mathrm{Al}(\mathrm{OH})_{4}^{-}(a q)
\end{aligned}
$$

The increase in solubility of $\mathrm{Al}(\mathrm{OH})_{3}$ in a basic medium is the result of the formation of the complex ion $\mathrm{Al}(\mathrm{OH})_{4}^{-}$in which $\mathrm{Al}(\mathrm{OH})_{3}$ acts as the Lewis acid and $\mathrm{OH}^{-}$acts as the Lewis base. Other amphoteric hydroxides react similarly with acids and bases.

## Checkpoint 17.5 Factors Affecting Solubility

17.5.1 Calculate the molar solubility of AgCl in $0.10 \mathrm{M} \mathrm{CaCl}_{2}$.
a) $1.6 \times 10^{-10} \mathrm{M}$
b) $1.6 \times 10^{-9} \mathrm{M}$
c) $8.0 \times 10^{-10} \mathrm{M}$
d) $1.3 \times 10^{-5} \mathrm{M}$
e) $2.6 \times 10^{-8} \mathrm{M}$
17.5.2 Which of the following substances will be more soluble in acidic solution than in pure water? (Select all that apply.)
a) $\mathrm{PbCO}_{3}$
b) AgS
c) AgI
d) $\mathrm{Fe}(\mathrm{OH})_{3}$
e) $\mathrm{CaF}_{2}$
17.5.3 In which of the solutions would the slightly soluble salt $\mathrm{MC}_{2}$ be most soluble, and in which would it be least soluble? (For clarity, water molecules and counter ions in soluble salts are not shown.)

(a)
(b)

(c)

(d)

### 17.6 Separation of Ions Using Differences in Solubility

In chemical analysis, it sometimes is necessary to remove one type of ion from solution by precipitation while leaving other ions in solution. For instance, the addition of sulfate ions to a solution containing both potassium and barium ions causes $\mathrm{BaSO}_{4}$ to precipitate out, thereby removing most of the $\mathrm{Ba}^{2+}$ ions from the solution. The other "product," $\mathrm{K}_{2} \mathrm{SO}_{4}$, is soluble and will remain in solution. The $\mathrm{BaSO}_{4}$ precipitate can be separated from the solution by filtration.

## Fractional Precipitation

Even when both products are insoluble, we can still achieve some degree of separation by choosing the proper reagent to bring about precipitation. Consider a solution that contains $\mathrm{Cl}^{-}, \mathrm{Br}^{-}$, and $\mathrm{I}^{-}$ions. One way to separate these ions is to convert them to insoluble silver halides. As the $K_{\text {sp }}$ values in the margin show, the solubility of the silver halides decreases from AgCl to AgI. Thus, when a soluble compound such as silver nitrate is slowly added to this solution, AgI begins to precipitate first, followed by AgBr , and then AgCl . This practice is known as fractional precipitation.

Sample Problem 17.13 describes the separation of only two ions $\left(\mathrm{Cl}^{-}\right.$and $\left.\mathrm{Br}^{-}\right)$, but the procedure can be applied to a solution containing more than two different types of ions.

## Sample Problem 17.13

Silver nitrate is added slowly to a solution that is $0.020 \mathrm{M} \mathrm{in}_{\mathrm{Cl}}{ }^{-}$ions and 0.020 M in $\mathrm{Br}^{-}$ions. Calculate the concentration of $\mathrm{Ag}^{+}$ions (in $\mathrm{mol} / \mathrm{L}$ ) required to initiate the precipitation of AgBr without precipitating AgCl .

Strategy Silver nitrate dissociates in solution to give $\mathrm{Ag}^{+}$and $\mathrm{NO}_{3}^{-}$ions. ${\mathrm{Adding} \mathrm{Ag}^{+} \text {ions in }}^{\text {in }}$ sufficient amount will cause the slightly soluble ionic compounds AgCl and AgBr to precipitate from solution. Knowing the $K_{\text {sp }}$ values for AgCl and AgBr (and the concentrations of $\mathrm{Cl}^{-}$and $\mathrm{Br}^{-}$already in solution), we can use the equilibrium expressions to calculate the maximum concentration of $\mathrm{Ag}^{+}$ that can exist in solution without exceeding $K_{\text {sp }}$ for each compound.

Setup The solubility equilibria, $K_{\text {sp }}$ values, and equilibrium expressions for AgCl and AgBr are

$$
\begin{array}{ll}
\mathrm{AgCl}(s) \rightleftarrows \mathrm{Ag}^{+}(a q)+\mathrm{Cl}^{-}(a q) & K_{\text {sp }}=1.6 \times 10^{-10}=\left[\mathrm{Ag}^{+}\right]\left[\mathrm{Cl}^{-}\right] \\
\mathrm{AgBr}(s) \rightleftarrows \mathrm{Ag}^{+}(a q)+\mathrm{Br}^{-}(a q) & K_{\text {sp }}=7.7 \times 10^{-13}=\left[\mathrm{Ag}^{+}\right]\left[\mathrm{Br}^{-}\right]
\end{array}
$$

Because the $K_{\text {sp }}$ for AgBr is smaller (by a factor of more than 200), AgBr should precipitate first; that is, it will require a lower concentration of added $\mathrm{Ag}^{+}$to begin precipitation. Therefore, we first solve for $\left[\mathrm{Ag}^{+}\right]$using the equilibrium expression for AgBr to determine the minimum $\mathrm{Ag}^{+}$concentration necessary to initiate precipitation of AgBr . We then solve for $\left[\mathrm{Ag}^{+}\right]$again, using the equilibrium expression for AgCl to determine the maximum $\mathrm{Ag}^{+}$concentration that can exist in the solution without initiating the precipitation of AgCl .

Solution Solving the AgBr equilibrium expression for $\mathrm{Ag}^{+}$concentration, we have

$$
\left[\mathrm{Ag}^{+}\right]=\frac{K_{\mathrm{sp}}}{\left[\mathrm{Br}^{-}\right]}
$$

and

$$
\left[\mathrm{Ag}^{+}\right]=\frac{7.7 \times 10^{-13}}{0.020}=3.9 \times 10^{-11} \mathrm{M}
$$

For AgBr to precipitate from solution, the silver ion concentration must exceed $3.9 \times 10^{-11} \mathrm{M}$. Solving the AgCl equilibrium expression for the $\mathrm{Ag}^{+}$concentration, we have

$$
\left[\mathrm{Ag}^{+}\right]=\frac{K_{\mathrm{sp}}}{\left[\mathrm{Cl}^{-}\right]}
$$

Think About It If we continue adding $\mathrm{AgNO}_{3}$ until the $\mathrm{Ag}^{+}$ concentration is high enough to begin the precipitation of AgCl , the concentration of $\mathrm{Br}^{-}$ remaining in solution can also be determined using the $K_{\text {sp }}$ expression:

$$
\begin{aligned}
{\left[\mathrm{Br}^{-}\right] } & =\frac{K_{\text {sp }}}{\left[\mathrm{Ag}^{+}\right]}=\frac{7.7 \times 10^{-13}}{8.0 \times 10^{-9}} \\
& =9.6 \times 10^{-5} \mathrm{M}
\end{aligned}
$$

Thus, by the time AgCl begins to precipitate, $\left(9.6 \times 10^{-5} M\right) \div$ $(0.020 M)=0.0048$, so less than 0.5 percent of the original bromide ion remains in the solution.

Student Annotation: Note that these group numbers do not correspond to groups in the periodic table.

Chemical Analysis-flame tests of metals.
and

$$
\left[\mathrm{Ag}^{+}\right]=\frac{1.6 \times 10^{-10}}{0.020}=8.0 \times 10^{-9} \mathrm{M}
$$

For AgCl not to precipitate from solution, the silver ion concentration must stay below $8.0 \times 10^{-9} \mathrm{M}$. Therefore, to precipitate the $\mathrm{Br}^{-}$ions without precipitating the $\mathrm{Cl}^{-}$from this solution, the $\mathrm{Ag}^{+}$ concentration must be greater than $3.9 \times 10^{-11} \mathrm{M}$ and less than $8.0 \times 10^{-9} \mathrm{M}$.

Practice Problem A Lead(II) nitrate is added slowly to a solution that is $0.020 \mathrm{M} \mathrm{in}^{-} \mathrm{Cl}^{-}$ions. Calculate the concentration of $\mathrm{Pb}^{2+}$ ions (in $\mathrm{mol} / \mathrm{L}$ ) required to initiate the precipitation of $\mathrm{PbCl}_{2}$. ( $K_{\text {sp }}$ for $\mathrm{PbCl}_{2}$ is $2.4 \times 10^{-4}$.)

EPPractice Problem B Calculate the concentration of $\mathrm{Ag}^{+}$(in mol/L) necessary to initiate the precipitation of (a) AgCl and (b) $\mathrm{Ag}_{3} \mathrm{PO}_{4}$ from a solution in which $\left[\mathrm{Cl}^{-}\right]$and $\left[\mathrm{PO}_{4}^{3-}\right]$ are each 0.10 M . $\left(K_{\text {sp }}\right.$ for $\mathrm{Ag}_{3} \mathrm{PO}_{4}$ is $1.8 \times 10^{-18}$. $)$

## Qualitative Analysis of Metal Ions in Solution

The principle of selective precipitation can be used to identify the types of ions present in a solution. This practice is called qualitative analysis. There are about 20 common cations that can be analyzed readily in aqueous solution. These cations can be divided into five groups according to the solubility products of their insoluble salts (Table 17.4). Because an unknown solution may contain from 1 to all 20 ions, any analysis must be carried out systematically from group 1 through group 5 . The general procedure for separating these 20 ions is as follows:

- Group 1 cations. When dilute HCl is added to the unknown solution, only the $\mathrm{Ag}^{+}, \mathrm{Hg}_{2}^{2+}$, and $\mathrm{Pb}^{2+}$ ions precipitate as insoluble chlorides. The other ions, whose chlorides are soluble, remain in solution.
- Group 2 cations. After the chloride precipitates have been removed by filtration, hydrogen sulfide is added to the unknown solution, which is acidic due to the addition of HCl . Metal ions from group 2 react to produce metal sulfides:

$$
\mathrm{M}^{2+}(a q)+\mathrm{H}_{2} \mathrm{~S}(a q) \rightleftarrows \mathrm{MS}(s)+2 \mathrm{H}^{+}(a q)
$$

In the presence of $\mathrm{H}^{+}$, this equilibrium shifts to the left. Therefore, only the metal sulfides with the smallest $K_{\text {sp }}$ values precipitate under acidic conditions. These are $\mathrm{Bi}_{2} \mathrm{~S}_{3}, \mathrm{CdS}, \mathrm{CuS}$, and SnS (see Table 17.4). The solution is then filtered to remove the insoluble sulfides.

- Group 3 cations. At this stage, sodium hydroxide is added to the solution to make it basic. In a basic solution, the metal sulfide equilibrium shifts to the right and the more soluble sulfides ( $\mathrm{CoS}, \mathrm{FeS}, \mathrm{MnS}, \mathrm{NiS}, \mathrm{ZnS}$ ) now precipitate out of solution. The $\mathrm{Al}^{3+}$ and $\mathrm{Cr}^{3+}$ ions actually precipitate as the hydroxides $\mathrm{Al}(\mathrm{OH})_{3}$ and $\mathrm{Cr}(\mathrm{OH})_{3}$, rather than as the sulfides, because the hydroxides are less soluble. The solution is filtered again to remove the insoluble sulfides and hydroxides.
- Group 4 cations. After all the group 1, 2, and 3 cations have been removed from solution, sodium carbonate is added to the basic solution to precipitate $\mathrm{Ba}^{2+}, \mathrm{Ca}^{2+}$, and $\mathrm{Sr}^{2+}$ ions as $\mathrm{BaCO}_{3}, \mathrm{CaCO}_{3}$, and $\mathrm{SrCO}_{3}$. These precipitates, too, are removed from solution by filtration.
- Group 5 cations. At this stage, the only cations possibly remaining in solution are $\mathrm{Na}^{+}, \mathrm{K}^{+}$, and $\mathrm{NH}_{4}^{+}$. The presence of $\mathrm{NH}_{4}^{+}$ions can be determined by adding sodium hydroxide:

$$
\mathrm{NaOH}(a q)+\mathrm{NH}_{4}^{+}(a q) \longrightarrow \mathrm{Na}^{+}(a q)+\mathrm{H}_{2} \mathrm{O}(l)+\mathrm{NH}_{3}(g)
$$

The ammonia gas is detected either by its characteristic odor or by observing a wet piece of red litmus paper turning blue when placed above (not in contact with) the solution. To confirm the presence of $\mathrm{Na}^{+}$and $\mathrm{K}^{+}$ions, a flame test is usually used in which a piece of platinum wire (chosen because platinum is inert) is dipped into the original solution and then held over a Bunsen burner flame. $\mathrm{Na}^{+}$ions emit a yellow flame when heated in this manner, whereas $\mathrm{K}^{+}$ions emit a violet flame (Figure 17.11). Figure 17.12 summarizes this scheme for separating metal ions.

## Checkpoint 17.6 $\quad$ Separation of Ions Using Differences in Solubility

17.6.1 A solution is 0.10 M in $\mathrm{Br}^{-}, \mathrm{CO}_{3}^{2-}, \mathrm{Cl}^{-}$, $\mathrm{I}^{-}$, and $\mathrm{SO}_{4}^{2-}$ ions. Which compound will precipitate first as silver nitrate is added to the solution?
a) AgBr
b) $\mathrm{Ag}_{2} \mathrm{CO}_{3}$
c) AgCl
d) AgI
e) $\mathrm{Ag}_{2} \mathrm{SO}_{4}$
17.6.2 Barium nitrate is added slowly to a solution that is 0.10 M in $\mathrm{SO}_{4}^{2-}$ ions and $0.10 M$ in $\mathrm{F}^{-}$ions. Calculate the concentration of $\mathrm{Ba}^{2+}$ ions (in $\mathrm{mol} / \mathrm{L}$ ) required to initiate the precipitation of $\mathrm{BaSO}_{4}$ without precipitating $\mathrm{BaF}_{2}$.
a) $1.7 \times 10^{-6} \mathrm{M}$
b) $1.1 \times 10^{-9} \mathrm{M}$
c) $1.7 \times 10^{-4} \mathrm{M}$
d) $1.7 \times 10^{-5} \mathrm{M}$
e) $1.1 \times 10^{-8} \mathrm{M}$

Figure 17.11 Flame tests for sodium (yellow flame) and potassium (violet flame).

Figure 17.12 A flowchart for the separation of cations in qualitative analysis.

## Applying What You've Learned

Most toothpastes contain fluoride, which helps to reduce tooth decay. The $\mathrm{F}^{-}$ions in toothpaste replace some of the $\mathrm{OH}^{-}$ions during the remineralization process:

$$
5 \mathrm{Ca}^{2+}(a q)+3 \mathrm{PO}_{4}^{3-}(a q)+\mathrm{F}^{-}(a q) \longleftrightarrow \mathrm{Ca}_{5}\left(\mathrm{PO}_{4}\right)_{3} \mathrm{~F}(s)
$$

Because $\mathrm{F}^{-}$is a weaker base than $\mathrm{OH}^{-}$, the modified enamel, called fluoroapatite, is more resistant to the acid produced by bacteria.

## Problems:

a) Calculate the molar solubility of hydroxyapatite given that its $K_{\mathrm{sp}}$ is $2 \times 10^{-59}$. [144 Sample Problem 17.7]
b) Calculate the $K_{\mathrm{sp}}$ of fluoroapatite given that its molar solubility is $7 \times 10^{-8} \mathrm{M}$. [14 Sample Problem 17.8]
c) Calculate the molar solubility of fluoroapatite in an aqueous solution in which the concentration of fluoride ion is 0.10 M . [ Kt Sample Problem 17.10]
d) Calculate the molar solubility of hydroxyapatite in a buffered aqueous solution with $\mathrm{pH}=4.0$. [ kH Sample Problem 17.10]

## Chapter Summary

## Section 17.1

- The presence of a common ion suppresses the ionization of a weak acid or weak base. This is known as the common ion effect.
- A common ion is added to a solution in the form of a salt.

## Section 17.2

- A solution that contains significant concentrations of both members of a conjugate acid-base pair (weak acid-conjugate base or weak base-conjugate acid) is a buffer solution or simply a buffer.
- Buffer solutions resist pH change upon addition of small amounts of strong acid or strong base. Buffers are important to biological systems.
- The pH of a buffer can be calculated using an equilibrium table or with the Henderson-Hasselbalch equation.
- The $\mathrm{p} K_{\mathrm{a}}$ of a weak acid is $-\log K_{\mathrm{a}}$. When the weak acid and conjugate base concentrations in a buffer solution are equal, $\mathrm{pH}=\mathrm{p} K_{\mathrm{a}}$.
- We can prepare a buffer with a specific pH by choosing a weak acid with a $\mathrm{p} K_{\mathrm{a}}$ close to the desired pH .

## Section 17.3

- The titration curve of a strong acid-strong base titration has a long, steep region near the equivalence point.
- Titration curves for weak acid - strong base or weak base-strong acid titrations have a significantly shorter steep region.
- The pH at the equivalence point of a strong acid-strong base titration is 7.00 .
- The pH at the equivalence point of a weak acid-strong base titration is above 7.00.
- The pH at the equivalence point of a weak base - strong acid titration is below 7.00.
- Acid-base indicators are usually weak organic acids that exhibit two different colors depending on the pH of the solution. The endpoint of a titration is the point at which the color of the indicator changes. It is used to estimate the equivalence point of a titration.
- The indicator used for a particular titration should exhibit a color change in the pH range corresponding to the steep region of the titration curve.

## Section 17.4

- The solubility product constant $\left(\boldsymbol{K}_{\mathrm{sp}}\right)$ is the equilibrium constant that indicates to what extent a slightly soluble ionic compound dissociates in water.
- $K_{\text {sp }}$ can be used to determine molar solubility or solubility in $\mathrm{g} / \mathrm{L}$, and vice versa.
- $K_{\text {sp }}$ can also be used to predict whether or not a precipitate will form when two solutions are mixed.

## Section 17.5

- Solubility is affected by common ions, pH , and complex ion formation. The formation constant $\left(\boldsymbol{K}_{\mathbf{f}}\right)$ indicates to what extent complex ions form.
- A salt that dissociates to give a strong conjugate base such as fluoride ion will be more soluble in acidic solution than in pure water.
- A salt that dissociates to give hydroxide ion will be more soluble at lower pH and less soluble at higher pH .
- The solubility of an ionic compound increases when the formation of a complex ion consumes one of the products of dissociation.

## Section 17.6

- Ions can be separated using fractional precipitation.
- Fractional precipitation schemes can be designed based on $K_{\text {sp }}$ values.
- Groups of cations can be identified through the use of selective precipitation. This is the basis of qualitative analysis.

\end{array}
$$

## Questions and Problems

## Section 17.1: The Common Ion Effect

## Review Questions

17.1 Use Le Châtelier's principle to explain how the common ion effect affects the pH of a weak acid solution.
17.2 Describe the effect on pH (increase, decrease, or no change) that results from each of the following additions: (a) potassium acetate to an acetic acid solution, (b) ammonium nitrate to an ammonia solution, (c) sodium formate (HCOONa) to a formic $\operatorname{acid}(\mathrm{HCOOH})$ solution, (d) potassium chloride to a hydrochloric acid solution, (e) barium iodide to a hydroiodic acid solution.
17.3 Define $\mathrm{p} K_{\mathrm{a}}$ for a weak acid. What is the relationship between the value of the $\mathrm{p} K_{\mathrm{a}}$ and the strength of the acid?
17.4 The $\mathrm{p} K_{\mathrm{a}}$ 's of two monoprotic acids HA and HB are 5.9 and 8.1, respectively. Which of the two is the stronger acid?

## Problems

EI17.5 Determine the pH of (a) a $0.40 \mathrm{MCH} \mathrm{CO}_{3} \mathrm{COOH}$ solution and (b) a solution that is 0.40 M CH 33 COOH and 0.20 M CH 33 COONa .

I 17.6 Determine the pH of (a) a $0.20 \mathrm{M} \mathrm{NH}_{3}$ solution, and (b) a solution that is $0.20 \mathrm{M} \mathrm{H}_{3}$ and $0.30 \mathrm{M} \mathrm{H}_{4} \mathrm{Cl}$.

## Section 17.2: Buffer Solutions

## 1 Visualizing Chemistry

Figure 17.1
VC 17.1 Which pair of substances can be dissolved together to prepare a buffer solution?
$\mathrm{CH}_{3} \mathrm{COOH}$
(i)
(ii)
$\mathrm{NaOH} \quad \mathrm{HCl} \quad \mathrm{NaCl}$
a) $\mathrm{i} / \mathrm{ii}$
b) $\mathrm{i} / \mathrm{ii}, \mathrm{i} / \mathrm{iii}, \mathrm{ii} / \mathrm{iv}$
c) $\mathrm{i} / \mathrm{ii}, \mathrm{i} / \mathrm{iii}, \mathrm{ii} / \mathrm{iii}, \mathrm{iv} / \mathrm{v}$

VC 17.2 Consider the buffer shown in Figure 17.1, in which $\left[\mathrm{CH}_{3} \mathrm{COOH}\right]=0.10 \mathrm{M},\left[\mathrm{CH}_{3} \mathrm{COO}^{-}\right]=0.10 \mathrm{M}$, and $\mathrm{pH}=4.74$. How would the pH of the buffer change if we doubled the volume by adding 100 mL of water?
a) The pH would increase.
b) The pH would decrease.
c) The pH would not change.

VC 17.3 Consider a buffer similar to the one shown in Figure 17.1, in which $\left[\mathrm{CH}_{3} \mathrm{COOH}\right]=0.50 \mathrm{M}$ and $\left[\mathrm{CH}_{3} \mathrm{COO}^{-}\right]=0.75 \mathrm{M}$. Which substance can we add more of without causing a drastic change in pH ?
a) HCl
b) NaOH
c) Neither

VC 17.4 According to Figure 17.1, the reaction that occurs when strong acid is added to the buffer is

$$
\mathrm{H}^{+}(a q)+\mathrm{CH}_{3} \mathrm{COO}^{-}(a q) \longrightarrow \mathrm{CH}_{3} \mathrm{COOH}(a q)
$$

Estimate the value of $K$ for this reaction.
a) $1 \times 10^{14}$
b) $6 \times 10^{-10}$
c) $6 \times 10^{4}$

## Review Questions

17.7 What is a buffer solution? What must a solution contain to be a buffer?
17.8 Using only a pH meter, water, and a graduated cylinder, how would you distinguish between an acid solution and a buffer solution at the same pH ?

## Problems

17.9 Which of the following solutions can act as a buffer: (a) $\mathrm{KCl} / \mathrm{HCl}$, (b) $\mathrm{KHSO}_{4} / \mathrm{H}_{2} \mathrm{SO}_{4}$, (c) $\mathrm{Na}_{2} \mathrm{HPO}_{4} / \mathrm{NaH}_{2} \mathrm{PO}_{4}$, (d) $\mathrm{KNO}_{2} / \mathrm{HNO}_{2}$ ?

E17.10 Which of the following solutions can act as a buffer:
(a) $\mathrm{KCN} / \mathrm{HCN}$, (b) $\mathrm{Na}_{2} \mathrm{SO}_{4} / \mathrm{NaHSO}_{4}$, (c) $\mathrm{NH}_{3} / \mathrm{NH}_{4} \mathrm{NO}_{3}$,
(d) $\mathrm{NaI} / \mathrm{HI}$ ?

EI 17.11 Calculate the pH of the buffer system made up of $0.15 \mathrm{M} \mathrm{H}_{3} / 0.35 \mathrm{M} \mathrm{NH}_{4} \mathrm{Cl}$.

E17.12 Calculate the pH of the following two buffer solutions: (a) 2.0 M $\mathrm{CH}_{3} \mathrm{COONa} / 2.0 \mathrm{M} \mathrm{CH} 3 \mathrm{COOH}$, (b) $0.20 \mathrm{M} \mathrm{CH}_{3} \mathrm{COONa} / 0.20 \mathrm{M}$ $\mathrm{CH}_{3} \mathrm{COOH}$. Which is the more effective buffer? Why?
17.13 The pH of a bicarbonate-carbonic acid buffer is 8.00. Calculate the ratio of the concentration of carbonic acid $\left(\mathrm{H}_{2} \mathrm{CO}_{3}\right)$ to that of the bicarbonate ion $\left(\mathrm{HCO}_{3}^{-}\right)$.

E 17.14 What is the pH of the buffer $0.10 M \mathrm{Na}_{2} \mathrm{HPO}_{4} / 0.15 M \mathrm{KH}_{2} \mathrm{PO}_{4}$ ?
$\boldsymbol{\Psi 1 7 . 1 5}$ The pH of a sodium acetate-acetic acid buffer is 4.50. Calculate the ratio $\left[\mathrm{CH}_{3} \mathrm{COO}^{-}\right] /\left[\mathrm{CH}_{3} \mathrm{COOH}\right]$.
17.16 The pH of blood plasma is 7.40 . Assuming the principal buffer system is $\mathrm{HCO}_{3}^{-} / \mathrm{H}_{2} \mathrm{CO}_{3}$, calculate the ratio $\left[\mathrm{HCO}_{3}^{-}\right] /\left[\mathrm{H}_{2} \mathrm{CO}_{3}\right]$. Is this buffer more effective against an added acid or an added base?
17.17 Calculate the pH of the $0.20 M \mathrm{NH}_{3} / 0.20 M \mathrm{NH}_{4} \mathrm{Cl}$ buffer. What is the pH of the buffer after the addition of 10.0 mL of 0.10 M HCl to 65.0 mL of the buffer?

G17.18 Calculate the pH of 1.00 L of the buffer $1.00 \mathrm{M} \mathrm{CH}_{3} \mathrm{COONa} / 1.00 \mathrm{M}$ $\mathrm{CH}_{3} \mathrm{COOH}$ before and after the addition of (a) 0.080 mol NaOH and (b) 0.12 mol HCl . (Assume that there is no change in volume.)
17.19 A diprotic acid, $\mathrm{H}_{2} \mathrm{~A}$, has the following ionization constants: $K_{\mathrm{a}_{1}}=1.1 \times 10^{-3}$ and $K_{\mathrm{a}_{2}}=2.5 \times 10^{-6}$. To make up a buffer solution of pH 5.80 , which combination would you choose: $\mathrm{NaHA} / \mathrm{H}_{2} \mathrm{~A}$ or $\mathrm{Na}_{2} \mathrm{~A} / \mathrm{NaHA}$ ?
17.20 A student is asked to prepare a buffer solution at pH 8.60 , using one of the following weak acids: HA $\left(K_{\mathrm{a}}=2.7 \times 10^{-3}\right)$, HB $\left(K_{\mathrm{a}}=4.4 \times 10^{-6}\right), \mathrm{HC}\left(K_{\mathrm{a}}=2.6 \times 10^{-9}\right)$. Which acid should the student choose? Why?
E17.21 The following diagrams contain one or more of the compounds: $\mathrm{H}_{2} \mathrm{~A}$, NaHA, and $\mathrm{Na}_{2} \mathrm{~A}$, where $\mathrm{H}_{2} \mathrm{~A}$ is a weak diprotic acid.
(1) Which of the solutions can act as buffer solutions? (2) Which solution is the most effective buffer solution? Water molecules and $\mathrm{Na}^{+}$ions have been omitted for clarity.

(a)

(b)
$O=\mathrm{A}^{2-}$

(c)

(d)

EI 17.22 The following diagrams represent solutions containing a weak acid HA $\left(\mathrm{p} K_{\mathrm{a}}=5.0\right)$ and its sodium salt NaA . (1) Which solution has the lowest pH ? Which has the highest pH ? (2) How many different species are present after the addition of two $\mathrm{H}^{+}$ions to solution (a)? (3) How many different species are present after the addition of two $\mathrm{OH}^{-}$ions to solution (b)?

$$
O=\mathrm{HA} \quad O=\mathrm{A}^{-}
$$

## Section 17.3: Acid-Base Titrations

## Review Questions

17.23 Briefly describe what happens in an acid-base titration.
17.24 Sketch titration curves for the following acid-base titrations: (a) HCl versus NaOH , (b) HCl versus $\mathrm{CH}_{3} \mathrm{NH}_{2}$, (c) $\mathrm{CH}_{3} \mathrm{COOH}$ versus NaOH . In each case, the base is added to the acid in an Erlenmeyer flask. Your graphs should show the pH on the $y$ axis and the volume of base added on the $x$ axis.
17.25 Explain how an acid-base indicator works in a titration. What are the criteria for choosing an indicator for a particular acid-base titration?
17.26 The amount of indicator used in an acid-base titration must be small. Why?

## Problems

$\boldsymbol{H}$ 17.27 A 0.2688 -g sample of a monoprotic acid neutralizes 16.4 mL of 0.08133 M KOH solution. Calculate the molar mass of the acid.

E17.28 A 5.00-g quantity of a diprotic acid was dissolved in water and made up to exactly 250 mL . Calculate the molar mass of the acid if 25.0 mL of this solution required 11.1 mL of 1.00 M KOH for neutralization. Assume that both protons of the acid were titrated.

G17.29 In a titration experiment, 12.5 mL of $0.500 \mathrm{M} \mathrm{H}_{2} \mathrm{SO}_{4}$ neutralizes 50.0 mL of NaOH . What is the concentration of the NaOH solution?

G17.30 In a titration experiment, 20.4 mL of 0.883 MHCOOH neutralizes 19.3 mL of $\mathrm{Ba}(\mathrm{OH})_{2}$. What is the concentration of the $\mathrm{Ba}(\mathrm{OH})_{2}$ solution?
17.31 A $0.1276-\mathrm{g}$ sample of an unknown monoprotic acid was dissolved in 25.0 mL of water and titrated with a 0.0633 M NaOH solution. The volume of base required to bring the solution to the equivalence point was 18.4 mL . (a) Calculate the molar mass of the acid. (b) After 10.0 mL of base had been added during the titration, the pH was determined to be 5.87 . What is the $K_{\mathrm{a}}$ of the unknown acid?

G17.32 A solution is made by mixing exactly 500 mL of 0.167 M NaOH with exactly 500 mL of $0.100 \mathrm{M} \mathrm{CH}_{3} \mathrm{COOH}$. Calculate the equilibrium concentrations of $\mathrm{H}^{+}, \mathrm{CH}_{3} \mathrm{COOH}, \mathrm{CH}_{3} \mathrm{COO}^{-}, \mathrm{OH}^{-}$, and $\mathrm{Na}^{+}$.
17.33 Calculate the pH at the equivalence point for the following titration: 0.20 M HCl versus 0.20 M methylamine $\left(\mathrm{CH}_{3} \mathrm{NH}_{2}\right)$.
17.34 Calculate the pH at the equivalence point for the following titration: 0.10 MHCOOH versus 0.10 M NaOH .

H17.35 A $25.0-\mathrm{mL}$ solution of $0.100 \mathrm{M} \mathrm{CH}_{3} \mathrm{COOH}$ is titrated with a 0.200 M KOH solution. Calculate the pH after the following additions of the KOH solution: (a) 0.0 mL , (b) 5.0 mL , (c) 10.0 mL , (d) 12.5 mL , (e) 15.0 mL .

E17.36 A $10.0-\mathrm{mL}$ solution of $0.300 \mathrm{M} \mathrm{NH}_{3}$ is titrated with a 0.100 M HCl solution. Calculate the pH after the following additions of the HCl solution: (a) 0.0 mL , (b) 10.0 mL , (c) 20.0 mL , (d) 30.0 mL , (e) 40.0 mL .
17.37 Referring to Table 17.3, specify which indicator or indicators you would use for the following titrations: (a) HCOOH versus NaOH , (b) HCl versus KOH , (c) $\mathrm{HNO}_{3}$ versus $\mathrm{CH}_{3} \mathrm{NH}_{2}$.
17.38 A student carried out an acid-base titration by adding NaOH solution from a burette to an Erlenmeyer flask containing an HCl solution and using phenolphthalein as the indicator. At the equivalence point, she observed a faint reddish-pink color. However, after a few minutes, the solution gradually turned colorless. What do you suppose happened?
17.39 The ionization constant $K_{\mathrm{a}}$ of an indicator HIn is $1.0 \times 10^{-6}$. The color of the nonionized form is red and that of the ionized form is yellow. What is the color of this indicator in a solution whose pH is 4.00 ?
© 17.40 The $K_{\mathrm{a}}$ of a certain indicator is $2.0 \times 10^{-6}$. The color of HIn is green and that of $\mathrm{In}^{-}$is red. A few drops of the indicator are added to an HCl solution, which is then titrated against an NaOH solution. At what pH will the indicator change color?
17.41 The following diagrams represent solutions at various stages in the titration of a weak base B (such as $\mathrm{NH}_{3}$ ) with HCl . Identify the solution that corresponds to (1) the initial stage before the addition of HCl , (2) halfway to the equivalence point, (3) the equivalence point, (4) beyond the equivalence point. Is the pH greater than, less than, or equal to 7 at the equivalence point? Water and $\mathrm{Cl}^{-}$ ions have been omitted for clarity.

(a)

(b)

(c)

(d)

E17.42 The following diagrams represent solutions at various stages in the titration of a weak acid HA with NaOH . Identify the solution that corresponds to (1) the initial stage before the addition of NaOH , (2) halfway to the equivalence point, (3) the equivalence point, (4) beyond the equivalence point. Is the pH greater than, less than, or equal to 7 at the equivalence point? Water and $\mathrm{Na}^{+}$ ions have been omitted for clarity.

## Section 17.4: Solubility Equilibria

## Review Questions

17.43 Use $\mathrm{BaSO}_{4}$ to distinguish between the terms solubility and solubility product.
17.44 Why do we usually not quote the $K_{\text {sp }}$ values for soluble ionic compounds?
17.45 Write balanced equations and solubility product expressions for the solubility equilibria of the following compounds: (a) CuBr , (b) $\mathrm{ZnC}_{2} \mathrm{O}_{4}$, (c) $\mathrm{Ag}_{2} \mathrm{CrO}_{4}$, (d) $\mathrm{Hg}_{2} \mathrm{Cl}_{2}$, (e) $\mathrm{AuCl}_{3}$, (f) $\mathrm{Mn}_{3}\left(\mathrm{PO}_{4}\right)_{2}$.
17.46 Write the solubility product expression for the ionic compound $\mathrm{A}_{x} \mathrm{~B}_{y}$.
17.47 How can we predict whether a precipitate will form when two solutions are mixed?
17.48 Silver chloride has a larger $K_{\text {sp }}$ than silver carbonate (see Table 17.4). Does this mean that AgCl also has a larger molar solubility than $\mathrm{Ag}_{2} \mathrm{CO}_{3}$ ?

## Problems

I17.49 Calculate the concentration of ions in the following saturated solutions: (a) $\left[\mathrm{I}^{-}\right]$in AgI solution with $\left[\mathrm{Ag}^{+}\right]=9.1 \times 10^{-9} \mathrm{M}$, (b) $\left[\mathrm{Al}^{3+}\right]$ in $\mathrm{Al}(\mathrm{OH})_{3}$ solution with $\left[\mathrm{OH}^{-}\right]=2.9 \times 10^{-9} \mathrm{M}$.
$\leftrightarrows 17.50$ From the solubility data given, calculate the solubility products for the following compounds: (a) $\mathrm{SrF}_{2}, 7.3 \times 10^{-2} \mathrm{~g} / \mathrm{L}$, (b) $\mathrm{Ag}_{3} \mathrm{PO}_{4}, 6.7 \times 10^{-3} \mathrm{~g} / \mathrm{L}$.

El17.51 The molar solubility of $\mathrm{MnCO}_{3}$ is $4.2 \times 10^{-6} M$. What is $K_{\text {sp }}$ for this compound?
17.52 The solubility of an ionic compound MX (molar mass $=346 \mathrm{~g}$ ) is $4.63 \times 10^{-3} \mathrm{~g} / \mathrm{L}$. What is $K_{\text {sp }}$ for this compound?
17.53 The solubility of an ionic compound $\mathrm{M}_{2} \mathrm{X}_{3}$ (molar mass $=288 \mathrm{~g}$ ) is $3.6 \times 10^{-17} \mathrm{~g} / \mathrm{L}$. What is $K_{\text {sp }}$ for this compound?
17.54 Using data from Table 17.4 , calculate the molar solubility of $\mathrm{CaF}_{2}$.
17.55 What is the pH of a saturated zinc hydroxide solution?

E17.56 The pH of a saturated solution of a metal hydroxide MOH is 9.68 . Calculate the $K_{\text {sp }}$ for this compound.
17.57 If 20.0 mL of $0.10 \mathrm{M} \mathrm{Ba}\left(\mathrm{NO}_{3}\right)_{2}$ is added to 50.0 mL of 0.10 M $\mathrm{Na}_{2} \mathrm{CO}_{3}$, will $\mathrm{BaCO}_{3}$ precipitate?
17.58 A volume of 75 mL of 0.060 M NaF is mixed with 25 mL of $0.15 M \operatorname{Sr}\left(\mathrm{NO}_{3}\right)_{2}$. Calculate the concentrations in the final solution of $\mathrm{NO}_{3}^{-}, \mathrm{Na}^{+}, \mathrm{Sr}^{2+}$, and $\mathrm{F}^{-}$. $\left(K_{\text {sp }}\right.$ for $\mathrm{SrF}_{2}=2.0 \times 10^{-10}$.)

## Section 17.5: Factors Affecting Solubility

## Visualizing Chemistry

Figure 17.8
VC 17.5 Which of the following would cause precipitation of the largest amount of AgCl when 0.1 mole is dissolved in the saturated solution shown in Figure 17.8?
a) NaCl
b) CsCl
c) Both would cause precipitation of the same amount.

VC 17.6 Which of the following would cause precipitation of the largest amount of AgCl when 0.1 g is dissolved in the saturated solution shown in Figure 17.8?
a) NaCl
b) CsCl
c) Both would cause precipitation of the same amount.

VC 17.7 How would the concentration of silver ion in the last view of Figure 17.8 be different if we dissolved the sodium chloride before dissolving the silver chloride?
a) It would be higher.
b) It would be lower.
c) It would not change.

VC 17.8 How would the concentration of silver ion in the last view of Figure 17.8 be different if we added silver nitrate to the saturated solution of AgCl instead of sodium chloride?
a) It would be higher.
b) It would be lower.
c) It would not change.

## Review Questions

17.59 How does the common ion effect influence solubility equilibria? Use Le Châtelier's principle to explain the decrease in solubility of $\mathrm{CaCO}_{3}$ in an $\mathrm{Na}_{2} \mathrm{CO}_{3}$ solution.
17.60 The molar solubility of AgCl in $6.5 \times 10^{-3} M \mathrm{AgNO}_{3}$ is $2.5 \times$ $10^{-8} \mathrm{M}$. In deriving $K_{\text {sp }}$ from these data, which of the following assumptions are reasonable? (a) $K_{\mathrm{sp}}$ is the same as solubility. (b) $K_{\text {sp }}$ of AgCl is the same in $6.5 \times 10^{-3} \mathrm{M} \mathrm{AgNO} 3$ as in pure water. (c) Solubility of AgCl is independent of the concentration of $\mathrm{AgNO}_{3}$. (d) $\left[\mathrm{Ag}^{+}\right]$in solution does not change significantly upon the addition of AgCl to $6.5 \times 10^{-3} M \mathrm{AgNO}_{3}$. (e) $\left[\mathrm{Ag}^{+}\right]$in solution after the addition of AgCl to $6.5 \times 10^{-3} M \mathrm{AgNO}_{3}$ is the same as it would be in pure water.
17.61 Give an example to illustrate the general effect of complex ion formation on solubility.

## Problems

E 17.62 How many grams of $\mathrm{CaCO}_{3}$ will dissolve in $3.0 \times 10^{2} \mathrm{~mL}$ of $0.050 \mathrm{M} \mathrm{Ca}\left(\mathrm{NO}_{3}\right)_{2}$ ?
17.63 The solubility product of $\mathrm{PbBr}_{2}$ is $8.9 \times 10^{-6}$. Determine the molar solubility in (a) pure water, (b) 0.20 M KBr solution, and (c) $0.20 M \mathrm{~Pb}\left(\mathrm{NO}_{3}\right)_{2}$ solution.

E17.64 Calculate the molar solubility of AgCl in a $1.00-\mathrm{L}$ solution containing 10.0 g of dissolved $\mathrm{CaCl}_{2}$.
17.65 Calculate the molar solubility of $\mathrm{BaSO}_{4}$ in (a) water and (b) a solution containing $1.0 \mathrm{M} \mathrm{SO}_{4}^{2-}$ ions.
17.66 Which of the following ionic compounds will be more soluble in acid solution than in water: (a) $\mathrm{BaSO}_{4}$, (b) $\mathrm{PbCl}_{2}$, (c) $\mathrm{Fe}(\mathrm{OH})_{3}$, (d) $\mathrm{CaCO}_{3}$ ?
17.67 Which of the following will be more soluble in acid solution than in pure water: (a) CuI , (b) $\mathrm{Ag}_{2} \mathrm{SO}_{4}$, (c) $\mathrm{Zn}(\mathrm{OH})_{2}$, (d) $\mathrm{BaC}_{2} \mathrm{O}_{4}$, (e) $\mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}$ ?

H17.68 Compare the molar solubility of $\mathrm{Mg}(\mathrm{OH})_{2}$ in water and in a solution buffered at a pH of 9.0 .
17.69 Calculate the molar solubility of $\mathrm{Fe}(\mathrm{OH})_{2}$ in a solution buffered at (a) a pH of 8.00 and (b) a pH of 10.00 .

El 17.70 The solubility product of $\mathrm{Mg}(\mathrm{OH})_{2}$ is $1.2 \times 10^{-11}$. What minimum $\mathrm{OH}^{-}$concentration must be attained (for example, by adding NaOH ) to decrease the Mg concentration in a solution of $\mathrm{Mg}\left(\mathrm{NO}_{3}\right)_{2}$ to less than $1.0 \times 10^{-10} M$ ?
17.71 Calculate whether or not a precipitate will form if 2.00 mL of $0.60 \mathrm{MHH}_{3}$ is added to 1.0 L of $1.0 \times 10^{-3} M \mathrm{FeSO}_{4}$.

G17.72 If 2.50 g of $\mathrm{CuSO}_{4}$ is dissolved in $9.0 \times 10^{2} \mathrm{~mL}$ of $0.30 \mathrm{M} \mathrm{H}_{3}$, what are the concentrations of $\mathrm{Cu}^{2+}, \mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}^{2+}$, and $\mathrm{NH}_{3}$ at equilibrium?
17.73 Calculate the concentrations of $\mathrm{Cd}^{2+}, \mathrm{Cd}(\mathrm{CN})_{4}^{2-}$, and $\mathrm{CN}^{-}$at equilibrium when 0.50 g of $\mathrm{Cd}\left(\mathrm{NO}_{3}\right)_{2}$ dissolves in $5.0 \times 10^{2} \mathrm{~mL}$ of 0.50 M NaCN .
17.74 If NaOH is added to $0.010 \mathrm{M} \mathrm{Al}^{3+}$, which will be the predominant species at equilibrium: $\mathrm{Al}(\mathrm{OH})_{3}$ or $\mathrm{Al}(\mathrm{OH})_{4}^{-}$? The pH of the solution is 14.00. [ $K_{\mathrm{f}}$ for $\mathrm{Al}(\mathrm{OH})_{4}^{-}=2.0 \times 10^{33}$.]
17.75 Calculate the molar solubility of AgI in a $1.0 \mathrm{M} \mathrm{H}_{3}$ solution.
17.76 Both $\mathrm{Ag}^{+}$and $\mathrm{Zn}^{2+}$ form complex ions with $\mathrm{NH}_{3}$. Write balanced equations for the reactions. However, $\mathrm{Zn}(\mathrm{OH})_{2}$ is soluble in 6 M NaOH , and AgOH is not. Explain.
17.77 Explain, with balanced ionic equations, why (a) $\mathrm{CuI}_{2}$ dissolves in ammonia solution, (b) AgBr dissolves in NaCN solution, and (c) $\mathrm{HgCl}_{2}$ dissolves in KCl solution.

## Section 17.6: Separation of lons Using Differences in Solubility

## Review Questions

17.78 Outline the general procedure of qualitative analysis.
17.79 Give two examples of metal ions in each group (1 through 5) in the qualitative analysis scheme.

## Problems

17.80 Solid NaI is slowly added to a solution that is 0.010 M in $\mathrm{Cu}^{+}$and 0.010 M in $\mathrm{Ag}^{+}$. (a) Which compound will begin to precipitate first? (b) Calculate $\left[\mathrm{Ag}^{+}\right]$when CuI just begins to precipitate. (c) What percent of $\mathrm{Ag}^{+}$remains in solution at this point?
17.81 Find the approximate pH range suitable for the separation of $\mathrm{Fe}^{3+}$ and $\mathrm{Zn}^{2+}$ ions by precipitation of $\mathrm{Fe}(\mathrm{OH})_{3}$ from a solution that is initially $0.010 M$ in both $\mathrm{Fe}^{3+}$ and $\mathrm{Zn}^{2+}$.
©17.82 In a group 1 analysis, a student obtained a precipitate containing both AgCl and $\mathrm{PbCl}_{2}$. Suggest one reagent that would enable the student to separate $\mathrm{AgCl}(s)$ from $\mathrm{PbCl}_{2}(s)$.

H17.83 In a group 1 analysis, a student adds HCl acid to the unknown solution to make $\left[\mathrm{Cl}^{-}\right]=0.15 \mathrm{M}$. Some $\mathrm{PbCl}_{2}$ precipitates. Calculate the concentration of $\mathrm{Pb}^{2+}$ remaining in solution.
17.84 Both KCl and $\mathrm{NH}_{4} \mathrm{Cl}$ are white solids. Suggest one reagent that would enable you to distinguish between these two compounds.
17.85 Describe a simple test that would allow you to distinguish between $\mathrm{AgNO}_{3}(s)$ and $\mathrm{Cu}\left(\mathrm{NO}_{3}\right)_{2}(s)$.

## Additional Problems

17.86 The buffer range is defined by the equation $\mathrm{pH}=\mathrm{p} K_{\mathrm{a}} \pm 1$. Calculate the range of the ratio [conjugate base]/[acid] that corresponds to this equation.
17.87 The $\mathrm{p} K_{\mathrm{a}}$ of the indicator methyl orange is 3.46 . Over what pH range does this indicator change from 90 percent HIn to 90 percent $\mathrm{In}^{-}$?
17.88 Sketch the titration curve of a weak acid with a strong base like the one shown in Figure 17.4. On your graph, indicate the volume of base used at the equivalence point and also at the half-equivalence point, that is, the point at which half of the acid has been neutralized. Explain how the measured pH at the half-equivalence point can be used to determine $K_{\mathrm{a}}$ of the acid.
17.89 A 200-mL volume of NaOH solution was added to 400 mL of a $2.00 \mathrm{M} \mathrm{HNO}_{2}$ solution. The pH of the mixed solution was 1.50 units greater than that of the original acid solution. Calculate the molarity of the NaOH solution.
$\leftrightarrows 17.90$ The $\mathrm{p} K_{\mathrm{a}}$ of butyric acid (HBut) is 4.7. Calculate $K_{\mathrm{b}}$ for the butyrate ion (But ${ }^{-}$).
-17.91 A solution is made by mixing exactly 500 mL of 0.167 M NaOH with exactly 500 mL 0.100 MHCOOH . Calculate the equilibrium concentrations of $\mathrm{H}^{+}, \mathrm{HCOOH}, \mathrm{HCOO}^{-}, \mathrm{OH}^{-}$, and $\mathrm{Na}^{+}$.

El 17.92 Tris [tris(hydroxymethyl)aminomethane] is a common buffer for studying biological systems: (a) Calculate the pH of the tris buffer after mixing 15.0 mL of 0.10 M HCl solution with 25.0 mL of $0.10 M$ tris. (b) This buffer was used to study an enzyme-catalyzed reaction. As a result of the reaction, 0.00015 mole of $\mathrm{H}^{+}$was consumed. What is the pH of the buffer at the end of the reaction? (c) What would be the final pH if no buffer were present?

17.93 $\mathrm{Cd}(\mathrm{OH})_{2}$ is an insoluble compound. It dissolves in excess NaOH in solution. Write a balanced ionic equation for this reaction. What type of reaction is this?

E17.94 A student mixes 50.0 mL of $1.00 \mathrm{MBa}(\mathrm{OH})_{2}$ with 86.4 mL of $0.494 \mathrm{M} \mathrm{H}_{2} \mathrm{SO}_{4}$. Calculate the mass of $\mathrm{BaSO}_{4}$ formed and the pH of the mixed solution.
17.95 For which of the following reactions is the equilibrium constant called a solubility product?
(a) $\mathrm{Zn}(\mathrm{OH})_{2}(s)+2 \mathrm{OH}^{-}(a q) \rightleftarrows \mathrm{Zn}(\mathrm{OH})_{4}^{2-}(a q)$
(b) $3 \mathrm{Ca}^{2+}(a q)+2 \mathrm{PO}_{4}^{3-}(a q) \rightleftarrows \mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}(s)$
(c) $\mathrm{CaCO}_{3}(s)+2 \mathrm{H}^{+}(a q) \rightleftarrows \mathrm{Ca}^{2+}(a q)+\mathrm{H}_{2} \mathrm{O}(l)+\mathrm{CO}_{2}(g)$
(d) $\mathrm{PbI}_{2}(s) \rightleftarrows \mathrm{Pb}^{2+}(a q)+2 \mathrm{I}^{-}(a q)$
17.96 A 2.0-L kettle contains 116 g of boiler scale $\left(\mathrm{CaCO}_{3}\right)$. How many times would the kettle have to be completely filled with distilled water to remove all the deposit at $25^{\circ} \mathrm{C}$ ?

H17.97 Equal volumes of $0.12 M \mathrm{AgNO}_{3}$ and $0.14 \mathrm{M}_{\mathrm{ZnCl}}^{2}$ solution are mixed. Calculate the equilibrium concentrations of $\mathrm{Ag}^{+}, \mathrm{Cl}^{-}$, $\mathrm{Zn}^{2+}$, and $\mathrm{NO}_{3}^{-}$.
17.98 Find the approximate pH range suitable for separating $\mathrm{Mg}^{2+}$ and $\mathrm{Zn}^{2+}$ by the precipitation of $\mathrm{Zn}(\mathrm{OH})_{2}$ from a solution that is initially 0.010 M in $\mathrm{Mg}^{2+}$ and $\mathrm{Zn}^{2+}$.

E17.99 Calculate the solubility (in $\mathrm{g} / \mathrm{L}$ ) of $\mathrm{Ag}_{2} \mathrm{CO}_{3}$.
17.100 A volume of 25.0 mL of 0.100 M HCl is titrated against a $0.100 \mathrm{M} \mathrm{CH}_{3} \mathrm{NH}_{2}$ solution added to it from a burette. Calculate the pH values of the solution after (a) 10.0 mL of $\mathrm{CH}_{3} \mathrm{NH}_{2}$ solution has been added, (b) 25.0 mL of $\mathrm{CH}_{3} \mathrm{NH}_{2}$ solution has been added, (c) 35.0 mL of $\mathrm{CH}_{3} \mathrm{NH}_{2}$ solution has been added.
17.101 The molar solubility of $\mathrm{Pb}\left(\mathrm{IO}_{3}\right)_{2}$ in a $0.10 \mathrm{M} \mathrm{NaIO}_{3}$ solution is $2.4 \times 10^{-11} \mathrm{~mol} / \mathrm{L}$. What is $K_{\text {sp }}$ for $\mathrm{Pb}\left(\mathrm{IO}_{3}\right)_{2}$ ?
17.102 When a KI solution was added to a solution of mercury(II) chloride, a precipitate [mercury(II) iodide] formed. A student plotted the mass of the precipitate versus the volume of the KI solution added and obtained the following graph. Explain the shape of the graph.

17.103 Barium is a toxic substance that can seriously impair heart function. For an X ray of the gastrointestinal tract, a patient drinks an aqueous suspension of $20 \mathrm{~g} \mathrm{BaSO}_{4}$. If this substance were to equilibrate with the 5.0 L of the blood in the patient's body, what would be $\left[\mathrm{Ba}^{2+}\right]$ ? For a good estimate, we may assume that the $K_{\text {sp }}$ of $\mathrm{BaSO}_{4}$ at body temperature is the same as at $25^{\circ} \mathrm{C}$. Why is $\mathrm{Ba}\left(\mathrm{NO}_{3}\right)_{2}$ not chosen for this procedure?
17.104 The $\mathrm{p} K_{\mathrm{a}}$ of phenolphthalein is 9.10 . Over what pH range does this indicator change from 95 percent HIn to 95 percent $\mathrm{In}^{-}$?

E17.105 Solid NaBr is slowly added to a solution that is 0.010 M in $\mathrm{Cu}^{+}$ and 0.010 M in $\mathrm{Ag}^{+}$. (a) Which compound will begin to precipitate first? (b) Calculate $\left[\mathrm{Ag}^{+}\right]$when CuBr just begins to precipitate. (c) What percent of $\mathrm{Ag}^{+}$remains in solution at this point?

I 17.106 Cacodylic acid is $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{AsO}_{2} \mathrm{H}$. Its ionization constant is $6.4 \times$ $10^{-7}$. (a) Calculate the pH of 50.0 mL of a 0.10 M solution of the acid. (b) Calculate the pH of 25.0 mL of $0.15 \mathrm{M}\left(\mathrm{CH}_{3}\right)_{2} \mathrm{AsO}_{2} \mathrm{Na}$. (c) Mix the solutions in parts (a) and (b). Calculate the pH of the resulting solution.

E17.107 Radiochemical techniques are useful in estimating the solubility product of many compounds. In one experiment, 50.0 mL of a $0.010 \mathrm{M} \mathrm{AgNO}_{3}$ solution containing a silver isotope with a radioactivity of 74,025 counts per min per mL was mixed with 100 mL of a $0.030 \mathrm{M} \mathrm{NaIO}_{3}$ solution. The mixed solution was diluted to 500 mL and filtered to remove all the $\mathrm{AgIO}_{3}$ precipitate. The remaining solution was found to have a radioactivity of 44.4 counts per min per mL. What is the $K_{\text {sp }}$ of $\mathrm{AgIO}_{3}$ ?
17.108 The molar mass of a certain metal carbonate, $\mathrm{MCO}_{3}$, can be determined by adding an excess of HCl acid to react with all the carbonate and then "back-titrating" the remaining acid with NaOH . (a) Write an equation for these reactions. (b) In a certain experiment, 20.00 mL of 0.0800 M HCl was added to a $0.1022-\mathrm{g}$ sample of $\mathrm{MCO}_{3}$. The excess HCl required 5.64 mL of 0.1000 M NaOH for neutralization. Calculate the molar mass of the carbonate and identify M.
17.109 Acid-base reactions usually go to completion. Confirm this statement by calculating the equilibrium constant for each of the following cases: (a) A strong acid reacting with a strong base. (b) A strong acid reacting with a weak base $\left(\mathrm{NH}_{3}\right)$. (c) A weak acid $\left(\mathrm{CH}_{3} \mathrm{COOH}\right)$ reacting with a strong base. (d) A weak acid $\left(\mathrm{CH}_{3} \mathrm{COOH}\right)$ reacting with a weak base $\left(\mathrm{NH}_{3}\right)$. (Hint: Strong acids exist as $\mathrm{H}^{+}$ions and strong bases exist as $\mathrm{OH}^{-}$ions in solution. You need to look up $K_{\mathrm{a}}, K_{\mathrm{b}}$, and $K_{\mathrm{w}}$.)
17.110 Calculate $x$, the number of molecules of water in oxalic acid hydrate $\left(\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4} \cdot x \mathrm{H}_{2} \mathrm{O}\right)$, from the following data: 5.00 g of the compound is made up to exactly 250 mL solution, and 25.0 mL of this solution requires 15.9 mL of 0.500 M NaOH solution for neutralization.
17.111 Describe how you would prepare a 1-L $0.20 \mathrm{MCH}_{3} \mathrm{COONa} / 0.20 \mathrm{M}$ $\mathrm{CH}_{3} \mathrm{COOH}$ buffer system by (a) mixing a solution of $\mathrm{CH}_{3} \mathrm{COOH}$ with a solution of $\mathrm{CH}_{3} \mathrm{COONa}$, (b) mixing a solution of $\mathrm{CH}_{3} \mathrm{COOH}$ with a solution of NaOH , and (c) mixing a solution of $\mathrm{CH}_{3} \mathrm{COONa}$ with a solution of HCl .
17.112 Phenolphthalein is the common indicator for the titration of a strong acid with a strong base. (a) If the $\mathrm{p} K_{\mathrm{a}}$ of phenolphthalein is 9.10 , what is the ratio of the nonionized form of the indicator (colorless) to the ionized form (reddish pink) at pH 8.00 ?
(b) If 2 drops of $0.060 M$ phenolphthalein are used in a titration involving a $50.0-\mathrm{mL}$ volume, what is the concentration of the ionized form at pH 8.00 ? (Assume that 1 drop $=0.050 \mathrm{~mL}$.)
17.113 Of the reactions depicted, which best represents (a) what occurs when strong acid is added to a buffer solution, and (b) what occurs when strong base is added to a buffer solution?

17.114 Oil paintings containing lead(II) compounds as constituents of their pigments darken over the years. Suggest a chemical reason for the color change.
17.115 What reagents would you employ to separate the following pairs of ions in solution: (a) $\mathrm{Na}^{+}$and $\mathrm{Ba}^{2+}$, (b) $\mathrm{K}^{+}$and $\mathrm{Pb}^{2+}$, (c) $\mathrm{Zn}^{2+}$ and $\mathrm{Hg}^{2+}$ ?
17.116 Look up the $K_{\text {sp }}$ values for $\mathrm{BaSO}_{4}$ and $\mathrm{SrSO}_{4}$ in Table 17.4. Calculate the concentrations of $\mathrm{Ba}^{2+}, \mathrm{Sr}^{2+}$, and $\mathrm{SO}_{4}^{2-}$ in a solution that is saturated with both compounds.
17.117 In principle, amphoteric oxides, such as $\mathrm{Al}_{2} \mathrm{O}_{3}$ and BeO can be used to prepare buffer solutions because they possess both acidic and basic properties (see Section 16.11). Explain why these compounds are of little practical use as buffer components.
$17.118 \mathrm{CaSO}_{4}\left(K_{\text {sp }}=2.4 \times 10^{-5}\right)$ has a larger $K_{\text {sp }}$ value than that of $\mathrm{Ag}_{2} \mathrm{SO}_{4}\left(K_{\text {sp }}=1.4 \times 10^{-5}\right)$. Does it necessarily follow that $\mathrm{CaSO}_{4}$ also has greater solubility (g/L)? Explain.
17.119 When lemon juice is added to tea, the color becomes lighter. In part, the color change is due to dilution, but the main reason for the change is an acid-base reaction. What is the reaction? (Hint: Tea contains "polyphenols," which are weak acids, and lemon juice contains citric acid.)

E17.120 How many milliliters of 1.0 M NaOH must be added to 200 mL of $0.10 \mathrm{M} \mathrm{NaH}_{2} \mathrm{PO}_{4}$ to make a buffer solution with a pH of 7.50 ?

G17.121 The maximum allowable concentration of $\mathrm{Pb}^{2+}$ ions in drinking water is 0.05 ppm (that is, 0.05 g of $\mathrm{Pb}^{2+}$ in 1 million grams of water). Is this guideline exceeded if an underground water supply is at equilibrium with the mineral anglesite $\left(\mathrm{PbSO}_{4}\right)$ $\left(K_{\text {sp }}=1.6 \times 10^{-8}\right)$ ?
17.122 One of the most common antibiotics is penicillin G (benzylpenicillinic acid), which has the following structure:

It is a weak monoprotic acid:

$$
\mathrm{HP} \rightleftarrows \mathrm{H}^{+}+\mathrm{P}^{-} \quad K_{\mathrm{a}}=1.64 \times 10^{-3}
$$

where HP denotes the parent acid and $\mathrm{P}^{-}$the conjugate base. Penicillin $G$ is produced by growing molds in fermentation tanks at $25^{\circ} \mathrm{C}$ and a pH range of 4.5 to 5.0. The crude form of this antibiotic is obtained by extracting the fermentation broth with an organic solvent in which the acid is soluble. (a) Identify the acidic hydrogen atom. (b) In one stage of purification, the organic extract of the crude penicillin G is treated with a buffer solution at $\mathrm{pH}=6.50$. What is the ratio of the conjugate base of penicillin G to the acid at this pH ? Would you expect the conjugate base to be more soluble in water than the acid? (c) Penicillin G is not suitable for oral administration, but the sodium salt ( NaP ) is because it is soluble. Calculate the pH of a 0.12 M NaP solution formed when a tablet containing the salt is dissolved in a glass of water.
17.123 Which of the following solutions has the highest $\left[\mathrm{H}^{+}\right]$: (a) 0.10 M HF , (b) 0.10 M HF in 0.10 M NaF , (c) 0.10 M HF in 0.10 M $\mathrm{SbF}_{5}$ ? (Hint: $\mathrm{SbF}_{5}$ reacts with $\mathrm{F}^{-}$to form the complex ion $\mathrm{SbF}_{6}^{-}$.)
17.124 Distribution curves show how the fractions of a nonionized acid and its conjugate base vary as a function of the pH of the medium. Plot distribution curves for $\mathrm{CH}_{3} \mathrm{COOH}$ and its conjugate base $\mathrm{CH}_{3} \mathrm{COO}^{-}$in solution. Your graph should show fraction as the $y$ axis and pH as the $x$ axis. What are the fractions and pH at the point where these two curves intersect?
17.125 Calcium oxalate is a major component of kidney stones. Predict whether the formation of kidney stones can be minimized by increasing or decreasing the pH of the fluid present in the kidney. The pH of normal kidney fluid is about 8.2. [The first and second acid ionization constants of oxalic acid $\left(\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}\right)$ are $6.5 \times 10^{-2}$ and $6.1 \times 10^{-5}$, respectively. The solubility product of calcium oxalate is $3.0 \times 10^{-9}$.]
17.126 Water containing $\mathrm{Ca}^{2+}$ and $\mathrm{Mg}^{2+}$ ions is called hard water and is unsuitable for some household and industrial use because these ions react with soap to form insoluble salts, or curds. One way to remove the $\mathrm{Ca}^{2+}$ ions from hard water is by adding washing soda $\left(\mathrm{Na}_{2} \mathrm{CO}_{3} \cdot 10 \mathrm{H}_{2} \mathrm{O}\right)$. (a) The molar solubility of $\mathrm{CaCO}_{3}$ is
$9.3 \times 10^{-5} \mathrm{M}$. What is its molar solubility in a $0.050 \mathrm{M} \mathrm{Na}_{2} \mathrm{CO}_{3}$ solution? (b) Why are $\mathrm{Mg}^{2+}$ ions not removed by this procedure? (c) The $\mathrm{Mg}^{2+}$ ions are removed as $\mathrm{Mg}(\mathrm{OH})_{2}$ by adding slaked lime $\left[\mathrm{Ca}(\mathrm{OH})_{2}\right]$ to the water to produce a saturated solution. Calculate the pH of a saturated $\mathrm{Ca}(\mathrm{OH})_{2}$ solution. (d) What is the concentration of $\mathrm{Mg}^{2+}$ ions at this pH ? (e) In general, which ion $\left(\mathrm{Ca}^{2+}\right.$ or $\left.\mathrm{Mg}^{2+}\right)$ would you remove first? Why?
17.127 Amino acids are building blocks of proteins. These compounds contain at least one amino group $\left(-\mathrm{NH}_{2}\right)$ and one carboxyl group $(-\mathrm{COOH})$. Consider glycine $\left(\mathrm{NH}_{2} \mathrm{CH}_{2} \mathrm{COOH}\right)$. Depending on the pH of the solution, glycine can exist in one of three possible forms:
Fully protonated: ${ }^{+} \mathrm{NH}_{3}-\mathrm{CH}_{2}-\mathrm{COOH}$
Dipolar ion: ${ }^{+} \mathrm{NH}_{3}-\mathrm{CH}_{2}-\mathrm{COO}^{-}$
Fully ionized: $\mathrm{NH}_{2}-\mathrm{CH}_{2}-\mathrm{COO}^{-}$
Predict the predominant form of glycine at $\mathrm{pH} 1.0,7.0$, and 12.0. The $\mathrm{p} K_{\mathrm{a}}$ of the carboxyl group is 2.3 and that of the ammonium $\operatorname{group}\left(-\mathrm{NH}_{3}^{+}\right)$is 9.6.
17.128 Consider the ionization of the following acid-base indicator:

$$
\mathrm{HIn}(a q) \rightleftarrows \mathrm{H}^{+}(a q)+\operatorname{In}^{-}(a q)
$$

The indicator changes color according to the ratios of the concentrations of the acid to its conjugate base. When $[\mathrm{HIn}] /\left[\mathrm{In}^{-}\right] \geq 10$, color of acid (HIn) predominates. When $[\mathrm{HIn}] /\left[\mathrm{In}^{-}\right] \leq 0.1$, color of conjugate base $\left(\mathrm{In}^{-}\right)$predominates. Show that the pH range over which the indicator changes from the acid color to the base color is $\mathrm{pH}=\mathrm{p} K_{\mathrm{a}} \pm 1$, where $K_{\mathrm{a}}$ is the ionization constant of the acid HIn.
17.129 One way to distinguish a buffer solution with an acid solution is by dilution. (a) Consider a buffer solution made of 0.500 M $\mathrm{CH}_{3} \mathrm{COOH}$ and 0.500 MCH COONa . Calculate its pH and the pH after it has been diluted 10 -fold. (b) Compare the result in part (a) with the pHs of a $0.500 \mathrm{M} \mathrm{CH}_{3} \mathrm{COOH}$ solution before and after it has been diluted 10 -fold.
17.130 (a) Referring to Figure 17.4, describe how you would determine the $\mathrm{p} K_{\mathrm{b}}$ of the base. (b) Derive an analogous HendersonHasselbalch equation relating pOH to $\mathrm{p} K_{\mathrm{b}}$ of a weak base B and its conjugate acid $\mathrm{HB}^{+}$. Sketch a titration curve showing the variation of the pOH of the base solution versus the volume of a strong acid added from a burette. Describe how you would determine the $\mathrm{p} K_{\mathrm{b}}$ from this curve.
17.131 $\mathrm{AgNO}_{3}$ is added slowly to a solution that contains 0.1 M each of $\mathrm{Br}^{-}, \mathrm{CO}_{3}^{2-}$, and $\mathrm{SO}_{4}^{2-}$ ions. What compound will precipitate first and what compound will precipitate last?
17.132 The diagrams represent solutions of MX, which may also contain one or both of the soluble salts, $\mathrm{MNO}_{3}$ and $\mathrm{NaX} .\left(\mathrm{Na}^{+}\right.$and $\mathrm{NO}_{3}^{-}$ ions are not shown.) If (a) represents a saturated solution of MX, classify each of the other solutions as unsaturated, saturated, or supersaturated.

17.133 Which of the following compounds, when added to water, will increase the solubility of CdS : (a) $\mathrm{LiNO}_{3}$, (b) $\mathrm{Na}_{2} \mathrm{SO}_{4}$, (c) KCN , (d) $\mathrm{NaClO}_{3}$ ?
17.134 The titration curve shown here represents the titration of a weak diprotic acid $\left(\mathrm{H}_{2} \mathrm{~A}\right)$ versus NaOH . (a) Label the major species present at the marked points. (b) Estimate the $\mathrm{p} K_{\mathrm{a}_{1}}$ and $\mathrm{p} K_{\mathrm{a}_{2}}$ values of the acid. Assume that any salt hydrolysis is negligible.

17.135 A 1.0-L saturated silver carbonate solution at $5^{\circ} \mathrm{C}$ is filtered to remove undissolved solid and treated with enough hydrochloric acid to decompose the dissolved compound. The carbon dioxide generated is collected in a $19-\mathrm{mL}$ vial and exerts a pressure of 114 mmHg at $25^{\circ} \mathrm{C}$. What is the $K_{\text {sp }}$ of silver carbonate at $5^{\circ} \mathrm{C}$ ?
17.136 Draw distribution curves for an aqueous carbonic acid solution. Your graph should show fraction of species present as the $y$ axis and pH as the $x$ axis. Note that at any pH , only two of the three species $\left(\mathrm{H}_{2} \mathrm{CO}_{3}, \mathrm{HCO}_{3}^{-}\right.$, and $\left.\mathrm{CO}_{3}^{2-}\right)$ are present in appreciable concentrations. Use the $K_{\mathrm{a}}$ values in Table 16.8.
$\leftrightarrows$ 17.137 A sample of 0.96 L of HCl gas at 372 mmHg and $22^{\circ} \mathrm{C}$ is bubbled into 0.034 L of $0.57 \mathrm{M} \mathrm{NH}_{3}$. What is the pH of the resulting solution? Assume the volume of solution remains constant and that the HCl is totally dissolved in the solution.
17.138 Histidine is one of the 20 amino acids found in proteins. Shown here is a fully protonated histidine molecule, where the numbers denote the $\mathrm{p} K_{\mathrm{a}}$ values of the acidic groups:

(a) Show stepwise ionization of histidine in solution. (Hint: The $\mathrm{H}^{+}$ion will first come off from the strongest acid group followed by the next strongest acid group and so on.) (b) A dipolar ion is one in which the species has an equal number of positive and negative charges. Identify the dipolar ion in part (a). (c) The pH at which the dipolar ion predominates is called the isoelectric point, denoted by $\mathrm{p} I$. The isoelectric point is the average of the $\mathrm{p} K_{\mathrm{a}}$ values leading to and following the formation of the dipolar ion. Calculate the $\mathrm{p} I$ of histidine. (d) The histidine group plays an important role in buffering blood (the pH of blood is about 7.4). Which conjugate acid-base pair shown in part (a) is responsible for maintaining the pH of blood?

## Pre-Professional Practice Exam Problems: Physical and Biological Sciences

Aqueous acid reacts with carbonate ions to produce carbonic acid, which produces carbon dioxide. A $1.0-\mathrm{L}$ saturated silver carbonate solution at $5^{\circ} \mathrm{C}$ is treated with enough hydrochloric acid to consume all the carbonate in solution. The carbon dioxide generated is collected in a $19-\mathrm{mL}$ vial and exerts a pressure of 114 mmHg at $25^{\circ} \mathrm{C}$.

1. Which of the following reactions represents the overall process of acid and carbonate reacting to give carbon dioxide?
a) $\mathrm{CO}_{3}^{2-}+2 \mathrm{H}^{+} \longrightarrow \mathrm{H}_{2} \mathrm{CO}_{3}$
b) $\mathrm{H}_{2} \mathrm{CO}_{3} \rightleftarrows \mathrm{H}_{2} \mathrm{O}+\mathrm{CO}_{2}$
c) $\mathrm{CO}_{3}^{2-}+2 \mathrm{H}^{+} \longrightarrow \mathrm{H}_{2} \mathrm{O}+\mathrm{CO}_{2}$
d) $\mathrm{Ag}_{2} \mathrm{CO}_{3}+2 \mathrm{H}^{+} \longrightarrow 2 \mathrm{Ag}^{+}+\mathrm{CO}_{2}+\mathrm{H}_{2} \mathrm{O}$
2. What is the $K_{\text {sp }}$ of silver carbonate at $5^{\circ} \mathrm{C}$ ?
a) $2.5 \times 10^{-11}$
b) $5.4 \times 10^{-8}$
c) $6.3 \times 10^{-12}$
d) $2.7 \times 10^{-8}$
3. At $25^{\circ} \mathrm{C}$, the $K_{\text {sp }}$ of silver carbonate is $8.1 \times 10^{-12}$. Based on this and the answer to Question 1, what can be said about the dissolution of silver carbonate?
a) It is endothermic.
b) It is exothermic.
c) It is neither exothermic nor endothermic.
d) It produces hydrogen gas.
4. Which of the following, if added to a saturated solution of $\mathrm{Ag}_{2} \mathrm{CO}_{3}$, would increase the solubility of $\mathrm{Ag}_{2} \mathrm{CO}_{3}$ ?
a) $\mathrm{Na}_{2} \mathrm{CO}_{3}$
b) $\mathrm{NaHCO}_{3}$
c) $\mathrm{AgNO}_{3}$
d) $\mathrm{HNO}_{3}$

## Entropy, Free Energy, and Equilibrium

## How Living Systems Must Obey the Laws of Thermodynamics

The painting "Plotkin's Entropy," by the artist Laurel Latto, is an abstract depiction of an extended polypeptide chain as it is synthesized in a biological cell. Under normal physiological conditions, the polypeptide spontaneously folds into a unique three-dimensional structure called the native protein, which performs various functions. Because the original chain can assume many possible configurations while the native protein can have only one specific arrangement, the folding process is accompanied by a decrease in entropy of the system. (Note that solvent molecules, water in this case, can also play a role in affecting the entropy change.) In accord with the second law of thermodynamics, any spontaneous process must result in an increase in the entropy of the universe. It follows, therefore, that there must be an increase in the entropy of the surroundings that outweighs the decrease in the entropy of the system. The intramolecular attractions between amino acid residues cause the folding of the polypeptide chain to be exothermic. The energy produced by the process spreads out, increasing molecular motion in the surroundings-thereby increasing the entropy of the surroundings.

At the end of this chapter, you will be able to answer several questions regarding entropy changes [ $\|$ Page 806].

## In This Chapter, You Will Learn:

About the three laws of thermodynamics and how to use thermodynamic quantities to determine whether or not a process is expected to be spontaneous.

## Before you begin, you should review

- System and surroundings [ 14 Section 5.1]
- Hess's law [14 Section 5.5]
- Equilibrium expressions [14 Section 15.3]

Student Annotation: The conditions that most often are specified are temperature, pressure, and in the case of a solution, concentration.

### 18.1 Spontaneous Processes

An understanding of thermodynamics enables us to predict whether or not a reaction will occur when reactants are combined. This is important in the synthesis of new compounds in the laboratory, the manufacturing of chemicals on an industrial scale, and the understanding of natural processes such as cell function. A process that does occur under a specific set of conditions is called a spontaneous process. One that does not occur under a specific set of conditions is called nonspontaneous. Table 18.1 lists examples of familiar spontaneous processes and their nonspontaneous counterparts. These examples illustrate what we know intuitively: Under a given set of conditions, a process that occurs spontaneously in one direction does not also occur spontaneously in the opposite direction.

Processes that result in a decrease in the energy of a system often are spontaneous. For example, the combustion of methane is exothermic:

$$
\mathrm{CH}_{4}(g)+2 \mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(l) \quad \Delta H^{\circ}=-890.4 \mathrm{~kJ} / \mathrm{mol}
$$

Thus, the energy of the system is lowered because heat is given off during the course of the reaction. Likewise, in the acid-base neutralization reaction,

$$
\mathrm{H}^{+}(a q)+\mathrm{OH}^{-}(a q) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l) \quad \Delta H^{\circ}=-56.2 \mathrm{~kJ} / \mathrm{mol}
$$

heat is given off, lowering the energy of the system. Each of these processes is spontaneous, and each results in a lowering of the system's energy.

Now consider the melting of ice:

$$
\mathrm{H}_{2} \mathrm{O}(s) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l) \quad \Delta H^{\circ}=6.01 \mathrm{~kJ} / \mathrm{mol}
$$

In this case, the process is endothermic and yet it is also spontaneous at temperatures above $0^{\circ} \mathrm{C}$. Conversely, the freezing of water is an exothermic process:

$$
\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}_{2} \mathrm{O}(s) \quad \Delta H^{\circ}=-6.01 \mathrm{~kJ} / \mathrm{mol}
$$

Yet it is not spontaneous at temperatures above $0^{\circ} \mathrm{C}$.
Based on the first two examples, and many others like them, we might conclude that exothermic processes tend to be spontaneous and, indeed, a negative $\Delta H$ does favor spontaneity. The last two examples, however, make it clear that the sign of $\Delta H$ alone is insufficient to predict spontaneity in every circumstance. For the remainder of this chapter, we will examine the two factors that determine whether or not a process is spontaneous under a given set of conditions.

### 18.2 Entropy

To predict the spontaneity of a chemical or physical process, we need to know both the change in enthalpy [ 144 Section 5.3] and the change in entropy associated with the process. We first encountered the concept of entropy in our discussion of solution formation [1/4 Section 13.2]. We will now look in more detail at what entropy is, and why it matters.

## TABLE 18.1 Familiar Spontaneous and Nonspontaneous Processes

## Spontaneous

Ice melting at room temperature
Sodium metal reacting violently with water to produce sodium hydroxide and hydrogen gas [144 Section 7.7]
A ball rolling downhill
The rusting of iron at room temperature
Water freezing at $-10^{\circ} \mathrm{C}$

## Nonspontaneous

Water freezing at room temperature
Sodium hydroxide reacting with hydrogen gas to produce sodium metal and water

## A ball rolling uphill

The conversion of rust back to iron metal at room temperature
Ice melting at $-10^{\circ} \mathrm{C}$

## A Qualitative Description of Entropy

Qualitatively, the entropy ( $\boldsymbol{S}$ ) of a system is a measure of how spread out or how dispersed the system's energy is. The simplest interpretation of this is how spread out a system's energy is in space. In other words, for a given system, the greater the volume it occupies, the greater its entropy. This interpretation explains how the process in Figure 18.1 occurs spontaneously despite there being no enthalpy change. Because they are moving, the gas molecules that were originally confined to one side of the container possess motional energy. In the absence of a barrier preventing it, the motional energy of molecules will spread out to occupy a larger volume. The dispersal of a system's motional energy to occupy a larger volume when the barrier is removed constitutes an increase in the system's entropy. Just as spontaneity is favored by a process being exothermic, spontaneity is also favored by an increase in the system's entropy. Whether it is the enthalpy change, the entropy change, or both, for a process to be spontaneous, something must favor spontaneity.

## A Quantitative Definition of Entropy

At this point, it is useful to introduce the mathematical definition of entropy proposed by Ludwig Boltzmann:

$$
S=k \ln W
$$

Equation 18.1
where $k$ is the Boltzmann constant $\left(1.38 \times 10^{-23} \mathrm{~J} / \mathrm{K}\right)$ and $W$ is the number of energetically equivalent different ways the molecules in a system can be arranged. To illustrate what this means, let's consider a simplified version of the process shown in Figure 18.1. Prior to the removal of the barrier between the left and right sides of the container, at any given instant, each molecule has a particular location, somewhere in the left side of the container. To narrow down the possible locations of the molecules, we imagine that each side of the container is divided into a number of equal smaller volumes called cells. In the simplest scenario, with just one molecule in the system, the number of possible locations of the molecule is equal to the number of cells. If the system contains two molecules, the number of possible arrangements is equal to the number of cells squared. (Note that a cell may contain more than one molecule.) Each time we increase the number of molecules by one, the number of possible arrangements increases by a factor equal to the number of cells. In general, for a volume consisting of $X$ cells, and containing $N$ molecules, the number of possible arrangements, $W$, is given by the equation

$$
W=X^{N}
$$

Equation 18.2
Figure 18.2 illustrates this for a simple case involving just two molecules. We imagine the container is divided into four cells each with volume $v$. Initially, both molecules are confined to the left side, which consists of two cells. With two molecules in two cells, there are $2^{2}=4$ possible arrangements of the molecules [Figure 18.2(a)]. When the barrier is removed, doubling the volume available to the molecules, the number of cells also doubles. With four cells available, there are $4^{2}=16$ possible arrangements of the molecules. Eight of the sixteen arrangements have the molecules on opposite sides of the container [Figure 18.2(b)]. Of the other eight arrangements, four have both molecules on the left side [as shown in Figure 18.2(a)], and four have both molecules on the right side (not shown). There are three different states possible for this system.

Student Annotation: Motional energy includes translational energy, in which the entire molecule moves through space [ 14 Section 5.1]; rotational energy, in which the molecule spins about an axis running through its center of mass; and vibrational energy, in which atoms of a molecule move relative to one another.

## Student Annotation: The Boltzmann

 constant is equal to the gas constant, $R$ (in J/K • mol), divided by Avogadro's constant, $N_{A}$.Student Annotation: The number of possible arrangements is sometimes called the number of microstates.

Figure 18.1 A spontaneous process. The rapidly moving gas molecules originally confined to one side of a container spread out to fill the whole container when the barrier is removed.

Figure 18.2 (a) Before the barrier is removed, the molecules are both in the left side of the container, which we imagine is divided into two cells of equal volume. There are four possible arrangements of two molecules in two cells. (b) When the barrier between the two sides of the container is removed, the volume (and the number of cells) available to the molecules doubles. The new number of possible arrangements is $4^{2}=16$, eight of which have the molecules in opposite sides of the container-the most probable outcome.

Student Annotation: The state with the largest number of possible arrangements has the greatest entropy.

1. One molecule on each side (eight possible arrangements)
2. Both molecules on the left (four possible arrangements)
3. Both molecules on the right (four possible arrangements)

The most probable state is the one with the largest number of possible arrangements. In this case, the most probable state is the one with one molecule on each side of the container. The same principle applies to systems with larger numbers of molecules. Increasing the number of molecules increases the number of possible arrangements, but the most probable state will be the one in which the gas molecules are divided evenly between the two sides of the container.

### 18.3 Entropy Changes in a System

## Calculating $\Delta S_{\text {sys }}$

The change in entropy of a system is the difference between the entropy of the final state and the entropy of the initial state.

$$
\Delta S_{\mathrm{sys}}=S_{\mathrm{final}}-S_{\text {initial }}
$$

Using Equation 18.1, we can write an expression for the entropy of each state,

$$
\Delta S_{\text {sys }}=k \ln W_{\text {final }}-k \ln W_{\text {initial }}=k \ln \frac{W_{\text {final }}}{W_{\text {initial }}}
$$

Combining this result with Equation 18.2 gives

$$
\Delta S_{\text {sys }}=k \ln \frac{\left(X_{\text {final }}\right)^{N}}{\left(X_{\text {initial }}\right)^{N}}=k \ln \left(\frac{X_{\text {final }}}{X_{\text {initial }}}\right)^{N}=k N \ln \left(\frac{X_{\text {final }}}{X_{\text {initial }}}\right)
$$

Because $X$ is the number of cells, and the volume of each cell is $v$, the total volume is related to the number of cells by

$$
V=X v \quad \text { or } \quad X=\frac{V}{v}
$$

We substitute $V_{\text {final }} / v$ for $X_{\text {final }}$ and $V_{\text {initial }} / v$ for $X_{\text {initial }}$ to get

$$
\Delta S_{\text {sys }}=k N \ln \frac{V_{\text {final }} / v}{V_{\text {initial }} / v}=k N \ln \frac{V_{\text {final }}}{V_{\text {initial }}}
$$

Finally, because the Boltzmann constant, $k$, is the gas constant, $R$, divided by Avogadro's constant,

$$
k=\frac{R}{N_{\mathrm{A}}}
$$

and because the number of molecules, $N$, is the product of the number of moles, $n$, and Avogadro's constant, $N_{\mathrm{A}}$;

$$
\begin{gathered}
N=n \times N_{\mathrm{A}} \\
k N=\left(\frac{R}{S_{\mathrm{A}}} \times n \times{y_{\mathrm{A}}}^{\prime}\right)=n R
\end{gathered}
$$

the equation becomes

$$
\begin{equation*}
\Delta S_{\mathrm{sys}}=n R \ln \frac{V_{\text {final }}}{V_{\text {initial }}} \tag{Equation 18.4}
\end{equation*}
$$

Sample Problem 18.1 shows how to use Equation 18.4 to calculate the entropy change for a process like the one shown in Figure 18.1, the expansion of an ideal gas at constant temperature.

## Sample Problem 18.1

Determine the change in entropy for 1.0 mole of an ideal gas originally confined to one-half of a 5.0-L container when the gas is allowed to expand to fill the entire container at constant temperature.

Strategy This is the isothermal expansion of an ideal gas. Because the molecules spread out to occupy a greater volume, we expect there to be an increase in the entropy of the system. Use Equation 18.3 to solve for $\Delta S_{\text {sys }}$.

Setup $R=8.314 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}, n=1.0 \mathrm{~mole}, V_{\text {final }}=5.0 \mathrm{~L}$, and $V_{\text {initial }}=2.5 \mathrm{~L}$.

## Solution

$$
\Delta S_{\text {sys }}=n R \ln \frac{V_{\text {final }}}{V_{\text {initial }}}=1.0 \operatorname{mot} \times \frac{8.314 \mathrm{~J}}{\mathrm{~K} \cdot \operatorname{mot}} \times \ln \frac{5.0 \mathrm{~L}}{2.5 \mathrm{~L}}=5.8 \mathrm{~J} / \mathrm{K}
$$

Practice Problem A Determine the change in entropy ( $\Delta S_{\text {sys }}$ ), for the expansion of 0.10 mole of an ideal gas from 2.0 L to 3.0 L at constant temperature.

HPractice Problem B To what fraction of its original volume must a 0.50 -mole sample of ideal gas be compressed at constant temperature for $\Delta S_{\text {sys }}$ to be $-6.7 \mathrm{~J} / \mathrm{K}$ ?

Student Annotation: Remember that the difference between two logs is equal to the log of the corresponding quotient:

$$
\ln A-\ln B=\ln \frac{A}{B}
$$

and that $\ln A^{x}=x \ln A[M$ Appendix 1].

Student Annotation: For even the simplest of hypothetical systems, where there are only two possible positions for molecules $(X=2)$, most calculators cannot display a number as large as the result of Equation 18.2 for even as few as 500 molecules-much less for the enormous number of molecules present in any real sample. (If your calculator is like most, with $X=2$, you can calculate the number of possible arrangements for $N \leq 332$ molecules. Try it: $2 \wedge 332=$ ? and $2 \wedge 333=$ ?)

Student Annotation: You will find that tables, including Appendix 2, contain negative absolute entropies for some aqueous ions. Unlike a substance, an individual ion cannot be studied experimentally. Therefore, standard entropies of ions are actually relative values, where a standard entropy of zero is arbitrarily assigned to the hydrated hydrogen ion. Depending on an ion's extent of hydration, its standard entropy may be positive or negative, relative to that of hydrogen ion.

## Standard Entropy, S $^{\circ}$

Although Equation 18.1 provides a quantitative definition of entropy, we seldom use it or Equation 18.3 to calculate the entropy change for a real process because of the difficulty involved in determining $W$, the number of different possible arrangements (Equation 18.2) in a macroscopic system. Instead, for processes other than isothermal expansion or compression of an ideal gas (for which we can use Equation 18.4), we routinely determine entropy changes using tabulated values.

Using calorimetry [ 144 Section 5.4], it is possible to determine the absolute value of the entropy of a substance, $S$; something we cannot do with either energy or enthalpy. (Recall that while we can determine $\Delta U$ and $\Delta H$ for a process that a system undergoes, we cannot determine the absolute values of either $U$ or $H$ for a system [1/4 Sections 5.2 and 5.3].) Standard entropy is the absolute entropy of a substance at 1 atm . (Tables of standard entropy values typically are the values at $25^{\circ} \mathrm{C}$ because so many processes are carried out at room temperature-although temperature is not part of the standard state definition and therefore must be specified.) Table 18.2 lists standard entropies of a few elements and compounds. Appendix 2 provides a more extensive listing. The units of entropy are $\mathrm{J} / \mathrm{K} \cdot \mathrm{mol}$. We use joules rather than kilojoules because entropy values typically are quite small. The entropies of substances (elements and compounds) are always positive (i.e., $S>0$ ), even for elements in their standard states. (Recall that the standard enthalpy of formation, $\Delta H_{\mathrm{f}}^{\circ}$, for elements in their standard states is arbitrarily defined as zero, and for compounds it may be either positive or negative [ 144 Section 5.6].)

Referring to Table 18.2, we can identify several important trends:

- For a given substance, the standard entropy is greater in the liquid phase than in the solid phase. [Compare the standard entropies of $\mathrm{Na}(s)$ and $\mathrm{Na}(l)$.] This results from there being greater molecular motion in a liquid, resulting in many possible arrangements of atoms in the liquid phase; whereas the positions of atoms in the solid are fixed.
- For a given substance, the standard entropy is greater in the gas phase than in the liquid phase. [Compare the standard entropies of $\mathrm{Na}(l)$ and $\mathrm{Na}(g)$ and those of $\mathrm{H}_{2} \mathrm{O}(l)$ and $\mathrm{H}_{2} \mathrm{O}(g)$.] This results from there being much greater molecular motion in a gas, resulting in many more possible arrangements of atoms in the gas phase than in the liquid phase-in part because the gas phase occupies a much greater volume than either of the condensed phases.
- For two monatomic species, the one with the larger molar mass has the greater standard entropy. [Compare the standard entropies of $\mathrm{He}(g)$ and $\mathrm{Ne}(g)$.]
- For two substances in the same phase, and with similar molar masses, the substance with the more complex molecular structure has the greater standard entropy. [Compare the standard entropies of $\mathrm{O}_{3}(g)$ and $\mathrm{F}_{2}(g)$.] The more complex a molecular structure, the more different types of motion the molecule can exhibit. A diatomic molecule such as $\mathrm{F}_{2}$, for example, exhibits only one type of vibration, whereas a bent triatomic molecule such as $\mathrm{O}_{3}$ exhibits three different types of vibrations. Each mode of motion contributes to the total number of available energy levels within which a system's energy can be dispersed. Figure 18.3 illustrates the ways in which the $\mathrm{F}_{2}$ and $\mathrm{O}_{3}$ molecules can rotate and vibrate.
- In cases where an element exists in two or more allotropic forms, the form in which the atoms are more mobile has the greater entropy. [Compare the standard entropies of C (diamond) and C (graphite). In diamond, the carbon atoms occupy fixed positions in a three-dimensional array. In graphite, although the carbon atoms occupy fixed positions within the two-dimensional sheets (See Figure 12.27), the sheets are free to move with respect to one another, which increases the mobility and, therefore, total number of possible arrangements of atoms within the solid.]

## TABLE 18.2

Standard Entropy Values $\left(S^{\circ}\right)$ for Some Substances at $25^{\circ} \mathrm{C}$

| Substance | $\left.\boldsymbol{S}^{\circ} \mathbf{( J / K} \cdot \mathbf{m o l}\right)$ | Substance | $\left.\boldsymbol{S}^{\circ} \mathbf{( J / K} \cdot \mathbf{m o l}\right)$ |
| :--- | :---: | :--- | :---: |
| $\mathrm{H}_{2} \mathrm{O}(l)$ | 69.9 | $\mathrm{C}($ diamond $)$ | 2.4 |
| $\mathrm{H}_{2} \mathrm{O}(g)$ | 188.7 | $\mathrm{C}($ graphite $)$ | 5.69 |
| $\mathrm{Na}(s)$ | 51.05 | $\mathrm{O}_{2}(g)$ | 205.0 |
| $\mathrm{Na}(l)$ | 57.56 | $\mathrm{O}_{3}(g)$ | 237.6 |
| $\mathrm{Na}(g)$ | 153.7 | $\mathrm{~F}_{2}(g)$ | 203.34 |
| $\mathrm{He}(g)$ | 126.1 | $\mathrm{Au}(s)$ | 47.7 |
| $\mathrm{Ne}(g)$ | 146.2 | $\mathrm{Hg}(l)$ | 77.4 |

$\qquad$

(a)

Figure 18.3 In addition to translational motion, molecules exhibit both vibrations, in which the atoms' positions relative to one another change, and rotations, in which the molecule rotates about its center of mass. (a) A diatomic molecule such as fluorine only exhibits one type of vibration. A bent, triatomic molecule such as ozone exhibits three types of vibration. (b) A diatomic molecule exhibits two different rotations, whereas a bent, triatomic molecule exhibits three different rotations. (Note that rotation of $\mathrm{F}_{2}$ about the $x$ axis would cause no change in the positions of either atom in the molecule.)

Now let's consider a process represented by the following chemical equation:

$$
a \mathrm{~A}+b \mathrm{~B} \longrightarrow c \mathrm{C}+d \mathrm{D}
$$

Just as the enthalpy change of a reaction is the difference between the enthalpies of the products and reactants (Equation 5.12), the entropy change is the difference between the entropies of the products and reactants:

$$
\Delta S_{\mathrm{rxn}}^{\circ}=\left[c S^{\circ}(\mathrm{C})+d S^{\circ}(\mathrm{D})\right]-\left[a S^{\circ}(\mathrm{A})+b S^{\circ}(\mathrm{B})\right] \quad \text { Equation } 18.5
$$

Or, using $\Sigma$ to represent summation and $m$ and $n$ to represent the stoichiometric coefficients of the reactants and products, respectively, Equation 18.5 can be generalized as follows:

$$
\Delta S_{\mathrm{rxn}}^{\circ}=\Sigma n S^{\circ}(\text { products })-\Sigma m S^{\circ}(\text { reactants })
$$

Equation 18.6
The standard entropy values of a large number of substances have been measured in $\mathrm{J} / \mathrm{K} \cdot \mathrm{mol}$. To calculate the standard entropy change for a reaction $\left(\Delta S_{\mathrm{rxn}}^{\circ}\right)$, we look up the standard entropies of the products and reactants and use Equation 18.5.

Sample Problem 18.2 demonstrates this approach.

Student Annotation: The reaction generally is the system. Therefore, $\Delta S_{\mathrm{rx}}^{\circ}$ is $\Delta S_{\text {sys }}^{\circ}$.

Student Annotation: Recall that here per mole means per mole of reaction as written [ 144 Section 5.6].

Think About It Remember to multiply each standard entropy value by the correct stoichiometric coefficient. Like Equation 5.12, Equation 18.5 can only be used with a balanced chemical equation.

## Sample Problem 18.2

From the standard entropy values in Appendix 2, calculate the standard entropy changes for the following reactions at $25^{\circ} \mathrm{C}$ :
(a) $\mathrm{CaCO}_{3}(s) \longrightarrow \mathrm{CaO}(s)+\mathrm{CO}_{2}(g)$
(b) $\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \longrightarrow 2 \mathrm{NH}_{3}(g)$
(c) $\mathrm{H}_{2}(g)+\mathrm{Cl}_{2}(g) \longrightarrow 2 \mathrm{HCl}(g)$

Strategy Look up standard entropy values and use Equation 18.5 to calculate $\Delta S_{\mathrm{rxn}}^{\circ}$. Just as we did when we calculated standard enthalpies of reaction, we consider stoichiometric coefficients to be dimensionless-giving $\Delta S_{\mathrm{rxn}}^{\circ}$ units of $\mathrm{J} / \mathrm{K} \cdot \mathrm{mol}$.

Setup From Appendix $2, S^{\circ}\left[\mathrm{CaCO}_{3}(s)\right]=92.9 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}, S^{\circ}[\mathrm{CaO}(s)]=39.8 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$, $S^{\circ}\left[\mathrm{CO}_{2}(g)\right]=213.6 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}, S^{\circ}\left[\mathrm{N}_{2}(g)\right]=191.5 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}, S^{\circ}\left[\mathrm{H}_{2}(g)\right]=131.0 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$, $S^{\circ}\left[\mathrm{NH}_{3}(g)\right]=193.0 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}, S^{\circ}\left[\mathrm{Cl}_{2}(g)\right]=223.0 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$, and $S^{\circ}[\mathrm{HCl}(g)]=187.0 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$.

Solution
(a) $\Delta S_{\mathrm{rxn}}^{\circ}=\left[S^{\circ}(\mathrm{CaO})+S^{\circ}\left(\mathrm{CO}_{2}\right)\right]-\left[S^{\circ}\left(\mathrm{CaCO}_{3}\right)\right]$

$$
=[(39.8 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol})+(213.6 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol})]-(92.9 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol})
$$

$$
=160.5 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol}
$$

(b) $\Delta S_{\text {rxn }}^{\circ}=\left[2 S^{\circ}\left(\mathrm{NH}_{3}\right)\right]-\left[S^{\circ}\left(\mathrm{N}_{2}\right)+3 S^{\circ}\left(\mathrm{H}_{2}\right)\right]$

$$
\begin{aligned}
& =(2)(193.0 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol})-[(191.5 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol})+(3)(131.0 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol})] \\
& =-198.5 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol}
\end{aligned}
$$

(c) $\Delta S_{\mathrm{rxn}}^{\circ}=\left[2 S^{\circ}(\mathrm{HCl})\right]-\left[S^{\circ}\left(\mathrm{H}_{2}\right)+S^{\circ}\left(\mathrm{Cl}_{2}\right)\right]$
$=(2)(187.0 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol})-[(131.0 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol})+(223.0 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol})]$
$=20.0 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$

Practice Problem A Calculate the standard entropy change for the following reactions at $25^{\circ} \mathrm{C}$. Predict first whether each one will be positive, negative, or too close to call.
(a) $2 \mathrm{CO}_{2}(g) \longrightarrow 2 \mathrm{CO}(g)+\mathrm{O}_{2}(g)$
(b) $3 \mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{O}_{3}(\mathrm{~g})$
(c) $2 \mathrm{NaHCO}_{3}(s) \longrightarrow \mathrm{Na}_{2} \mathrm{CO}_{3}(s)+\mathrm{H}_{2} \mathrm{O}(l)+\mathrm{CO}_{2}(g)$

FPractice Problem B In each of the following reactions, there is one species for which the standard entropy is not listed in Appendix 2. In each case, using the values that are in Appendix 2 and the $\Delta S_{\mathrm{rxn}}^{\circ}$ that is given, determine the value of the missing standard entropy at $25^{\circ} \mathrm{C}$ : (a) $\mathrm{K}(s) \longrightarrow \mathrm{K}(l)$, $\Delta S_{\text {rxn }}^{\circ}=7.9 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$, (b) 2 S (rhombic) $+\mathrm{Cl}_{2}(g) \longrightarrow \mathrm{S}_{2} \mathrm{Cl}_{2}(g), \Delta S_{\mathrm{rxn}}^{\circ}=44.74 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$, (c) $\mathrm{O}_{2}(g)+2 \mathrm{MgF}_{2}(s) \longrightarrow 2 \mathrm{MgO}(s)+2 \mathrm{~F}_{2}(g), \Delta S_{\mathrm{rxn}}^{\circ}=140.76 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$.

## Qualitatively Predicting the Sign of $\Delta S_{\text {sys }}^{\circ}$

Equation 18.5 enables us to calculate $\Delta S_{\mathrm{rxn}}^{\circ}$ for a process when the standard entropies of the products and reactants are known. However, sometimes it's useful just to know the sign of $\Delta S_{\text {rxn }}^{\circ}$. Although multiple factors can influence the sign of $\Delta S_{\mathrm{rxn}}^{\circ}$, the outcome is often dominated by a single factor, which can be used to make a qualitative prediction. Several processes that lead to an increase in entropy are

- Melting
- Vaporization or sublimation
- Temperature increase
- Reaction resulting in a greater number of gas molecules

When a solid is melted, the molecules have greater energy and are more mobile. They go from being in fixed positions in the solid, to being free to move about in the liquid. As we saw in the discussion of standard entropy, this leads to many more possible arrangements of the molecules and, therefore, greater entropy. The same rationale holds for the vaporization or sublimation of a substance. There is a dramatic increase in energy/mobility, and in the number of possible arrangements of a system's molecules when the molecules go from a condensed phase to the gas phase. Therefore, there is a much larger increase in the system's entropy, relative to the solid-to-liquid transition.

When the temperature of a system is increased, the energy of the system's molecules increases. To visualize this, recall from the discussion of kinetic molecular theory that increasing the temperature of a gas increases its average kinetic energy. This corresponds to an increase in the average speed of the gas molecules and a spreading out of the range of molecular speeds. [See Figure 11.20(a).] If we think of each of the possible molecular speeds within the range as a discrete energy level, we can see that at higher temperatures, there is a greater number of possible molecular speeds and, therefore, a greater number of energy states available to the molecules in the system. With a greater number of available energy states, there is a greater number of possible arrangements of molecules within those states and, therefore, a greater entropy.

Because the entropy of a substance in the gas phase is always significantly greater than its entropy in either the liquid or solid phase, a reaction that results in an increase in the number of gas molecules causes an increase in the system's entropy. For reactions that do not involve gases, an increase in the number of solid, liquid, or aqueous molecules also usually causes an entropy increase.

By considering these factors, we can usually make a reasonably good prediction of the sign of $\Delta S_{\text {rxn }}^{\circ}$ for a physical or chemical process, without having to look up the absolute entropy values for the species involved. Figure 18.4 summarizes the factors that can be used to compare entropies and illustrates several comparisons.

In addition to melting, vaporization/sublimation, temperature increase, and reactions that increase the number of gas molecules, which can always be counted upon to result in an entropy increase, the process of dissolving a substance often leads to an increase in entropy. In the case of a molecular solute, such as sucrose (sugar), dissolving causes dispersal of the molecules (and consequently, of the system's energy) into a larger volume-resulting in an increase in entropy. In the case of an ionic solute, the analysis is slightly more complicated. We saw in our discussion of solution formation [ 14 Section 13.2] that the dissolution of ammonium nitrate $\left(\mathrm{NH}_{4} \mathrm{NO}_{3}\right)$ is spontaneous, even though it is endothermic, because the system's entropy increases when the ionic solid dissociates and is dispersed throughout the solution. In general, this is the case for ionic solutes in which the charges on ions are small. (In the case of $\mathrm{NH}_{4} \mathrm{NO}_{3}$, they are +1 and -1 .) However, when ions are dispersed in water, they become hydrated (surrounded by water molecules in a specific arrangement [ 144 Figure 4.4 page 124]). This leads to a decrease in the entropy of the water, as hydration reduces the mobility of some of the water molecules by fixing them in positions around the dissolved ions. When the charges on ions are low, the increase in entropy of the solute typically outweighs the decrease in entropy of the water-resulting in an overall increase in the entropy of the system-as is the case with $\mathrm{NH}_{4} \mathrm{NO}_{3}$. By contrast, when highly charged ions such as $\mathrm{Al}^{3+}$ and $\mathrm{Fe}^{3+}$ are hydrated, the decrease in entropy of the water can actually outweigh the increase in entropy of the solute, leading to an overall decrease in entropy of the system. Table 18.3 lists the changes in entropy associated with the spontaneous dissolution of several ionic solids.

## TABLE 18.3

Entropy Changes for the Dissolution $\left(\Delta S_{\text {soln }}^{\circ}\right)$ of Some Ionic Solids at $25^{\circ} \mathrm{C}$

## Dissolution Equation

$\mathrm{NH}_{4} \mathrm{NO}_{3}(s) \longrightarrow \mathrm{NH}_{4}^{+}(a q)+\mathrm{NO}_{3}^{-}(a q)$
$\mathrm{AlCl}_{3}(s) \longrightarrow \mathrm{Al}^{3+}(a q)+3 \mathrm{Cl}^{-}(a q)$
$\mathrm{FeCl}_{3}(s) \longrightarrow \mathrm{Fe}^{3+}(a q)+3 \mathrm{Cl}^{-}(a q)$
$\Delta S_{\text {soln }}^{\circ}(\mathrm{J} / \mathrm{K} \cdot \mathrm{mol})$
108.1
-253.2
-266.1

Student Annotation: Note that the subscript "rxn" in $\Delta S_{\mathrm{xx}}^{\circ}$ changes to "soln" to refer specifically to the solution process.

Figure 18.4

## Factors That Influence the Entropy of a System

## Volume Change

Quantum mechanical analysis shows that the spacing between translational energy levels is inversely proportional to the volume of the container. Thus, when the volume is increased, more energy levels become available within which the system's energy can be dispersed.

## Temperature Change

At higher temperatures, molecules have greater kinetic energy-making more energy levels accessible. This increases the number of energy levels within which the system's energy can be dispersed, causing entropy to increase.

## Volecular complexity

Unlike atoms, which exhibit only translational motion, molecules can also exhibit rotational and vibrational motions. The greater a molecule's complexity, the greater the number of possible ways it can rotate and vibrate. The ozone molecule $\left(\mathrm{O}_{3}\right)$, for example, is more complex than the fluorine molecule $\left(\mathrm{F}_{2}\right)$ and exhibits more different kinds of vibrations and rotations. (See Figure 18.3.) This results in more energy levels within which the system's energy can be dispersed. The number and spacing of additional energy levels have been simplified to keep the illustration clear.

## Molar Mass

The energy levels for a substance with a larger molar mass are more closely spaced. Kr , for example, has roughly twice the molar mass of Ar. Thus, Kr has roughly twice as many energy levels within which the system's energy can be dispersed.

## Phase Change

Because of greater mobility, there are many more different possible arrangements ( $W$ ) of molecules in the liquid phase than there are in the solid phase; and there are many, many more different possible arrangements of molecules in the gas phase than there are in the liquid phase. Entropy of a substance increases when it is melted $(s \rightarrow l)$, vaporized $(l \rightarrow g)$, or sublimed $(s \rightarrow g)$.

## Chemical Reaction

When a chemical reaction produces more gas molecules than it consumes, the number of different possible arrangements of molecules $(W)$ increases and entropy increases.

## What's the point?

Although several factors can influence the entropy of a system or the entropy change associated with a process, often one factor dominates the outcome. Each of these comparisons shows a qualitative illustration of one of the important factors.

Sample Problem 18.3 lets you practice making qualitative predictions of the sign of $\Delta S_{\mathrm{rxn}}^{\circ}$.

## Sample Problem 18.3

For each process, determine the sign of $\Delta S$ for the system: (a) decomposition of $\mathrm{CaCO}_{3}(s)$ to give $\mathrm{CaO}(s)$ and $\mathrm{CO}_{2}(g)$, (b) heating bromine vapor from $45^{\circ} \mathrm{C}$ to $80^{\circ} \mathrm{C}$, (c) condensation of water vapor on a cold surface, (d) reaction of $\mathrm{NH}_{3}(g)$ and $\mathrm{HCl}(g)$ to give $\mathrm{NH}_{4} \mathrm{Cl}(s)$, and (e) dissolution of sugar in water.

Strategy Consider the change in energy/mobility of atoms and the resulting change in number of possible positions that each particle can occupy in each case. An increase in the number of arrangements corresponds to an increase in entropy and therefore a positive $\Delta S$.

Think About It For reactions involving only liquids and solids, predicting the sign of $\Delta S^{\circ}$ can be more difficult, but in many such cases an increase in the total number of molecules and/or ions is accompanied by an increase in entropy.

Setup Increases in entropy generally accompany solid-to-liquid, liquid-to-gas, and solid-to-gas transitions; the dissolving of one substance in another; a temperature increase; and reactions that increase the net number of moles of gas.

Solution $\Delta S$ is (a) positive, (b) positive, (c) negative, (d) negative, and (e) positive.

Practice Problem A For each of the following processes, determine the sign of $\Delta S$ : (a) crystallization of sucrose from a supersaturated solution, (b) cooling water vapor from $150^{\circ} \mathrm{C}$ to $110^{\circ} \mathrm{C}$, (c) sublimation of dry ice.

HPractice Problem B Make a qualitative prediction of the sign of $\Delta H_{\text {soln }}^{\circ}$ for $\mathrm{AlCl}_{3}(s)$ and the dissolution of $\mathrm{FeCl}_{3}(s)$. See Table 18.3 on page 785. Explain your reasoning.

## Checkpoint 18.3 Entropy Changes in a System

18.3.1 For which of the following physical processes is $\Delta S$ negative? (Select all that apply.)
a) Freezing ethanol
b) Evaporating water
c) Mixing carbon tetrachloride and benzene
d) Heating water
e) Condensing bromine vapor
18.3.2 For which of the following chemical reactions is $\Delta S$ negative? (Select all that apply.)
a) $2 \mathrm{O}_{3}(\mathrm{~g}) \longrightarrow 3 \mathrm{O}_{2}(\mathrm{~g})$
b) $4 \mathrm{Fe}(s)+3 \mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{Fe}_{2} \mathrm{O}_{3}(s)$
c) $2 \mathrm{H}_{2} \mathrm{O}_{2}(a q) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{O}_{2}(g)$
d) $2 \mathrm{Li}(s)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{LiOH}(a q)+\mathrm{H}_{2}(g)$
e) $2 \mathrm{NH}_{3}(g) \longrightarrow \mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g)$
18.3.3 Consider the gas-phase reaction of $\mathrm{A}_{2}$ (blue) and $\mathrm{B}_{2}$ (orange) to form $\mathrm{AB}_{3}$. What are the correct balanced equation and the sign of $\Delta S$ for the reaction?

a) $\mathrm{A}_{2}+\mathrm{B}_{2} \longrightarrow \mathrm{AB}_{3}$, negative
b) $2 \mathrm{~A}_{2}+3 \mathrm{~B}_{2} \longrightarrow 4 \mathrm{AB}_{3}$, positive
c) $2 \mathrm{~A}_{2}+3 \mathrm{~B}_{2} \longrightarrow 4 \mathrm{AB}_{3}$, negative
d) $\mathrm{A}_{2}+3 \mathrm{~B}_{2} \longrightarrow 2 \mathrm{AB}_{3}$, negative
e) $\mathrm{A}_{2}+3 \mathrm{~B}_{2} \longrightarrow 2 \mathrm{AB}_{3}$, positive

### 18.4 Entropy Changes in the Universe

Recall that the system typically is the part of the universe we are investigating (e.g., the reactants and products in a chemical reaction). The surroundings are everything else [ 1 k 4 Section 5.1]. Together, the system and surroundings make up the universe. We have seen that the dispersal or spreading out of a system's energy corresponds to an increase in the system's entropy. Moreover, an increase in the system's entropy is one of the factors that determines whether or not a process is spontaneous. However, correctly predicting the spontaneity of a process requires us to consider entropy changes in both the system and the surroundings.

Consider the following processes:

- An ice cube spontaneously melts in a room where the temperature is $25^{\circ} \mathrm{C}$. In this case, the motional energy of the air molecules at $25^{\circ} \mathrm{C}$ is transferred to the ice cube (at $0^{\circ} \mathrm{C}$ ), causing the ice to melt. There is no temperature change during a phase change. However, because the molecules are more mobile and there are many more different possible arrangements in liquid water than there are in ice, there is an increase in the entropy of the system. In this case, because the process of melting is endothermic, heat is transferred from the surroundings to the system and the temperature of the surroundings decreases. The slight decrease in temperature causes a small decrease in molecular motion and a decrease in the entropy of the surroundings.

$$
\begin{aligned}
& \Delta S_{\text {sys }} \text { is positive. } \\
& \Delta S_{\text {surr }} \text { is negative. }
\end{aligned}
$$

- A cup of hot water spontaneously cools to room temperature as the motional energy of the water molecules spreads out to the cooler surrounding air. Although the loss of energy from the system and corresponding temperature decrease cause a decrease in the entropy of the system, the increased temperature of the surrounding air causes an increase in the entropy of the surroundings.

$$
\begin{aligned}
& \Delta S_{\text {sys }} \text { is negative. } \\
& \Delta S_{\text {surr }} \text { is positive. }
\end{aligned}
$$

Thus, it is not just the entropy of the system that determines if a process is spontaneous, the entropy of the surroundings is also important. There are also examples of spontaneous processes in which $\Delta S_{\text {sys }}$ and $\Delta S_{\text {sur }}$ are both positive. The decomposition of hydrogen peroxide produces water and oxygen gas, $2 \mathrm{H}_{2} \mathrm{O}_{2}(l) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{O}_{2}(g)$. Because the reaction results in an increase in the number of gas molecules, we know that there is an increase in the entropy of the system. However, this is an exothermic reaction, meaning that it also gives off heat to the surroundings. An increase in temperature of the surroundings causes an increase in the entropy of the surroundings as well. (Note that there are no spontaneous processes in which $\Delta S_{\text {sys }}$ and $\Delta S_{\text {surr }}$ are both negative, which will become clear shortly.)

## Calculating $\Delta S_{\text {surr }}$

When an exothermic process takes place, the heat transferred from the system to the surroundings increases the temperature of the molecules in the surroundings. Consequently, there is an increase in the number of energy states accessible to the molecules in the surroundings and the entropy of the surroundings increases. Conversely, in an endothermic process, heat is transferred from the surroundings to the system, decreasing the entropy of the surroundings. Remember that for constant-pressure processes, the heat released or absorbed, $q$, is equal to the enthalpy change of the system, $\Delta H_{\text {sys }}$ [ $1 / 4$ Section 5.3]. The change in entropy for the surroundings, $\Delta S_{\text {surr }}$, is directly proportional to $\Delta H_{\text {sys }}$ :

$$
\Delta S_{\text {sur }} \propto-\Delta H_{\text {sys }}
$$

The minus sign indicates that a negative enthalpy change in the system (an exothermic process) corresponds to a positive entropy change in the surroundings. For an endothermic process, the enthalpy change in the system is a positive number and corresponds to a negative entropy change in the surroundings.

In addition to being directly proportional to $\Delta H_{\text {sys }}, \Delta S_{\text {surr }}$ is inversely proportional to temperature:

$$
\Delta S_{\text {surr }} \propto \frac{1}{T}
$$

Combining the two expressions gives

$$
\Delta S_{\text {surr }}=\frac{-\Delta H_{\text {sys }}}{T} \quad \text { Equation } 18.7
$$

Student Annotation: Most of the equilibrium processes that we will encounter are phase changes.

Student Annotation: The spontaneity that we have seen as favored by a process being exothermic is due to the spreading out of energy from the system to the surroundings; thus, the negative $\Delta H_{\text {sys }}$ corresponds to a positive $\Delta S_{\text {surr }}$.t is this positive contribution to the overall $\Delta S_{\text {univ }}$ that actually favors spontaneity.

## The Second Law of Thermodynamics

We have seen that both the system and surroundings can undergo changes in entropy during a process. The sum of the entropy changes for the system and the surroundings is the entropy change for the universe overall:

$$
\Delta S_{\text {univ }}=\Delta S_{\text {sys }}+\Delta S_{\text {surr }}
$$

Equation 18.8
The second law of thermodynamics says that for a process to be spontaneous as written (in the forward direction), $\Delta S_{\text {univ }}$ must be positive. Therefore, the system may undergo a decrease in entropy, as long as the surroundings undergoes a larger increase in entropy, and vice versa. A process for which $\Delta S_{\text {univ }}$ is negative is not spontaneous as written.

In some cases, $\Delta S_{\text {univ }}$ is neither positive nor negative but is equal to zero. This happens when the entropy changes of the system and surroundings are equal in magnitude and opposite in sign and describes a specific type of process known as an equilibrium process. An equilibrium process is one that does not occur spontaneously in either the net forward or net reverse direction but can be made to occur by the addition or removal of energy to a system at equilibrium. An example of an equilibrium process is the melting of ice at $0^{\circ} \mathrm{C}$. (Remember that at $0^{\circ} \mathrm{C}$, ice and liquid water are in equilibrium with each other [ 144 Section 12.6].)

With Equations 18.6 and 18.7, we can calculate the entropy changes for both the system and surroundings in a process. We can then use the second law of thermodynamics (Equation 18.8) to determine if the process is spontaneous or nonspontaneous as written or if it is an equilibrium process.

Consider the synthesis of ammonia at $25^{\circ} \mathrm{C}$ :

$$
\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \longrightarrow 2 \mathrm{NH}_{3}(g) \quad \Delta H_{\mathrm{rxn}}^{\circ}=-92.6 \mathrm{~kJ} / \mathrm{mol}
$$

From Sample Problem $18.2(\mathrm{~b})$, we have $\Delta S_{\text {sys }}^{\circ}=-199 \mathrm{~J} / \mathrm{K} \cdot$ mol, and substituting $\Delta H_{\text {sys }}^{\circ}$ ( $-92.6 \mathrm{~kJ} / \mathrm{mol}$ ) into Equation 18.7, we get

$$
\Delta S_{\text {surr }}=\frac{-(-92.6 \times 1000) \mathrm{J} / \mathrm{mol}}{298 \mathrm{~K}}=311 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol}
$$

The entropy change for the universe is

$$
\begin{aligned}
\Delta S_{\text {univ }}^{\circ} & =\Delta S_{\text {sys }}^{\circ}+\Delta S_{\text {surr }}^{\circ} \\
& =-199 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol}+311 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol} \\
& =112 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol}
\end{aligned}
$$

Because $\Delta S_{\text {univ }}^{\circ}$ is positive, the reaction will be spontaneous at $25^{\circ} \mathrm{C}$. Keep in mind, though, that just because a reaction is spontaneous does not mean that it will occur at an observable rate. The synthesis of ammonia is, in fact, extremely slow at room temperature. Thermodynamics can tell us whether or not a reaction will occur spontaneously under specific conditions, but it does not tell us how fast it will occur.

Sample Problem 18.4 lets you practice identifying spontaneous, nonspontaneous, and equilibrium processes.

## Sample Problem 18.4

Determine if each of the following is a spontaneous process, a nonspontaneous process, or an equilibrium process at the specified temperature: (a) $\mathrm{H}_{2}(g)+\mathrm{I}_{2}(g) \longrightarrow 2 \mathrm{HI}(g)$ at $0^{\circ} \mathrm{C}$,
(b) $\mathrm{CaCO}_{3}(s) \longrightarrow \mathrm{CaO}(s)+\mathrm{CO}_{2}(g)$ at $200^{\circ} \mathrm{C}$, (c) $\mathrm{CaCO}_{3}(s) \longrightarrow \mathrm{CaO}(s)+\mathrm{CO}_{2}(g)$ at $1000^{\circ} \mathrm{C}$, (d) $\mathrm{Na}(s) \longrightarrow \mathrm{Na}(l)$ at $98^{\circ} \mathrm{C}$. (Assume that the thermodynamic data in Appendix 2 do not vary with temperature.)

Strategy For each process, use Equation 18.6 to determine $\Delta S_{\text {sys }}^{\circ}$ and Equations 5.12 and 18.7 to determine $\Delta H_{\text {sys }}^{\circ}$ and $\Delta S_{\text {surr }}^{\circ}$. At the specified temperature, the process is spontaneous if $\Delta S_{\text {sys }}$ and $\Delta S_{\text {surr }}$ sum to a positive number, nonspontaneous if they sum to a negative number, and an equilibrium process if they sum to zero. Note that because the reaction is the system, $\Delta S_{\mathrm{rxn}}$ and $\Delta S_{\mathrm{sys}}$ are used interchangeably.

Setup From Appendix 2,
(a) $S^{\circ}\left[\mathrm{H}_{2}(g)\right]=131.0 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}, S^{\circ}\left[\mathrm{I}_{2}(g)\right]=260.57 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}, S^{\circ}[\mathrm{HI}(g)]=206.3 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$; $\Delta H_{\mathrm{f}}^{\circ}\left[\mathrm{H}_{2}(g)\right]=0 \mathrm{~kJ} / \mathrm{mol}, \Delta H_{\mathrm{f}}^{\circ}\left[\mathrm{I}_{2}(g)\right]=62.25 \mathrm{~kJ} / \mathrm{mol}, \Delta H_{\mathrm{f}}^{\circ}[\mathrm{HI}(\mathrm{g})]=25.9 \mathrm{~kJ} / \mathrm{mol}$.
(b), (c) In Sample Problem 18.2(a), we determined that for this reaction, $\Delta S_{\mathrm{rxn}}^{\circ}=160.5 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$, $\Delta H_{\mathrm{f}}^{\circ}\left[\mathrm{CaCO}_{3}(s)\right]=-1206.9 \mathrm{~kJ} / \mathrm{mol}, \Delta H_{\mathrm{f}}^{\circ}[\mathrm{CaO}(s)]=-635.6 \mathrm{~kJ} / \mathrm{mol}, \Delta H_{\mathrm{f}}^{\circ}\left[\mathrm{CO}_{2}(g)\right]=-393.5 \mathrm{~kJ} / \mathrm{mol}$. (d) $S^{\circ}[\mathrm{Na}(s)]=51.05 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}, S^{\circ}[\mathrm{Na}(l)]=57.56 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol} ; \Delta H_{\mathrm{f}}^{\circ}[\mathrm{Na}(s)]=0 \mathrm{~kJ} / \mathrm{mol}$, $\Delta H_{\mathrm{f}}^{\circ}[\mathrm{Na}(l)]=2.41 \mathrm{~kJ} / \mathrm{mol}$.

## Solution

(a) $\Delta S_{\mathrm{rxn}}^{\circ}=\left[2 S^{\circ}(\mathrm{HI})\right]-\left[S^{\circ}\left(\mathrm{H}_{2}\right)+S^{\circ}\left(\mathrm{I}_{2}\right)\right]$

$$
\begin{aligned}
& =(2)(206.3 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol})-[131.0 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol}+260.57 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol}]=21.03 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol} \\
\Delta H_{\mathrm{rxn}}^{\circ} & =\left[2 \Delta H_{\mathrm{f}}^{\circ}(\mathrm{HI})\right]-\left[\Delta H_{\mathrm{f}}^{\circ}\left(\mathrm{H}_{2}\right)+\Delta H_{\mathrm{f}}^{\circ}\left(\mathrm{I}_{2}\right)\right] \\
& =(2)(25.9 \mathrm{~kJ} / \mathrm{mol})-[0 \mathrm{~kJ} / \mathrm{mol}+62.25 \mathrm{~kJ} / \mathrm{mol}]=-10.5 \mathrm{~kJ} / \mathrm{mol} \\
\Delta S_{\text {surr }} & =\frac{-\Delta H_{\mathrm{rxn}}}{T}=\frac{-(-10.5 \mathrm{~kJ} / \mathrm{mol})}{273 \mathrm{~K}}=0.0385 \mathrm{~kJ} / \mathrm{K} \cdot \mathrm{~mol}=38.5 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol} \\
\Delta S_{\text {univ }} & =\Delta S_{\text {sys }}+\Delta S_{\text {surr }}=21.03 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol}+38.5 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol}=59.5 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol}
\end{aligned}
$$

$\Delta S_{\text {univ }}$ is positive; therefore the reaction is spontaneous at $0^{\circ} \mathrm{C}$.
(b), (c) $\Delta S_{\mathrm{rxn}}^{\circ}=160.5 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$

$$
\begin{aligned}
\Delta H_{\mathrm{rxn}}^{\circ} & =\left[\Delta H_{\mathrm{f}}^{\circ}(\mathrm{CaO})+\Delta H_{\mathrm{f}}^{\circ}\left(\mathrm{CO}_{2}\right)\right]-\left[\Delta H_{\mathrm{f}}^{\circ}\left(\mathrm{CaCO}_{3}\right)\right] \\
& =[-635.6 \mathrm{~kJ} / \mathrm{mol}+(-393.5 \mathrm{~kJ} / \mathrm{mol})]-(-1206.9 \mathrm{~kJ} / \mathrm{mol})=177.8 \mathrm{~kJ} / \mathrm{mol}
\end{aligned}
$$

(b) $\quad T=200^{\circ} \mathrm{C}$ and

$$
\begin{aligned}
& \Delta S_{\text {surr }}=\frac{-\Delta H_{\text {sys }}}{T}=\frac{-(177.8 \mathrm{~kJ} / \mathrm{mol})}{473 \mathrm{~K}}=-0.376 \mathrm{~kJ} / \mathrm{K} \cdot \mathrm{~mol}=-376 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol} \\
& \Delta S_{\text {univ }}=\Delta S_{\text {sys }}+\Delta S_{\text {surr }}=160.5 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol}+(-376 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol})=-216 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol}
\end{aligned}
$$

$\Delta S_{\text {univ }}$ is negative, therefore the reaction is nonspontaneous at $200^{\circ} \mathrm{C}$.
(c) $\quad T=1000^{\circ} \mathrm{C}$ and

$$
\begin{aligned}
& \Delta S_{\text {surr }}=\frac{-\Delta H_{\text {sys }}}{T}=\frac{-(177.8 \mathrm{~kJ} / \mathrm{mol})}{1273 \mathrm{~K}}=-0.1397 \mathrm{~kJ} / \mathrm{K} \cdot \mathrm{~mol}=-139.7 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol} \\
& \Delta S_{\text {univ }}=\Delta S_{\text {sys }}+\Delta S_{\text {surr }}=160.5 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol}+(-139.7 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol})=20.8 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol}
\end{aligned}
$$

In this case, $\Delta S_{\text {univ }}$ is positive; therefore, the reaction is spontaneous at $1000^{\circ} \mathrm{C}$.
(d) $\Delta S_{\mathrm{rxn}}^{\circ}=S^{\circ}[\mathrm{Na}(l)]-S^{\circ}[\mathrm{Na}(s)]=57.56 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}-51.05 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}=6.51 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$

$$
\begin{aligned}
& \Delta H_{\mathrm{rxn}}^{\circ}=\Delta H_{\mathrm{f}}^{\circ}[\mathrm{Na}(l)]-\Delta H_{\mathrm{f}}^{\circ}[\mathrm{Na}(\mathrm{~s})]=2.41 \mathrm{~kJ} / \mathrm{mol}-0 \mathrm{~kJ} / \mathrm{mol}=2.41 \mathrm{~kJ} / \mathrm{mol} \\
& \Delta S_{\text {surr }}=\frac{-\Delta H_{\mathrm{rxn}}}{T}=\frac{-(2.41 \mathrm{~kJ} / \mathrm{mol})}{371 \mathrm{~K}}=-0.0650 \mathrm{~kJ} / \mathrm{K} \cdot \mathrm{~mol}=-6.50 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol} \\
& \Delta S_{\text {univ }}=\Delta S_{\text {sys }}+\Delta S_{\text {surr }}=6.51 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol}+(-6.50 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol})=0.01 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol} \approx 0
\end{aligned}
$$

$\Delta S_{\text {univ }}$ is zero; therefore, the reaction is an equilibrium process at $98^{\circ} \mathrm{C}$. In fact, this is the melting point of sodium.

Practice Problem A For each of the following, calculate $\Delta S_{\text {univ }}$ and identify the process as a spontaneous process, a nonspontaneous process, or an equilibrium process at the specified temperature: (a) $\mathrm{CO}_{2}(g) \longrightarrow \mathrm{CO}_{2}(a q)$ at $25^{\circ} \mathrm{C}$, (b) $\mathrm{N}_{2} \mathrm{O}_{4}(g) \longrightarrow 2 \mathrm{NO}_{2}(g)$ at $10.4^{\circ} \mathrm{C}$, (c) $\mathrm{PCl}_{3}(l) \longrightarrow \mathrm{PCl}_{3}(g)$ at $61.2^{\circ} \mathrm{C}$. (Assume that the thermodynamic data in Appendix 2 do not vary with temperature.)
$\boldsymbol{H}$ Practice Problem B (a) Calculate $\Delta S_{\text {univ }}$ and determine if the reaction $\mathrm{H}_{2} \mathrm{O}_{2}(l) \longrightarrow \mathrm{H}_{2} \mathrm{O}_{2}(g)$ is spontaneous, nonspontaneous, or an equilibrium process at $163^{\circ} \mathrm{C}$. (b) The reaction $\mathrm{NH}_{3}(g)+$ $\mathrm{HCl}(g) \longrightarrow \mathrm{NH}_{4} \mathrm{Cl}(s)$ is spontaneous in the forward direction at room temperature but, because it is exothermic, becomes less spontaneous with increasing temperature. Determine the temperature at which it is no longer spontaneous in the forward direction. (c) Determine the boiling point of $\mathrm{Br}_{2}$. (Assume that the thermodynamic data in Appendix 2 do not vary with temperature.)

Student Annotation: The small difference between the magnitudes of $\Delta S_{\text {sys }}$ and $\Delta S_{\text {surr }}$ results from thermodynamic values not being entirely independent of temperature. The tabulated values of $S^{\circ}$ and $\Delta H_{f}^{\circ}$ are for $25^{\circ} \mathrm{C}$.

Think About It Remember that standard enthalpies of formation have units of $\mathrm{kJ} / \mathrm{mol}$, whereas standard absolute entropies have units of $\mathrm{J} / \mathrm{K} \cdot \mathrm{mol}$. Make sure that you convert kilojoules to joules, or vice versa, before combining the terms.

## The Third Law of Thermodynamics

Finally, we consider the third law of thermodynamics briefly in connection with the determination of standard entropy. We have related the entropy of a system to the number of possible arrangements of the system's molecules. The larger the number of possible arrangements, the larger the entropy. Imagine a pure, perfect crystalline substance at absolute zero $(0 \mathrm{~K})$. Under these conditions, there is essentially no molecular motion and, because the molecules occupy fixed positions in the solid, there is only one way to arrange the molecules. From Equation 18.1, we write

$$
S=k \ln W=k \ln 1=0
$$

According to the third law of thermodynamics, the entropy of a perfect crystalline substance is zero at absolute zero. As temperature increases, molecular motion increases, causing an increase in the number of possible arrangements of the molecules and in the number of accessible energy states, among which the system's energy can be dispersed. (See Figure 18.4.) This results in an increase in the system's entropy. Thus, the entropy of any substance at any temperature above 0 K is greater than zero. If the crystalline substance is impure or imperfect in any way, then its entropy is greater than zero even at 0 K because without perfect crystalline order, there is more than one possible arrangement of molecules.

The significance of the third law of thermodynamics is that it enables us to determine experimentally the absolute entropies of substances. Starting with the knowledge that the entropy of a pure crystalline substance is zero at 0 K , we can measure the increase in entropy of the substance as it is heated. The change in entropy of a substance, $\Delta S$, is the difference between the final and initial entropy values:

$$
\Delta S=S_{\text {final }}-S_{\text {initial }}
$$

where $S_{\text {initial }}$ is zero if the substance starts at 0 K . Therefore, the measured change in entropy is equal to the absolute entropy of the substance at the final temperature.

$$
\Delta S=S_{\text {final }}
$$

The entropy values arrived at in this way are called absolute entropies because they are true values-unlike standard enthalpies of formation, which are derived using an arbitrary reference. Because the tabulated values are determined at 1 atm , we usually refer to absolute entropies as standard entropies, $S^{\circ}$. Figure 18.5 shows the increase in entropy of a substance as temperature increases from absolute zero. At 0 K , it has a zero entropy value (assuming that it is a perfect crystalline substance). As it is heated, its entropy increases gradually at first because of greater

molecular motion within the crystal. At the melting point, there is a large increase in entropy as the solid is transformed into the liquid. Further heating increases the entropy of the liquid again due to increased molecular motion. At the boiling point, there is a large increase in entropy as a result of the liquid-to-vapor transition. Beyond that temperature, the entropy of the gas continues to increase with increasing temperature.

## Checkpoint 18.4 Entropy Changes in the Universe

18.4.1 Using data from Appendix 2, calculate $\Delta S^{\circ}$ (in J/K $\cdot \mathrm{mol}$ ) for the following reaction:

$$
2 \mathrm{NO}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{NO}_{2}(g)
$$

a) $145.3 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$
b) $-145.3 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$
c) $59.7 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$
d) $-59.7 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$
e) $-421.2 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$
18.4.2 Using data from Appendix 2, calculate $\Delta S^{\circ}$ (in J/K $\cdot \mathrm{mol}$ ) for the following reaction:

$$
\mathrm{CH}_{4}(g)+2 \mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(l)
$$

a) $107.7 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$
b) $-107.7 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$
c) $2.6 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$
d) $242.8 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$
e) $-242.8 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$
18.4.3 The diagrams show a spontaneous chemical reaction. What can we deduce about $\Delta S_{\text {surr }}$ for this process?

a) $\Delta S_{\text {surr }}$ is positive.
b) $\Delta S_{\text {surr }}$ is negative.
c) $\Delta S_{\text {surr }}$ is zero.
d) There is not enough information to deduce the sign of $\Delta S_{\text {surr }}$.

### 18.5 Predicting Spontaneity

## Gibbs Free-Energy Change, $\Delta G$

According to the second law of thermodynamics, $\Delta S_{\text {univ }}>0$ for a spontaneous process. What we are usually concerned with and usually measure, however, are the properties of the system rather than those of the surroundings or those of the universe overall. Therefore, it is convenient to have a thermodynamic function that enables us to determine whether or not a process is spontaneous by considering the system alone.

We begin with Equation 18.8. For a spontaneous process,

$$
\Delta S_{\text {univ }}=\Delta S_{\text {sys }}+\Delta S_{\text {surr }}>0
$$

Substituting $-\Delta H_{\text {sys }} / T$ for $\Delta S_{\text {surr }}$, we write

$$
\Delta S_{\text {univ }}=\Delta S_{\text {sys }}+\left(-\frac{\Delta H_{\text {sys }}}{T}\right)>0
$$

Multiplying both sides of the equation by $T$ gives

$$
T \Delta S_{\text {univ }}=T \Delta S_{\text {sys }}-\Delta H_{\text {sys }}>0
$$

Now we have an equation that expresses the second law of thermodynamics (and predicts whether or not a process is spontaneous) in terms of only the system. We no longer need to consider the surroundings. For convenience, we can rearrange the preceding equation, multiply through by -1 , and replace the $>$ sign with a $<$ sign:

$$
-T \Delta S_{\text {univ }}=\Delta H_{\text {sys }}-T \Delta S_{\text {sys }}<0
$$

According to this equation, a process carried out at constant pressure and temperature is spontaneous if the changes in enthalpy and entropy of the system are such that $\Delta H_{\mathrm{sys}}-T \Delta S_{\mathrm{sys}}$ is less than zero.

Student Annotation: In this context, free energy is the energy available to do work. Thus, if a particular process is accompanied by a release of usable energy (i.e., if $\Delta G$ is negative), this fact alone guarantees that it is spontaneous, and there is no need to consider what happens to the rest of the universe.

To express the spontaneity of a process more directly, we introduce another thermodynamic function called the Gibbs ${ }^{1}$ free energy $(\boldsymbol{G})$, or simply free energy.

Equation 18.9

$$
G=H-T S
$$

Each of the terms in Equation 18.9 pertains to the system. $G$ has units of energy just as $H$ and $T S$ do. Furthermore, like enthalpy and entropy, free energy is a state function. The change in free energy, $\Delta G$, of a system for a process that occurs at constant temperature is

$$
\text { Equation } 18.10 \quad \Delta G=\Delta H-T \Delta S
$$

Equation 18.10 enables us to predict the spontaneity of a process using the change in enthalpy, the change in entropy, and the absolute temperature. At constant temperature and pressure, for processes that are spontaneous as written (in the forward direction), $\Delta G$ is negative. For processes that are not spontaneous as written but that are spontaneous in the reverse direction, $\Delta G$ is positive. For systems at equilibrium, $\Delta G$ is zero.

- $\Delta G<0 \quad$ The reaction is spontaneous in the forward direction (and nonspontaneous in the reverse direction).
- $\Delta G>0 \quad$ The reaction is nonspontaneous in the forward direction (and spontaneous in the reverse direction).
- $\Delta G=0 \quad$ The system is at equilibrium.

Often we can predict the sign of $\Delta G$ for a process if we know the signs of $\Delta H$ and $\Delta S$. Table 18.4 shows how we can use Equation 18.10 to make such predictions.

Based on the information in Table 18.4, you may wonder what constitutes a "low" or a "high" temperature. For the example given in the table, $0^{\circ} \mathrm{C}$ is the temperature that divides high from low. Water freezes spontaneously at temperatures below $0^{\circ} \mathrm{C}$, and ice melts spontaneously at temperatures above $0^{\circ} \mathrm{C}$. At $0^{\circ} \mathrm{C}$, a system of ice and water is at equilibrium. The temperature that divides "high" from "low" depends, though, on the individual reaction. To determine that temperature, we must set $\Delta G$ equal to 0 in Equation 18.10 (i.e., the equilibrium condition):

$$
0=\Delta H-T \Delta S
$$

Rearranging to solve for $T$ yields

$$
T=\frac{\Delta H}{\Delta S}
$$

The temperature that divides high from low for a particular reaction can now be calculated if the values of $\Delta H$ and $\Delta S$ are known.

Sample Problem 18.5 demonstrates the use of this approach.

## TABLE 18.4 Predicting the Sign of $\Delta G$ Using Equation 18.10 and the Signs of $\Delta H$ and $\Delta S$

| When $\Delta \boldsymbol{H}$ Is | And $\Delta \boldsymbol{S}$ Is | $\Delta \boldsymbol{G}$ Will Be | And the Process Is | Example |
| :--- | :--- | :--- | :--- | :--- |
| Negative | Positive | Negative | Always spontaneous | $2 \mathrm{H}_{2} \mathrm{O}_{2}(a q) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{O}_{2}(g)$ |
| Positive | Negative | Positive | Always nonspontaneous | $3 \mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{O}_{3}(g)$ | Negative $\quad$ Negative | Negative when $T \Delta S<\Delta H$ |
| :--- |
| Positive when $T \Delta S>\Delta H$ | | Spontaneous at low $T$ |
| :--- |
| Nonspontaneous at high $T$ | $\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}_{2} \mathrm{O}(s)$ (freezing of water)

[^42]
## Sample Problem 18.5

According to Table 18.4, a reaction will be spontaneous only at high temperatures if both $\Delta H$ and $\Delta S$ are positive. For a reaction in which $\Delta H=199.5 \mathrm{~kJ} / \mathrm{mol}$ and $\Delta S=476 \mathrm{~J} / \mathrm{K} \cdot$ mol, determine the temperature (in ${ }^{\circ} \mathrm{C}$ ) above which the reaction is spontaneous.

Strategy The temperature that divides high from low is the temperature at which $\Delta H=T \Delta S$ $(\Delta G=0)$. Therefore, we use Equation 18.10 , substituting 0 for $\Delta G$ and solving for $T$ to determine temperature in kelvins; we then convert to degrees Celsius.

Setup

$$
\Delta S=\left(\frac{476 \mathrm{~J}}{\mathrm{~K} \cdot \mathrm{~mol}}\right)\left(\frac{1 \mathrm{~kJ}}{1000 \mathrm{~J}}\right)=0.476 \mathrm{~kJ} / \mathrm{K} \cdot \mathrm{~mol}
$$

Solution

$$
\begin{aligned}
T & =\frac{\Delta H}{\Delta S}=\frac{199.5 \mathrm{~kJ} / \mathrm{mol}}{0.476 \mathrm{~kJ} / \mathrm{K} \cdot \mathrm{~mol}}=419 \mathrm{~K} \\
& =(419-273)=146^{\circ} \mathrm{C}
\end{aligned}
$$

Practice Problem A A reaction will be spontaneous only at low temperatures if both $\Delta H$ and $\Delta S$ are negative. For a reaction in which $\Delta H=-380.1 \mathrm{~kJ} / \mathrm{mol}$ and $\Delta S=-95.00 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$, determine the temperature (in ${ }^{\circ} \mathrm{C}$ ) below which the reaction is spontaneous.
$\leftrightarrows$ Practice Problem B Given that the reaction $4 \mathrm{Fe}(s)+3 \mathrm{O}_{2}(g)+6 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 4 \mathrm{Fe}(\mathrm{OH})_{3}(s)$ is spontaneous at temperatures below $1950^{\circ} \mathrm{C}$, estimate the standard entropy of $\mathrm{Fe}(\mathrm{OH})_{3}(s)$.

## Standard Free-Energy Changes, $\Delta \mathbf{G}^{\circ}$

The standard free energy of reaction $\left(\Delta \boldsymbol{G}_{r x n}^{\circ}\right)$ is the free-energy change for a reaction when it occurs under standard-state conditions-that is, when reactants in their standard states are converted to products in their standard states. The conventions used by chemists to define the standard states of pure substances and solutions are

- Gases 1 atm pressure
- Liquids Pure liquid
- Solids Pure solid
- Elements The most stable allotropic form at 1 atm and $25^{\circ} \mathrm{C}$
- Solutions 1 molar concentration

To calculate $\Delta G_{\mathrm{rx}}^{\circ}$, we start with the general equation

$$
a \mathrm{~A}+b \mathrm{~B} \longrightarrow c \mathrm{C}+d \mathrm{D}
$$

The standard free-energy change for this reaction is given by

$$
\Delta G_{\mathrm{rxn}}^{\circ}=\left[c \Delta G_{\mathrm{f}}^{\circ}(\mathrm{C})+d \Delta G_{\mathrm{f}}^{\circ}(\mathrm{D})\right]-\left[a \Delta G_{\mathrm{f}}^{\circ}(\mathrm{A})+b \Delta G_{\mathrm{f}}^{\circ}(\mathrm{B})\right] \quad \text { Equation } 18.11
$$

Equation 18.11 can be generalized as follows:

$$
\begin{equation*}
\Delta G_{\mathrm{rxn}}^{\circ}=\sum n \Delta G_{\mathrm{f}}^{\circ} \text { (products) }-\sum m \Delta G_{\mathrm{f}}^{\circ} \text { (reactants) } \tag{Equation 18.12}
\end{equation*}
$$

where $m$ and $n$ are stoichiometric coefficients. The term $\Delta \boldsymbol{G}_{f}^{\circ}$ is the standard free energy of formation of a compound-that is, the free-energy change that occurs when 1 mole of the compound is synthesized from its constituent elements, each in its standard state. For the combustion of graphite,

$$
\mathrm{C}(\text { graphite })+\mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(\mathrm{~g})
$$

the standard free-energy change (from Equation 18.12) is

$$
\Delta G_{\mathrm{rxn}}^{\circ}=\left[\Delta G_{\mathrm{f}}^{\circ}\left(\mathrm{CO}_{2}\right)\right]-\left[\Delta G_{\mathrm{f}}^{\circ}(\mathrm{C}, \text { graphite })+\Delta G_{\mathrm{f}}^{\circ}\left(\mathrm{O}_{2}\right)\right]
$$

Student Annotation: The introduction of the
term $\Delta G^{\circ}$ enables us to write Equation 18.10 as

$$
\Delta G^{\circ}=\Delta H^{\circ}-T \Delta S^{\circ}
$$

Think About It Spontaneity is favored by a release of energy ( $\Delta H$ being negative) and by an increase in entropy ( $\Delta S$ being positive). When both quantities are positive, as in this case, only the entropy change favors spontaneity. For an endothermic process such as this, which requires the input of heat, it should make sense that adding more heat by increasing the temperature will shift the equilibrium to the right, thus making it "more spontaneous."

Think About It Note that, like standard enthalpies of formation $\left(\Delta H_{\mathrm{f}}^{\circ}\right)$, standard free energies of formation $\left(\Delta G_{f}^{\circ}\right)$ depend on the state of matter. Using water as an example, $\Delta G_{\mathrm{f}}^{\circ}\left[\mathrm{H}_{2} \mathrm{O}(l)\right]=$ $-237.2 \mathrm{~kJ} / \mathrm{mol}$ and $\Delta G_{\mathrm{f}}^{\circ}\left[\mathrm{H}_{2} \mathrm{O}(g)\right]$ $=-228.6 \mathrm{~kJ} / \mathrm{mol}$. Always double-check to make sure you have selected the right value from the table.

Student Annotation: The sign of $\Delta G^{\circ}$ does indicate whether or not a process is spontaneous when all reactants and products are in their standard states, but this is very seldom the case.

As with standard enthalpy of formation, the standard free energy of formation of any element (in its most stable allotropic form at 1 atm ) is defined as zero. Thus,

$$
\Delta G_{\mathrm{f}}^{\circ}(\mathrm{C}, \text { graphite })=0 \quad \text { and } \quad \Delta G_{\mathrm{f}}^{\circ}\left(\mathrm{O}_{2}\right)=0
$$

Therefore, the standard free-energy change for the reaction in this case is equal to the standard free energy of formation of $\mathrm{CO}_{2}$ :

$$
\Delta G_{\mathrm{rxn}}^{\circ}=\Delta G_{\mathrm{f}}^{\circ}\left(\mathrm{CO}_{2}\right)
$$

Appendix 2 lists the values of $\Delta G_{\mathrm{f}}^{\circ}$ at $25^{\circ} \mathrm{C}$ for a number of compounds.
Sample Problem 18.6 demonstrates the calculation of standard free-energy changes.

## Sample Problem 18.6

Calculate the standard free-energy changes for the following reactions at $25^{\circ} \mathrm{C}$ :
(a) $\mathrm{CH}_{4}(g)+2 \mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(l)$
(b) $2 \mathrm{MgO}(s) \longrightarrow 2 \mathrm{Mg}(s)+\mathrm{O}_{2}(g)$

Strategy Look up the $\Delta G_{\mathrm{f}}^{\circ}$ values for the reactants and products in each equation, and use Equation 18.12 to solve for $\Delta G_{\mathrm{rxn}}^{\circ}$.

Setup From Appendix 2, we have the following values: $\Delta G_{\mathrm{f}}^{\mathrm{o}}\left[\mathrm{CH}_{4}(g)\right]=-50.8 \mathrm{~kJ} / \mathrm{mol}$, $\Delta G_{\mathrm{f}}^{\circ}\left[\mathrm{CO}_{2}(g)\right]=-394.4 \mathrm{~kJ} / \mathrm{mol}, \Delta G_{\mathrm{f}}^{\circ}\left[\mathrm{H}_{2} \mathrm{O}(l)\right]=-237.2 \mathrm{~kJ} / \mathrm{mol}$, and $\Delta G_{\mathrm{f}}^{\circ}[\mathrm{MgO}(s)]=-569.6 \mathrm{~kJ} / \mathrm{mol}$. All the other substances are elements in their standard states and have, by definition, $\Delta G_{\mathrm{f}}^{\circ}=0$.

## Solution

(a) $\Delta G_{\mathrm{rxn}}^{\circ}=\left(\Delta G_{\mathrm{f}}^{\circ}\left[\mathrm{CO}_{2}(g)\right]+2 \Delta G_{\mathrm{f}}^{\mathrm{o}}\left[\mathrm{H}_{2} \mathrm{O}(l)\right]\right)-\left(\Delta G_{\mathrm{f}}^{\circ}\left[\mathrm{CH}_{4}(g)\right]+2 \Delta G_{\mathrm{f}}^{\circ}\left[\mathrm{O}_{2}(g)\right]\right)$

$$
=[(-394.4 \mathrm{~kJ} / \mathrm{mol})+(2)(-237.2 \mathrm{~kJ} / \mathrm{mol})]-[(-50.8 \mathrm{~kJ} / \mathrm{mol})+(2)(0 \mathrm{~kJ} / \mathrm{mol})]
$$

$$
=-818.0 \mathrm{~kJ} / \mathrm{mol}
$$

(b) $\Delta G_{\mathrm{rxn}}^{\circ}=\left(2 \Delta G_{\mathrm{f}}^{\circ}[\mathrm{Mg}(s)]+\Delta G_{\mathrm{f}}^{\circ}\left[\mathrm{O}_{2}(g)\right]\right)-\left(2 \Delta G_{\mathrm{f}}^{\circ}[\mathrm{MgO}(s)]\right)$

$$
\begin{aligned}
& =[(2)(0 \mathrm{~kJ} / \mathrm{mol})+(0 \mathrm{~kJ} / \mathrm{mol})]-[(2)(-569.6 \mathrm{~kJ} / \mathrm{mol})] \\
& =1139 \mathrm{~kJ} / \mathrm{mol}
\end{aligned}
$$

Practice Problem A Calculate the standard free-energy changes for the following reactions at $25^{\circ} \mathrm{C}$ :
(a) $\mathrm{H}_{2}(g)+\mathrm{Br}_{2}(l) \longrightarrow 2 \mathrm{HBr}(g)$
(b) $2 \mathrm{C}_{2} \mathrm{H}_{6}(g)+7 \mathrm{O}_{2}(g) \longrightarrow 4 \mathrm{CO}_{2}(g)+6 \mathrm{H}_{2} \mathrm{O}(l)$

EPractice Problem B For each reaction, determine the value of $\Delta G_{\mathrm{f}}^{\circ}$ that is not listed in Appendix 2:
(a) $\mathrm{Li}_{2} \mathrm{O}(s)+2 \mathrm{HCl}(g) \longrightarrow 2 \mathrm{LiCl}(s)+\mathrm{H}_{2} \mathrm{O}(g)$
$\Delta G_{\mathrm{rxn}}^{\circ}=-244.88 \mathrm{~kJ} / \mathrm{mol}$
(b) $\mathrm{Na}_{2} \mathrm{O}(s)+2 \mathrm{HI}(g) \longrightarrow 2 \mathrm{NaI}(s)+\mathrm{H}_{2} \mathrm{O}(l)$
$\Delta G_{\mathrm{rxn}}^{\circ}=-435.44 \mathrm{~kJ} / \mathrm{mol}$

## Using $\Delta \boldsymbol{G}$ and $\Delta \boldsymbol{G}^{\circ}$ to Solve Problems

It is the sign of $\Delta G$, the free-energy change, not the sign of $\Delta G^{\circ}$, the standard free-energy change, that indicates whether or not a process will occur spontaneously under a given set of conditions. What the sign of $\Delta G^{\circ}$ tells us is the same thing that the magnitude of the equilibrium constant $(K)$ tells us [ 14 Section 15.2]. A negative $\Delta G^{\circ}$ value corresponds to a large $K$ value (products favored at equilibrium), whereas a positive $\Delta G^{\circ}$ value corresponds to a small $K$ value (reactants favored at equilibrium).

Like equilibrium constants, $\Delta G^{\circ}$ values change with temperature. One of the uses of Equation 18.10 is to determine the temperature at which a particular equilibrium will begin to favor a desired product. For example, calcium oxide $(\mathrm{CaO})$, also called quicklime, is an extremely valuable inorganic substance with a variety of industrial uses, including water treatment and pollution control. It is prepared by heating limestone $\left(\mathrm{CaCO}_{3}\right)$, which decomposes at a high temperature:

$$
\mathrm{CaCO}_{3}(s) \rightleftarrows \mathrm{CaO}(s)+\mathrm{CO}_{2}(g)
$$

The reaction is reversible, and under the right conditions, CaO and $\mathrm{CO}_{2}$ readily recombine to form $\mathrm{CaCO}_{3}$ again. To prevent this from happening in the industrial preparation, the system is never
maintained at equilibrium; rather, $\mathrm{CO}_{2}$ is constantly removed as it forms, shifting the equilibrium from left to right, thus promoting the formation of calcium oxide.

An important piece of information for the chemist responsible for maximizing CaO production is the temperature at which the decomposition equilibrium of $\mathrm{CaCO}_{3}$ begins to favor products. We can make a reliable estimate of that temperature as follows. First we calculate $\Delta H^{\circ}$ and $\Delta S^{\circ}$ for the reaction at $25^{\circ} \mathrm{C}$, using the data in Appendix 2. To determine $\Delta H^{\circ}$, we apply Equation 5.19:

$$
\begin{aligned}
\Delta H^{\circ} & =\left[\Delta H_{\mathrm{f}}^{\circ}(\mathrm{CaO})+\Delta H_{\mathrm{f}}^{\circ}\left(\mathrm{CO}_{2}\right)\right]-\left[\Delta H_{\mathrm{f}}^{\circ}\left(\mathrm{CaCO}_{3}\right)\right] \\
& =[(-635.6 \mathrm{~kJ} / \mathrm{mol})+(-393.5 \mathrm{~kJ} / \mathrm{mol})]-(-1206.9 \mathrm{~kJ} / \mathrm{mol}) \\
& =177.8 \mathrm{~kJ} / \mathrm{mol}
\end{aligned}
$$

Next we apply Equation 18.6 to find $\Delta S^{\circ}$ :

$$
\begin{aligned}
\Delta S^{\circ} & \left.=\left[S^{\circ}(\mathrm{CaO})+S^{\circ} \mathrm{CO}_{2}\right)\right]-S^{\circ}\left(\mathrm{CaCO}_{3}\right) \\
& =[(39.8 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol})+(213.6 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol})]-(92.9 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol}) \\
& =160.5 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol}
\end{aligned}
$$

From Equation 18.10, we can write

$$
\Delta G^{\circ}=\Delta H^{\circ}-T \Delta S^{\circ}
$$

and we obtain

$$
\begin{aligned}
\Delta G^{\circ} & =(177.8 \mathrm{~kJ} / \mathrm{mol})-(298 \mathrm{~K})(0.1605 \mathrm{~kJ} / \mathrm{K} \cdot \mathrm{~mol}) \\
& =130.0 \mathrm{~kJ} / \mathrm{mol}
\end{aligned}
$$

Because $\Delta G^{\circ}$ is a large positive number, the reaction does not favor product formation at $25^{\circ} \mathrm{C}$ ( 298 K ). And, because $\Delta H^{\circ}$ and $\Delta S^{\circ}$ are both positive, we know that $\Delta G^{\circ}$ will be negative (product formation will be favored) at high temperatures. We can determine what constitutes a high temperature for this reaction by calculating the temperature at which $\Delta G^{\circ}$ is zero.

$$
0=\Delta H^{\circ}-T \Delta S^{\circ}
$$

or

$$
\begin{aligned}
T & =\frac{\Delta H^{\circ}}{\Delta S^{\circ}} \\
& =\frac{(177.8 \mathrm{~kJ} / \mathrm{mol})(1000 \mathrm{~J} / \mathrm{kJ})}{0.1605 \mathrm{~kJ} / \mathrm{K} \cdot \mathrm{~mol}} \\
& =1108 \mathrm{~K}\left(835^{\circ} \mathrm{C}\right)
\end{aligned}
$$

At temperatures higher than $835^{\circ} \mathrm{C}, \Delta G^{\circ}$ becomes negative, indicating that the reaction would then favor the formation of CaO and $\mathrm{CO}_{2}$. At $840^{\circ} \mathrm{C}(1113 \mathrm{~K})$, for example,

$$
\begin{aligned}
\Delta G^{\circ} & =\Delta H^{\circ}-T \Delta S^{\circ} \\
& =177.8 \mathrm{~kJ} / \mathrm{mol}-(1113 \mathrm{~K})(0.1605 \mathrm{~kJ} / \mathrm{K} \cdot \mathrm{~mol})\left(\frac{1 \mathrm{~kJ}}{1000 \mathrm{~J}}\right) \\
& =-0.8 \mathrm{~kJ} / \mathrm{mol}
\end{aligned}
$$

At still higher temperatures, $\Delta G^{\circ}$ becomes increasingly negative, thus favoring product formation even more. Note that in this example we used the $\Delta H^{\circ}$ and $\Delta S^{\circ}$ values at $25^{\circ} \mathrm{C}$ to calculate changes to $\Delta G^{\circ}$ at much higher temperatures. Because both $\Delta H^{\circ}$ and $\Delta S^{\circ}$ actually change with temperature, this approach does not give us a truly accurate value for $\Delta G^{\circ}$, but it does give us a reasonably good estimate.

Equation 18.10 can also be used to calculate the change in entropy that accompanies a phase change. At the temperature at which a phase change occurs (i.e., the melting point or boiling point of a substance), the system is at equilibrium $(\Delta G=0)$. Therefore, Equation 18.10 becomes

$$
0=\Delta H-T \Delta S
$$

or

$$
\Delta S=\frac{\Delta H}{T}
$$

Student Annotation: Be careful with units in problems of this type. $S^{\circ}$ values are tabulated using joules, whereas $\Delta H_{\ddagger}^{\circ}$ values are tabulated using kilojoules.

Consider the ice-water equilibrium. For the ice-to-water transition, $\Delta H$ is the molar heat of fusion (see Table 12.8) and $T$ is the melting point. The entropy change is therefore

$$
\Delta S_{\text {ice }} \rightarrow \text { water }=\frac{6010 \mathrm{~J} / \mathrm{mol}}{273 \mathrm{~K}}=22.0 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol}
$$

Thus, when 1 mole of ice melts at $0^{\circ} \mathrm{C}$, there is an increase in entropy of $22.0 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$. The increase in entropy is consistent with the increase in microstates from solid to liquid. Conversely, for the water-to-ice transition, the decrease in entropy is given by

$$
\Delta S_{\text {water } \rightarrow \text { ice }}=\frac{-6010 \mathrm{~J} / \mathrm{mol}}{273 \mathrm{~K}}=-22.0 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol}
$$

The same approach can be applied to the water-to-steam transition. In this case, $\Delta H$ is the heat of vaporization and $T$ is the boiling point of water.

Sample Problem 18.7 examines the phase transitions in benzene.

## Sample Problem 18.7

The molar heats of fusion and vaporization of benzene are 10.9 and $31.0 \mathrm{~kJ} / \mathrm{mol}$, respectively. Calculate the entropy changes for the solid-to-liquid and liquid-to-vapor transitions for benzene. At 1 atm pressure, benzene melts at $5.5^{\circ} \mathrm{C}$ and boils at $80.1^{\circ} \mathrm{C}$.

Strategy The solid-liquid transition at the melting point and the liquid-vapor transition at the boiling point are equilibrium processes. Therefore, because $\Delta G$ is zero at equilibrium, in each case we can use Equation 18.10 , substituting 0 for $\Delta G$ and solving for $\Delta S$, to determine the entropy change associated with the process.

Setup The melting point of benzene is $5.5+273.15=278.7 \mathrm{~K}$ and the boiling point is $80.1+$ $273.15=353.3 \mathrm{~K}$.

## Solution

$$
\begin{aligned}
\Delta S_{\text {fus }} & =\frac{\Delta H_{\text {fus }}}{T_{\text {melting }}}=\frac{10.9 \mathrm{~kJ} / \mathrm{mol}}{278.7 \mathrm{~K}} \\
& =0.0391 \mathrm{~kJ} / \mathrm{K} \cdot \mathrm{~mol} \text { or } 39.1 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol} \\
\Delta S_{\text {vap }} & =\frac{\Delta H_{\text {vap }}}{T_{\text {boiling }}}=\frac{31.0 \mathrm{~kJ} / \mathrm{mol}}{353.3 \mathrm{~K}} \\
& =0.0877 \mathrm{~kJ} / \mathrm{K} \cdot \mathrm{~mol} \text { or } \quad 87.7 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol}
\end{aligned}
$$

Practice Problem A The molar heats of fusion and vaporization of argon are 1.3 and $6.3 \mathrm{~kJ} / \mathrm{mol}$, respectively, and argon's melting point and boiling point are $-190^{\circ} \mathrm{C}$ and $-186^{\circ} \mathrm{C}$, respectively. Calculate the entropy changes for the fusion and vaporization of argon.
\&Practice Problem B Using data from Appendix 2 and assuming that the tabulated values do not change with temperature, (a) calculate $\Delta H_{\text {fus }}^{\circ}$ and $\Delta S_{\text {fus }}^{\circ}$ for sodium metal and determine the melting temperature of sodium, and (b) calculate $\Delta H_{\text {vap }}^{\circ}$ and $\Delta S_{\text {vap }}^{\circ}$ for sodium metal and determine the boiling temperature of sodium.

## Checkpoint 18.5 Predicting Spontaneity

18.5.1 A reaction for which $\Delta H$ and $\Delta S$ are both negative is
a) nonspontaneous at all temperatures
b) spontaneous at all temperatures
c) spontaneous at high temperatures
d) spontaneous at low temperatures
e) at equilibrium
18.5.2 At what temperature (in ${ }^{\circ} \mathrm{C}$ ) does a reaction go from being nonspontaneous to spontaneous if it has $\Delta H=171 \mathrm{~kJ} / \mathrm{mol}$ and $\Delta S=161 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$ ?
a) $270^{\circ} \mathrm{C}$
b) $670^{\circ} \mathrm{C}$
c) $1100^{\circ} \mathrm{C}$
d) $790^{\circ} \mathrm{C}$
e) $28^{\circ} \mathrm{C}$
18.5.3 Using data from Appendix 2, calculate $\Delta G^{\circ}$ (in $\mathrm{kJ} / \mathrm{mol}$ ) at $25^{\circ} \mathrm{C}$ for the reaction:

$$
\mathrm{CH}_{4}(g)+2 \mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(g)
$$

a) $-580.8 \mathrm{~kJ} / \mathrm{mol}$
b) $580.8 \mathrm{~kJ} / \mathrm{mol}$
c) $-572.0 \mathrm{~kJ} / \mathrm{mol}$
d) $-800.8 \mathrm{~kJ} / \mathrm{mol}$
e) $-818.0 \mathrm{~kJ} / \mathrm{mol}$
18.5.4 Calculate $\Delta S_{\text {sub }}$ (in $\mathrm{J} / \mathrm{K} \cdot \mathrm{mol}$ ) for the sublimation of iodine in a closed flask at $45^{\circ} \mathrm{C}$.

$$
\mathrm{I}_{2}(s) \longrightarrow \mathrm{I}_{2}(g)
$$

$\Delta H_{\text {sub }}=62.4 \mathrm{~kJ} / \mathrm{mol}$.
a) $1.4 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$
b) $196 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$
c) $1387 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$
d) $0.196 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$
e) $721 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$

### 18.6 Free Energy and Chemical Equilibrium

Reactants and products in a chemical reaction are almost always in something other than their standard states-that is, solutions usually have concentrations other than 1 M and gases usually have pressures other than 1 atm . To determine whether or not a reaction is spontaneous, therefore, we must take into account the actual concentrations and/or pressures of the species involved. And although we can determine $\Delta G^{\circ}$ from tabulated values, we need to know $\Delta G$ to determine spontaneity.

## Relationship Between $\Delta \boldsymbol{G}$ and $\Delta \boldsymbol{G}^{\circ}$

The relationship between $\Delta G$ and $\Delta G^{\circ}$, which is derived from thermodynamics, is

$$
\begin{equation*}
\Delta G=\Delta G^{\circ}+R T \ln Q \tag{Equation 18.13}
\end{equation*}
$$

where $R$ is the gas constant $\left(8.314 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}\right.$ or $\left.8.314 \times 10^{-3} \mathrm{~kJ} / \mathrm{K} \cdot \mathrm{mol}\right), T$ is the absolute temperature at which the reaction takes place, and $Q$ is the reaction quotient [is Section 15.2]. Thus, $\Delta G$ depends on two terms: $\Delta G^{\circ}$ and $R T \ln Q$. For a given reaction at temperature $T$, the value of $\Delta G^{\circ}$ is fixed but that of $R T \ln Q$ can vary because $Q$ varies according to the composition of the reaction mixture.

Consider the following equilibrium:

$$
\mathrm{H}_{2}(g)+\mathrm{I}_{2}(g) \rightleftarrows 2 \mathrm{HI}(g)
$$

Using Equation 18.12 and information from Appendix 2, we find that $\Delta G^{\circ}$ for this reaction at $25^{\circ} \mathrm{C}$ is $2.60 \mathrm{~kJ} / \mathrm{mol}$. The value of $\Delta G$, however, depends on the pressures of all three gaseous species. If we start with a mixture of gases in which $P_{\mathrm{H}_{2}}=2.0 \mathrm{~atm}, P_{\mathrm{I}_{2}}=2.0 \mathrm{~atm}$, and $P_{\mathrm{HI}}=3.0 \mathrm{~atm}$, the reaction quotient, $Q_{P}$, is

$$
\begin{aligned}
Q_{P} & =\frac{\left(P_{\mathrm{HI}}\right)^{2}}{\left(P_{\mathrm{H}_{2}}\right)\left(P_{\mathrm{I}_{2}}\right)}=\frac{(3.0)^{2}}{(2.0)(2.0)}=\frac{9.0}{4.0} \\
& =2.25
\end{aligned}
$$

Using this value in Equation 18.13 gives

$$
\begin{aligned}
\Delta G & =\frac{2.60 \mathrm{~kJ}}{\mathrm{~mol}}+\left(\frac{8.314 \times 10^{-3} \mathrm{~kJ}}{\mathrm{~K} \cdot \mathrm{~mol}}\right)(298 \mathrm{~K})(\ln 2.25) \\
& =4.3 \mathrm{~kJ} / \mathrm{mol}
\end{aligned}
$$

Because $\Delta G$ is positive, we conclude that, starting with these concentrations, the forward reaction will not occur spontaneously as written. Instead, the reverse reaction will occur spontaneously and the system will reach equilibrium by consuming part of the HI initially present and producing more $\mathrm{H}_{2}$ and $\mathrm{I}_{2}$.

If, on the other hand, we start with a mixture of gases in which $P_{\mathrm{H}_{2}}=2.0 \mathrm{~atm}, P_{\mathrm{I}_{2}}=2.0 \mathrm{~atm}$, and $P_{\mathrm{HI}}=1.0 \mathrm{~atm}$, the reaction quotient, $Q_{P}$, is

$$
\begin{aligned}
Q_{P} & =\frac{\left(P_{\mathrm{HI}}\right)^{2}}{\left(P_{\mathrm{H}_{2}}\right)\left(P_{\mathrm{I}_{2}}\right)}=\frac{(1.0)^{2}}{(2.0)(2.0)}=\frac{1}{4} \\
& =0.25
\end{aligned}
$$

Student Annotation: Even for a reaction that starts with all reactants and products in their standard states, as soon as the reaction begins, the concentrations of all species change and standard-state conditions no longer exist.

Student Annotation: The $Q$ used in Equation 18.13 can be either $Q_{c}$ (for reactions that take place in solution) or $Q_{p}$ (for reactions that take place in the gas phase)

Think About It Remember, a reaction with a positive $\Delta G^{\circ}$ value can be spontaneous if the starting concentrations of reactants and products are such that $Q<K$.

Using this value in Equation 18.13 gives

$$
\begin{aligned}
\Delta G & =\frac{2.6 \mathrm{~kJ}}{\mathrm{~mol}}+\left(\frac{8.314 \times 10^{-3} \mathrm{~kJ}}{\mathrm{~K} \cdot \mathrm{~mol}}\right)(298 \mathrm{~K})(\ln 0.25) \\
& =-0.8 \mathrm{~kJ} / \mathrm{mol}
\end{aligned}
$$

With a negative value for $\Delta G$, the reaction will be spontaneous as written-in the forward direction. In this case, the system will achieve equilibrium by consuming some of the $\mathrm{H}_{2}$ and $\mathrm{I}_{2}$ to produce more HI.

Sample Problem 18.8 uses $\Delta G^{\circ}$ and the reaction quotient to determine in which direction a reaction is spontaneous.

## Sample Problem 18.8

The equilibrium constant, $K_{P}$, for the reaction

$$
\mathrm{N}_{2} \mathrm{O}_{4}(g) \rightleftarrows 2 \mathrm{NO}_{2}(g)
$$

is 0.113 at 298 K , which corresponds to a standard free-energy change of $5.4 \mathrm{~kJ} / \mathrm{mol}$. In a certain experiment, the initial pressures are $P_{\mathrm{N}_{2} \mathrm{O}_{4}}=0.453 \mathrm{~atm}$ and $P_{\mathrm{NO}_{2}}=0.122 \mathrm{~atm}$. Calculate $\Delta G$ for the reaction at these pressures, and predict the direction in which the reaction will proceed spontaneously to establish equilibrium.

Strategy Use the partial pressures of $\mathrm{N}_{2} \mathrm{O}_{4}$ and $\mathrm{NO}_{2}$ to calculate the reaction quotient $Q_{P}$, and then use Equation 18.13 to calculate $\Delta G$.

Setup The reaction quotient expression is

$$
Q_{P}=\frac{\left(P_{\mathrm{NO}_{2}}\right)^{2}}{P_{\mathrm{N}_{2} \mathrm{O}_{4}}}=\frac{(0.122)^{2}}{0.453}=0.0329
$$

## Solution

$$
\begin{aligned}
\Delta G & =\Delta G^{\circ}+R T \ln Q_{P} \\
& =\frac{5.4 \mathrm{~kJ}}{\mathrm{~mol}}+\left(\frac{8.314 \times 10^{-3} \mathrm{~kJ}}{\mathrm{~K} \cdot \mathrm{~mol}}\right)(298 \mathrm{~K})(\ln 0.0329) \\
& =5.4 \mathrm{~kJ} / \mathrm{mol}-8.46 \mathrm{~kJ} / \mathrm{mol} \\
& =-3.1 \mathrm{~kJ} / \mathrm{mol}
\end{aligned}
$$

Because $\Delta G$ is negative, the reaction proceeds spontaneously from left to right to reach equilibrium.

Practice Problem A $\Delta G^{\circ}$ for the reaction

$$
\mathrm{H}_{2}(g)+\mathrm{I}_{2}(g) \rightleftarrows 2 \mathrm{HI}(g)
$$

is $2.60 \mathrm{~kJ} / \mathrm{mol}$ at $25^{\circ} \mathrm{C}$. Calculate $\Delta G$, and predict the direction in which the reaction is spontaneous if the starting concentrations are $P_{\mathrm{H}_{2}}=3.5 \mathrm{~atm}, P_{\mathrm{I}_{2}}=1.5 \mathrm{~atm}$, and $P_{\mathrm{HI}}=1.75 \mathrm{~atm}$.

GPractice Problem B What is the minimum partial pressure of $\mathrm{I}_{2}$ required for the preceding reaction to be spontaneous in the forward direction at $25^{\circ} \mathrm{C}$ if the partial pressures of $\mathrm{H}_{2}$ and HI are 3.5 and 1.75 atm , respectively?

## Relationship Between $\Delta \boldsymbol{G}^{\circ}$ and $K$

By definition, $\Delta G=0$ and $Q=K$ at equilibrium, where $K$ is the equilibrium constant. Thus, $\Delta G=\Delta G^{\circ}+R T \ln Q$ (Equation 18.13) becomes

$$
0=\Delta G^{\circ}+R T \ln K
$$

or
Equation 18.14

$$
\Delta G^{\circ}=-R T \ln K
$$

According to Equation 18.14 , then, the larger $K$ is, the more negative $\Delta G^{\circ}$ is. For chemists, Equation 18.14 is one of the most important equations in thermodynamics because it enables us to find the equilibrium constant of a reaction if we know the change in standard free energy, and vice versa.

It is significant that Equation 18.14 relates the equilibrium constant to the standard freeenergy change, $\Delta G^{\circ}$, rather than to the actual free-energy change, $\Delta G$. The actual free-energy change of the system varies as the reaction progresses and becomes zero at equilibrium. On the other hand, $\Delta G^{\circ}$, like $K$, is a constant for a particular reaction at a given temperature. Figure 18.6 shows plots of the free energy of a reacting system versus the extent of the reaction for two reactions. Table 18.5 summarizes the relationship between the magnitude of an equilibrium constant and the sign of the corresponding $\Delta G^{\circ}$. Remember this important distinction: It is the sign of $\Delta G$ and not that of $\Delta G^{\circ}$ that determines the direction of reaction spontaneity. The sign of $\Delta G^{\circ}$ only tells us the relative amounts of products and reactants when equilibrium is reached, not the direction the reaction must go to reach equilibrium.

(b)

Multimedia
Chemical Equilibrium—equilibrium.

Chemical Kinetics-interactive reaction coordinate diagram.

Student Annotation: The sign of $\Delta G^{\circ}$ tells us the same thing that the magnitude of $K$ tells us. The sign of $\Delta G$ tells us the same thing as the comparison of $Q$ and $K$ values [ 144 Section 15.4].

Figure 18.6 (a) $\Delta G^{\circ}<0$. At equilibrium, there is a significant conversion of reactants to products. (b) $\Delta G^{\circ}>0$. At equilibrium, reactants are favored over products. In both cases, the net reaction toward equilibrium is from left to right (reactants to products) if $Q<K$ and right to left (products to reactants) if $Q>K$. At equilibrium, $Q=K$.

## TABLE 18.5 $\quad$ Relationship Between $K$ and $\Delta G^{\circ}$ as Predicted by Equation 18.14

| $\boldsymbol{K}$ | In $\boldsymbol{K}$ | $\boldsymbol{\Delta G}^{\boldsymbol{\circ}}$ | Result at Equilibrium |
| :--- | :--- | :--- | :--- |
| $>1$ | Positive | Negative | Products are favored. |
| $=1$ | 0 | 0 | Neither products nor reactants are favored. |
| $<1$ | Negative | Positive | Reactants are favored. |

For reactions with very large or very small equilibrium constants, it can be very difficultsometimes impossible-to determine $K$ values by measuring the concentrations of the reactants and products. Consider, for example, the formation of nitric oxide from molecular nitrogen and molecular oxygen:

$$
\mathrm{N}_{2}(g)+\mathrm{O}_{2}(g) \rightleftarrows 2 \mathrm{NO}(g)
$$

At $25^{\circ} \mathrm{C}$, the equilibrium constant, $K_{P}$, is

$$
K_{P}=\frac{\left(P_{\mathrm{NO}}\right)^{2}}{\left(P_{\mathrm{N}_{2}}\right)\left(P_{\mathrm{O}_{2}}\right)}=4.0 \times 10^{-31}
$$

The very small value of $K_{P}$ means that the concentration of NO at equilibrium will be exceedingly low and, for all intents and purposes, impossible to measure directly. In such a case, the equilibrium constant is more conveniently determined using $\Delta G^{\circ}$, which can be calculated either from tabulated $\Delta G_{\mathrm{f}}^{\circ}$ values or from $\Delta H^{\circ}$ and $\Delta S^{\circ}$.

Sample Problems 18.9 and 18.10 show how to use $\Delta G^{\circ}$ to calculate $K$ and how to use $K$ to calculate $\Delta G^{\circ}$, respectively.

## Sample Problem 18.9

Using data from Appendix 2, calculate the equilibrium constant, $K_{P}$, for the following reaction at $25^{\circ} \mathrm{C}$ :

$$
2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftarrows 2 \mathrm{H}_{2}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g})
$$

Strategy Use data from Appendix 2 and Equation 18.12 to calculate $\Delta G^{\circ}$ for the reaction. Then use Equation 18.14 to solve for $K_{P}$.

Setup

$$
\begin{aligned}
\Delta G^{\circ} & =\left(2 \Delta G_{\mathrm{f}}^{\circ}\left[\mathrm{H}_{2}(\mathrm{~g})\right]+\Delta G_{\mathrm{f}}^{\circ}\left[\mathrm{O}_{2}(\mathrm{~g})\right]\right)-\left(2 \Delta G_{\mathrm{f}}^{\circ}\left[\mathrm{H}_{2} \mathrm{O}(\mathrm{l})\right]\right) \\
& =[(2)(0 \mathrm{~kJ} / \mathrm{mol})+(2)(0 \mathrm{~kJ} / \mathrm{mol})]-[(2)(-237.2 \mathrm{~kJ} / \mathrm{mol})] \\
& =474.4 \mathrm{~kJ} / \mathrm{mol}
\end{aligned}
$$

## Solution

$$
\begin{aligned}
\Delta G^{\circ} & =-R T \ln K_{P} \\
\frac{474.4 \mathrm{~kJ}}{\mathrm{~mol}} & =-\left(\frac{8.314 \times 10^{-3} \mathrm{~kJ}}{\mathrm{~K} \cdot \mathrm{~mol}}\right)(298 \mathrm{~K}) \ln K_{P} \\
-191.5 & =\ln K_{P} \\
K_{P} & =e^{-191.5} \\
& =7 \times 10^{-84}
\end{aligned}
$$

Practice Problem A Using data from Appendix 2, calculate the equilibrium constant, $K_{P}$, for the following reaction at $25^{\circ} \mathrm{C}$ :

$$
2 \mathrm{O}_{3}(\mathrm{~g}) \rightleftarrows 3 \mathrm{O}_{2}(\mathrm{~g})
$$

\& Practice Problem B $K_{\mathrm{f}}$ for the complex ion $\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}^{+}$is $1.5 \times 10^{7}$ at $25^{\circ} \mathrm{C}$. Using this and data from Appendix 2, calculate the value of $\Delta G_{\mathrm{f}}^{\circ}$ for $\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}^{+}(a q)$.

## Sample Problem 18.10

The equilibrium constant, $K_{\mathrm{sp}}$, for the dissolution of silver chloride in water at $25^{\circ} \mathrm{C}$,

$$
\mathrm{AgCl}(s) \rightleftarrows \mathrm{Ag}^{+}(a q)+\mathrm{Cl}^{-}(a q)
$$

is $1.6 \times 10^{-10}$. Calculate $\Delta G^{\circ}$ for the process.
Strategy Use Equation 18.14 to calculate $\Delta G^{\circ}$.
Setup $R=8.314 \times 10^{-3} \mathrm{~kJ} / \mathrm{K} \cdot \mathrm{mol}$ and $T=(25+273)=298 \mathrm{~K}$.
Solution

$$
\begin{aligned}
\Delta G^{\circ} & =-R T \ln K_{\mathrm{sp}} \\
& =-\left(\frac{8.314 \times 10^{-3} \mathrm{~kJ}}{\mathrm{~K} \cdot \mathrm{~mol}}\right)(298 \mathrm{~K}) \ln \left(1.6 \times 10^{-10}\right) \\
& =55.9 \mathrm{~kJ} / \mathrm{mol}
\end{aligned}
$$

Think About lt The relatively large, positive $\Delta G^{\circ}$, like the very small $K$ value, corresponds to a process that lies very far to the left. Note that the $K$ in Equation 18.14 can be any type of $K_{\mathrm{c}}\left(K_{\mathrm{a}}, K_{\mathrm{b}}, K_{\mathrm{sp}}\right.$, etc.) or $K_{P}$.

Practice Problem A Calculate $\Delta G^{\circ}$ for the process:

$$
\mathrm{BaF}_{2}(s) \rightleftarrows \mathrm{Ba}^{2+}(a q)+2 \mathrm{~F}^{-}(a q)
$$

The $K_{\text {sp }}$ of $\mathrm{BaF}_{2}$ at $25^{\circ} \mathrm{C}$ is $1.7 \times 10^{-6}$.
EPractice Problem B $K_{\text {sp }}$ for $\mathrm{Co}(\mathrm{OH})_{2}$ at $25^{\circ} \mathrm{C}$ is $3.3 \times 10^{-16}$. Using this and data from Appendix 2, calculate the value of $\Delta G_{\mathrm{f}}^{\mathrm{o}}$ for $\mathrm{Co}(\mathrm{OH})_{2}(s)$.

## Checkpoint 18.6 Free Energy and Chemical Equilibrium

18.6.1 For the reaction

$$
\mathrm{A}(a q)+\mathrm{B}(a q) \rightleftarrows \mathrm{C}(a q)
$$

$\Delta G^{\circ}=-1.95 \mathrm{~kJ} / \mathrm{mol}$ at $25^{\circ} \mathrm{C}$. What is $\Delta G$ (in $\mathrm{kJ} / \mathrm{mol}$ ) at $25^{\circ} \mathrm{C}$ when the concentrations are $[\mathrm{A}]=[\mathrm{B}]=0.315 \mathrm{M}$ and $[\mathrm{C}]=0.405 \mathrm{M}$ ?
a) $-1.95 \mathrm{~kJ} / \mathrm{mol}$
b) $1.53 \mathrm{~kJ} / \mathrm{mol}$
c) $-5.43 \mathrm{~kJ} / \mathrm{mol}$
d) $8.16 \mathrm{~kJ} / \mathrm{mol}$
e) $-12.1 \mathrm{~kJ} / \mathrm{mol}$
18.6.2 Consider the reaction

$$
\mathrm{X}(g)+\mathrm{Y}(g) \rightleftarrows \mathrm{Z}(g)
$$

for which $\Delta G^{\circ}=-1.2 \mathrm{~kJ} / \mathrm{mol}$ at $25^{\circ} \mathrm{C}$. Without knowing the pressures of the reactants and the product, we know that this reaction
a) is spontaneous as written.
b) is nonspontaneous as written.
c) favors reactants at equilibrium.
d) favors products at equilibrium.
e) is at equilibrium.
18.6.3 The $\Delta G^{\circ}$ for the reaction

$$
\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \rightleftarrows 2 \mathrm{NH}_{3}(g)
$$

is $-33.3 \mathrm{~kJ} / \mathrm{mol}$ at $25^{\circ} \mathrm{C}$. What is the value of $K_{P}$ ?
a) $2 \times 10^{-6}$
b) $7 \times 10^{5}$
c) $3 \times 10^{-70}$
d) 1
e) $1 \times 10^{-1}$
18.6.4 The $K_{\text {sp }}$ for iron(III) hydroxide $\left[\mathrm{Fe}(\mathrm{OH})_{3}\right]$ is $1.1 \times 10^{-36}$ at $25^{\circ} \mathrm{C}$. For the process
$\mathrm{Fe}(\mathrm{OH})_{3}(s) \rightleftarrows \mathrm{Fe}^{3+}(a q)+3 \mathrm{OH}^{-}(a q)$ determine $\Delta G^{\circ}$ (in $\mathrm{kJ} / \mathrm{mol}$ ) at $25^{\circ} \mathrm{C}$.
a) $-2.73 \times 10^{-36} \mathrm{~kJ} / \mathrm{mol}$
b) $-17.2 \mathrm{~kJ} / \mathrm{mol}$
c) $17.2 \mathrm{~kJ} / \mathrm{mol}$
d) $-205 \mathrm{~kJ} / \mathrm{mol}$
e) $205 \mathrm{~kJ} / \mathrm{mol}$

### 18.7 Thermodynamics in Living Systems

Many biochemical reactions have a positive $\Delta G^{\circ}$ value, yet they are essential to the maintenance of life. In living systems, these reactions are coupled to an energetically favorable process, one that has a negative $\Delta G^{\circ}$ value. The principle of coupled reactions is based on a simple concept: we can use a thermodynamically favorable reaction to drive an unfavorable one. Suppose, for example, that we want to extract zinc from a zinc sulfide ( ZnS ). The following reaction will not work because it has a large positive $\Delta G^{\circ}$ value:

$$
\mathrm{ZnS}(s) \longrightarrow \mathrm{Zn}(s)+\mathrm{S}(s) \quad \Delta G^{\circ}=198.3 \mathrm{~kJ} / \mathrm{mol}
$$

On the other hand, the combustion of sulfur to form sulfur dioxide is favored because of its large negative $\Delta G^{\circ}$ value:

$$
\mathrm{S}(s)+\mathrm{O}_{2}(g) \longrightarrow \mathrm{SO}_{2}(g) \quad \Delta G^{\circ}=-300.1 \mathrm{~kJ} / \mathrm{mol}
$$

By coupling the two processes, we can bring about the separation of zinc from zinc sulfide. In practice, this means heating ZnS in air so that the tendency of S to form $\mathrm{SO}_{2}$ will promote the decomposition of ZnS :

$$
\begin{array}{cl}
\mathrm{ZnS}(s) \longrightarrow \mathrm{Zn}(s)+\mathrm{S}(s) & \Delta G^{\circ}=198.3 \mathrm{~kJ} / \mathrm{mol} \\
\frac{\mathrm{~S}(s)+\mathrm{O}_{2}(g) \longrightarrow \mathrm{SO}_{2}(g)}{\mathrm{ZnS}(s)+\mathrm{O}_{2}(g) \longrightarrow \mathrm{Zn}(s)+\mathrm{SO}_{2}(g)} & \Delta G^{\circ}=-300.1 \mathrm{~kJ} / \mathrm{mol} \\
\Delta G^{\circ}=-101.8 \mathrm{~kJ} / \mathrm{mol}
\end{array}
$$

Coupled reactions play a crucial role in our survival. In biological systems, enzymes facilitate a wide variety of nonspontaneous reactions. In the human body, for example, food molecules, represented by glucose $\left(\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}\right)$, are converted to carbon dioxide and water during metabolism, resulting in a substantial release of free energy:

$$
\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}(s)+6 \mathrm{O}_{2}(g) \longrightarrow 6 \mathrm{CO}_{2}(g)+6 \mathrm{H}_{2} \mathrm{O}(l) \quad \Delta G^{\circ}=-2880 \mathrm{~kJ} / \mathrm{mol}
$$

In a living cell, this reaction does not take place in a single step; rather, the glucose molecule is broken down with the aid of enzymes in a series of steps. Much of the free energy released along the way is used to synthesize adenosine triphosphate (ATP) from adenosine diphosphate (ADP) and phosphoric acid (Figure 18.7):

$$
\mathrm{ADP}+\mathrm{H}_{3} \mathrm{PO}_{4} \longrightarrow \mathrm{ATP}+\mathrm{H}_{2} \mathrm{O} \quad \Delta G^{\circ}=31 \mathrm{~kJ} / \mathrm{mol}
$$

The function of ATP is to store free energy until it is needed by cells. Under appropriate conditions, ATP undergoes hydrolysis to give ADP and phosphoric acid, with a release of $31 \mathrm{~kJ} / \mathrm{mol}$ of free energy, which can be used to drive energetically unfavorable reactions, such as protein synthesis.

Proteins are polymers made of amino acids. The stepwise synthesis of a protein molecule involves the joining of individual amino acids. Consider the formation of the dipeptide (a unit composed of two amino acids) alanylglycine from alanine and glycine. This reaction represents the first step in the synthesis of a protein molecule:

$$
\text { alanine }+ \text { glycine } \longrightarrow \text { alanylglycine } \quad \Delta G^{\circ}=29 \mathrm{~kJ} / \mathrm{mol}
$$

Figure 18.7 Structures of ATP and ADP.

Adenosine triphosphate
(ATP)

Adenosine diphosphate
(ADP)

Figure 18.8 Schematic representation of ATP synthesis and coupled reactions in living systems. The conversion of glucose to carbon dioxide and water during metabolism releases free energy. The released free energy is used to convert ADP to ATP. The ATP molecules are then used as an energy source to drive unfavorable reactions such as protein synthesis from amino acids.

The positive $\Delta G^{\circ}$ value means this reaction does not favor the formation of product, so only a little of the dipeptide would be formed at equilibrium. With the aid of an enzyme, however, the reaction is coupled to the hydrolysis of ATP as follows:

$$
\text { ATP }+\mathrm{H}_{2} \mathrm{O}+\text { alanine }+ \text { glycine } \longrightarrow \mathrm{ADP}+\mathrm{H}_{3} \mathrm{PO}_{4}+\text { alanylglycine }
$$

The overall free-energy change is given by $\Delta G^{\circ}=-31 \mathrm{~kJ} / \mathrm{mol}+29 \mathrm{~kJ} / \mathrm{mol}=-2 \mathrm{~kJ} / \mathrm{mol}$, which means that the coupled reaction now favors the formation of product and an appreciable amount of alanylglycine will be formed under these conditions. Figure 18.8 shows the ATP-ADP interconversions that act as energy storage (from metabolism) and free-energy release (from ATP hydrolysis) to drive essential reactions.

## Applying What You've Learned

When a folded protein in solution is heated to a high enough temperature, its polypeptide chain will unfold to become the denatured protein-a process known as "denaturation." The temperature at which most of the protein unfolds is called the "melting" temperature. The melting temperature of a certain protein is found to be $63^{\circ} \mathrm{C}$, and the enthalpy of denaturation is $510 \mathrm{~kJ} / \mathrm{mol}$.

## Problems:

a) Estimate the entropy of denaturation, assuming that the denaturation is a single-step equilibrium process; that is, folded protein $\rightleftarrows$ denatured protein. [ 14 Sample Problem 18.7] The single polypeptide protein chain has 98 amino acids. Calculate the entropy of denaturation per amino acid.
b) Assuming that $\Delta H$ and $\Delta S$ do not change with temperature, determine $\Delta G$ for the denaturation at $20^{\circ} \mathrm{C}$. [ 14 Sample Problem 18.5]
c) Assuming that the $\Delta G$ value from part (b) is $\Delta G^{\circ}$ for the denaturation, determine the value of the equilibrium constant for the process at $20^{\circ} \mathrm{C}$. [ 1 Lt Sample Problem 18.9]

## Chapter Summary

## Section 18.1

- A spontaneous process is one that occurs under a specified set of conditions.
- A nonspontaneous process is one that does not occur under a specified set of conditions.
- Spontaneous processes do not necessarily happen quickly.

## Section 18.2

- Entropy is a thermodynamic state function that measures how dispersed or spread out a system's energy is.

## Section 18.3

- Entropy change for a process can be calculated using standard entropy values or can be predicted qualitatively based on factors such as temperature, phase, and number of molecules.
- Whether or not a process is spontaneous depends on the change in enthalpy and the change in entropy of the system.
- Tabulated standard entropy values are absolute values.

## Section 18.4

- According to the second law of thermodynamics, the entropy change for the universe is positive for a spontaneous process and zero for an equilibrium process.
- According to the third law of thermodynamics, the entropy of a perfectly crystalline substance at 0 K is zero.

## Section 18.5

- The Gibbs free energy ( $\boldsymbol{G}$ ) or simply the free energy of a system is the energy available to do work.
- The standard free energy of reaction $\left(\Delta G_{r x n}^{\circ}\right)$ for a reaction tells us whether the equilibrium lies to the right (negative $\Delta G_{\mathrm{rxn}}^{\circ}$ ) or to the left (positive $\Delta G_{\mathrm{rxn}}^{\circ}$ ).
- Standard free energies of formation $\left(\Delta \boldsymbol{G}_{f}^{\circ}\right)$ can be used to calculate standard free energies of reaction.

## Section 18.6

- The free-energy change $(\Delta G)$ is determined using the standard freeenergy change ( $\Delta G^{\circ}$ ) and the reaction quotient ( $Q$ ).
- The sign of $\Delta G$ tells us whether the reaction is spontaneous under the conditions described.
- $\Delta G^{\circ}$ is related to the equilibrium constant, $K$. A negative $\Delta G^{\circ}$ corresponds to a large $K$; a positive $\Delta G^{\circ}$ corresponds to a small $K$.

## Section 18.7

- In living systems, thermodynamically favorable reactions provide the free energy needed to drive necessary but thermodynamically unfavorable reactions.

## Key Words

| 18.13 | $\Delta G=\Delta G^{\circ}+R T \ln Q$ |
| 18.14 | $\Delta G^{\circ}=-R T \ln K$ |

## Questions and Problems

## Section 18.1: Spontaneous Processes

## Review Questions

18.1 Explain what is meant by a spontaneous process. Give two examples each of spontaneous and nonspontaneous processes.
18.2 Which of the following processes are spontaneous and which are nonspontaneous: (a) dissolving table salt $(\mathrm{NaCl})$ in hot soup, (b) climbing Mt. Everest, (c) spreading fragrance in a room by removing the cap from a perfume bottle, (d) separating helium and neon from a mixture of the gases?
18.3 Which of the following processes are spontaneous and which are nonspontaneous at a given temperature?
$\begin{array}{ll}\begin{array}{l}\text { (a) } \mathrm{NaNO}_{3}(s) \\ \text { (b) } \mathrm{NaNO}_{3}(s) \\ \text { (c) } \mathrm{NaNO}_{3}(s)\end{array} \xrightarrow{\mathrm{H}_{2} \mathrm{O}} \mathrm{H}_{2} \mathrm{O} \\ \mathrm{HaNO}_{3}(a q) & \text { unsaturated soln } \\ \mathrm{NaNO}_{3}(a q) & \text { supersaturated soln }\end{array}$

## Section 18.2: Entropy

## Review Questions

18.4 Describe what is meant by the term entropy. What are the units of entropy?
18.5 What is the relationship between entropy and the number of possible arrangements of molecules in a system?

## Problems

18.6 Referring to the setup in Figure 18.2, determine the number of possible arrangements, $W$, and calculate the entropy before and after removal of the barrier if the number of molecules is (a) 10 , (b) 50, (c) 100 .
18.7 In the setup shown, a container is divided into eight cells and contains two molecules. Initially, both molecules are confined to the left side of the container. (a) Determine the number of possible arrangements before and after removal of the central barrier. (b) After the removal of the barrier, how many of the arrangements correspond to the state in which both molecules are in the left side of the container? How many correspond to the state in which both molecules are in the right side of the container? How many correspond to the state in which the molecules are in opposite sides of the container? Calculate the entropy for each state and comment on the most probable state of the system after removal of the barrier.

## Section 18.3: Entropy Changes in a System

## Visualizing Chemistry Figure 18.4

VC 18.1 Consider two gas samples at STP: one consisting of a mole of $\mathrm{F}_{2}$ gas $\left(S^{\circ}=203.34 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}\right)$ and one consisting of a mole of F gas $\left(S^{\circ}=158.7 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}\right)$. What factors account for the difference in standard entropies of these two species?
Volume Molar mass Temperature Phase Molecular complexity
(i)
(ii)
(iii)
(iv)
(v)
a) i, ii, iii, and iv
b) ii and $v$
c) ii, iv, and v

VC 18.2 Now consider the reaction $\mathrm{F}_{2}(g) \longrightarrow 2 \mathrm{~F}(g)$ at constant temperature and pressure. What factors contribute to the entropy increase associated with the reaction?

|  | Molar | Increased |  | Increase in |
| :---: | :---: | :---: | :---: | :---: |
| Volume | mass | number | Phase | molecular |
| increase | increase | of molecules | change | complexity |
| (i) | (ii) | (iii) | (iv) | (v) |

a) i and iii
b) i, ii, and iii
c) i, iv, and v

VC 18.3 Which of the following best describes why entropy always increases with temperature?
a) As temperature increases, the number of molecules increases.
b) As temperature increases, energy states become more closely spaced.
c) As temperature increases, the molecules become more energetic and can access more energy states.
VC 18.4 Which of the following best explains why entropy typically increases with molar mass?
a) As molar mass increases, the number of molecules increases.
b) As molar mass increases, energy states become more closely spaced.
c) As molar mass increases, the molecules become more energetic and can access more energy states.

## Review Questions

18.8 How does the entropy of a system change for each of the following processes?
(a) A solid melts.
(b) A liquid freezes.
(c) A liquid boils.
(d) A vapor is converted to a solid.
(e) A vapor condenses to a liquid.
(f) A solid sublimes.
(g) A solid dissolves in water.
18.9 How does the entropy of a system change for each of the following processes?
(a) Bromine liquid vaporizes.
(b) Water freezes to form ice.
(c) Naphthalene, the key component of mothballs, sublimes.
(d) Sugar crystals form from a supersaturated solution.
(e) A block of lead melts.
(f) Iodine vapor condenses to form solid iodine.
(g) Carbon tetrachloride dissolves in liquid benzene.
18.10 Predict whether the entropy change is positive or negative for each of the following reactions. Give reasons for your predictions.
(a) $2 \mathrm{KClO}_{4}(s) \longrightarrow 2 \mathrm{KClO}_{3}(s)+\mathrm{O}_{2}(g)$
(b) $\mathrm{H}_{2} \mathrm{O}(g) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)$
(c) $2 \mathrm{Na}(s)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{NaOH}(a q)+\mathrm{H}_{2}(g)$
$(d) \mathrm{N}_{2}(g) \longrightarrow 2 \mathrm{~N}(g)$
18.11 State whether the sign of the entropy change expected for each of the following processes will be positive or negative, and explain your predictions.
(a) $\mathrm{PCl}_{3}(l)+\mathrm{Cl}_{2}(g) \longrightarrow \mathrm{PCl}_{5}(g)$
(b) $2 \mathrm{HgO}(s) \longrightarrow 2 \mathrm{Hg}(l)+\mathrm{O}_{2}(g)$
(c) $\mathrm{H}_{2}(g) \longrightarrow 2 \mathrm{H}(g)$
(d) $\mathrm{U}(s)+3 \mathrm{~F}_{2}(g) \longrightarrow \mathrm{UF}_{6}(s)$

## Problems

18.12 Calculate $\Delta S_{\text {sys }}$ for (a) the isothermal expansion of 2.0 moles of an ideal gas from 10.0 L to 15.0 L , (b) the isothermal expansion of 1.5 moles of an ideal gas from 20.0 L to 22.5 L , and (c) the isothermal compression of 5.0 moles of an ideal gas from 100.0 L to 75.0 L .
18.13 Calculate $\Delta S_{\text {sys }}$ for (a) the isothermal compression of 0.0050 mole of an ideal gas from 112 mL to 52.5 mL , (b) the isothermal compression of 0.015 mole of an ideal gas from 225 mL to 22.5 mL , and (c) the isothermal expansion of 22.1 moles of an ideal gas from 122 L to 275 L .

E18.14 For each pair of substances listed here, choose the one having the larger standard entropy value at $25^{\circ} \mathrm{C}$. The same molar amount is used in the comparison. Explain the basis for your choice. (a) $\mathrm{Li}(s)$ or $\mathrm{Li}(l)$, (b) $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(l)$ or $\mathrm{CH}_{3} \mathrm{OCH}_{3}(l)$ (Hint: Which molecule can hydrogen-bond?), (c) $\operatorname{Ar}(g)$ or $\mathrm{Xe}(g)$, (d) $\mathrm{CO}(g)$ or $\mathrm{CO}_{2}(g)$, (e) $\mathrm{O}_{2}(g)$ or $\mathrm{O}_{3}(g)$, (f) $\mathrm{NO}_{2}(g)$ or $\mathrm{N}_{2} \mathrm{O}_{4}(g)$.
18.15 Arrange the following substances (1 mole each) in order of increasing entropy at $25^{\circ} \mathrm{C}$ : (a) $\mathrm{Ne}(g)$, (b) $\mathrm{SO}_{2}(g)$, (c) $\mathrm{Na}(s)$, (d) $\mathrm{NaCl}(s)$, (e) $\mathrm{H}_{2}(g)$. Give the reasons for your arrangement.

H18.16 Using the data in Appendix 2, calculate the standard entropy changes for the following reactions at $25^{\circ} \mathrm{C}$ :
(a) S (rhombic) $+\mathrm{O}_{2}(g) \longrightarrow \mathrm{SO}_{2}(g)$
(b) $\mathrm{MgCO}_{3}(s) \longrightarrow \mathrm{MgO}(s)+\mathrm{CO}_{2}(g)$
(c) $2 \mathrm{C}_{2} \mathrm{H}_{6}(g)+7 \mathrm{O}_{2}(g) \longrightarrow 4 \mathrm{CO}_{2}(g)+6 \mathrm{H}_{2} \mathrm{O}(l)$
-18.17 Using the data in Appendix 2, calculate the standard entropy changes for the following reactions at $25^{\circ} \mathrm{C}$ :
(a) $\mathrm{H}_{2}(g)+\mathrm{CuO}(s) \longrightarrow \mathrm{Cu}(s)+\mathrm{H}_{2} \mathrm{O}(g)$
(b) $2 \mathrm{Al}(s)+3 \mathrm{ZnO}(s) \longrightarrow \mathrm{Al}_{2} \mathrm{O}_{3}(s)+3 \mathrm{Zn}(s)$
(c) $\mathrm{CH}_{4}(g)+2 \mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(l)$

## Section 18.4: Entropy Changes in the Universe

## Review Questions

18.18 State the second law of thermodynamics in words, and express it mathematically.
18.19 State the third law of thermodynamics in words, and explain its usefulness in calculating entropy values.

## Problems

18.20 Calculate $\Delta S_{\text {surr }}$ for each of the reactions in Problem 18.16 and determine if each reaction is spontaneous at $25^{\circ} \mathrm{C}$.
18.21 Calculate $\Delta S_{\text {surr }}$ for each of the reactions in Problem 18.17 and determine if each reaction is spontaneous at $25^{\circ} \mathrm{C}$.
§18.22 Using data from Appendix 2, calculate $\Delta S_{\mathrm{rxn}}^{\circ}$ and $\Delta S_{\text {surr }}$ for each of the reactions in Problem 18.10 and determine if each reaction is spontaneous at $25^{\circ} \mathrm{C}$.
18.23 Using data from Appendix 2, calculate $\Delta S_{\mathrm{rxn}}^{\circ}$ and $\Delta S_{\text {surr }}$ for each of the reactions in Problem 18.11 and determine if each reaction is spontaneous at $25^{\circ} \mathrm{C}$.

## Section 18.5: Predicting Spontaneity

## Review Questions

18.24 Define free energy. What are its units?

H18.25 Why is it more convenient to predict the direction of a reaction in terms of $\Delta G_{\text {sys }}$ instead of $\Delta S_{\text {univ }}$ ? Under what conditions can $\Delta G_{\text {sys }}$ be used to predict the spontaneity of a reaction?

H18.26 What is the significance of the sign of $\Delta G_{\text {sys }}$ ?
18.27 From the following combinations of $\Delta H$ and $\Delta S$, predict if a process will be spontaneous at a high or low temperature:
(a) both $\Delta H$ and $\Delta S$ are negative, (b) $\Delta H$ is negative and $\Delta S$ is positive, (c) both $\Delta H$ and $\Delta S$ are positive, (d) $\Delta H$ is positive and $\Delta S$ is negative.

## Problems

$\leftrightarrows 18.28$ Calculate $\Delta G^{\circ}$ for the following reactions at $25^{\circ} \mathrm{C}$ :
(a) $\mathrm{N}_{2}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{NO}(g)$
(b) $\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow \mathrm{H}_{2} \mathrm{O}(g)$
(c) $2 \mathrm{C}_{2} \mathrm{H}_{2}(g)+5 \mathrm{O}_{2}(g) \longrightarrow 4 \mathrm{CO}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(l)$
(Hint: Look up the standard free energies of formation of the reactants and products in Appendix 2.)

G18.29 Calculate $\Delta G^{\circ}$ for the following reactions at $25^{\circ} \mathrm{C}$ :
(a) $2 \mathrm{Mg}(s)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{MgO}(s)$
(b) $2 \mathrm{SO}_{2}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{SO}_{3}(g)$
(c) $2 \mathrm{C}_{2} \mathrm{H}_{6}(g)+7 \mathrm{O}_{2}(g) \longrightarrow 4 \mathrm{CO}_{2}(g)+6 \mathrm{H}_{2} \mathrm{O}(l)$
(See Appendix 2 for thermodynamic data.)
G18.30 From the values of $\Delta H$ and $\Delta S$, predict which of the following reactions would be spontaneous at $25^{\circ} \mathrm{C}$ : reaction A: $\Delta H=10.5 \mathrm{~kJ} / \mathrm{mol}, \Delta S=30 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$; reaction B: $\Delta H=$ $1.8 \mathrm{~kJ} / \mathrm{mol}, \Delta S=-113 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$. If either of the reactions is nonspontaneous at $25^{\circ} \mathrm{C}$, at what temperature might it become spontaneous?
18.31 Find the temperatures at which reactions with the following $\Delta H$ and $\Delta S$ values would become spontaneous: (a) $\Delta H=$ $-126 \mathrm{~kJ} / \mathrm{mol}, \Delta S=84 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$; (b) $\Delta H=-11.7 \mathrm{~kJ} / \mathrm{mol}$, $\Delta S=-105 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$.
18.32 The molar heats of fusion and vaporization of ethanol are 7.61 and $26.0 \mathrm{~kJ} / \mathrm{mol}$, respectively. Calculate the molar entropy changes for the solid-liquid and liquid-vapor transitions for ethanol. At 1 atm pressure, ethanol melts at $-117.3^{\circ} \mathrm{C}$ and boils at $78.3^{\circ} \mathrm{C}$.
18.33 The molar heats of fusion and vaporization of mercury are 23.4 and $59.0 \mathrm{~kJ} / \mathrm{mol}$, respectively. Calculate the molar entropy changes for the solid-liquid and liquid-vapor transitions for mercury. At 1 atm pressure, mercury melts at $-38.9^{\circ} \mathrm{C}$ and boils at $357^{\circ} \mathrm{C}$.
18.34 Consider the formation of a dimeric protein:

$$
2 \mathrm{P} \longrightarrow \mathrm{P}_{2}
$$

At $25^{\circ} \mathrm{C}$, we have $\Delta H^{\circ}=17 \mathrm{~kJ} / \mathrm{mol}$ and $\Delta S^{\circ}=65 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$. Is the dimerization favored at this temperature? Comment on the effect of lowering the temperature. Does your result explain why some enzymes lose their activities under cold conditions?
18.35 Use the values listed in Appendix 2 to calculate $\Delta G^{\circ}$ for the following alcohol fermentation:

$$
\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}(s) \longrightarrow 2 \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(l)+2 \mathrm{CO}_{2}(g)
$$

18.36 As an approximation, we can assume that proteins exist either in the native (physiologically functioning) state or the denatured state. The standard molar enthalpy and entropy of the denaturation of a certain protein are $512 \mathrm{~kJ} / \mathrm{mol}$ and $1.60 \mathrm{~kJ} / \mathrm{K} \cdot \mathrm{mol}$, respectively. Comment on the signs and magnitudes of these quantities, and calculate the temperature at which the denaturation becomes spontaneous.
18.37 Certain bacteria in the soil obtain the necessary energy for growth by oxidizing nitrites to nitrates:

$$
2 \mathrm{NO}_{2}^{-}+\mathrm{O}_{2} \longrightarrow 2 \mathrm{NO}_{3}^{-}
$$

Given that the standard Gibbs free energies of formation of $\mathrm{NO}_{2}^{-}$ and $\mathrm{NO}_{3}^{-}$are -34.6 and $-110.5 \mathrm{~kJ} / \mathrm{mol}$, respectively, calculate the amount of Gibbs free energy released when 1 mole of $\mathrm{NO}_{2}^{-}$is oxidized to 1 mole of $\mathrm{NO}_{3}^{-}$.

## Section 18.6: Free Energy and Chemical Equilibrium

## Review Questions

18.38 Explain the difference between $\Delta G$ and $\Delta G^{\circ}$.
18.39 Explain why Equation 18.14 is of great importance in chemistry.

I18.40 Fill in the missing entries in the following table:

| $\boldsymbol{K}$ | $\ln \boldsymbol{K}$ | $\Delta \boldsymbol{G}^{\circ}$ | Result at equilibrium |
| :---: | :---: | :---: | :---: |
| $<1$ |  |  |  |
|  |  | 0 |  |
|  |  |  | Products are favored |

## Problems

E 18.41 Calculate $K_{P}$ for the following reaction at $25^{\circ} \mathrm{C}$ :

$$
\mathrm{H}_{2}(g)+\mathrm{I}_{2}(g) \rightleftarrows 2 \mathrm{HI}(g) \quad \Delta G^{\circ}=2.60 \mathrm{~kJ} / \mathrm{mol}
$$

E 18.42 For the autoionization of water at $25^{\circ} \mathrm{C}$,

$$
\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{H}^{+}(a q)+\mathrm{OH}^{-}(a q)
$$

$K_{\mathrm{w}}$ is $1.0 \times 10^{-14}$. What is $\Delta G^{\circ}$ for the process?
$\$ 18.43$ Consider the following reaction at $25^{\circ} \mathrm{C}$ :

$$
\mathrm{Fe}(\mathrm{OH})_{2}(s) \rightleftarrows \mathrm{Fe}^{2+}(a q)+2 \mathrm{OH}^{-}(a q)
$$

Calculate $\Delta G^{\circ}$ for the reaction. $K_{\text {sp }}$ for $\mathrm{Fe}(\mathrm{OH})_{2}$ is $1.6 \times 10^{-14}$.
§18.44 Calculate $\Delta G^{\circ}$ and $K_{P}$ for the following equilibrium reaction at $25^{\circ} \mathrm{C}$ :

$$
2 \mathrm{H}_{2} \mathrm{O}(g) \rightleftarrows 2 \mathrm{H}_{2}(g)+\mathrm{O}_{2}(g)
$$

$\leftrightarrows 18.45$ (a) Calculate $\Delta G^{\circ}$ and $K_{P}$ for the following equilibrium reaction at $25^{\circ} \mathrm{C}$.

$$
\mathrm{PCl}_{5}(g) \rightleftarrows \mathrm{PCl}_{3}(g)+\mathrm{Cl}_{2}(g)
$$

(b) Calculate $\Delta G$ for the reaction if the partial pressures of the initial mixture are $P_{\mathrm{PCl}_{5}}=0.0029 \mathrm{~atm}, P_{\mathrm{PCl}_{3}}=0.27 \mathrm{~atm}$, and $P_{\mathrm{Cl}_{2}}=0.40 \mathrm{~atm}$.
$\$ 18.46$ The equilibrium constant $\left(K_{P}\right)$ for the reaction

$$
\mathrm{H}_{2}(g)+\mathrm{CO}_{2}(g) \rightleftarrows \mathrm{H}_{2} \mathrm{O}(g)+\mathrm{CO}(g)
$$

is 4.40 at 2000 K . (a) Calculate $\Delta G^{\circ}$ for the reaction. (b) Calculate $\Delta G$ for the reaction when the partial pressures are $P_{\mathrm{H}_{2}}=0.25 \mathrm{~atm}, P_{\mathrm{CO}_{2}}=0.78 \mathrm{~atm}, P_{\mathrm{H}_{2} \mathrm{O}}=0.66 \mathrm{~atm}$, and $P_{\mathrm{CO}}=1.20 \mathrm{~atm}$.

H18.47 Consider the decomposition of calcium carbonate:

$$
\mathrm{CaCO}_{3}(s) \rightleftarrows \mathrm{CaO}(s)+\mathrm{CO}_{2}(g)
$$

Calculate the pressure in atm of $\mathrm{CO}_{2}$ in an equilibrium process (a) at $25^{\circ} \mathrm{C}$ and (b) at $800^{\circ} \mathrm{C}$. Assume that $\Delta H^{\circ}=177.8 \mathrm{~kJ} / \mathrm{mol}$ and $\Delta S^{\circ}=160.5 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$ for the temperature range.
$\$ 18.48$ The equilibrium constant $K_{P}$ for the reaction

$$
\mathrm{CO}(g)+\mathrm{Cl}_{2}(g) \rightleftarrows \mathrm{COCl}_{2}(g)
$$

is $5.62 \times 10^{35}$ at $25^{\circ} \mathrm{C}$. Calculate $\Delta G_{\mathrm{f}}^{\circ}$ for $\mathrm{COCl}_{2}$ at $25^{\circ} \mathrm{C}$.
18.49 At $25^{\circ} \mathrm{C}, \Delta G^{\circ}$ for the process

$$
\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftarrows \mathrm{H}_{2} \mathrm{O}(\mathrm{~g})
$$

is $8.6 \mathrm{~kJ} / \mathrm{mol}$. Calculate the vapor pressure of water at this temperature.
18.50 Calculate $\Delta G^{\circ}$ for the process

$$
\mathrm{C}(\text { diamond }) \rightleftarrows \mathrm{C}(\text { graphite })
$$

Is the formation of graphite from diamond favored at $25^{\circ} \mathrm{C}$ ? If so, why is it that diamonds do not become graphite on standing?

## Section 18.7: Thermodynamics in Living Systems

## Review Questions

18.51 What is a coupled reaction? What is its importance in biological reactions?
18.52 What is the role of ATP in biological reactions?

## Problems

18.53 Referring to the metabolic process involving glucose on page 804, calculate the maximum number of moles of ATP that can be synthesized from ADP from the breakdown of 1 mole of glucose.
18.54 In the metabolism of glucose, the first step is the conversion of glucose to glucose 6-phosphate:
glucose $+\mathrm{H}_{3} \mathrm{PO}_{4} \longrightarrow$ glucose 6-phosphate $+\mathrm{H}_{2} \mathrm{O}$

$$
\Delta G^{\circ}=13.4 \mathrm{~kJ} / \mathrm{mol}
$$

Because $\Delta G^{\circ}$ is positive, this reaction does not favor the formation of products. Show how this reaction can be made to
proceed by coupling it with the hydrolysis of ATP. Write an equation for the coupled reaction, and estimate the equilibrium constant for the coupled process.

## Additional Problems

18.55 Predict the signs of $\Delta H, \Delta S$, and $\Delta G$ of the system for the following processes at 1 atm : (a) ammonia melts at $-60^{\circ} \mathrm{C}$, (b) ammonia melts at $-77.7^{\circ} \mathrm{C}$, (c) ammonia melts at $-100^{\circ} \mathrm{C}$. (The normal melting point of ammonia is $-77.7^{\circ} \mathrm{C}$.)

H18.56 Calculate $\Delta G$ for the reaction

$$
\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{H}^{+}(a q)+\mathrm{OH}^{-}(a q)
$$

at $25^{\circ} \mathrm{C}$ for the following initial concentrations:
(a) $\left[\mathrm{H}^{+}\right]=1.0 \times 10^{-7} M,\left[\mathrm{OH}^{-}\right]=1.0 \times 10^{-7} M$
(b) $\left[\mathrm{H}^{+}\right]=1.0 \times 10^{-3} M,\left[\mathrm{OH}^{-}\right]=1.0 \times 10^{-4} \mathrm{M}$
(c) $\left[\mathrm{H}^{+}\right]=1.0 \times 10^{-12} M,\left[\mathrm{OH}^{-}\right]=2.0 \times 10^{-8} M$
(d) $\left[\mathrm{H}^{+}\right]=3.5 \mathrm{M},\left[\mathrm{OH}^{-}\right]=4.8 \times 10^{-4} \mathrm{M}$
18.57 Which of the following thermodynamic functions are associated only with the first law of thermodynamics: $S, U, G$, and $H$ ?
18.58 A student placed 1 g of each of three compounds A, B, and C in a container and found that after 1 week no change had occurred. Offer some possible explanations for the fact that no reactions took place. Assume that A, B, and C are totally miscible liquids.
18.59 The enthalpy change in the denaturation of a certain protein is $125 \mathrm{~kJ} / \mathrm{mol}$. If the entropy change is $397 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$, calculate the minimum temperature at which the protein would denature spontaneously.
18.60 Consider the following facts: Water freezes spontaneously at $-5^{\circ} \mathrm{C}$ and 1 atm , and ice has a lower entropy than liquid water. Explain how a spontaneous process can lead to a decrease in entropy.
18.61 Ammonium nitrate $\left(\mathrm{NH}_{4} \mathrm{NO}_{3}\right)$ dissolves spontaneously and endothermically in water. What can you deduce about the sign of $\Delta S$ for the solution process?

E18.62 Calculate the equilibrium pressure of $\mathrm{CO}_{2}$ due to the decomposition of barium carbonate $\left(\mathrm{BaCO}_{3}\right)$ at $25^{\circ} \mathrm{C}$.
18.63 (a) Trouton's rule states that the ratio of the molar heat of vaporization of a liquid ( $\Delta H_{\text {vap }}$ ) to its boiling point in kelvins is approximately $90 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$. Use the following data to show that this is the case and explain why Trouton's rule holds true:

|  | $\boldsymbol{T}_{\mathbf{b p}}\left({ }^{\circ} \mathbf{C}\right)$ | $\Delta \boldsymbol{H}_{\text {vap }}(\mathbf{k J} / \mathbf{m o l})$ |
| :--- | :---: | :---: |
| Benzene | 80.1 | 31.0 |
| Hexane | 68.7 | 30.8 |
| Mercury | 357 | 59.0 |
| Toluene | 110.6 | 35.2 |

(b) Use the values in Table 12.6 to calculate the same ratio for ethanol and water. Explain why Trouton's rule does not apply to these two substances as well as it does to other liquids.
18.64 Referring to Problem 18.63, explain why the ratio is considerably smaller than $90 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$ for liquid HF .

H18.65 Carbon monoxide (CO) and nitric oxide (NO) are polluting gases contained in automobile exhaust. Under suitable conditions, these gases can be made to react to form nitrogen $\left(\mathrm{N}_{2}\right)$ and the less harmful carbon dioxide $\left(\mathrm{CO}_{2}\right)$. (a) Write an equation for this reaction. (b) Identify the oxidizing and reducing agents.
(c) Calculate the $K_{P}$ for the reaction at $25^{\circ} \mathrm{C}$. (d) Under normal atmospheric conditions, the partial pressures are $P_{\mathrm{N}_{2}}=0.80 \mathrm{~atm}$, $P_{\mathrm{CO}_{2}}=3.0 \times 10^{-4} \mathrm{~atm}, P_{\mathrm{CO}}=5.0 \times 10^{-5} \mathrm{~atm}$, and $P_{\mathrm{NO}}=$ $5.0 \times 10^{-7} \mathrm{~atm}$. Calculate $Q_{P}$, and predict the direction toward which the reaction will proceed. (e) Will raising the temperature favor the formation of $\mathrm{N}_{2}$ and $\mathrm{CO}_{2}$ ?
$\$ 18.66$ For reactions carried out under standard-state conditions, Equation 18.10 takes the form $\Delta G^{\circ}=\Delta H^{\circ}-T \Delta S^{\circ}$. (a) Assuming $\Delta H^{\circ}$ and $\Delta S^{\circ}$ are independent of temperature, derive the equation

$$
\ln \frac{K_{2}}{K_{1}}=\frac{\Delta H^{\circ}}{R}\left(\frac{T_{2}-T_{1}}{T_{1} T_{2}}\right)
$$

where $K_{1}$ and $K_{2}$ are the equilibrium constants at $T_{1}$ and $T_{2}$, respectively. (b) Given that at $25^{\circ} \mathrm{C} K_{\mathrm{c}}$ is $4.63 \times 10^{-3}$ for the reaction

$$
\mathrm{N}_{2} \mathrm{O}_{4}(g) \rightleftarrows 2 \mathrm{NO}_{2}(g) \quad \Delta H^{\circ}=58.0 \mathrm{~kJ} / \mathrm{mol}
$$

calculate the equilibrium constant at $65^{\circ} \mathrm{C}$.
$\leftrightarrows 18.67$ The $K_{\text {sp }}$ of AgCl is given in Table 17.4. What is its value at $60^{\circ} \mathrm{C}$ ? [Hint: You need the result of Problem 18.66(a) and the data in Appendix 2 to calculate $\Delta H^{\circ}$.]
18.68 Under what conditions does a substance have a standard entropy of zero? Can an element or a compound ever have a negative standard entropy?

G18.69 Water gas, a mixture of $\mathrm{H}_{2}$ and CO , is a fuel made by combining steam with red-hot coke (a by-product of coal distillation):

$$
\mathrm{H}_{2} \mathrm{O}(g)+\mathrm{C}(s) \rightleftarrows \mathrm{CO}(g)+\mathrm{H}_{2}(g)
$$

From the data in Appendix 2, estimate the temperature at which the reaction begins to favor the formation of products.

G18.70 Consider the following Brønsted acid-base reaction at $25^{\circ} \mathrm{C}$ :

$$
\mathrm{HF}(a q)+\mathrm{Cl}^{-}(a q) \rightleftarrows \mathrm{HCl}(a q)+\mathrm{F}^{-}(a q)
$$

(a) Predict whether $K$ will be greater or smaller than 1. (b) Does $\Delta S^{\circ}$ or $\Delta H^{\circ}$ make a greater contribution to $\Delta G^{\circ}$ ? (c) Is $\Delta H^{\circ}$ likely to be positive or negative?
18.71 The pH of gastric juice is about 1.00 and that of blood plasma is 7.40. Calculate the Gibbs free energy required to secrete a mole of $\mathrm{H}^{+}$ions from blood plasma to the stomach at $37^{\circ} \mathrm{C}$.

G18.72 Crystallization of sodium acetate from a supersaturated solution occurs spontaneously (see page 541). Based on this, what can you deduce about the signs of $\Delta S$ and $\Delta H$ ?
18.73 Consider the thermal decomposition of $\mathrm{CaCO}_{3}$ :

$$
\mathrm{CaCO}_{3}(s) \rightleftarrows \mathrm{CaO}(s)+\mathrm{CO}_{2}(g)
$$

The equilibrium vapor pressures of $\mathrm{CO}_{2}$ are 22.6 mmHg at $700^{\circ} \mathrm{C}$ and 1829 mmHg at $950^{\circ} \mathrm{C}$. Calculate the standard enthalpy of the reaction. [Hint: See Problem 18.66(a).]

H18.74 A certain reaction is spontaneous at $72^{\circ} \mathrm{C}$. If the enthalpy change for the reaction is $19 \mathrm{~kJ} / \mathrm{mol}$, what is the minimum value of $\Delta S$ (in $\mathrm{J} / \mathrm{K} \cdot \mathrm{mol}$ ) for the reaction?

H18.75 Predict whether the entropy change is positive or negative for each of these reactions:
(a) $\mathrm{Zn}(s)+2 \mathrm{HCl}(a q) \rightleftarrows \mathrm{ZnCl}_{2}(a q)+\mathrm{H}_{2}(g)$
(b) $\mathrm{O}(g)+\mathrm{O}(g) \rightleftarrows \mathrm{O}_{2}(g)$
(c) $\mathrm{NH}_{4} \mathrm{NO}_{3}(s) \rightleftarrows \mathrm{N}_{2} \mathrm{O}(g)+2 \mathrm{H}_{2} \mathrm{O}(g)$
(d) $2 \mathrm{H}_{2} \mathrm{O}_{2}(l) \rightleftarrows 2 \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{O}_{2}(g)$
18.76 The reaction $\mathrm{NH}_{3}(g)+\mathrm{HCl}(g) \longrightarrow \mathrm{NH}_{4} \mathrm{Cl}(s)$ proceeds spontaneously at $25^{\circ} \mathrm{C}$ even though there is a decrease in entropy in the system (gases are converted to a solid). Explain.
18.77 Use the following data to determine the normal boiling point, in kelvins, of mercury. What assumptions must you make to do the calculation?

$$
\begin{aligned}
\operatorname{Hg}(l): \Delta H_{\mathrm{f}}^{\circ} & =0(\text { by definition }) \\
S^{\circ} & =77.4 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol} \\
\operatorname{Hg}(g): \Delta H_{\mathrm{f}}^{\circ} & =60.78 \mathrm{~kJ} / \mathrm{mol} \\
S^{\circ} & =174.7 \mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol}
\end{aligned}
$$

E 18.78 The molar heat of vaporization of ethanol is $39.3 \mathrm{~kJ} / \mathrm{mol}$, and the boiling point of ethanol is $78.3^{\circ} \mathrm{C}$. Calculate $\Delta S$ for the vaporization of 0.50 mole of ethanol.
18.79 A certain reaction is known to have a $\Delta G^{\circ}$ value of $-122 \mathrm{~kJ} / \mathrm{mol}$. Will the reaction necessarily occur if the reactants are mixed together?

G18.80 In the Mond process for the purification of nickel, carbon monoxide is combined with heated nickel to produce $\mathrm{Ni}(\mathrm{CO})_{4}$, which is a gas and can therefore be separated from solid impurities:

$$
\mathrm{Ni}(s)+4 \mathrm{CO}(g) \rightleftarrows \mathrm{Ni}(\mathrm{CO})_{4}(g)
$$

Given that the standard free energies of formation of $\mathrm{CO}(g)$ and $\mathrm{Ni}(\mathrm{CO})_{4}(g)$ are -137.3 and $-587.4 \mathrm{~kJ} / \mathrm{mol}$, respectively, calculate the equilibrium constant of the reaction at $80^{\circ} \mathrm{C}$. Assume that $\Delta G_{\mathrm{f}}^{\circ}$ is temperature independent.

H18.81 Calculate $\Delta G^{\circ}$ and $K_{P}$ for the following processes at $25^{\circ} \mathrm{C}$ :
(a) $\mathrm{H}_{2}(g)+\mathrm{Br}_{2}(l) \rightleftarrows 2 \mathrm{HBr}(g)$
(b) $\frac{1}{2} \mathrm{H}_{2}(g)+\frac{1}{2} \mathrm{Br}_{2}(l) \rightleftarrows \mathrm{HBr}(g)$

Account for the differences in $\Delta G^{\circ}$ and $K_{P}$ obtained for parts (a) and (b).

G18.82 Calculate the pressure of $\mathrm{O}_{2}$ (in atm) over a sample of NiO at $25^{\circ} \mathrm{C}$ if $\Delta G^{\circ}=212 \mathrm{~kJ} / \mathrm{mol}$ for the reaction

$$
\mathrm{NiO}(s) \rightleftarrows \mathrm{Ni}(s)+\frac{1}{2} \mathrm{O}_{2}(g)
$$

18.83 Comment on the statement: "Just talking about entropy increases its value in the universe."
18.84 For a reaction with a negative $\Delta G^{\circ}$ value, which of the following statements is false? (a) The equilibrium constant $K$ is greater than one. (b) The reaction is spontaneous when all the reactants and products are in their standard states. (c) The reaction is always exothermic.
18.85 Consider the reaction

$$
\mathrm{N}_{2}(g)+\mathrm{O}_{2}(g) \rightleftarrows 2 \mathrm{NO}(g)
$$

Given that $\Delta G^{\circ}$ for the reaction at $25^{\circ} \mathrm{C}$ is $173.4 \mathrm{~kJ} / \mathrm{mol}$, (a) calculate the standard free energy of formation of NO and (b) calculate $K_{P}$ of the reaction. (c) One of the starting substances in smog formation is NO. Assuming that the temperature in a running automobile engine is $1100^{\circ} \mathrm{C}$, estimate $K_{P}$ for the given reaction. (d) As farmers know, lightning helps to produce a better crop. Why?

H18.86 Heating copper(II) oxide at $400^{\circ} \mathrm{C}$ does not produce any appreciable amount of Cu :

$$
\mathrm{CuO}(s) \rightleftarrows \mathrm{Cu}(s)+\frac{1}{2} \mathrm{O}_{2}(g) \quad \Delta G^{\circ}=127.2 \mathrm{~kJ} / \mathrm{mol}
$$

However, if this reaction is coupled to the conversion of graphite to carbon monoxide, it becomes spontaneous. Write an equation
for the coupled process, and calculate the equilibrium constant for the coupled reaction.
$\$ 18.87$ Consider the decomposition of magnesium carbonate:

$$
\mathrm{MgCO}_{3}(s) \rightleftarrows \mathrm{MgO}(s)+\mathrm{CO}_{2}(g)
$$

Calculate the temperature at which the decomposition begins to favor products. Assume that both $\Delta H^{\circ}$ and $\Delta S^{\circ}$ are independent of temperature.
18.88 (a) Over the years, there have been numerous claims about "perpetual motion machines," machines that will produce useful work with no input of energy. Explain why the first law of thermodynamics prohibits the possibility of such a machine existing. (b) Another kind of machine, sometimes called a "perpetual motion of the second kind," operates as follows. Suppose an ocean liner sails by scooping up water from the ocean and then extracting heat from the water, converting the heat to electric power to run the ship, and dumping the water back into the ocean. This process does not violate the first law of thermodynamics, for no energy is created-energy from the ocean is just converted to electric energy. Show that the second law of thermodynamics prohibits the existence of such a machine.
18.89 The activity series in Table 4.5 shows that reaction (a) is spontaneous whereas reaction (b) is nonspontaneous at $25^{\circ} \mathrm{C}$ :
(a) $\mathrm{Fe}(s)+2 \mathrm{H}^{+} \longrightarrow \mathrm{Fe}^{2+}(a q)+\mathrm{H}_{2}(g)$
(b) $\mathrm{Cu}(s)+2 \mathrm{H}^{+} \longrightarrow \mathrm{Cu}^{2+}(a q)+\mathrm{H}_{2}(g)$

Use the data in Appendix 2 to calculate the equilibrium constant for these reactions and hence confirm that the activity series is correct.

H18.90 The rate constant for the elementary reaction

$$
2 \mathrm{NO}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{NO}_{2}(g)
$$

is $7.1 \times 10^{9} / \mathrm{M}^{2} \cdot \mathrm{~s}$ at $25^{\circ} \mathrm{C}$. What is the rate constant for the reverse reaction at the same temperature?
18.91 The following reaction was described as the cause of sulfur deposits formed at volcanic sites.

$$
2 \mathrm{H}_{2} \mathrm{~S}(g)+\mathrm{SO}_{2}(g) \rightleftarrows 3 \mathrm{~S}(s)+2 \mathrm{H}_{2} \mathrm{O}(g)
$$

It may also be used to remove $\mathrm{SO}_{2}$ from powerplant stack gases. (a) Identify the type of redox reaction it is. (b) Calculate the equilibrium constant $\left(K_{P}\right)$ at $25^{\circ} \mathrm{C}$, and comment on whether this method is feasible for removing $\mathrm{SO}_{2}$. (c) Would this procedure become more effective or less effective at a higher temperature?
$\leftrightarrows 18.92$ Describe two ways that you could determine $\Delta G^{\circ}$ of a reaction.
18.93 The following reaction represents the removal of ozone in the stratosphere:

$$
2 \mathrm{O}_{3}(\mathrm{~g}) \rightleftarrows 3 \mathrm{O}_{2}(\mathrm{~g})
$$

Calculate the equilibrium constant $\left(K_{P}\right)$ for this reaction. In view of the magnitude of the equilibrium constant, explain why this reaction is not considered a major cause of ozone depletion in the absence of human-made pollutants such as the nitrogen oxides and CFCs. Assume the temperature of the stratosphere is $-30^{\circ} \mathrm{C}$ and $\Delta G_{\mathrm{f}}^{\mathrm{o}}$ is temperature independent.

H18.94 When a native protein in solution is heated to a high enough temperature, its polypeptide chain will unfold to become the denatured protein. The temperature at which a large portion of the protein unfolds is called the melting temperature. The melting temperature of a certain protein is found to be $46^{\circ} \mathrm{C}$, and the enthalpy of denaturation is $382 \mathrm{~kJ} / \mathrm{mol}$. Estimate the entropy of denaturation, assuming that the denaturation is a two-state
process; that is, native protein $\longrightarrow$ denatured protein. The single polypeptide protein chain has 122 amino acids. Calculate the entropy of denaturation per amino acid. Comment on your result.

H18.95 A 74.6-g ice cube floats in the Arctic Sea. The pressure and temperature of the system and surroundings are at 1 atm and $0^{\circ} \mathrm{C}$, respectively. Calculate $\Delta S_{\text {sys }}, \Delta S_{\text {surr }}$, and $\Delta S_{\text {univ }}$ for the melting of the ice cube. What can you conclude about the nature of the process from the value of $\Delta S_{\text {univ }}$ ? (The molar heat of fusion of water is $6.01 \mathrm{~kJ} / \mathrm{mol}$.)
18.96 Comment on the feasibility of extracting copper from its ore chalcocite $\left(\mathrm{Cu}_{2} \mathrm{~S}\right)$ by heating:

$$
\mathrm{Cu}_{2} \mathrm{~S}(s) \longrightarrow 2 \mathrm{Cu}(s)+\mathrm{S}(s)
$$

Calculate the $\Delta G^{\circ}$ for the overall reaction if this process is coupled to the conversion of sulfur to sulfur dioxide and $\Delta G_{\mathrm{f}}^{\circ}\left(\mathrm{Cu}_{2} \mathrm{~S}\right)=-86.1 \mathrm{~kJ} / \mathrm{mol}$.
18.97 Active transport is the process in which a substance is transferred from a region of lower concentration to one of higher concentration. This is a nonspontaneous process and must be coupled to a spontaneous process, such as the hydrolysis of ATP. The concentrations of $\mathrm{K}^{+}$ions in the blood plasma and in nerve cells are $15 \mathrm{~m} M$ and $400 \mathrm{~m} M$, respectively $\left(1 \mathrm{~m} M=1 \times 10^{-3} M\right)$. Use Equation 18.13 to calculate $\Delta G$ for the process at the physiological temperature of $37^{\circ} \mathrm{C}$ :

$$
\mathrm{K}^{+}(15 \mathrm{~m} M) \longrightarrow \mathrm{K}^{+}(400 \mathrm{~m} M)
$$

In this calculation, the $\Delta G^{\circ}$ term can be set to zero. What is the justification for this step?
\$18.98 Large quantities of hydrogen are needed for the synthesis of ammonia. One preparation of hydrogen involves the reaction between carbon monoxide and steam at $300^{\circ} \mathrm{C}$ in the presence of a copper-zinc catalyst:

$$
\mathrm{CO}(g)+\mathrm{H}_{2} \mathrm{O}(g) \rightleftarrows \mathrm{CO}_{2}(g)+\mathrm{H}_{2}(g)
$$

Calculate the equilibrium constant $\left(K_{P}\right)$ for the reaction and the temperature at which the reaction favors the formation of CO and $\mathrm{H}_{2} \mathrm{O}$. Will a larger $K_{P}$ be attained at the same temperature if a more efficient catalyst is used?
18.99 Consider two carboxylic acids (acids that contain the -COOH group): $\mathrm{CH}_{3} \mathrm{COOH}$ (acetic acid, $K_{\mathrm{a}}=1.8 \times 10^{-5}$ ) and $\mathrm{CH}_{2} \mathrm{ClCOOH}$ (chloroacetic acid, $K_{\mathrm{a}}=1.4 \times 10^{-3}$ ). (a) Calculate $\Delta G^{\circ}$ for the ionization of these acids at $25^{\circ} \mathrm{C}$. (b) From the equation $\Delta G^{\circ}=\Delta H^{\circ}-T \Delta S^{\circ}$, we see that the contributions to the $\Delta G^{\circ}$ term are an enthalpy term $\left(\Delta H^{\circ}\right)$ and a temperature times entropy term $\left(T \Delta S^{\circ}\right)$. These contributions are listed here for the two acids:

|  | $\Delta \boldsymbol{H}^{\circ}(\mathbf{k J} / \mathbf{m o l})$ | $\boldsymbol{T} \Delta \boldsymbol{S}^{\circ}(\mathbf{k J} / \mathbf{m o l})$ |
| :--- | :---: | :---: |
| $\mathrm{CH}_{3} \mathrm{COOH}$ | -0.57 | -27.6 |
| $\mathrm{CH}_{2} \mathrm{ClCOOH}$ | -4.7 | -21.1 |

Which is the dominant term in determining the value of $\Delta G^{\circ}$ (and hence $K_{\mathrm{a}}$ of the acid)? (c) What processes contribute to $\Delta H^{\circ} ?$ (Consider the ionization of the acids as a Brønsted acidbase reaction.) (d) Explain why the $T \Delta S^{\circ}$ term is more negative for $\mathrm{CH}_{3} \mathrm{COOH}$.
18.100 Many hydrocarbons exist as structural isomers, which are compounds that have the same molecular formula but different structures. For example, both butane and isobutane have the same molecular formula of $\mathrm{C}_{4} \mathrm{H}_{10}$ (see Problem 12.20 on page 530). Calculate the mole percent of these molecules in an equilibrium mixture at $25^{\circ} \mathrm{C}$, given that the standard free energy of formation of butane is $-15.9 \mathrm{~kJ} / \mathrm{mol}$ and that of isobutane
is $-18.0 \mathrm{~kJ} / \mathrm{mol}$. Does your result support the notion that straight-chain hydrocarbons (that is, hydrocarbons in which the C atoms are joined along a line) are less stable than branch-chain hydrocarbons?

E18.101 One of the steps in the extraction of iron from its ore $(\mathrm{FeO})$ is the reduction of iron(II) oxide by carbon monoxide at $900^{\circ} \mathrm{C}$ :

$$
\mathrm{FeO}(s)+\mathrm{CO}(g) \rightleftarrows \mathrm{Fe}(s)+\mathrm{CO}_{2}(g)
$$

If CO is allowed to react with an excess of FeO , calculate the mole fractions of CO and $\mathrm{CO}_{2}$ at equilibrium. State any assumptions.
18.102 Derive the equation

$$
\Delta G=R T \ln \frac{Q}{K}
$$

where $Q$ is the reaction quotient, and describe how you would use it to predict the spontaneity of a reaction.

E18.103 The sublimation of carbon dioxide at $-78^{\circ} \mathrm{C}$ is given by

$$
\mathrm{CO}_{2}(s) \longrightarrow \mathrm{CO}_{2}(g) \quad \Delta H_{\text {sub }}=25.2 \mathrm{~kJ} / \mathrm{mol}
$$

Calculate $\Delta S_{\text {sub }}$ when 84.8 g of $\mathrm{CO}_{2}$ sublimes at this temperature.
18.104 A student looked up the $\Delta G_{\mathrm{f}}^{\circ}, \Delta H_{\mathrm{f}}^{\circ}$, and $\Delta S^{\circ}$ values for $\mathrm{CO}_{2}$ in Appendix 2. Plugging these values into Equation 18.10, the student found that $\Delta G_{\mathrm{f}}^{\circ} \neq \Delta H_{\mathrm{f}}^{\circ}-T \Delta S^{\circ}$ at 298 K . What is wrong with this approach?
18.105 Consider the following reaction at 298 K :

$$
2 \mathrm{H}_{2}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l) \quad \Delta H^{\circ}=-571.6 \mathrm{~kJ} / \mathrm{mol}
$$

Calculate $\Delta S_{\text {sys }}, \Delta S_{\text {surr }}$, and $\Delta S_{\text {univ }}$ for the reaction.
E18.106 The concentration of glucose inside a cell is $0.12 \mathrm{~m} M$ and that outside a cell is $12.3 \mathrm{~m} M$. Calculate the Gibbs free-energy change for the transport of 3 moles of glucose into the cell at $37^{\circ} \mathrm{C}$.
18.107 Which of the following are not state functions: $S, H, q, w, T$ ?
18.108 Which of the following is not accompanied by an increase in the entropy of the system: (a) mixing of two gases at the same temperature and pressure, (b) mixing of ethanol and water, (c) discharging a battery, (d) expansion of a gas followed by compression to its original temperature, pressure, and volume?
18.109 Hydrogenation reactions (for example, the process of converting $\mathrm{C}=\mathrm{C}$ bonds to $\mathrm{C}-\mathrm{C}$ bonds in the food industry) are facilitated by the use of a transition metal catalyst, such as Ni or Pt. The initial step is the adsorption, or binding, of hydrogen gas onto the metal surface. Predict the signs of $\Delta H, \Delta S$, and $\Delta G$ when hydrogen gas is adsorbed onto the surface of Ni metal.
18.110 Give a detailed example of each of the following, with an explanation: (a) a thermodynamically spontaneous process, (b) a process that would violate the first law of thermodynamics, (c) a process that would violate the second law of thermodynamics, (d) an irreversible process, (e) an equilibrium process.
18.111 At 0 K , the entropy of carbon monoxide crystal is not zero but has a value of $4.2 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$, called the residual entropy. According to the third law of thermodynamics, this means that the crystal does not have a perfect arrangement of the CO molecules. (a) What would be the residual entropy if the arrangement were totally random? (b) Comment on the difference between the result in part (a) and $4.2 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$. (Hint: Assume that each CO molecule has two choices for orientation, and use Equation 18.1 to calculate the residual entropy.)
18.112 The following diagram shows the variation of the equilibrium constant with temperature for the reaction

$$
\mathrm{I}_{2}(g) \rightleftarrows 2 \mathrm{I}(g)
$$

Calculate $\Delta G^{\circ}, \Delta H^{\circ}$, and $\Delta S^{\circ}$ for the reaction at 872 K . (Hint: See Problem 18.66.)

G18.113 The standard enthalpy of formation and the standard entropy of gaseous benzene are $82.93 \mathrm{~kJ} / \mathrm{mol}$ and $269.2 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$, respectively. Calculate $\Delta H^{\circ}, \Delta S^{\circ}$, and $\Delta G^{\circ}$ for the given process at $25^{\circ} \mathrm{C}$. Comment on your answers.

$$
\mathrm{C}_{6} \mathrm{H}_{6}(l) \longrightarrow \mathrm{C}_{6} \mathrm{H}_{6}(\mathrm{~g})
$$

18.114 Consider the gas-phase reaction between $\mathrm{A}_{2}$ (green) and $\mathrm{B}_{2}$ (red) to form AB at 298 K :

$$
\mathrm{A}_{2}(g)+\mathrm{B}_{2}(g) \rightleftarrows 2 \mathrm{AB}(g) \quad \Delta G^{\circ}=-3.4 \mathrm{~kJ} / \mathrm{mol}
$$

(a) Which of the following reaction mixtures is at equilibrium?
(b) Which of the following reaction mixtures has a negative $\Delta G$ value?
(c) Which of the following reaction mixtures has a positive $\Delta G$ value?
The partial pressures of the gases in each frame are equal to the number of $\mathrm{A}_{2}, \mathrm{~B}_{2}$, and AB molecules times 0.10 atm . Round your results to two significant figures.

## Pre-Professional Practice Exam Problems: Physical and Biological Sciences

In chemistry, the standard state for a solution is $1 M$. This means that each solute concentration expressed in molarity is divided by 1 M . In biological systems, however, we define the standard state for the $\mathrm{H}^{+}$ions to be $1 \times$ $10^{-7} M$. Consequently, the change in the standard Gibbs free energy according to these two conventions will be different for reactions involving the uptake or release of $\mathrm{H}^{+}$ions, depending on which convention is used. We will therefore replace $\Delta G^{\circ}$ with $\Delta G^{\circ \prime}$, where the prime denotes that it is the standard Gibbs free-energy change for a biological process.

1. What is most likely the reason for the standard state for $\mathrm{H}^{+}$being defined as $1 \times 10^{-7} M$ in biological systems?
a) It is an arbitrary convention.
b) Physiological conditions reduce all concentrations by a factor of $10^{7}$
c) Physiological conditions increase all concentrations by a factor of $10^{7}$.
d) Biological systems have a pH of about 7 .
2. Consider the reaction

$$
\mathrm{A}+\mathrm{B} \longrightarrow \mathrm{C}+x \mathrm{H}^{+}
$$

where $x$ is a stoichiometric coefficient. Using the equation

$$
\Delta G=\Delta G^{\circ}+R T \ln Q
$$

determine the relationship between $\Delta G^{\circ \prime}$ and $\Delta G^{\circ}$, keeping in mind that $\Delta G$ is the same for a process regardless of which convention is used.
a) $\Delta G^{\circ \prime}=\Delta G^{\circ}+R T \ln \left(1 \times 10^{7}\right)$
b) $\Delta G^{\circ \prime}=\Delta G^{\circ}+R T \ln \left(1 \times 10^{-7}\right)^{x}$
c) $\Delta G^{\circ \prime}=\Delta G^{\circ}+e^{-7 / R T}$
d) $\Delta G^{\circ \prime}=\Delta G^{\circ}+R T \times e^{-7}$
3. Determine the relationship between $\Delta G^{\circ \prime}$ and $\Delta G^{\circ}$ for the reverse process:

$$
\mathrm{C}+x \mathrm{H}^{+} \longrightarrow \mathrm{A}+\mathrm{B}
$$

a) $\Delta G^{\circ \prime}=\Delta G^{\circ}+R T \ln \left(1 \times 10^{7}\right)^{x}$
b) $\Delta G^{\circ \prime}=\Delta G^{\circ}+R T \ln \left(1 \times 10^{-7}\right)$
c) $\Delta G^{\circ \prime}=\Delta G^{\circ}+e^{7 / R T}$
d) $\Delta G^{\circ \prime}=\Delta G^{\circ}+R T \times e^{7}$
4. $\mathrm{NAD}^{+}$and NADH are the oxidized and reduced forms of nicotinamide adenine dinucleotide, two key compounds in the metabolic pathways. For the oxidation of NADH

$$
\mathrm{NADH}+\mathrm{H}^{+} \longrightarrow \mathrm{NAD}^{+}+\mathrm{H}_{2}
$$

$\Delta G^{\circ}$ is $-21.8 \mathrm{~kJ} / \mathrm{mol}$ at 298 K . Calculate $\Delta G^{\circ \prime}$ for this process, and calculate $\Delta G$ using either the chemical or the biological convention when $[\mathrm{NADH}]=1.5 \times 10^{-2} M,\left[\mathrm{H}^{+}\right]=3.0 \times 10^{-5} M,[\mathrm{NAD}]=$ $4.6 \times 10^{-3} \mathrm{M}$, and $P_{\mathrm{H}_{2}}=0.010 \mathrm{~atm}$.
a) $18.1 \mathrm{~kJ} / \mathrm{mol}, 50.3 \mathrm{~kJ} / \mathrm{mol}$
b) $21.8 \mathrm{~kJ} / \mathrm{mol}, 29.6 \mathrm{~kJ} / \mathrm{mol}$
c) $18.1 \mathrm{~kJ} / \mathrm{mol}, 10.3 \mathrm{~kJ} / \mathrm{mol}$
d) $21.8 \mathrm{~kJ} / \mathrm{mol}, 10.3 \mathrm{~kJ} / \mathrm{mol}$

## Answers to In-Chapter Materials

## Answers to Practice Problems

18.1A $0.34 \mathrm{~J} / \mathrm{K}$. 18.1B $\frac{1}{5}$. 18.2A (a) $173.6 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$, (b) $-139.8 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$, (c) $215.3 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$. 18.2B (a) $S^{\circ}[\mathrm{K}(l)]=71.5 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$, (b) $S^{\circ}\left[\mathrm{S}_{2} \mathrm{Cl}_{2}(g)\right]=$ $331.5 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$, (c) $S^{\circ}\left[\mathrm{MgF}_{2}(\mathrm{~s})\right]=57.24 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$. 18.3A (a) Negative, (b) negative, (c) positive. 18.3B The sign of $\Delta H^{\circ}$ for both dissolution processes is negative. Something must favor spontaneity; if not entropy change, then enthalpy change. Because these processes both involve decreases in the system's entropy, they must be exothermic, or they could not be spontaneous. 18.4 A (a) $\Delta S_{\text {univ }}=-27.2 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$, nonspontaneous, (b) $\Delta S_{\text {univ }}=-28.1 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$, nonspontaneous, (c) $\Delta S_{\text {univ }}=0 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$, equilibrium. 18.4B (a) $\Delta S_{\text {univ }}=5.2 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$, spontaneous, (b) $346^{\circ} \mathrm{C}$, (c) $58^{\circ} \mathrm{C}$. 18.5A $3728^{\circ} \mathrm{C}$. 18.5B $108 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$. 18.6A (a) $-106 \mathrm{~kJ} / \mathrm{mol}$, (b) $-2935 \mathrm{~kJ} / \mathrm{mol}$. 18.6B (a) $\Delta G_{\mathrm{f}}^{\circ}\left[\mathrm{Li}_{2} \mathrm{O}(s)\right]=-561.2 \mathrm{~kJ} / \mathrm{mol}$, (b) $\Delta G_{\mathrm{f}}^{\mathrm{o}}[\mathrm{NaI}(s)]=-286.1 \mathrm{~kJ} / \mathrm{mol}$. 18.7A $\Delta S_{\text {fus }}=16 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$, $\Delta S_{\text {vap }}=72 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol} .18 .7 \mathrm{~B}$ (a) $\Delta H_{\text {fus }}^{\circ}=2.41 \mathrm{~kJ} / \mathrm{mol}, \Delta S_{\text {fus }}^{\circ}=$ $6.51 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}, T_{\text {melting }}=97^{\circ} \mathrm{C}$. (b) $\Delta H_{\text {vap }}^{\circ}=105.3 \mathrm{~kJ} / \mathrm{mol}, \Delta S_{\text {vap }}^{\circ}=$ $96.1 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}, T_{\text {boiling }}=823^{\circ} \mathrm{C}$. 18.8A $1.3 \mathrm{~kJ} / \mathrm{mol}$, reverse reaction is spontaneous. 18.8B 2.5 atm . 18.9A $2 \times 10^{57}$. 18.9B $-16.8 \mathrm{~kJ} / \mathrm{mol}$. 18.10A $32.9 \mathrm{~kJ} / \mathrm{mol}$. 18.10B $-454.4 \mathrm{~kJ} / \mathrm{mol}$.

## Answers to Checkpoints

## How Electrochemistry Can Cause Dental Pain

Anyone who accidentally bites on a piece of aluminum foil in such a way that the foil touches an amalgam dental filling will experience a momentary sharp pain. The pain is actually the result of electrical stimulation of the nerve of a tooth caused by a current flowing between the aluminum foil and the metal in the filling. Historically, the material most commonly used to fill cavities is known as dental amalgam. (An amalgam is a substance made by combining mercury with one or more other metals.) Dental amalgam consists of liquid mercury mixed in roughly equal parts with an alloy powder containing silver, tin, copper, and sometimes smaller amounts of other metals such as zinc.

What happens is this: the aluminum and the dental filling act as electrodes in a galvanic cell. Aluminum acts as the anode, and the amalgam acts as the cathode. In effect, when the aluminum comes into contact with the amalgam, an electrochemical cell is established in the mouth, causing a current to flow. This current stimulates the nerve of the tooth, causing a very unpleasant sensation.

The pain caused by having aluminum foil contact an amalgam filling is the result of electrochemistry.

Used with permission of Atlantic Feature Syndicate for Mark Parisi.

At the end of this chapter, you will be able to solve a series of problems related to the electrochemistry associated with dental pain [ 1 Page 848].

## In This Chapter, You Will Learn:

How chemical reactions can produce electric energy and how reaction conditions affect the energy production. You will also learn how electric energy can be used to drive chemical reactions that otherwise would not occur.

## Before you begin, you should review

- Oxidation numbers [ 14 Section 4.4]
- The reaction quotient, $Q$ [ kt Section 15.2]
- Gibbs free energy [14 Section 18.5]

Student Annotation: Now is a good time to review how oxidation numbers are assigned [14 Section 4.4].

### 19.1 Balancing Redox Reactions

In Chapter 4 we briefly discussed oxidation-reduction or "redox" reactions, those in which electrons are transferred from one species to another. In this section we review how to identify a reaction as a redox reaction and look more closely at how such reactions are balanced.

A redox reaction is one in which there are changes in oxidation states, which we identify using the rules introduced in Chapter 4. The following are examples of redox reactions:

$$
\left.\begin{array}{l}
2 \mathrm{KClO}_{3}(s) \longrightarrow 2 \mathrm{KCl}(s)+3 \mathrm{O}_{2}(g) \\
\oplus 1+5-2 \\
\mathrm{CH}_{4}(g)+2 \mathrm{O}_{2}(\mathrm{~g})
\end{array} \longrightarrow \mathrm{CO}_{2}(\mathrm{~g})+2 \mathrm{H}_{2} \mathrm{O}(l) \mathrm{l}\right)
$$

Equations for redox reactions, such as those shown here, can be balanced by inspection, the method of balancing introduced in Chapter 3 [ WH Section 3.3], but remember that redox equations must be balanced for mass (number of atoms) and for charge (number of electrons) [ 14 Section 4.4]. In this section we introduce the half-reaction method to balance equations that cannot be balanced simply by inspection.

Consider the aqueous reaction of the iron(II) ion $\left(\mathrm{Fe}^{2+}\right)$ with the dichromate ion $\left(\mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}\right)$ :

$$
\mathrm{Fe}^{2+}+\mathrm{Cr}_{2} \mathrm{O}_{7}^{2-} \longrightarrow \mathrm{Fe}^{3+}+\mathrm{Cr}^{3+}
$$

Because there is no species containing oxygen on the product side of the equation, it would not be possible to balance this equation simply by adjusting the coefficients of reactants and products. However, there are two things about the reaction that make it possible to add species to the equation to balance it-without changing the chemical reaction it represents:

- The reaction takes place in aqueous solution, so we can add $\mathrm{H}_{2} \mathrm{O}$ as needed to balance the equation.
- This particular reaction takes place in acidic solution, so we can add $\mathrm{H}^{+}$as needed to balance the equation. (Some reactions take place in basic solution, enabling us to add $\mathrm{OH}^{-}$as needed for balancing. We will learn more about this shortly.)
After writing the unbalanced equation, we balance it stepwise as follows:

1. Separate the unbalanced reaction into half-reactions. A half-reaction is an oxidation or a reduction that occurs as part of the overall redox reaction.

$$
\begin{array}{lrl}
\text { Oxidation: } & \mathrm{Fe}^{2+} \longrightarrow \mathrm{Fe}^{3+} \\
\text { Reduction: } & \mathrm{Cr}_{2} \mathrm{O}_{7}^{2-} \longrightarrow \mathrm{Cr}^{3+}
\end{array}
$$

2. Balance each of the half-reactions with regard to atoms other than O and H . In this case, no change is required for the oxidation half-reaction. We adjust the coefficient of the chromium(III) ion to balance the reduction half-reaction.

$$
\begin{array}{lr}
\text { Oxidation: } & \mathrm{Fe}^{2+} \longrightarrow \mathrm{Fe}^{3+} \\
\text { Reduction: } & \mathrm{Cr}_{2} \mathrm{O}_{7}^{2-} \longrightarrow 2 \mathrm{Cr}^{3+}
\end{array}
$$

3. Balance both half-reactions for O by adding $\mathrm{H}_{2} \mathrm{O}$. Again, the oxidation in this case requires no change, but we must add seven water molecules to the product side of the reduction.

$$
\begin{array}{lrl}
\text { Oxidation: } & \mathrm{Fe}^{2+} \longrightarrow \mathrm{Fe}^{3+} \\
\text { Reduction: } & \mathrm{Cr}_{2} \mathrm{O}_{7}^{2-} \longrightarrow 2 \mathrm{Cr}^{3+}+7 \mathrm{H}_{2} \mathrm{O}
\end{array}
$$

4. Balance both half-reactions for H by adding $\mathrm{H}^{+}$. Once again, the oxidation in this case requires no change, but we must add 14 hydrogen ions to the reactant side of the reduction.

$$
\begin{aligned}
& \text { Oxidation: } \mathrm{Fe}^{2+} \longrightarrow \mathrm{Fe}^{3+} \\
& \text { Reduction: } 14 \mathrm{H}^{+}+\mathrm{Cr}_{2} \mathrm{O}_{7}^{2-} \longrightarrow 2 \mathrm{Cr}^{3+}+7 \mathrm{H}_{2} \mathrm{O}
\end{aligned}
$$

5. Balance both half-reactions for charge by adding electrons. To do this, we determine the total charge on each side and add electrons to make the total charges equal. In the case of the oxidation, there is a charge of +2 on the reactant side and a charge of +3 on the product side. Adding one electron to the product side makes the charges equal.

$$
\begin{aligned}
& \text { Oxidation: } \\
& \text { Total charge: } \\
& \mathrm{Fe}^{2+}
\end{aligned} \underbrace{\mathrm{Fe}^{3+}+e^{-}}_{+2}
$$

In the case of the reduction, there is a total charge of $[(14)(+1)+(1)(-2)]=+12$ on the reactant side and a total charge of $[(2)(+3)]=+6$ on the product side. Adding six electrons to the reactant side makes the charges equal.

$$
\begin{aligned}
& \text { Reduction: } \quad \frac{6 e^{-}+14 \mathrm{H}^{+}+\mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}}{+6} \longrightarrow \frac{2 \mathrm{Cr}^{3+}+7 \mathrm{H}_{2} \mathrm{O}}{+6} \\
& \text { Total charge: }
\end{aligned}
$$

6. If the number of electrons in the balanced oxidation half-reaction is not the same as the number of electrons in the balanced reduction half-reaction, multiply one or both of the halfreactions by the number(s) required to make the number of electrons the same in both. In this case, with one electron in the oxidation and six in the reduction, multiplying the oxidation by 6 accomplishes this.

7. Finally, add the balanced half-reactions back together and cancel the electrons, in addition to any other identical terms that appear on both sides.

$$
\begin{aligned}
& 6 \mathrm{Fe}^{2+} \longrightarrow 6 \mathrm{Fe}^{3+}+6 e^{?} \\
& 6 e^{P}+14 \mathrm{H}^{+}+\mathrm{Cr}_{2} \mathrm{O}_{7}^{2-} \longrightarrow 2 \mathrm{Cr}^{3+}+7 \mathrm{H}_{2} \mathrm{O} \\
& 6 \mathrm{Fe}^{2+}+14 \mathrm{H}^{+}+\mathrm{Cr}_{2} \mathrm{O}_{7}^{2-} \longrightarrow 6 \mathrm{Fe}^{3+}+2 \mathrm{Cr}^{3+}+7 \mathrm{H}_{2} \mathrm{O}
\end{aligned}
$$

A final check shows that the resulting equation is balanced both for mass and for charge.
Some redox reactions occur in basic solution. When this is the case, balancing by the halfreaction method is done exactly as described for reactions in acidic solution, but it requires two additional steps:
8. For each $\mathrm{H}^{+}$ion in the final equation, add one $\mathrm{OH}^{-}$ion to each side of the equation, combining the $\mathrm{H}^{+}$and $\mathrm{OH}^{-}$ions to produce $\mathrm{H}_{2} \mathrm{O}$.
9. Make any additional cancellations made necessary by the new $\mathrm{H}_{2} \mathrm{O}$ molecules.

Sample Problem 19.1 shows how to use the half-reaction method to balance a reaction that takes place in basic solution.

## Sample Problem 19.1

Permanganate ion and iodide ion react in basic solution to produce manganese(IV) oxide and molecular iodine. Use the half-reaction method to balance the equation:

$$
\mathrm{MnO}_{4}^{-}+\mathrm{I}^{-} \longrightarrow \mathrm{MnO}_{2}+\mathrm{I}_{2}
$$

Strategy The reaction takes place in basic solution, so apply steps 1 through 9 to balance for mass and for charge.

Setup Identify the oxidation and reduction half-reactions by assigning oxidation numbers.

## Solution

Step 1. Separate the unbalanced reaction into half-reactions.
Oxidation: $\quad \mathrm{I}^{-} \longrightarrow \mathrm{I}_{2}$
Reduction: $\mathrm{MnO}_{4}^{-} \longrightarrow \mathrm{MnO}_{2}$

Think About It Verify that the final equation is balanced for mass and for charge. Remember that electrons cannot appear in the overall balanced equation.

Step 2. Balance each half-reaction for mass, excluding O and H .

$$
\begin{aligned}
2 \mathrm{I}^{-} & \longrightarrow \mathrm{I}_{2} \\
\mathrm{MnO}_{4}^{-} & \longrightarrow \mathrm{MnO}_{2}
\end{aligned}
$$

Step 3. Balance both half-reactions for O by adding $\mathrm{H}_{2} \mathrm{O}$.

$$
\begin{aligned}
2 \mathrm{I}^{-} & \longrightarrow \mathrm{I}_{2} \\
\mathrm{MnO}_{4}^{-} & \longrightarrow \mathrm{MnO}_{2}+2 \mathrm{H}_{2} \mathrm{O}
\end{aligned}
$$

Step 4. Balance both half-reactions for H by adding $\mathrm{H}^{+}$.

$$
\begin{aligned}
2 \mathrm{I}^{-} & \longrightarrow \mathrm{I}_{2} \\
4 \mathrm{H}^{+}+\mathrm{MnO}_{4}^{-} & \longrightarrow \mathrm{MnO}_{2}+2 \mathrm{H}_{2} \mathrm{O}
\end{aligned}
$$

Step 5. Balance the total charge of both half-reactions by adding electrons.

$$
\begin{aligned}
2 \mathrm{I}^{-} & \longrightarrow \mathrm{I}_{2}+2 e^{-} \\
3 e^{-}+4 \mathrm{H}^{+}+\mathrm{MnO}_{4}^{-} & \longrightarrow \mathrm{MnO}_{2}+2 \mathrm{H}_{2} \mathrm{O}
\end{aligned}
$$

Step 6. Multiply the half-reactions to make the numbers of electrons the same in both.

$$
\begin{aligned}
3\left(2 \mathrm{I}^{-}\right. & \left.\longrightarrow \mathrm{I}_{2}+2 e^{-}\right) \\
2\left(3 e^{-}+4 \mathrm{H}^{+}+\mathrm{MnO}_{4}^{-}\right. & \left.\longrightarrow \mathrm{MnO}_{2}+2 \mathrm{H}_{2} \mathrm{O}\right)
\end{aligned}
$$

Step 7. Add the half-reactions back together, cancelling electrons.

$$
\begin{aligned}
& 6 \mathrm{I}^{-} \longrightarrow 3 \mathrm{I}_{2}+6 e^{t} \\
& 6 e^{t}+8 \mathrm{H}^{+}+2 \mathrm{MnO}_{4}^{-} \longrightarrow 2 \mathrm{MnO}_{2}+4 \mathrm{H}_{2} \mathrm{O} \\
& 8 \mathrm{H}^{+}+2 \mathrm{MnO}_{4}^{-}+6 \mathrm{I}^{-} \longrightarrow 2 \mathrm{MnO}_{2}+3 \mathrm{I}_{2}+4 \mathrm{H}_{2} \mathrm{O}
\end{aligned}
$$

Step 8. For each $\mathrm{H}^{+}$ion in the final equation, add one $\mathrm{OH}^{-}$ion to each side of the equation, combining the $\mathrm{H}^{+}$and $\mathrm{OH}^{-}$ions to produce $\mathrm{H}_{2} \mathrm{O}$.

$$
\begin{aligned}
& 8 \mathrm{H}^{+}+2 \mathrm{MnO}_{4}^{-}+6 \mathrm{I}^{-} \longrightarrow 2 \mathrm{MnO}_{2}+3 \mathrm{I}_{2}+4 \mathrm{H}_{2} \mathrm{O} \\
& +8 \mathrm{OH}^{-} \\
& \hline 8 \mathrm{H}_{2} \mathrm{O}+2 \mathrm{MnO}_{4}^{-}+6 \mathrm{I}^{-} \longrightarrow 2 \mathrm{MnO}_{2}+3 \mathrm{I}_{2}+4 \mathrm{H}_{2} \mathrm{O}+8 \mathrm{OH}^{-}
\end{aligned}
$$

Step 9. Carry out any cancellations made necessary by the additional $\mathrm{H}_{2} \mathrm{O}$ molecules.

$$
4 \mathrm{H}_{2} \mathrm{O}+2 \mathrm{MnO}_{4}^{-}+6 \mathrm{I}^{-} \longrightarrow 2 \mathrm{MnO}_{2}+3 \mathrm{I}_{2}+8 \mathrm{OH}^{-}
$$

Practice Problem A Use the half-reaction method to balance the following equation in basic solution:

$$
\mathrm{CN}^{-}+\mathrm{MnO}_{4}^{-} \longrightarrow \mathrm{CNO}^{-}+\mathrm{MnO}_{2}
$$

GPractice Problem B Use the half-reaction method to balance the following equation in acidic solution:

$$
\mathrm{Fe}^{2+}+\mathrm{MnO}_{4}^{-} \longrightarrow \mathrm{Fe}^{3+}+\mathrm{Mn}^{2+}
$$

## Checkpoint 19.1 Balancing Redox Reactions

19.1.1 Which of the following equations does not represent a redox reaction? (Select all that apply.)
a) $\mathrm{NH}_{3}+\mathrm{HCl} \longrightarrow \mathrm{NH}_{4} \mathrm{Cl}$
b) $2 \mathrm{H}_{2} \mathrm{O}_{2} \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}+\mathrm{O}_{2}$
c) $2 \mathrm{O}_{3} \longrightarrow 3 \mathrm{O}_{2}$
d) $3 \mathrm{NO}_{2}+\mathrm{H}_{2} \mathrm{O} \longrightarrow \mathrm{NO}+2 \mathrm{HNO}_{3}$
e) $\mathrm{LiCl} \longrightarrow \mathrm{Li}^{+}+\mathrm{Cl}^{-}$

### 19.2 Galvanic Cells

When zinc metal is placed in a solution containing copper(II) ions, Zn is oxidized to $\mathrm{Zn}^{2+}$ ions whereas $\mathrm{Cu}^{2+}$ ions are reduced to $\mathrm{Cu}[14$ Section 4.4]:

$$
\mathrm{Zn}(s)+\mathrm{Cu}^{2+}(a q) \longrightarrow \mathrm{Zn}^{2+}(a q)+\mathrm{Cu}(s)
$$

The electrons are transferred directly from the reducing agent, Zn , to the oxidizing agent, $\mathrm{Cu}^{2+}$, in solution. However, if we physically separate two half-reactions from each other, we can arrange it such that the electrons must travel through a wire to pass from the Zn atoms to the $\mathrm{Cu}^{2+}$ ions. As the reaction progresses, it generates a flow of electrons through the wire and thereby generates electricity.

The experimental apparatus for generating electricity through the use of a spontaneous reaction is called a galvanic cell. Figure 19.1 shows the essential components of a galvanic cell. A zinc bar is immersed in an aqueous $\mathrm{ZnSO}_{4}$ solution in one container, and a copper bar is immersed in an aqueous $\mathrm{CuSO}_{4}$ solution in another container. The cell operates on the principle that the oxidation of Zn to $\mathrm{Zn}^{2+}$ and the reduction of $\mathrm{Cu}^{2+}$ to Cu can be made to take place simultaneously in separate locations with the transfer of electrons between them occurring through an external wire. The zinc and copper bars are called electrodes. By definition, the anode in a galvanic cell is the electrode at which oxidation occurs and the cathode is the electrode at which reduction occurs. (Each combination of container, electrode, and solution is called a half-cell.) This particular arrangement of electrodes and electrolytes is called a Daniell cell.

The half-reactions for the galvanic cell shown in Figure 19.1 are

$$
\begin{aligned}
& \text { Oxidation: } \quad \mathrm{Zn}(s) \longrightarrow \mathrm{Zn}^{2+}(a q)+2 e^{-} \\
& \text {Reduction: } \mathrm{Cu}^{2+}(a q)+2 e^{-} \longrightarrow \mathrm{Cu}(s)
\end{aligned}
$$

To complete the electric circuit, and allow electrons to flow through the external wire, the solutions must be connected by a conducting medium through which the cations and anions can move from one half-cell to the other. This requirement is satisfied by a salt bridge, which, in its simplest form, is an inverted U tube containing an inert electrolyte solution, such as KCl or $\mathrm{NH}_{4} \mathrm{NO}_{3}$. The ions in the salt bridge must not react with the other ions in solution or with the electrodes (see Figure 19.1). During the course of the redox reaction, electrons flow through the external wire from the anode ( Zn electrode) to the cathode ( Cu electrode). In the solution, the cations $\left(\mathrm{Zn}^{2+}, \mathrm{Cu}^{2+}\right.$, and $\left.\mathrm{K}^{+}\right)$ move toward the cathode, while the anions ( $\mathrm{SO}_{4}^{2-}$ and $\mathrm{Cl}^{-}$) move toward the anode. Without the salt bridge connecting the two solutions, the buildup of positive charge in the anode compartment (due to the departure of electrons and the resulting formation of $\mathrm{Zn}^{2+}$ ) and the buildup of negative charge in the cathode compartment (created by the arrival of electrons and the reduction of $\mathrm{Cu}^{2+}$ ions to Cu ) would quickly prevent the cell from operating.

An electric current flows from the anode to the cathode because there is a difference in electrical potential energy between the electrodes. This flow of electric current is analogous to the flow of water down a waterfall, which occurs because there is a difference in the gravitational potential energy, or the flow of gas from a high-pressure region to a low-pressure region. Experimentally the difference in electrical potential between the anode and the cathode is measured by a voltmeter (Figure 19.2) and the reading (in volts) is called the cell potential $\left(\boldsymbol{E}_{\text {cell }}\right)$. The potential of a cell depends not only on the nature of the electrodes and the ions in solution, but also on the concentrations of the ions and the temperature at which the cell is operated.

The conventional notation for representing galvanic cells is the cell diagram. For the cell shown in Figure 19.1, if we assume that the concentrations of $\mathrm{Zn}^{2+}$ and $\mathrm{Cu}^{2+}$ ions are $1 M$, the cell diagram is

$$
\mathrm{Zn}(s)\left|\mathrm{Zn}^{2+}(1 M) \| \mathrm{Cu}^{2+}(1 M)\right| \mathrm{Cu}(s)
$$

The single vertical line represents a phase boundary. For example, the zinc electrode is a solid and the $\mathrm{Zn}^{2+}$ ions are in solution. Thus, we draw a line between Zn and $\mathrm{Zn}^{2+}$ to show the phase boundary. The double vertical lines denote the salt bridge. By convention, the anode is written first, to the left of the double lines, and the other components appear in the order in which we would encounter them in moving from the anode to the cathode (from left to right in the cell diagram).

Student Annotation: This reaction is shown in Figure 4.5.

Student Annotation: A galvanic cell can also be called a voltaic cell. Both terms refer to a cell in which a spontaneous chemical reaction generates a flow of electrons.

Media Player/MPEG Animation: Figure 19.1, Construction of a Galvanic Cell, pp. 822-823.

Student Annotation: This is the origin of the terms cathode and anode:

- Cations move toward the cathode.
- Anions move toward the anode.

Student Annotation: The volt is a derived
Sl unit: $1 \mathrm{~V}=1 \mathrm{~J} / 1 \mathrm{C}$.

Student Annotation: The terms cell potential, cell voltage, cell electromotive force, and cell emf are used interchangeably and are all symbolized the same way with $E_{\text {cell }}$

Figure 19.1

## Construction of a Galvanic Cell

We add a salt bridge, a tube containing a solution of a strong electrolyte-in this case $\mathrm{Na}_{2} \mathrm{SO}_{4}$. Having this solution in electrical contact with the two solutions in the beakers allows ions to migrate toward the electrodes, ensuring that the two compartments remain electrically neutral.

The two metal pieces are the electrodes in the galvanic cell. We connect the electrodes with a length of wire routed through a voltmeter and a switch so that we can complete the circuit when we have completed construction of the cell.

To make the reaction between zinc and copper more useful, we can construct a galvanic cell. In one beaker, we place a piece of zinc metal in a 1.00 M solution of $\mathrm{Zn}^{2+}$ ions. In the other, we place a piece of copper metal in a 1.00 M solution of $\mathrm{Cu}^{2+}$ ions.

As shown in Figure 4.5, when zinc metal $(\mathrm{Zn})$ is immersed in a solution containing copper ions $\left(\mathrm{Cu}^{2+}\right)$, the zinc is oxidized to zinc ions $\left(\mathrm{Zn}^{2+}\right)$, and copper ions are reduced to copper metal $(\mathrm{Cu})$.
$\mathrm{Zn}(s)+\mathrm{Cu}^{2+}(a q) \longrightarrow \mathrm{Zn}^{2+}(a q)+\mathrm{Cu}(s)$
This is an oxidation-reduction reaction in which electrons flow spontaneously from zinc metal to the copper ions in solution. The lightening of the blue color indicates that the concentration of $\mathrm{Cu}^{2+}$ has decreased. Copper metal is deposited on the solid zinc surface. Some of the zinc metal has gone into solution as $\mathrm{Zn}^{2+}$ ions, which do not impart any color in the solution.

When we replace the voltmeter with a lightbulb, electrons flow from the zinc electrode (the anode) to the copper electrode (the cathode). The flow of electrons lights the bulb. Anions in the salt bridge migrate toward the anode; cations migrate toward the cathode.

When we close the switch, we complete the circuit; the voltmeter indicates the initial potential of the cell: 1.10 V .

As the reaction proceeds, zinc metal from the anode is oxidized, increasing the $\mathrm{Zn}^{2+}$ concentration in the beaker on the left; and additional copper metal is deposited on the cathode, decreasing the $\mathrm{Cu}^{2+}$ concentration in the beaker on the right. As the concentrations of both ions change, the potential of the cell decreases. After allowing the reaction to proceed for a time, we can reinsert the voltmeter to measure the decreased voltage.

## What's the point?

Zinc is a stronger reducing agent than copper, so there is a natural tendency for electrons to flow from zinc metal to copper ions. We can harness this flow of electrons by forcing the half-reactions to occur in separate compartments. Electrons still flow from Zn to $\mathrm{Cu}^{2+}$, but they must flow through the wire connecting the two electrodes. The potential of the cell decreases as the reaction proceeds, as the reading on the voltmeter shows.

## Multimedia

Electrochemistry-an interactive voltaic cell.
Student Annotation: A cell in which different half-reactions take place will have a different emf.

### 19.3 Standard Reduction Potentials

When the concentrations of the $\mathrm{Cu}^{2+}$ and $\mathrm{Zn}^{2+}$ ions are both 1.0 M , the cell potential of the cell described in Section 19.2 is 1.10 V at $25^{\circ} \mathrm{C}$ (see Figure 19.2). This measured potential is related to the half-reactions that take place in the anode and cathode compartments. The overall cell potential is the difference between the electric potentials at the Zn and Cu electrodes-known as the half-cell potentials. Just as it is impossible for only one of the half-reactions to occur independently, it is impossible to measure the potential of just a single half-cell. However, if we arbitrarily define the potential value of a particular half-cell as zero, we can use it to determine the relative potentials of other half-cells. Then we can use these relative potentials to determine overall cell potentials. The hydrogen electrode, shown in Figure 19.3, serves as the reference for this purpose. Hydrogen gas is bubbled into a hydrochloric acid solution at $25^{\circ} \mathrm{C}$. The platinum electrode has two functions. First, it provides a surface on which the dissociation (and oxidation) of hydrogen molecules can take place:

$$
\mathrm{H}_{2} \longrightarrow 2 \mathrm{H}^{+}+2 e^{-}
$$

Second, it serves as an electrical conductor to the external circuit.

Figure 19.4 (a) A cell consisting of a zinc electrode and a hydrogen electrode. (b) A cell consisting of a copper electrode and a hydrogen electrode. Both cells are operating under standard-state conditions. Note that in (a) the SHE is the cathode, but in (b) it is the anode.

Under standard-state conditions [14 Section 18.5], when the pressure of $\mathrm{H}_{2}$ is 1 atm and the concentration of HCl solution is 1 M , the potential for the reduction of $\mathrm{H}^{+}$at $25^{\circ} \mathrm{C}$ is defined as exactly zero:

$$
2 \mathrm{H}^{+}(1 M)+2 e^{-} \longrightarrow \mathrm{H}_{2}(1 \mathrm{~atm}) \quad E^{\circ}=0 \mathrm{~V}
$$

As before, the ${ }^{\circ}$ superscript denotes standard-state conditions, and $E^{\circ}$ is the standard reduction potential; that is, $E^{\circ}$ is the potential associated with a reduction half-reaction at an electrode when the ion concentration is $1 M$ and the gas pressure is 1 atm . Because the hydrogen electrode is used to determine all other electrode potentials, it is called the standard hydrogen electrode (SHE).

A half-cell potential is measured by constructing a galvanic cell in which one of the electrodes is the SHE. The measured voltage is then used to determine the potential for the other half-cell. Figure 19.4(a) shows a galvanic cell with a zinc electrode and a SHE. When the circuit is completed in this cell, electrons flow from the zinc electrode to the SHE, thereby oxidizing Zn to $\mathrm{Zn}^{2+}$ and reducing $\mathrm{H}^{+}$ions to $\mathrm{H}_{2}$. In this case, therefore, the zinc electrode is the anode (where oxidation takes place) and the SHE is the cathode (where reduction takes place). The cell diagram is

$$
\mathrm{Zn}(s)\left|\mathrm{Zn}^{2+}(1 M) \| \mathrm{H}^{+}(1 M)\right| \mathrm{H}_{2}(1 \mathrm{~atm}) \mid \operatorname{Pt}(s)
$$

The measured potential for this cell is 0.76 V at $25^{\circ} \mathrm{C}$. We can write the half-cell reactions as follows:

By convention, the standard cell potential, $E_{\text {cell }}^{\circ}$, which is composed of a contribution from the anode and a contribution from the cathode, is given by

$$
\begin{equation*}
E_{\text {cell }}^{\circ}=E_{\text {cathode }}^{\circ}-E_{\text {anode }}^{\circ} \tag{Equation 19.1}
\end{equation*}
$$

where $E_{\text {cathode }}^{\circ}$ and $E_{\text {anode }}^{\circ}$ are the standard reduction potentials of the cathode and anode, respectively. For the Zn -SHE cell, we write

$$
\begin{aligned}
E_{\text {cell }}^{\circ} & =E_{\mathrm{H}^{+} / \mathrm{H}_{2}}^{\circ}-E_{\mathrm{Zn}^{2+} / \mathrm{Zn}}^{\circ} \\
0.76 \mathrm{~V} & =0-E_{\mathrm{Zn}^{2+} / \mathrm{Zn}}^{\circ}
\end{aligned}
$$

where the subscript " $\mathrm{H}^{+} / \mathrm{H}_{2}$ " means " $2 \mathrm{H}^{+}+2 e^{-} \longrightarrow \mathrm{H}_{2}$ " and the subscript " $\mathrm{Zn}{ }^{2+} / \mathrm{Zn}$ " means " $\mathrm{Zn}^{2+}+2 e^{-} \longrightarrow \mathrm{Zn}$ ". Thus, the standard reduction potential of zinc, $E_{\mathrm{Zn}}{ }^{2+} / \mathrm{Zn} 1$ is -0.76 V .

The standard reduction potential of copper can be determined in a similar fashion, by using a cell with a copper electrode and a SHE [Figure 19.4(b)]. In this case, electrons flow from the SHE to the copper electrode when the circuit is completed; that is, the copper electrode is the cathode and the SHE is the anode.

Student Annotation: One indication of the direction of electron flow is the fact that as the reaction proceeds, the mass of the zinc electrode decreases as a result of the oxidation half-reaction:

$$
\mathrm{Zn}(s) \longrightarrow \mathrm{Zn}^{2+}(a q)+2 \mathrm{e}^{-}
$$

Student Annotation: Reduction of $\mathrm{Cu}^{2+}$ ions causes the mass of the Cu electrode to increase.

Student Annotation: The half-reaction with the greater reduction potential has the greater potential to occur as a reduction.

Student Annotation: The electrode where reduction occurs is the cathode. Therefore, $E_{\text {cathode }}^{\circ}=0.34 \mathrm{~V}$.

Student Annotation: The electrode where oxidation occurs is the anode. Therefore,
$E_{\text {anode }}^{\circ}=-0.76 \mathrm{~V}$.

The cell diagram is

$$
\mathrm{Pt}(s)\left|\mathrm{H}_{2}(1 \mathrm{~atm})\right| \mathrm{H}^{+}(1 M) \| \mathrm{Cu}^{2+}(1 M) \mid \mathrm{Cu}(s)
$$

and the half-cell reactions are

| Anode (oxidation): | $\mathrm{H}_{2}(1 \mathrm{~atm}) \longrightarrow 2 \mathrm{H}^{+}(1 M)+2 e^{-}$ |
| :--- | ---: |
| Cathode (reduction): | $\mathrm{Cu}^{2+}(1 M)+2 e^{-} \longrightarrow \mathrm{Cu}(s)$ |
| Overall: | $\mathrm{H}_{2}(1 \mathrm{~atm})+\mathrm{Cu}^{2+}(1 M) \longrightarrow 2 \mathrm{H}^{+}(1 M)+\mathrm{Cu}(s)$ |

Under standard-state conditions and at $25^{\circ} \mathrm{C}$, the measured potential for the cell is 0.34 V , so we write

$$
\begin{aligned}
E_{\text {cell }}^{\circ} & =E_{\text {cathode }}^{\circ}-E_{\text {anode }}^{\circ} \\
& =E_{\mathrm{Cu}^{2+} / \mathrm{Cu}}^{\circ}-E_{\mathrm{H}^{+} / \mathrm{H}_{2}}^{\circ} \\
0.34 \mathrm{~V} & =E_{\mathrm{Cu}^{2+} / \mathrm{Cu}}^{\circ}-0
\end{aligned}
$$

Thus, the standard reduction potential of copper, $E_{\mathrm{Cu}^{2+} / \mathrm{Cu}}^{\circ}$, is 0.34 V , where the subscript " $\mathrm{Cu}^{2+} / \mathrm{Cu}$ " means " $\mathrm{Cu}^{2+}+2 e^{-} \longrightarrow$ Cu."

Having determined the standard reduction potentials of Zn and Cu , we can use Equation 19.1 to calculate the cell potential for the Daniell cell described in Section 19.2:

$$
\begin{aligned}
E_{\text {cell }}^{\circ} & =E_{\text {cathode }}^{\circ}-E_{\text {anode }}^{\circ} \\
& =E_{\mathrm{Cu}}{ }^{2+} / \mathrm{Cu}-E_{\mathrm{Zn}^{2+} / \mathrm{Zn}}^{\circ} \\
& =0.34 \mathrm{~V}-(-0.76 \mathrm{~V}) \\
& =1.10 \mathrm{~V}
\end{aligned}
$$

As in the case of $\Delta G^{\circ}$ [ 14 Section 18.5], we can use the sign of $E^{\circ}$ to predict whether a reaction lies to the right or to the left. A positive $E^{\circ}$ means that the redox reaction will favor the formation of products at equilibrium. Conversely, a negative $E^{\circ}$ indicates that reactants will be favored at equilibrium. We will examine how $E_{\text {cell }}^{\circ}, \Delta G^{\circ}$, and $K$ are related in Section 19.4.

Table 19.1 lists standard reduction potentials, in order of decreasing reduction potential, for a number of half-cell reactions. To avoid ambiguity, all half-cell reactions are shown as reductions. A galvanic cell is composed of two half-cells, and therefore two half-cell reactions. Whether or not a particular half-cell reaction occurs as a reduction in a galvanic cell depends on how its reduction potential compares to that of the other half-cell reaction. If it has the greater (or more positive) reduction potential of the two, it will occur as a reduction. If it has the smaller (or more negative) reduction potential of the two, it will occur in the reverse direction, as an oxidation.

Consider the example of the cell described in Section 19.2. The two half-cell reactions and their standard reduction potentials are

$$
\begin{array}{ll}
\mathrm{Cu}^{2+}+2 e^{-} \longrightarrow \mathrm{Cu} & E^{\circ}=0.34 \mathrm{~V} \\
\mathrm{Zn}^{2+}+2 e^{-} \longrightarrow \mathrm{Zn} & E^{\circ}=-0.76 \mathrm{~V}
\end{array}
$$

The Cu half-reaction, having a greater (more positive) reduction potential, is the half-reaction that will occur as a reduction:

$$
\mathrm{Cu}^{2+}+2 e^{-} \longrightarrow \mathrm{Cu}
$$

The Zn half-reaction has a smaller (less positive) reduction potential and will occur, instead, as an oxidation:

$$
\mathrm{Zn} \longrightarrow \mathrm{Zn}^{2+}+2 e^{-}
$$

Adding the two half-reactions gives the overall cell reaction:

$$
\mathrm{Zn}+\mathrm{Cu}^{2+} \longrightarrow \mathrm{Zn}^{2+}+\mathrm{Cu}
$$

Consider, however, what would happen if we were to construct a galvanic cell combining the Zn half-cell with an Mn half-cell. The reduction potential of Mn is -1.18 V .

$$
\begin{aligned}
\mathrm{Zn}^{2+}+2 e^{-} \longrightarrow \mathrm{Zn} & E^{\circ}=-0.76 \mathrm{~V} \\
\mathrm{Mn}^{2+}+2 e^{-} \longrightarrow \mathrm{Mn} & E^{\circ}=-1.18 \mathrm{~V}
\end{aligned}
$$

## TABLE 19.1

Standard Reduction Potentials at $25^{\circ} \mathrm{C}^{*}$

[^43]Student Annotation: It is a common error to multiply $E^{\circ}$ values by the same number as the half-cell equation. Think of the reduction potential as the height of a waterfall. Just as water falls from a higher elevation to a lower elevation, electrons move from an electrode with a higher potential toward one with a lower potential. The amount of water falling does not affect the net change in its elevation. Likewise, the number of electrons moving from higher potential to lower potential does not affect the size of the change in potential.

In this case, the greater (less negative) reduction potential is that of Zn , so the Zn half-reaction will occur as a reduction and the Zn electrode will be the cathode. The Mn electrode will be the anode. The cell potential is therefore

$$
\begin{aligned}
E_{\text {cell }}^{\circ} & =E_{\text {cathode }}^{\circ}-E_{\text {anode }}^{\circ} \\
& =E_{\mathrm{Zn}^{2+} / \mathrm{Zn}}^{\circ}-E_{\mathrm{Mn}^{2+} / \mathrm{Mn}}^{\circ} \\
& =(-0.76 \mathrm{~V})-(-1.18 \mathrm{~V}) \\
& =0.42 \mathrm{~V}
\end{aligned}
$$

The overall cell reaction is

$$
\mathrm{Mn}+\mathrm{Zn}^{2+} \longrightarrow \mathrm{Mn}^{2+}+\mathrm{Zn}
$$

By using Equation 19.1, we can predict the direction of an overall cell reaction.
It is important to understand that the standard reduction potential is an intensive property (like temperature and density), not an extensive property (like mass and volume) [ W4 Section 1.4]. This means that the value of the standard reduction potential does not depend on the amount of a substance involved. Therefore, when it is necessary to multiply one of the half-reactions by a coefficient to balance the overall equation, the value of $E^{\circ}$ for the half-reaction remains the same. Consider a galvanic cell made up of a Zn half-cell and an Ag half-cell:

$$
\mathrm{Zn}(s)\left|\mathrm{Zn}^{2+}(1 M) \| \mathrm{Ag}^{+}(1 M)\right| \mathrm{Ag}(s)
$$

The half-cell reactions are

$$
\begin{aligned}
\mathrm{Ag}^{+}+e^{-} \longrightarrow \mathrm{Ag} & E^{\circ}=0.80 \mathrm{~V} \\
\mathrm{Zn}^{2+}+2 e^{-} \longrightarrow \mathrm{Zn} & E^{\circ}=-0.76 \mathrm{~V}
\end{aligned}
$$

The Ag half-reaction, with the more positive standard reduction potential, will occur as a reduction, and the Zn half-reaction will occur as an oxidation. Balancing the equation for the overall cell reaction requires multiplying the reduction (the Ag half-reaction) by 2 :

$$
2\left(\mathrm{Ag}^{+}+e^{-} \longrightarrow \mathrm{Ag}\right)
$$

We can then add the two half-reactions and cancel the electrons to get the overall, balanced equation:

$$
\begin{aligned}
& 2 \mathrm{Ag}^{+}+2 e^{\nearrow} \longrightarrow 2 \mathrm{Ag} \\
&+\mathrm{Zn} \longrightarrow \mathrm{Zn}^{2+}+2 e^{-} \\
& 2 \mathrm{Ag}^{+}+\mathrm{Zn} \longrightarrow 2 \mathrm{Ag}+\mathrm{Zn}^{2+}
\end{aligned}
$$

The standard cell potential can be calculated using Equation 19.1:

$$
\begin{aligned}
E_{\text {cell }}^{\circ} & =E_{\text {cathode }}^{\circ}-E_{\text {anode }}^{\circ} \\
& =E_{\mathrm{Ag}^{+} / \mathrm{Ag}}^{\circ}-E_{\mathrm{Zn}^{2+} / \mathrm{Zn}}^{\circ} \\
& =0.80 \mathrm{~V}-(-0.76 \mathrm{~V}) \\
& =1.56 \mathrm{~V}
\end{aligned}
$$

Although we multiplied the Ag half-reaction by 2, we did not multiply its standard reduction potential by 2 .

Table 19.1 is essentially an extended version of the activity series [144 Section 4.4]. Sample Problem 19.2 illustrates how to use standard reduction potentials to predict the direction of the overall reaction in a galvanic cell.

## Sample Problem 19.2

A galvanic cell consists of an Mg electrode in a $1.0 \mathrm{M} \mathrm{Mg}\left(\mathrm{NO}_{3}\right)_{2}$ solution and a Cd electrode in a $1.0 \mathrm{MCd}\left(\mathrm{NO}_{3}\right)_{2}$ solution. Determine the overall cell reaction, and calculate the standard cell potential at $25^{\circ} \mathrm{C}$.

Strategy Use the tabulated values of $E^{\circ}$ to determine which electrode is the cathode and which is the anode, combine cathode and anode half-cell reactions to get the overall cell reaction, and use Equation 19.1 to calculate $E_{\text {cell }}^{\circ}$.

Setup The half-cell reactions and their standard reduction potentials are

$$
\begin{array}{ll}
\mathrm{Mg}^{2+}+2 e^{-} \longrightarrow \mathrm{Mg} & E^{\circ}=-2.37 \mathrm{~V} \\
\mathrm{Cd}^{2+}+2 e^{-} \longrightarrow \mathrm{Cd} & E^{\circ}=-0.40 \mathrm{~V}
\end{array}
$$

Because the Cd half-cell reaction has the greater (less negative) standard reduction potential, it will occur as the reduction. The Mg half-cell reaction will occur as the oxidation. Therefore, $E_{\text {cathode }}^{\circ}=$ -0.40 V and $E_{\text {anode }}^{\circ}=-2.37 \mathrm{~V}$.

Solution Adding the two half-cell reactions together gives the overall cell reaction:

$$
\begin{aligned}
& \mathrm{Mg} \longrightarrow \mathrm{Mg}^{2+}+2 e^{-} \\
& \text {Overall: } \mathrm{Cd}^{2+}+2 e^{-} \longrightarrow \mathrm{Cd} \\
& \mathrm{Mg}+\mathrm{Cd}^{2+} \longrightarrow \mathrm{Mg}^{2+}+\mathrm{Cd}
\end{aligned}
$$

The standard cell potential is

$$
\begin{aligned}
E_{\text {cell }}^{\circ} & =E_{\text {cathode }}^{\circ}-E_{\text {anode }}^{\circ} \\
& =E_{\mathrm{Cd}^{2+} / \mathrm{Cd}}^{\circ}-E_{\mathrm{Mg}^{2+} / \mathrm{Mg}}^{\circ} \\
& =(-0.40 \mathrm{~V})-(-2.37 \mathrm{~V}) \\
& =1.97 \mathrm{~V}
\end{aligned}
$$

Practice Problem A Determine the overall cell reaction and $E_{\text {cell }}^{\circ}$ (at $25^{\circ} \mathrm{C}$ ) of a galvanic cell made of a Cd electrode in a $1.0 \mathrm{M} \mathrm{Cd}\left(\mathrm{NO}_{3}\right)_{2}$ solution and a Pb electrode in a $1.0 \mathrm{M} \mathrm{Pb}\left(\mathrm{NO}_{3}\right)_{2}$ solution.

EfPractice Problem B A galvanic cell with $E_{\text {cell }}^{\circ}=0.30 \mathrm{~V}$ can be constructed using an iron electrode in a $1.0 \mathrm{M} \mathrm{Fe}\left(\mathrm{NO}_{3}\right)_{2}$ solution, and either a tin electrode in a $1.0 \mathrm{M} \mathrm{Sn}\left(\mathrm{NO}_{3}\right)_{2}$ solution, or a chromium electrode in a $1.0 \mathrm{MCr}\left(\mathrm{NO}_{3}\right)_{3}$ solution-even though $\mathrm{Sn}^{2+} / \mathrm{Sn}$ and $\mathrm{Cr}^{3+} / \mathrm{Cr}$ have different standard reduction potentials. Explain and give the overall balanced reaction for each cell.

Standard reduction potentials can also be used to determine what, if any, redox reaction will take place when reactants are combined in the same beaker-rather than divided into half-cells. Unlike a galvanic cell, in which we use reduction potentials to determine if the reaction proceeds in the forward or reverse direction, when the reaction is not divided into half-cells, we use reduction potentials to determine if the reaction will occur as written-or not.

Sample Problem 19.3 illustrates this technique.

## Sample Problem 19.3

Predict what redox reaction will take place, if any, when molecular bromine $\left(\mathrm{Br}_{2}\right)$ is added to (a) a $1 M$ solution of NaI and (b) a $1 M$ solution of NaCl . (Assume a temperature of $25^{\circ} \mathrm{C}$.)

Strategy In each case, write the equation for the redox reaction that might take place and use $E^{\circ}$ values to determine whether or not the proposed reaction will actually occur.

Setup From Table 19.1:

$$
\begin{aligned}
\mathrm{Br}_{2}(l)+2 e^{-} \longrightarrow 2 \mathrm{Br}^{-}(a q) & E^{\circ}=1.07 \mathrm{~V} \\
\mathrm{I}_{2}(s)+2 e^{-} \longrightarrow 2 \mathrm{I}^{-}(a q) & E^{\circ}=0.53 \mathrm{~V} \\
\mathrm{Cl}_{2}(g)+2 e^{-} \longrightarrow 2 \mathrm{Cl}^{-}(a q) & E^{\circ}=1.36 \mathrm{~V}
\end{aligned}
$$

Solution (a) If a redox reaction is to occur, it will be the oxidation of $\mathrm{I}^{-}$ions by $\mathrm{Br}_{2}$ :

$$
\mathrm{Br}_{2}(l)+2 \mathrm{I}^{-}(a q) \longrightarrow 2 \mathrm{Br}^{-}(a q)+\mathrm{I}_{2}(s)
$$

Because the reduction potential of $\mathrm{Br}_{2}$ is greater than that of $\mathrm{I}_{2}, \mathrm{Br}_{2}$ will be reduced to $\mathrm{Br}^{-}$and $\mathrm{I}^{-}$will be oxidized to $\mathrm{I}_{2}$. Thus, the preceding reaction will occur.

Think About It If you ever calculate a negative voltage for a galvanic cell potential, you have done something wrong-check your work. Under standard-state conditions, the overall cell reaction will proceed in the direction that gives a positive $E_{\text {cell }}^{\circ}$.

Think About It We can use Equation 19.1 and treat problems of this type like galvanic cell problems. Write the proposed redox reaction, and identify the "cathode" and the "anode." If the calculated $E_{\text {cell }}^{\circ}$ is positive, the reaction will occur. If the calculated $E_{\text {cell }}^{\circ}$ is negative, the reaction will not occur.
(b) In this case, the proposed reaction is the reduction of $\mathrm{Br}_{2}$ by $\mathrm{Cl}^{-}$ions:

$$
\mathrm{Br}_{2}(l)+2 \mathrm{Cl}^{-}(a q) \longrightarrow 2 \mathrm{Br}^{-}(a q)+\mathrm{Cl}_{2}(g)
$$

However, because the reduction potential of $\mathrm{Br}_{2}$ is smaller than that of $\mathrm{Cl}_{2}$, this reaction will not occur. $\mathrm{Cl}_{2}$ is more readily reduced than $\mathrm{Br}_{2}$, so $\mathrm{Br}_{2}$ is not reduced by $\mathrm{Cl}^{-}$.

Practice Problem A Determine what redox reaction, if any, occurs (at $25^{\circ} \mathrm{C}$ ) when lead metal ( Pb ) is added to (a) a 1.0 M solution of $\mathrm{NiCl}_{2}$ and (b) a 1.0 M solution of HCl .

EPractice Problem B Would it be safer to store a cobalt(II) chloride solution in a tin container or an iron container? Explain.

## Checkpoint 19.3 $\quad$ Standard Reduction Potentials

19.3.1 Calculate $E_{\text {cell }}^{\circ}$ at $25^{\circ} \mathrm{C}$ for a galvanic cell made of a Cr electrode in a solution that is 1.0 M in $\mathrm{Cr}^{3+}$ and an Au electrode in a solution that is 1.0 M in $\mathrm{Au}^{3+}$.
a) -2.03 V
b) 1.11 V
c) -1.11 V
d) 2.24 V
e) 0.76 V
19.3.2 Calculate $E_{\text {cell }}^{\circ}$ at $25^{\circ} \mathrm{C}$ for a galvanic cell made of a Cr electrode in a solution that is $1.0 \mathrm{M} \mathrm{in}_{\mathrm{Cr}}{ }^{3+}$ and an Ag electrode in a solution that is 1.0 M in $\mathrm{Ag}^{+}$.
a) 0.06 V
b) -0.06 V
c) 1.54 V
d) 3.14 V
e) 3.02 V
19.3.3 What redox reaction, if any, will occur at $25^{\circ} \mathrm{C}$ when Al metal is placed in a solution that is 1.0 M in $\mathrm{Cr}^{3+}$ ?
a) $\mathrm{Al}^{3+}+\mathrm{Cr} \longrightarrow \mathrm{Al}+\mathrm{Cr}^{3+}$
b) $\mathrm{Cr}^{3+}+\mathrm{Al} \longrightarrow \mathrm{Cr}+\mathrm{Al}^{3+}$
c) $\mathrm{Al}^{3+}+\mathrm{Cr}^{3+} \longrightarrow \mathrm{Al}+\mathrm{Cr}$
d) $\mathrm{Al}+\mathrm{Cr} \longrightarrow \mathrm{Al}^{3+}+\mathrm{Cr}^{3+}$
e) No redox reaction will occur.
19.3.4 What redox reaction, if any, will occur at $25^{\circ} \mathrm{C}$ when Zn metal is placed in a solution that is 1.0 M in $\mathrm{Sr}^{2+}$ ?
a) $\mathrm{Zn}^{2+}+\mathrm{Sr} \longrightarrow \mathrm{Zn}+\mathrm{Sr}^{2+}$
b) $\mathrm{Sr}^{2+}+\mathrm{Zn} \longrightarrow \mathrm{Sr}+\mathrm{Zn}^{2+}$
c) $\mathrm{Zn}^{2+}+\mathrm{Sr}^{2+} \longrightarrow \mathrm{Zn}+\mathrm{Sr}$
d) $\mathrm{Zn}+\mathrm{Sr} \longrightarrow \mathrm{Zn}^{2+}+\mathrm{Sr}^{2+}$
e) No redox reaction will occur.

### 19.4 Spontaneity of Redox Reactions Under

 Standard-State ConditionsWe now look at how $E_{\text {cell }}^{\circ}$ is related to thermodynamic quantities such as $\Delta G^{\circ}$ and $K$. In a galvanic cell, chemical energy is converted to electric energy. The electric energy produced in a galvanic cell is the product of the cell potential and the total electric charge (in coulombs) that passes through the cell:

$$
\begin{aligned}
\text { electric energy } & =\text { volts } \times \text { coulombs } \\
& =\text { joules }
\end{aligned}
$$

The total charge is determined by the number of moles of electrons ( $n$ ) that pass through the circuit. By definition,

$$
\text { total charge }=n F
$$

where $F$, the Faraday ${ }^{1}$ constant, is the electric charge contained in 1 mole of electrons. One faraday is equivalent to $96,485.3 \mathrm{C}$, although we usually round the number to three significant figures. Thus,

$$
1 F=96,500 \mathrm{C} / \mathrm{mol} e^{-}
$$

[^44]Because

$$
1 \mathrm{~J}=1 \mathrm{C} \times 1 \mathrm{~V}
$$

we can also express the units of faraday as

$$
1 F=96,500 \mathrm{~J} / \mathrm{V} \cdot \mathrm{~mol} e^{-}
$$

The measured cell potential is the maximum voltage that the cell can produce. This value is used to calculate the maximum amount of electric energy that can be obtained from the chemical reaction. This energy is used to do electrical work ( $w_{\text {electrical }}$ ), so

$$
\begin{aligned}
w_{\max } & =w_{\text {electrical }} \\
& =-n F E_{\mathrm{cell}}
\end{aligned}
$$

where $w_{\max }$ is the maximum amount of work that can be done. The negative sign on the right-hand side indicates that the electrical work is done by the system on the surroundings. In Chapter 18 we defined free energy as the energy available to do work. Specifically, the change in free energy, $\Delta G$, represents the maximum amount of useful work that can be obtained from a reaction:

$$
\Delta G=w_{\max }
$$

Therefore, we can write

$$
\begin{equation*}
\Delta G=-n F E_{\text {cell }} \tag{Equation 19.2}
\end{equation*}
$$

Both $n$ and $F$ are positive quantities and $\Delta G$ is negative for a spontaneous process, so $E_{\text {cell }}$ must be positive for a spontaneous process. For reactions in which reactants and products are in their standard states, Equation 19.2 becomes

$$
\begin{equation*}
\Delta G^{\circ}=-n F E_{\text {cell }}^{\circ} \tag{Equation 19.3}
\end{equation*}
$$

Equation 19.3 makes it possible to relate $E_{\text {cell }}^{\circ}$ to the equilibrium constant, $K$, of a redox reaction. In Section 18.6 we saw that the standard free-energy change, $\Delta G^{\circ}$, for a reaction is related to its equilibrium constant as follows [ 144 Section 18.6, Equation 18.14]:

$$
\Delta G^{\circ}=-R T \ln K
$$

Therefore, if we combine Equations 18.14 and 19.3, we get

$$
-n F E_{\text {cell }}^{\circ}=-R T \ln K
$$

Solving for $E_{\text {cell }}^{\circ}$ gives

$$
E_{\text {cell }}^{\circ}=\frac{R T}{n F} \ln K
$$

Equation 19.4

When $T=298 \mathrm{~K}$ and $n$ moles of electrons are transferred per mole of reaction, Equation 19.4 can be simplified by inserting the values for $R$ and $F$ :

$$
\begin{aligned}
E_{\text {cell }}^{\circ} & =\frac{\left(8.314 \frac{\mathrm{~J}}{\mathrm{~K} \cdot \mathrm{~mol}}\right)(298 \mathrm{~K})}{(n)\left(96,500 \frac{\mathrm{~J}}{\mathrm{~V} \cdot \mathrm{~mol}}\right)} \\
& =\frac{0.0257 \mathrm{~V}}{n} \ln K
\end{aligned}
$$

And, by converting to the base-10 logarithm of $K$, we get

$$
E_{\text {cell }}^{\circ}=\frac{0.0592 \mathrm{~V}}{n} \log K \quad\left(\text { at } 25^{\circ} \mathrm{C}\right) \quad \text { Equation } 19.5
$$

Thus, if we know any one of the three quantities $\Delta G^{\circ}, K$, or $E_{\text {cell }}^{\circ}$, we can convert to the others by using Equations 18.14, 19.3, and 19.5.

Sample Problems 19.4 and 19.5 demonstrate the interconversions among $\Delta G^{\circ}, K$, and $E_{\text {cell }}^{\circ}$. For simplicity, the subscript "cell" is not shown.

## Sample Problem 19.4

Calculate the standard free-energy change for the following reaction at $25^{\circ} \mathrm{C}$ :

$$
2 \mathrm{Au}(s)+3 \mathrm{Ca}^{2+}(a q)(1.0 M) \rightleftarrows 2 \mathrm{Au}^{3+}(a q)(1.0 M)+3 \mathrm{Ca}(s)
$$

Strategy Use $E^{\circ}$ values from Table 19.1 to calculate $E^{\circ}$ for the reaction, and then use Equation 19.3 to calculate the standard free-energy change.

Setup The half-cell reactions are

$$
\begin{array}{lrl}
\text { Cathode (reduction): } & 3 \mathrm{Ca}^{2+}(a q)+6 e^{-} & \longrightarrow 3 \mathrm{Ca}(s) \\
\text { Anode (oxidation): } & 2 \mathrm{Au}(s) \longrightarrow 2 \mathrm{Au}^{3+}(a q)+6 e^{-}
\end{array}
$$

From Table 19.1, $E_{\mathrm{Ca}^{2+} / \mathrm{Ca}}^{\circ}=-2.87 \mathrm{~V}$ and $E_{\mathrm{Au}^{3+} / \mathrm{Au}}^{\circ}=1.50 \mathrm{~V}$.

## Solution

$$
\begin{aligned}
E_{\text {cell }}^{\circ} & =E_{\text {cathode }}^{\circ}-E_{\text {anode }}^{\circ} \\
& =E_{\mathrm{Ca}^{2+} / \mathrm{Ca}}^{\circ}-E_{\mathrm{Au}^{3+} / \mathrm{Au}}^{\circ} \\
& =-2.87 \mathrm{~V}-1.50 \mathrm{~V} \\
& =-4.37 \mathrm{~V}
\end{aligned}
$$

Next, substitute this value of $E^{\circ}$ into Equation 19.3 to obtain $\Delta G^{\circ}$ :

$$
\Delta G^{\circ}=-n F E^{\circ}
$$

The overall reaction shows that $n=6$, so

$$
\begin{aligned}
\Delta G^{\circ} & =-\left(6 e^{-}\right)\left(96,500 \mathrm{~J} / \mathrm{V} \cdot \mathrm{~mol} e^{-}\right)(-4.37 \mathrm{~V}) \\
& =2.53 \times 10^{6} \mathrm{~J} / \mathrm{mol} \\
& =2.53 \times 10^{3} \mathrm{~kJ} / \mathrm{mol}
\end{aligned}
$$

Practice Problem A Calculate $\Delta G^{\circ}$ for the following reaction at $25^{\circ} \mathrm{C}$ :

$$
3 \mathrm{Mg}(s)+2 \mathrm{Al}^{3+}(a q) \rightleftarrows 3 \mathrm{Mg}^{2+}(a q)+2 \mathrm{Al}(s)
$$

GPractice Problem B Calculate $\Delta G^{\circ}$ for the following reaction at $25^{\circ} \mathrm{C}$ :

$$
\mathrm{Pb}(s)+\mathrm{Ni}^{2+}(a q) \rightleftarrows \mathrm{Pb}^{2+}(a q)+\mathrm{Ni}(s)
$$

## Sample Problem 19.5

Calculate the equilibrium constant for the following reaction at $25^{\circ} \mathrm{C}$ :

$$
\mathrm{Sn}(s)+2 \mathrm{Cu}^{2+}(a q) \rightleftarrows \mathrm{Sn}^{2+}(a q)+2 \mathrm{Cu}^{+}(a q)
$$

Strategy Use $E^{\circ}$ values from Table 19.1 to calculate $E^{\circ}$ for the reaction, and then calculate the equilibrium constant using Equation 19.5 (rearranged to solve for $K$ ).

Setup The half-cell reactions are

$$
\begin{array}{lrl}
\text { Cathode (reduction): } & 2 \mathrm{Cu}^{2+}(a q)+2 e^{-} \longrightarrow 2 \mathrm{Cu}^{+}(a q) \\
\text { Anode (oxidation): } & \mathrm{Sn}(s) \longrightarrow \mathrm{Sn}^{2+}(a q)+2 e^{-}
\end{array}
$$

From Table 19.1, $E_{\mathrm{Cu}^{2+} / \mathrm{Cu}^{+}}^{\circ}=0.15 \mathrm{~V}$ and $E_{\mathrm{Sn}^{2+} / \mathrm{Sn}}^{\circ}=-0.14 \mathrm{~V}$.

Solution

$$
\begin{aligned}
E_{\text {cell }}^{\circ} & =E_{\text {cathode }}^{\circ}-E_{\text {anode }}^{\circ} \\
& =E_{\mathrm{Cu}^{2+} / \mathrm{Cu}^{+}}^{\circ}-E_{\mathrm{Sn}^{2+} / \mathrm{Sn}}^{\circ} \\
& =0.15 \mathrm{~V}-(-0.14 \mathrm{~V}) \\
& =0.29 \mathrm{~V}
\end{aligned}
$$

Solving Equation 19.5 for $K$ gives

$$
\begin{aligned}
K & =10^{n E^{\circ}(0.0592 \mathrm{~V}} \\
& =10^{(2)(0.29 \mathrm{~V}) 0.0592 \mathrm{~V}} \\
& =6 \times 10^{9}
\end{aligned}
$$

Think About It A positive standard cell potential corresponds to a large equilibrium constant.

Practice Problem A Calculate the equilibrium constant for the following reaction at $25^{\circ} \mathrm{C}$ :

$$
2 \mathrm{Ag}(s)+\mathrm{Fe}^{2+}(a q) \rightleftarrows 2 \mathrm{Ag}^{+}(a q)+\mathrm{Fe}(s)
$$

- Practice Problem B Like equilibrium constants, $E_{\text {cell }}^{\circ}$ values are temperature dependent. At $80^{\circ} \mathrm{C}$,
$E_{\text {cell }}^{\circ}$ for the cell diagram shown is 0.18 V .

$$
\mathrm{Pt}\left|\mathrm{H}_{2}(g)\right| \mathrm{HCl}(a q) \| \mathrm{AgCl}(s) \mid \mathrm{Ag}(s)
$$

The corresponding cell reaction is

$$
\mathrm{H}_{2}(g)+2 \mathrm{AgCl}(s) \rightleftarrows 2 \mathrm{Ag}(s)+2 \mathrm{H}^{+}(a q)+2 \mathrm{Cl}^{-}(a q)
$$

Calculate the equilibrium constant for this reaction at $80^{\circ} \mathrm{C}$.

## Checkpoint 19.4 Spontaneity of Redox Reactions Under Standard-State Conditions

19.4.1 Calculate $K$ at $25^{\circ} \mathrm{C}$ for the following reaction:

$$
\mathrm{Fe}^{2+}(a q)+\mathrm{Ni}(s) \rightleftarrows \mathrm{Fe}(s)+\mathrm{Ni}^{2+}(a q)
$$

a) $6 \times 10^{-4}$
b) $4 \times 10^{-7}$
c) $3 \times 10^{6}$
d) $1 \times 10^{-13}$
e) $2 \times 10^{3}$
19.4.2 Calculate $\Delta G^{\circ}$ at $25^{\circ} \mathrm{C}$ for the following reaction:

$$
3 \mathrm{Cu}^{2+}(a q)+\mathrm{Cr}(s) \rightleftarrows 3 \mathrm{Cu}^{+}(a q)+\mathrm{Cr}^{3+}(a q)
$$

a) $2.6 \times 10^{2} \mathrm{~kJ} / \mathrm{mol}$
b) $-2.6 \times 10^{2} \mathrm{~kJ} / \mathrm{mol}$
c) $1 \times 10^{45} \mathrm{~kJ} / \mathrm{mol}$
d) $-86 \mathrm{~kJ} / \mathrm{mol}$
e) $86 \mathrm{~kJ} / \mathrm{mol}$

### 19.5 Spontaneity of Redox Reactions Under Conditions Other Than Standard State

So far we have focused on redox reactions in which the reactants and products are in their standard states. Standard-state conditions, though, are difficult to come by and usually impossible to maintain. Just as there is an equation that relates $\Delta G$ to $\Delta G^{\circ}$ [ $\kappa 4$ Section 18.6, Equation 18.13], there is an equation that relates $E$ to $E^{\circ}$. We will now derive this equation.

## The Nernst Equation

Consider a redox reaction of the type

$$
a \mathrm{~A}+b \mathrm{~B} \longrightarrow c \mathrm{C}+d \mathrm{D}
$$

From Equation 18.13,

$$
\Delta G=\Delta G^{\circ}+R T \ln Q
$$

Because $\Delta G=-n F E$ and $\Delta G^{\circ}=-n F E^{\circ}$, the equation can be expressed as

$$
-n F E=-n F E^{\circ}+R T \ln Q
$$

Dividing the equation through by $-n F$, we get
Equation 19.6

$$
E=E^{\circ}-\frac{R T}{n F} \ln Q
$$

where $Q$ is the reaction quotient [ $1 \mathbb{4}$ Section 15.2]. Equation 19.6 is known as the Nernst $^{2}$ equation. At 298 K, Equation 19.6 can be rewritten as

$$
E=E^{\circ}-\frac{0.0257 \mathrm{~V}}{n} \ln Q
$$

or using the base-10 logarithm of $Q$ as
Equation 19.7

$$
E=E^{\circ}-\frac{0.0592 \mathrm{~V}}{n} \log Q
$$

During the operation of a galvanic cell, electrons flow from the anode to the cathode, resulting in product formation and a decrease in reactant concentration. Thus, $Q$ increases, which means that $E$ decreases. Eventually, the cell reaches equilibrium. At equilibrium, there is no net transfer of electrons, so $E=0$ and $Q=K$, where $K$ is the equilibrium constant.

The Nernst equation enables us to calculate $E$ as a function of reactant and product concentrations in a redox reaction. For example, for the cell pictured in Figure 19.1,

$$
\mathrm{Zn}(s)+\mathrm{Cu}^{2+}(a q) \longrightarrow \mathrm{Zn}^{2+}(a q)+\mathrm{Cu}(s)
$$

The Nernst equation for this cell at $25^{\circ} \mathrm{C}$ can be written as

$$
E=1.10 \mathrm{~V}-\frac{0.0592 \mathrm{~V}}{2} \log \frac{\left[\mathrm{Zn}^{2+}\right]}{\left[\mathrm{Cu}^{2+}\right]}
$$

If the ratio $\left[\mathrm{Zn}^{2+}\right] /\left[\mathrm{Cu}^{2+}\right]$ is less than $1, \log \left(\left[\mathrm{Zn}^{2+}\right] /\left[\mathrm{Cu}^{2+}\right]\right)$ is a negative number, making the second term on the right-hand side of the preceding equation a positive quantity. Under this condition, $E$ is greater than the standard potential $E^{\circ}$. If the ratio is greater than $1, E$ is smaller than $E^{\circ}$.

Sample Problem 19.6 shows how to use the Nernst equation.

## Sample Problem 19.6

Predict whether the following reaction will occur spontaneously as written at 298 K :

$$
\mathrm{Co}(s)+\mathrm{Fe}^{2+}(a q) \longrightarrow \mathrm{Co}^{2+}(a q)+\mathrm{Fe}(s)
$$

assuming $\left[\mathrm{Co}^{2+}\right]=0.15 \mathrm{M}$ and $\left[\mathrm{Fe}^{2+}\right]=0.68 \mathrm{M}$.
Strategy Use $E^{\circ}$ values from Table 19.1 to determine $E^{\circ}$ for the reaction, and use Equation 19.7 to calculate $E$. If $E$ is positive, the reaction will occur spontaneously.

Setup From Table 19.1,

$$
\begin{aligned}
& \text { Cathode (reduction): } \mathrm{Fe}^{2+}(a q)+2 e^{-} \longrightarrow \mathrm{Fe}(s) \\
& \text { Anode (oxidation): } \quad \mathrm{Co}(s) \longrightarrow \mathrm{Co}^{2+}(a q)+2 e^{-} \\
& E_{\text {cell }}^{\circ}=E_{\text {cathode }}^{\circ}-E_{\text {anode }}^{\circ} \\
& =E^{\circ}{ }_{\mathrm{Fe}}{ }^{2+} / \mathrm{Fe}-E_{\mathrm{Co}^{2+} / \mathrm{Co}} \\
& =-0.44 \mathrm{~V}-(-0.28 \mathrm{~V}) \\
& =-0.16 \mathrm{~V}
\end{aligned}
$$

The reaction quotient, $Q$, for the reaction is $\left[\mathrm{Co}^{2+}\right] /\left[\mathrm{Fe}^{2+}\right]$. Therefore, $Q=(0.15 / 0.68)=0.22$.

[^45]Solution From Equation 19.7,

$$
\begin{aligned}
E & =E^{\circ}-\frac{0.0592 \mathrm{~V}}{n} \log Q \\
& =-0.16 \mathrm{~V}-\frac{0.0592 \mathrm{~V}}{2} \log 0.22 \\
& =-0.14 \mathrm{~V}
\end{aligned}
$$

The negative $E$ value indicates that the reaction is not spontaneous as written under the conditions described.

Practice Problem A Will the following reaction occur spontaneously at 298 K if $\left[\mathrm{Fe}^{2+}\right]=0.60 \mathrm{M}$ and $\left[\mathrm{Cd}^{2+}\right]=0.010 \mathrm{M}$ ?

$$
\mathrm{Cd}(s)+\mathrm{Fe}^{2+}(a q) \longrightarrow \mathrm{Cd}^{2+}(a q)+\mathrm{Fe}(s)
$$

Think About It For this reaction to be spontaneous as written, the ratio of $\left[\mathrm{Fe}^{2+}\right]$ to $\left[\mathrm{Co}^{2+}\right]$ would have to be enormous. We can determine the required ratio by first setting $E$ equal to zero:

$$
\begin{aligned}
0 \mathrm{~V} & =-0.16 \mathrm{~V}-\frac{0.0592 \mathrm{~V}}{2} \log Q \\
-\frac{(0.16 \mathrm{~V})(2)}{0.0592 \mathrm{~V}} & =\log Q \\
\log Q & =-5.4 \\
Q & =10^{-5.4}=\frac{\left[\mathrm{Co}^{2+}\right]}{\left[\mathrm{Fe}^{2+}\right]}=4 \times 10^{-6}
\end{aligned}
$$

For $E$ to be positive, therefore, the ratio of $\left[\mathrm{Fe}^{2+}\right]$ to $\left[\mathrm{Co}^{2+}\right]$, the reciprocal of $Q$, would have to be greater than $3 \times 10^{5}$ to 1 .

EPractice Problem B Consider the electrochemical cell in Practice Problem 19.5B (page 833), for which $E_{\text {cell }}^{\circ}=0.18 \mathrm{~V}$ at $80^{\circ} \mathrm{C}$.

$$
\mathrm{H}_{2}(g)+2 \mathrm{AgCl}(s) \rightleftarrows 2 \mathrm{Ag}(s)+2 \mathrm{H}^{+}(a q)+2 \mathrm{Cl}^{-}(a q)
$$

If $\mathrm{pH}=1.05$ in the anode compartment, and $\left[\mathrm{Cl}^{-}\right]=2.5 \mathrm{M}$ in the cathode compartment, determine the partial pressure of $\mathrm{H}_{2}$ necessary in the anode compartment for the cell potential to be 0.27 V at $80^{\circ} \mathrm{C}$.

## Concentration Cells

Because electrode potential depends on ion concentrations, it is possible to construct a galvanic cell from two half-cells composed of the same material but differing in ion concentrations. Such a cell is called a concentration cell.

Consider a galvanic cell consisting of a zinc electrode in 0.10 M zinc sulfate in one compartment and a zinc electrode in 1.0 M zinc sulfate in the other compartment (Figure 19.5). According to Le Châtelier's principle, the tendency for the reduction

$$
\mathrm{Zn}^{2+}(a q)+2 e^{-} \longrightarrow \mathrm{Zn}(s)
$$

to occur increases with increasing concentration of $\mathrm{Zn}^{2+}$ ions. Therefore, reduction should occur in the more concentrated compartment and oxidation should take place on the more dilute side. The cell diagram is

$$
\mathrm{Zn}(s)\left|\mathrm{Zn}^{2+}(0.10 M) \| \mathrm{Zn}^{2+}(1.0 M)\right| \mathrm{Zn}(s)
$$

and the half-cell reactions are

$$
\begin{array}{lr}
\text { Oxidation: } & \mathrm{Zn}(s) \longrightarrow \mathrm{Zn}^{2+}(0.10 M)+2 e^{-} \\
\text {Reduction: } & \frac{\mathrm{Zn}^{2+}(1.0 M)+2 e^{-} \longrightarrow \mathrm{Zn}(s)}{\mathrm{Zn}^{2+}(1.0 M) \longrightarrow \mathrm{Zn}^{2+}(0.10 M)} \\
\text { Overall: } &
\end{array}
$$

The cell potential is

$$
E=E^{\circ}-\frac{0.0592 \mathrm{~V}}{2} \log \frac{\left[\mathrm{Zn}^{2+}\right]_{\text {dilute }}}{\left[\mathrm{Zn}^{2+}\right]_{\text {concentrated }}}
$$

where the subscripts "dilute" and "concentrated" refer to the 0.10 M and 1.0 M concentrations, respectively. The $E^{\circ}$ for this cell is zero (because the same electrode-ion combination is used in both half-cells; i.e., $E_{\text {cathode }}^{\circ}=E_{\text {anode }}^{\circ}$ ), so

$$
\begin{aligned}
E & =0-\frac{0.0592 \mathrm{~V}}{2} \log \frac{0.10}{1.0} \\
& =0.030 \mathrm{~V}
\end{aligned}
$$

The cell potential for a concentration cell is typically small and decreases continually during the operation of the cell as the concentrations in the two compartments approach each other. When the concentrations of the ions in the two compartments are equal, $E$ becomes zero and no further change occurs.

Figure 19.5 A concentration cell. Oxidation will occur in the container with the lower $\mathrm{Zn}^{2+}$ concentration. Reduction will occur in the container with the higher $\mathrm{Zn}^{2+}$ concentration.

Patient with ECG electrodes

## Bringing Chemistry to Life

## Biological Concentration Cells

A biological cell can be compared to a concentration cell for the purpose of calculating its membrane potential. Membrane potential is the electric potential that exists across the membrane of various kinds of cells, including muscle cells and nerve cells. This potential is responsible for the propagation of nerve impulses and heartbeat. A membrane potential is established whenever there are unequal concentrations of the same type of ion in the interior and exterior of a cell-and the membrane is permeable to the ion. For example, the concentrations of $\mathrm{Na}^{+}$ions in the interior and exterior of a nerve cell are $1.5 \times 10^{-2} M$ and $1.5 \times 10^{-1} M$, respectively. Treating the situation as a concentration cell and applying the Nernst equation for a single ion, we can write

$$
\begin{aligned}
E_{\mathrm{Na}^{+}} & =E_{\mathrm{Na}^{+}}^{\circ}-\frac{0.0592 \mathrm{~V}}{1} \log \frac{\left[\mathrm{Na}^{+}\right]_{\mathrm{ex}}}{\left[\mathrm{Na}^{+}\right]_{\mathrm{in}}} \\
& =-(0.0592 \mathrm{~V}) \log \frac{1.5 \times 10^{-1}}{1.5 \times 10^{-2}} \\
& =0.059 \mathrm{~V} \quad \text { or } \quad 59 \mathrm{mV}
\end{aligned}
$$

where the subscripts "ex" and "in" denote "exterior" and "interior," respectively. We have set $E_{\mathrm{Na}}^{\circ}=0$ because the same type of ion is involved. Thus, an electric potential of 59 mV exists across the membrane due to the unequal concentrations of $\mathrm{Na}^{+}$ions.

When a nerve cell is stimulated, there is a large change in the membrane permeability, decreasing the membrane potential temporarily to about 34 mV . This sudden change in the potential is called the action potential. Once created, the action potential propagates along the nerve fiber until it reaches either a synaptic junction (the connection between nerve cells) or a neuromuscular junction (the connection between a nerve cell and a muscle cell). In the muscle cell of the heart, an action potential is generated during the heartbeat. This potential produces enough current to be detected by electrodes placed on the chest. The amplified signals can be recorded either on a moving chart or displayed on an oscilloscope. The record, called an electrocardiogram (ECG, also known as an EKG, where K is from the German word kardio for heart), is a valuable tool in the diagnosis of heart disease.

## FAQ You May be Wondering...

## How Are Very Small Solution Concentrations Measured?

In Chapter 17, we studied solubility equilibria and learned how to use tabulated $K_{\mathrm{sp}}$ values to determine solubilities of ionic compounds that are only very slightly soluble. The tabulated $K_{\text {sp }}$ values are determined by measuring the concentration of one of a compound's constituent ions in a saturated solution of the compound. For example, to determine the $K_{\text {sp }}$ of silver bromide $(\mathrm{AgBr})$, we must measure the concentration of $\mathrm{Ag}^{+}$, or the concentration of $\mathrm{Br}^{-}$. Because the $K_{\text {sp }}$ of silver bromide is $7.7 \times 10^{-13}$, the concen-
tration of either ion in a saturated solution is $8.8 \times 10^{-7} \mathrm{M}$. You may have wondered how such a small concentration is measured. It cannot be done using visible spectrophotometry, the method described in Chapter 4; not only because the concentration is so low, but also because a solution AgBr is colorless-meaning that it does not absorb visible light. In fact, concentrations of ions in these cases are measured using concentration cells.

Sample Problem 19.7 illustrates this process.

## Sample Problem 19.7

An electrochemical cell is constructed for the purpose of determining the $K_{\text {sp }}$ of silver cyanide $(\mathrm{AgCN})$ at $25^{\circ} \mathrm{C}$. One half-cell consists of a silver electrode in a 1.00 M solution of silver nitrate. The other half-cell consists of a silver electrode in a saturated solution of silver cyanide. The cell potential is measured and found to be 0.470 V . Determine the concentration of silver ion in the saturated silver cyanide solution and the value of $K_{\text {sp }}$ for AgCN .

Strategy Use Equation 19.7 to solve for the unknown concentration of silver ion. The half-cell with the higher $\mathrm{Ag}^{+}\left(1.0 \mathrm{M} \mathrm{AgNO}_{3}\right)$ concentration will be the cathode; the half-cell with the lower, unknown $\mathrm{Ag}^{+}$concentration (saturated AgCN solution) will be the anode. The overall reaction is $\mathrm{Ag}^{+}(1.0 M) \longrightarrow \mathrm{Ag}^{+}(x M)$.

Setup Because this is a concentration cell, $E_{\text {cell }}^{\circ}=0 \mathrm{~V}$. The reaction quotient, $Q$, is $(x M) /(1.00 M)$; and the value of $n$ is 1 .

Solution

$$
\begin{aligned}
E_{\text {cell }} & =E_{\text {cell }}^{\circ}-\frac{0.0592 \mathrm{~V}}{n} \log Q \\
0.470 \mathrm{~V} & =0-\frac{0.0592 \mathrm{~V}}{1} \log \frac{x}{1.00} \\
-7.939 & =\log \frac{x}{1.00} \\
10^{-7.939} & =1.15 \times 10^{-8}=\log \frac{x}{1.00} \\
x & =1.15 \times 10^{-8}
\end{aligned}
$$

Therefore, $\left[\mathrm{Ag}^{+}\right]=1.15 \times 10^{-8} M$ and $K_{\mathrm{sp}}$ for $\mathrm{AgCN}=x^{2}=1.3 \times 10^{-16}$.

Practice Problem A An electrochemical cell is constructed for the purpose of determining the $K_{\text {sp }}$ of copper(I) chloride, CuCl , at $25^{\circ} \mathrm{C}$. One half-cell consists of a copper electrode in a 1.00 M solution of copper(I) nitrate. The other half-cell consists of a copper electrode in a saturated solution of copper(I) chloride. The measured cell potential is 0.175 V . Determine the concentration of copper(I) ion in the saturated copper(I) chloride solution and the value of $K_{\text {sp }}$ for CuCl .
$\leftrightarrows$ Practice Problem B The $K_{\text {sp }}$ of copper(II) ferrocyanide $\left(\mathrm{Cu}_{2}\left[\mathrm{Fe}(\mathrm{CN})_{6}\right]\right)$ is $1.3 \times 10^{-16}$ at $25^{\circ} \mathrm{C}$. Determine the potential of a concentration cell in which one half-cell consists of a copper electrode in 1.00 M copper(II) nitrate, and the other consists of a copper electrode in a saturated solution of $\mathrm{Cu}_{2}\left[\mathrm{Fe}(\mathrm{CN})_{6}\right]$. Ferrocyanide, $\left(\left[\mathrm{Fe}(\mathrm{CN})_{6}\right]^{4-}\right)$, is a complex ion $[14$ Section 17.5].

## Checkpoint 19.5 Spontaneity of Redox Reactions Under Conditions Other Than Standard State

19.5.1 Calculate $E$ at $25^{\circ} \mathrm{C}$ for a galvanic cell based on the reaction,

$$
\mathrm{Zn}(s)+\mathrm{Cu}^{2+}(a q) \longrightarrow \mathrm{Zn}^{2+}(a q)+\mathrm{Cu}(s)
$$

in which $\left[\mathrm{Zn}^{2+}\right]=0.55 \mathrm{M}$ and $\left[\mathrm{Cu}^{2+}\right]=1.02 \mathrm{M}$.
a) 1.10 V
b) 1.11 V
c) 1.09 V
d) 0.0118 V
e) 1.03 V
19.5.2 Calculate the cell potential at $25^{\circ} \mathrm{C}$ of a galvanic cell consisting of an Ag electrode in $0.15 \mathrm{M} \mathrm{AgNO}_{3}$ and an Ag electrode in $1.0 \mathrm{M} \mathrm{AgNO}_{3}$.
a) 0.0 V
b) 0.049 V
c) -0.049 V
d) 0.024 V
e) -0.024 V
19.5.3 Calculate $E_{\text {cell }}^{\circ}$ at $80^{\circ} \mathrm{C}$ for a galvanic cell based on the reaction $\mathrm{H}_{2}(g)+2 \mathrm{AgCl}(s) \rightleftarrows 2 \mathrm{Ag}(s)+2 \mathrm{H}^{+}(a q)+2 \mathrm{Cl}^{-}(a q)$ in which $\left[\mathrm{H}^{+}\right]=0.10 \mathrm{M},\left[\mathrm{Cl}^{-}\right]=1.5 M$, and $P=1.25 \mathrm{~atm}$. $\left(E_{\text {cell }}^{\circ}=0.18 \mathrm{~V}\right.$ at $80^{\circ} \mathrm{C}$.)
a) 0.12 V
b) 0.16 V
c) 0.18 V
d) 0.22 V
e) 0.24 V
19.5.4 Which of these would cause an increase in the cell potential of the electrochemical cell in Question 19.5.2?
(i) Adding $\mathrm{AgNO}_{3}$ to the cathode compartment
(ii) Adding saturated AgCl solution to the anode compartment
(iii) Adding NaCl to the anode compartment
a) i and iii
b) ii and iii
c) iii only
d) i, ii, and iii
e) None of these

To answer Questions 19.5 .5 and 19.5 .6 , consider the following cell diagram:

$$
\mathrm{Pb}(s)\left|\mathrm{Pb}\left(\mathrm{NO}_{3}\right)_{2}(0.60 M) \| \mathrm{AgNO}_{3}(0.40 M)\right| \mathrm{Ag}(s)
$$

19.5.5 Determine the initial value of $E_{\text {cell }}$ under the conditions shown in the cell diagram; and determine the initial value of $E_{\text {cell }}$ if $\left[\mathrm{Ag}^{+}\right]$ were increased by a factor of 4 at $25^{\circ} \mathrm{C}$.
a) $0.91 \mathrm{~V}, 0.88 \mathrm{~V}$
b) $0.91 \mathrm{~V}, 0.95 \mathrm{~V}$
c) $0.93 \mathrm{~V}, 0.95 \mathrm{~V}$
d) $0.93 \mathrm{~V}, 0.96 \mathrm{~V}$
e) $0.92 \mathrm{~V}, 0.88 \mathrm{~V}$
19.5.6 Which of the following would cause a decrease in the cell potential?
(i) Adding $\mathrm{NH}_{3}$ to the cathode compartment
(ii) Adding $\mathrm{NH}_{3}$ to the anode compartment
(iii) Adding $\mathrm{NaNO}_{3}$ to the anode compartment
a) i only
b) i and iii
c) iii only
d) i, ii, and iii
e) None of these

### 19.6 Batteries

A battery is a galvanic cell, or a series of connected galvanic cells, that can be used as a portable, self-contained source of direct electric current. In this section we examine several types of batteries.

## Dry Cells and Alkaline Batteries

The most common batteries, dry cells and alkaline batteries, are those used in flashlights, toys, and certain portable electronics such as CD players. The two are similar in appearance, but differ in the spontaneous chemical reaction responsible for producing a voltage. Although the reactions that take place in these batteries are somewhat complex, the reactions shown here approximate the overall processes.

A dry cell, so named because it has no fluid component, consists of a zinc container (the anode) in contact with manganese dioxide and an electrolyte (Figure 19.6). The electrolyte consists of ammonium chloride and zinc chloride in water, to which starch is added to thicken the
solution to a paste so that it is less likely to leak. A carbon rod, immersed in the electrolyte in the center of the cell, serves as the cathode. The cell reactions are:

Anode:

$$
\mathrm{Zn}(s) \longrightarrow \mathrm{Zn}^{2+}(a q)+2 e^{-}
$$

Cathode: $\quad 2 \mathrm{NH}_{4}^{+}(a q)+2 \mathrm{MnO}_{2}(s)+2 e^{-} \longrightarrow \mathrm{Mn}_{2} \mathrm{O}_{3}(s)+2 \mathrm{NH}_{3}(a q)+\mathrm{H}_{2} \mathrm{O}(l)$
Overall: $\quad \mathrm{Zn}(s)+2 \mathrm{NH}_{4}^{+}(a q)+2 \mathrm{MnO}_{2}(s) \longrightarrow \mathrm{Zn}^{2+}(a q)+\mathrm{Mn}_{2} \mathrm{O}_{3}(s)+2 \mathrm{NH}_{3}(a q)+\mathrm{H}_{2} \mathrm{O}(l)$
The voltage produced by a dry cell is about 1.5 V .
An alkaline battery is also based on the reduction of manganese dioxide and the oxidation of zinc. However, the reactions take place in a basic medium, hence the name alkaline battery. The anode consists of powdered zinc suspended in a gel, which is in contact with a concentrated solution of KOH. The cathode is a mixture of manganese dioxide and graphite. The anode and cathode are separated by a porous barrier (Figure 19.7).

```
Cathode: \(\quad 2 \mathrm{MnO}_{2}(s)+2 \mathrm{H}_{2} \mathrm{O}(l)+2 e^{-} \longrightarrow 2 \mathrm{MnO}(\mathrm{OH})(s)+2 \mathrm{OH}^{-}(a q)\)
Anode:
\[
\mathrm{Zn}(s)+2 \mathrm{OH}^{-}(a q) \longrightarrow \mathrm{Zn}(\mathrm{OH})_{2}(s)+2 e^{-}
\]
\[
\text { Overall: } \mathrm{Zn}(s)+2 \mathrm{MnO}_{2}(s)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{Zn}(\mathrm{OH})_{2}(s)+2 \mathrm{MnO}(\mathrm{OH})(s)+2 \mathrm{OH}^{-}(a q)
\]
```

Alkaline batteries are more expensive than dry cells and offer superior performance and shelf life.

## Lead Storage Batteries

The lead storage battery commonly used in automobiles consists of six identical cells joined together in series. Each cell has a lead anode and a cathode made of lead dioxide $\left(\mathrm{PbO}_{2}\right)$ packed on a metal plate (Figure 19.8). Both the cathode and the anode are immersed in an aqueous solution of sulfuric acid, which acts as the electrolyte. The cell reactions are

$$
\begin{array}{lr}
\text { Anode: } & \mathrm{Pb}(s)+\mathrm{SO}_{4}^{2-}(a q) \longrightarrow \mathrm{PbSO}_{4}(s)+2 e^{-} \\
\text {Cathode: } & \mathrm{PbO}_{2}(s)+4 \mathrm{H}^{+}(a q)+\mathrm{SO}_{4}^{2-}(a q)+2 e^{-} \longrightarrow \mathrm{PbSO}_{4}(s)+2 \mathrm{H}_{2} \mathrm{O}(l) \\
\text { Overall: } & \mathrm{Pb}(s)+\mathrm{PbO}_{2}(s)+4 \mathrm{H}^{+}(a q)+2 \mathrm{SO}_{4}^{2-}(a q) \longrightarrow 2 \mathrm{PbSO}_{4}(s)+2 \mathrm{H}_{2} \mathrm{O}(l)
\end{array}
$$

Under normal operating conditions, each cell produces 2 V . A total of 12 V from the six cells is used to power the ignition circuit of the automobile and its other electric systems. The lead storage battery can deliver large amounts of current for a short time, such as the time it takes to start the engine.

Unlike dry cells and alkaline batteries, the lead storage battery is rechargeable. Recharging the battery means reversing the normal electrochemical reaction by applying an external voltage at the cathode and the anode. (This kind of process is called electrolysis, which we discuss in Section 19.7.)

Figure 19.6 Interior view of the type of dry cell used in flashlights and other small devices.

Figure 19.7 Interior view of an alkaline battery.

Figure 19.8 Interior view of a lead storage battery. Under normal operating conditions, the concentration of the sulfuric acid solution is about 38 percent by mass.

Student Annotation: Lithium has the largest negative reduction potential of all the metals, making it a powerful reducing agent.

Student Annotation: Strictly speaking, a fuel cell is not a battery because it is not self-contained.

Figure 19.9 A hydrogen-oxygen fuel cell. The Ni and NiO embedded in the porous carbon electrodes are catalysts.

## Lithium-Ion Batteries

Sometimes called "the battery of the future," lithium-ion batteries have several advantages over other battery types. The overall reaction that takes place in the lithium-ion battery is

$$
\begin{array}{lr}
\text { Anode: } & \mathrm{Li}(s) \longrightarrow \mathrm{Li}^{+}+e^{-} \\
\text {Cathode: } & \mathrm{Li}^{+}+\mathrm{CoO}_{2}+e^{-} \longrightarrow \mathrm{LiCoO}_{2}(s) \\
\text { Overall: } & \mathrm{Li}(s)+\mathrm{CoO}_{2} \longrightarrow \mathrm{LiCoO}_{2}(s)
\end{array}
$$

The overall cell potential is 3.4 V , which is relatively large. Lithium is also the lightest metalonly 6.941 g of Li (its molar mass) are needed to produce 1 mole of electrons. Furthermore, a lithium-ion battery can be recharged hundreds of times. These qualities make lithium batteries suitable for use in portable devices such as cell phones, digital cameras, and laptop computers.

## Fuel Cells

Fossil fuels are a major source of energy, but the conversion of fossil fuel into electric energy is a highly inefficient process. Consider the combustion of methane:

$$
\mathrm{CH}_{4}(g)+2 \mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(l)+\text { energy }
$$

To generate electricity, heat produced by the reaction is first used to convert water to steam, which then drives a turbine, which then drives a generator. A significant fraction of the energy released in the form of heat is lost to the surroundings at each step (even the most efficient power plant converts only about 40 percent of the original chemical energy into electricity). Because combustion reactions are redox reactions, it is more desirable to carry them out directly by electrochemical means, thereby greatly increasing the efficiency of power production. This objective can be accomplished by a device known as a fuel cell, a galvanic cell that requires a continuous supply of reactants to keep functioning.

In its simplest form, a hydrogen-oxygen fuel cell consists of an electrolyte solution, such as a potassium hydroxide solution, and two inert electrodes. Hydrogen and oxygen gases are bubbled through the anode and cathode compartments (Figure 19.9), where the following reactions take place:

$$
\begin{array}{lc}
\text { Anode: } & 2 \mathrm{H}_{2}(g)+4 \mathrm{OH}^{-}(a q) \longrightarrow 4 \mathrm{H}_{2} \mathrm{O}(l)+4 e^{-} \\
\text {Cathode: } & \frac{\mathrm{O}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(l)+4 e^{-} \longrightarrow 4 \mathrm{OH}^{-}(a q)}{} \\
\text { Overall: } & 2 \mathrm{H}_{2}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l)
\end{array}
$$

Using $E^{\circ}$ values from Table 19.1, the standard cell potential is calculated as follows:

$$
\begin{aligned}
E_{\text {cell }}^{\circ} & =E_{\text {cathode }}^{\circ}-E_{\text {anode }}^{\circ} \\
& =0.40 \mathrm{~V}-(-0.83 \mathrm{~V}) \\
& =1.23 \mathrm{~V}
\end{aligned}
$$

Thus, the cell reaction is spontaneous under standard-state conditions. Note that the reaction is the same as the hydrogen combustion reaction, but the oxidation and reduction are carried out separately at the anode and the cathode. Like platinum in the standard hydrogen electrode, the electrodes serve two purposes. They serve as electrical conductors, and they provide the necessary surfaces for the initial decomposition of the molecules into atomic species, which must take place before electrons can be transferred. Electrodes that serve this particular purpose are called "electrocatalysts." Metals such as platinum, nickel, and rhodium also make good electrocatalysts.

In addition to the $\mathrm{H}_{2}-\mathrm{O}_{2}$ system, a number of other fuel cells have been developed. Among these is the propane-oxygen fuel cell. The corresponding half-cell reactions are

Anode: $\quad \mathrm{C}_{3} \mathrm{H}_{8}(g)+6 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 3 \mathrm{CO}_{2}(g)+20 \mathrm{H}^{+}(a q)+20 e^{-}$
Cathode: $5 \mathrm{O}_{2}(g)+20 \mathrm{H}^{+}(a q)+20 e^{-} \longrightarrow 10 \mathrm{H}_{2} \mathrm{O}(l)$
Overall: $\quad \mathrm{C}_{3} \mathrm{H}_{8}(\mathrm{~g})+5 \mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 3 \mathrm{CO}_{2}(\mathrm{~g})+4 \mathrm{H}_{2} \mathrm{O}(l)$
The overall reaction is identical to the burning of propane in oxygen.
Unlike batteries, fuel cells do not store chemical energy. Reactants must be constantly resupplied as they are consumed, and products must be removed as they form. However, properly designed fuel cells may be as much as 70 percent efficient, which is about twice as efficient as an internal combustion engine. In addition, fuel-cell generators are free of the noise, vibration, heat transfer, thermal pollution, and other problems normally associated with conventional power plants. Nevertheless, fuel cells are not yet in widespread use. One major problem is the expense of electrocatalysts that can function efficiently for long periods of time without contamination. One notable application of fuel cells is their use in space vehicles. Hydrogen-oxygen fuel cells provide electric power (and drinking water!) for space flight.

### 19.7 Electrolysis

In Section 19.6, we mentioned that lead storage batteries are rechargeable and that recharging means reversing the electrochemical processes by which the battery ordinarily operates through the application of an external voltage. This process, the use of electric energy to drive a nonspontaneous chemical reaction, is called electrolysis. An electrolytic cell is one used to carry out electrolysis. The same principles apply to the processes in both galvanic and electrolytic cells. In this section, we discuss three examples of electrolysis based on those principles. We then examine some of the quantitative aspects of electrolysis.

## Electrolysis of Molten Sodium Chloride

In its molten (melted) state, sodium chloride, an ionic compound, can be electrolyzed to separate it into its constituent elements, sodium and chlorine. Figure 19.10(a) is a diagram of a Downs cell, which is used for the large-scale electrolysis of NaCl . In molten NaCl , the cations and anions are the $\mathrm{Na}^{+}$and $\mathrm{Cl}^{-}$ions, respectively. Figure 19.10(b) is a simplified diagram showing the reactions that occur at the electrodes. The electrolytic cell contains a pair of electrodes connected to the battery. The battery serves to push electrons in the direction they would not flow spontaneously. The electrode toward which the electrons are pushed is the cathode, where reduction takes place. The electrode away from which electrons are drawn is the anode, where oxidation takes place. The reactions at the electrodes are

$$
\begin{array}{lc}
\text { Anode (oxidation): } & 2 \mathrm{Cl}^{-}(l) \longrightarrow \mathrm{Cl}_{2}(g)+2 e^{-} \\
\text {Cathode (reduction): } & \frac{2 \mathrm{Na}^{+}(l)+2 e^{-} \longrightarrow 2 \mathrm{Na}(l)}{} \begin{array}{l}
\text { Overall: }
\end{array} \\
2 \mathrm{Na}^{+}(l)+2 \mathrm{Cl}^{-}(l) \longrightarrow 2 \mathrm{Na}(l)+\mathrm{Cl}_{2}(g)
\end{array}
$$

This process is a major industrial source of pure sodium metal and chlorine gas.

Electrochemistry-the electrolysis of potassium iodide.

| Student Annotation: |  |  |
| :--- | :--- | :--- |
| Cell | Chemical <br> Reaction | Electric |
| Type | Energy |  |
| Galvanic | Spontaneous | Produced |
| Electrolytic | Nonspontaneous | Consumed |

Figure 19.10 (a) A practical arrangement called a Downs cell for the electrolysis of molten NaCl (m.p. $=801^{\circ} \mathrm{C}$ ). The sodium metal formed at the cathodes is in the liquid state. Because liquid sodium metal is lighter than molten NaCl , the sodium floats to the surface, as shown, and is collected. Chlorine gas forms at the anode and is collected at the top. (b) A simplified diagram showing the electrode reactions during the electrolysis of molten NaCl . The battery is needed to drive the nonspontaneous reaction.

Student Annotation: We can only estimate the value of $E_{\text {cell }}^{\circ}$ because the values in Table 19.1 refer to the species in aqueous solution.

Student Annotation: Remember that at $25^{\circ} \mathrm{C}$ pure water has only a very low concentration of ions [ 14 Section 16.2]:

$$
\left[\mathrm{H}^{+}\right]=\left[\mathrm{OH}^{-}\right]=1 \times 10^{-7} \mathrm{M}
$$

Using data from Table 19.1, we estimate $E_{\text {cell }}^{\circ}$ to be -4 V for this process. The negative standard reduction potential indicates that for the process to occur as written, a minimum of approximately 4 V must be supplied by the battery to drive the reaction in the desired direction. In practice, an even higher voltage is required because of inefficiencies in the electrolytic process and because of overvoltage, a phenomenon we will discuss later in this section.

## Electrolysis of Water

Under ordinary atmospheric conditions ( 1 atm and $25^{\circ} \mathrm{C}$ ), water will not spontaneously decompose to form hydrogen and oxygen gas because the standard free-energy change for the reaction is a large positive quantity:

$$
2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{H}_{2}(g)+\mathrm{O}_{2}(g) \quad \Delta G^{\circ}=474.4 \mathrm{~kJ} / \mathrm{mol}
$$

However, this reaction can be made to occur in an electrolytic cell like the one shown in Figure 19.11. This cell consists of a pair of electrodes made of a nonreactive metal, such as platinum, immersed in water. When the electrodes are connected to the battery, nothing happens because there are not enough ions in pure water to carry much of an electric current. The reaction occurs readily in a $0.1 M_{H_{2}} \mathrm{SO}_{4}$ solution, however, because there is a sufficient ion concentration to conduct electricity. Immediately, gas bubbles begin to appear at both electrodes.

The processes at the electrodes are

Note that there is no net consumption of the acid.

## Electrolysis of an Aqueous Sodium Chloride Solution

An aqueous sodium chloride solution is the most complicated of the three examples of electrolysis considered here because $\mathrm{NaCl}(a q)$ contains several species that could be oxidized and reduced. The reductions that might occur at the cathode are

$$
\begin{array}{ll}
2 \mathrm{H}^{+}(a q)+2 e^{-} \longrightarrow \mathrm{H}_{2}(g) & E^{\circ}=0.00 \mathrm{~V} \\
2 \mathrm{H}_{2} \mathrm{O}(l)+2 e^{-} \longrightarrow \mathrm{H}_{2}(g)+2 \mathrm{OH}^{-}(a q) & E^{\circ}=-0.83 \mathrm{~V}
\end{array}
$$

or

$$
\mathrm{Na}^{+}(a q)+e^{-} \longrightarrow \mathrm{Na}(s) \quad E^{\circ}=-2.71 \mathrm{~V}
$$

We can rule out the reduction of $\mathrm{Na}^{+}$ion because of the large negative $E^{\circ}$ value. Under standardstate conditions, the reduction of $\mathrm{H}^{+}$is more apt to occur than the reduction of $\mathrm{H}_{2} \mathrm{O}$. However, in a solution of NaCl , the $\mathrm{H}^{+}$concentration is very low, making the reduction of $\mathrm{H}_{2} \mathrm{O}$ the more probable reaction at the cathode.

The oxidation reactions that might occur at the anode are

$$
2 \mathrm{Cl}^{-}(a q) \longrightarrow \mathrm{Cl}_{2}(g)+2 e^{-}
$$

or

$$
2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{O}_{2}(g)+4 \mathrm{H}^{+}(a q)+4 e^{-}
$$

Referring to Table 19.1, we find

$$
\begin{aligned}
\mathrm{Cl}_{2}(g)+2 e^{-} \longrightarrow 2 \mathrm{Cl}^{-}(a q) & E^{\circ}=1.36 \mathrm{~V} \\
\mathrm{O}_{2}(g)+4 \mathrm{H}^{+}(a q)+4 e^{-} \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l) & E^{\circ}=1.23 \mathrm{~V}
\end{aligned}
$$

The standard reduction potentials of the two reactions are not very different, but the values do suggest that the oxidation of $\mathrm{H}_{2} \mathrm{O}$ should occur more readily. However, by experiment we find that the gas produced at the anode is $\mathrm{Cl}_{2}$, not $\mathrm{O}_{2}$. In the study of electrolytic processes, we sometimes find that the voltage required for a reaction is considerably higher than the electrode potentials would indicate. The overvoltage is the difference between the calculated voltage and the actual voltage required to cause electrolysis. The overvoltage for $\mathrm{O}_{2}$ formation is quite high. Under normal operating conditions, therefore, $\mathrm{Cl}_{2}$ gas forms at the anode instead of $\mathrm{O}_{2}$.

Thus, the half-cell reactions in the electrolysis of aqueous sodium chloride are

$$
\begin{array}{lc}
\text { Anode (oxidation): } & 2 \mathrm{Cl}^{-}(a q) \longrightarrow \mathrm{Cl}_{2}(g)+2 e^{-} \\
\text {Cathode (reduction): } & \frac{2 \mathrm{H}_{2} \mathrm{O}(l)+2 e^{-} \longrightarrow \mathrm{H}_{2}(g)+2 \mathrm{OH}^{-}(a q)}{2 \mathrm{H}_{2} \mathrm{O}(l)+2 \mathrm{Cl}^{-}(a q) \longrightarrow \mathrm{H}_{2}(g)+\mathrm{Cl}_{2}(g)+2 \mathrm{OH}^{-}(a q)} \\
\text { Overall: }
\end{array}
$$

As the overall reaction shows, the concentration of the $\mathrm{Cl}^{-}$ions decreases during electrolysis and that of the $\mathrm{OH}^{-}$ions increases. Therefore, in addition to $\mathrm{H}_{2}$ and $\mathrm{Cl}_{2}$, the useful by-product NaOH can be obtained by evaporating the aqueous solution at the end of the electrolysis.

Electrolysis has many important applications in industry, mainly in the extraction and purification of metals. We discuss some of these applications in Chapter 23.

Figure 19.11 Apparatus for small-scale electrolysis of water. The volume of hydrogen gas generated at the cathode is twice that of oxygen gas generated at the anode.

Student Annotation: Keep in mind that in the electrolysis of aqueous solutions, the water itself may be oxidized and/or reduced.

Figure 19.12 Steps involved in calculating amounts of substances reduced or oxidized in electrolysis.

## Quantitative Applications of Electrolysis

The quantitative treatment of electrolysis was developed primarily by Faraday. He observed that the mass of product formed (or reactant consumed) at an electrode was proportional to both the amount of electricity transferred at the electrode and the molar mass of the substance being produced (or consumed). In the electrolysis of molten NaCl , for example, the cathode reaction tells us that one Na atom is produced when one $\mathrm{Na}^{+}$ion accepts an electron from the electrode. To reduce 1 mole of $\mathrm{Na}^{+}$ions, we must supply an Avogadro's number $\left(6.02 \times 10^{23}\right)$ of electrons to the cathode. On the other hand, stoichiometry tells us that it takes 2 moles of electrons to reduce 1 mole of $\mathrm{Mg}^{2+}$ ions and 3 moles of electrons to reduce 1 mole of $\mathrm{Al}^{3+}$ ions:

$$
\begin{aligned}
\mathrm{Na}^{+}+e^{-} & \longrightarrow \mathrm{Na} \\
\mathrm{Mg}^{2+}+2 e^{-} & \longrightarrow \mathrm{Mg} \\
\mathrm{Al}^{3+}+3 e^{-} & \longrightarrow \mathrm{Al}
\end{aligned}
$$

In an electrolysis experiment, we generally measure the current (in amperes) that passes through an electrolytic cell in a given period of time. The relationship between charge (in coulombs) and the current is

$$
1 \mathrm{C}=1 \mathrm{~A} \times 1 \mathrm{~s}
$$

That is, a coulomb is the quantity of electric charge passing any point in the circuit in 1 s when the current is 1 A . Therefore, if we know the current (in amperes) and how long it is applied (in seconds), we can calculate the charge (in coulombs). Knowing the charge enables us to determine the number of moles of electrons. And knowing the number of moles of electrons allows us to use stoichiometry to determine the number of moles of product. Figure 19.12 shows the steps involved in calculating the quantities of substances produced in electrolysis.

To illustrate this approach, consider an electrolytic cell in which molten $\mathrm{CaCl}_{2}$ is separated into its constituent elements, Ca and $\mathrm{Cl}_{2}$. Suppose a current of 0.452 A is passed through the cell for 1.50 h . How much product will be formed at each electrode? The first step is to determine which species will be oxidized at the anode and which species will be reduced at the cathode. Here the choice is straightforward because we have only $\mathrm{Ca}^{2+}$ and $\mathrm{Cl}^{-}$ions. The cell reactions are

The quantities of calcium metal and chlorine gas formed depend on the number of electrons that pass through the electrolytic cell, which in turn depends on charge, or current $\times$ time:

$$
\text { coulombs }=0.452 A \times 1.50 \not K \times \frac{3600,8}{1 \not K} \times \frac{1 \mathrm{C}}{1 A \cdot 8}=2.441 \times 10^{3} \mathrm{C}
$$

Because $1 \mathrm{~mol} e^{-}=96,500 \mathrm{C}$ and $2 \mathrm{~mol} e^{-}$are required to reduce 1 mole of $\mathrm{Ca}^{2+}$ ions, the mass of Ca metal formed at the cathode is calculated as follows:

$$
\text { grams } \mathrm{Ca}=\left(2.441 \times 10^{3} \text { C }\right)\left(\frac{1 \text { mote }}{96,500 \varnothing}\right)\left(\frac{1 \text { mot Ca }}{2 \text { mote }}\right)\left(\frac{40.08 \mathrm{~g} \mathrm{Ca}}{1 \text { mot Ca }}\right)=0.507 \mathrm{~g} \mathrm{Ca}
$$

The anode reaction indicates that 1 mole of chlorine is produced per $2 \mathrm{~mol} e^{-}$of electricity. Hence, the mass of chlorine gas formed is

$$
\text { grams } \mathrm{Cl}_{2}=\left(2.441 \times 10^{3} \not \subset\right)\left(\frac{1 \text { mote }}{96,500 \varnothing}\right)\left(\frac{1 \mathrm{motel}_{2}}{2 \text { mote }}\right)\left(\frac{70.90 \mathrm{~g} \mathrm{Cl}_{2}}{1 \mathrm{~mol} \mathrm{Cl}_{2}}\right)=0.897 \mathrm{~g} \mathrm{Cl}_{2}
$$

Sample Problem 19.8 applies this approach to electrolysis in an aqueous solution.

## Sample Problem 19.8

A current of 1.26 A is passed through an electrolytic cell containing a dilute sulfuric acid solution for 7.44 h . Write the half-cell reactions, and calculate the volume of gases generated at STP.

Strategy As shown in Figure 19.12, we can use current and time to determine charge. We can then convert charge to moles of electrons, and use the balanced half-reactions to determine how many moles of product form at each electrode. Finally, we can convert moles to volume.

Setup The half-cell reactions for the electrolysis of water are

$$
\begin{array}{lr}
\text { Anode: } & 2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{O}_{2}(g)+4 \mathrm{H}^{+}(a q)+4 e^{-} \\
\text {Cathode: } & 4 \mathrm{H}^{+}(a q)+4 e^{-} \longrightarrow 2 \mathrm{H}_{2}(g) \\
\text { Overall: } & 2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{O}_{2}(g)+2 \mathrm{H}_{2}(g)
\end{array}
$$

Remember that STP for gases means 273 K and 1 atm .

## Solution

$$
\text { coulombs }=(1.26 A)(7.44 \text { hx })\left(\frac{3600,8}{1 \not ด}\right)\left(\frac{1 \mathrm{C}}{1 A \cdot g}\right)=3.375 \times 10^{4} \mathrm{C}
$$

At the anode:

$$
\text { moles } \mathrm{O}_{2}=\left(3.375 \times 10^{4} \varnothing\right)\left(\frac{1 \text { mote }}{96,500 \varnothing}\right)\left(\frac{1 \mathrm{~mol} \mathrm{O}_{2}}{4 \mathrm{mote}}\right)=0.0874 \mathrm{~mol} \mathrm{O}_{2}
$$

The volume of $0.0874 \mathrm{~mol} \mathrm{O}_{2}$ at STP is given by

$$
\begin{aligned}
V & =\frac{n R T}{P} \\
& =\frac{(0.0874 \mathrm{~mol})(0.08206 \mathrm{~L} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{~mol})(273.15)}{1 \mathrm{~atm}}=1.96 \mathrm{~L} \mathrm{O}_{2}
\end{aligned}
$$

Similarly, for hydrogen we write

$$
\text { moles } \mathrm{H}_{2}\left(3.375 \times 10^{4} \ell\right)\left(\frac{1 \text { mote }}{96,500 \varnothing}\right)\left(\frac{1 \mathrm{~mol} \mathrm{H}_{2}}{2 \mathrm{~mole}}\right)=0.175 \mathrm{~mol} \mathrm{H}_{2}
$$

The volume of $0.175 \mathrm{~mol} \mathrm{H}_{2}$ at STP is given by

$$
\begin{aligned}
V & =\frac{n R T}{P} \\
& =\frac{(0.175 \mathrm{~mol})(0.08206 \mathrm{~L} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{~mol})(273.15)}{1 \mathrm{~atm}}=3.92 \mathrm{~L} \mathrm{H}_{2}
\end{aligned}
$$

Practice Problem A A constant current of 0.912 A is passed through an electrolytic cell containing molten $\mathrm{MgCl}_{2}$ for 18 h . What mass of Mg is produced?
$\$$ Practice Problem B A constant current is passed through an electrolytic cell containing molten $\mathrm{MgCl}_{2}$ for 12 h . If 4.83 L of $\mathrm{Cl}_{2}$ (at STP) is produced at the anode, what is the current in amperes?

## Checkpoint 19.7 Electrolysis

19.7.1 In the electrolysis of molten $\mathrm{CaCl}_{2}$, a current of 1.12 A is passed through the cell for 3.0 h . What is the mass of Ca produced at the cathode?
a) 2.51 g
b) 1.26 g
c) 5.02 g
d) 10.0 g
e) $2.42 \times 10^{5} \mathrm{~g}$
19.7.2 How long will a current of 0.995 A need
to be passed through water (containing
$\mathrm{H}_{2} \mathrm{SO}_{4}$ ) for 5.00 L of $\mathrm{O}_{2}$ to be produced $\mathrm{H}_{2} \mathrm{SO}_{4}$ ) for 5.00 L of $\mathrm{O}_{2}$ to be produced at STP?
a) 6.0 h
b) 8.2 h
c) 1.5 h
d) 3.0 h
e) 24.0 h
b) 8.2 h
b) 1.5
19.7.3 The diagram shows an electrolytic cell being powered by a galvanic cell. Identify each of the electrodes from left to right as an anode or a cathode.
a) Cathode, anode, anode, cathode
b) Cathode, anode, cathode, anode
c) Anode, cathode, anode, cathode
d) Anode, anode, cathode, cathode
e) Anode, cathode, cathode, anode

Think About It The volume of $\mathrm{H}_{2}$ is twice that of $\mathrm{O}_{2}$ (see Figure 19.11), which is what we would expect based on Avogadro's law (at the same temperature and pressure, volume is directly proportional to the number of moles of gas: $V \propto n$ ) [/W4 Section 11.2].

Media Player/ MPEG Content
Electrochemistry-the production of aluminum.

Student Annotation: From Table 19.1:

$$
\begin{aligned}
& \mathrm{Fe}^{2+}(a q)+2 \mathrm{e}^{-} \longrightarrow \mathrm{Fe}(s) E^{\circ}=-0.44 \mathrm{~V} \\
& \mathrm{Al}^{3+}(a q)+3 \mathrm{e}^{-} \longrightarrow \mathrm{Al}(s) E^{\circ}=-1.66 \mathrm{~V}
\end{aligned}
$$

Al, with the more negative reduction potential, is less likely to be reduced (more likely to be oxidized) than Fe .

Figure 19.13 The electrochemical process involved in rust formation. The $\mathrm{H}^{+}$ions are supplied by $\mathrm{H}_{2} \mathrm{CO}_{3}$, which forms when $\mathrm{CO}_{2}$ from air dissolves in water.

### 19.8 Corrosion

The term corrosion generally refers to the deterioration of a metal by an electrochemical process. There are many examples of corrosion, including rust on iron, tarnish on silver, and the green layer that forms on copper and brass. In this section we discuss the processes involved in corrosion and some of the measures taken to prevent it.

The formation of rust on iron requires oxygen and water. Although the reactions involved are quite complex and not completely understood, the main steps are believed to be as follows. A region of the metal's surface serves as the anode, where the following oxidation occurs:

$$
\mathrm{Fe}(s) \longrightarrow \mathrm{Fe}^{2+}(a q)+2 e^{-}
$$

The electrons given up by iron reduce atmospheric oxygen to water at the cathode, which is another region of the same metal's surface:

$$
\mathrm{O}_{2}(g)+4 \mathrm{H}^{+}(a q)+4 e^{-} \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l)
$$

The overall redox reaction is

$$
2 \mathrm{Fe}(s)+\mathrm{O}_{2}(g)+4 \mathrm{H}^{+}(a q) \longrightarrow 2 \mathrm{Fe}^{2+}(g)+2 \mathrm{H}_{2} \mathrm{O}(l)
$$

With data from Table 19.1, the standard potential for this process can be calculated as follows:

$$
\begin{aligned}
E_{\text {cell }}^{\circ} & =E_{\text {cathode }}^{\circ}-E_{\text {anode }}^{\circ} \\
& =1.23 \mathrm{~V}-(-0.44 \mathrm{~V}) \\
& =1.67 \mathrm{~V}
\end{aligned}
$$

Note that this reaction occurs in an acidic medium; the $\mathrm{H}^{+}$ions are supplied in part by the reaction of atmospheric carbon dioxide with water to form the weak acid, carbonic acid $\left(\mathrm{H}_{2} \mathrm{CO}_{3}\right)$.

The $\mathrm{Fe}^{2+}$ ions formed at the anode are further oxidized by oxygen as follows:

$$
4 \mathrm{Fe}^{2+}(a q)+\mathrm{O}_{2}(g)+(4+2 x) \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{Fe}_{2} \mathrm{O}_{3} \cdot x \mathrm{H}_{2} \mathrm{O}(s)+8 \mathrm{H}^{+}(a q)
$$

This hydrated form of iron(III) oxide is known as rust. The amount of water associated with the iron(III) oxide varies, so we represent the formula as $\mathrm{Fe}_{2} \mathrm{O}_{3} \cdot x \mathrm{H}_{2} \mathrm{O}$.

Figure 19.13 shows the mechanism of rust formation. The electric circuit is completed by the migration of electrons and ions; this is why rusting occurs so rapidly in saltwater. In cold climates, salts $\left(\mathrm{NaCl}\right.$ or $\left.\mathrm{CaCl}_{2}\right)$ spread on roadways to melt ice and snow are a major cause of rust formation on automobiles.

Other metals also undergo oxidation. Aluminum, for example, which is used to make airplanes, beverage cans, and aluminum foil, has a much greater tendency to oxidize than does iron. Unlike the corrosion of iron, though, corrosion of aluminum produces an insoluble layer of protective coating $\left(\mathrm{Al}_{2} \mathrm{O}_{3}\right)$ that prevents the underlying metal from additional corrosion.

Coinage metals such as copper and silver also corrode, but much more slowly than either iron or aluminum:

$$
\begin{aligned}
& \mathrm{Cu}(s) \longrightarrow \mathrm{Cu}^{2+}(a q)+2 e^{-} \\
& \mathrm{Ag}(s) \longrightarrow \mathrm{Ag}^{+}(a q)+e^{-}
\end{aligned}
$$

In ordinary atmospheric exposure, copper forms a layer of copper carbonate $\left(\mathrm{CuCO}_{3}\right)$, a green substance referred to as patina, that protects the metal underneath from further corrosion. Likewise, silverware that comes into contact with foodstuffs develops a layer of silver sulfide $\left(\mathrm{Ag}_{2} \mathrm{~S}\right)$.

A number of methods have been devised to protect metals from corrosion. Most of these methods are aimed at preventing rust formation. The most obvious approach is to coat the metal surface with paint to prevent exposure to the substances necessary for corrosion. If the paint is scratched or otherwise damaged, however, thus exposing even the smallest area of bare metal, rust will form under the paint layer. The surface of iron metal can be made inactive by a process called passivation. A thin oxide layer is formed when the metal is treated with a strong oxidizing agent such as concentrated nitric acid. A solution of sodium chromate is often added to cooling systems and radiators to prevent rust formation.

The tendency for iron to oxidize is greatly reduced when it is alloyed with certain other metals. For example, in stainless steel, an alloy of iron and chromium, a layer of chromium oxide forms that protects the iron from corrosion.

An iron container can be covered with a layer of another metal such as tin or zinc. A "tin" can is made by applying a thin layer of tin over iron. Rust formation is prevented as long as the tin layer remains intact. However, once the surface has been breached by a scratch or a dent, rusting occurs rapidly. If we look up the standard reduction potentials in Table 19.1, we find that when tin and iron are in contact with each other, tin, with its greater reduction potential, acts as a cathode. Iron acts as an anode and is therefore oxidized.

$$
\begin{array}{ll}
\mathrm{Sn}^{2+}(a q)+2 e^{-} \longrightarrow \mathrm{Sn}(s) & E^{\circ}=-0.14 \mathrm{~V} \\
\mathrm{Fe}^{2+}(a q)+2 e^{-} \longrightarrow \mathrm{Fe}(s) & E^{\circ}=-0.44 \mathrm{~V}
\end{array}
$$

Zinc-plating, or galvanization, protects iron from corrosion by a different mechanism. According to Table 19.1,

$$
\mathrm{Zn}^{2+}(a q)+2 e^{-} \longrightarrow \mathrm{Zn}(s) \quad E^{\circ}=-0.76 \mathrm{~V}
$$

so zinc is more easily oxidized than iron. Like aluminum, zinc oxidizes to form a protective coating. Even when the zinc layer is compromised, though, and the underlying iron is exposed, zinc is still the more easily oxidized of the two metals and will act as the anode. Iron will be the cathode, thereby remaining reduced.

Galvanization is one example of cathodic protection, the process by which a metal is protected by being made the cathode in what amounts to a galvanic cell. Another example is the use of zinc or magnesium bars to protect underground storage tanks and ships. When a steel tank or hull is connected to a more easily oxidized metal, corrosion of the steel is prevented.

Electrochemistry-chrome plating

## Applying What You've Learned

The pain caused by having aluminum foil contact an amalgam dental filling results from the filling being made the cathode in an electrochemical cell. Another type of discomfort can result from the filling being made the anode in an electrochemical cell. This occurs when the filling touches a metal with a greater reduction potential than the components of the amalgam, such as gold. When an amalgam filling comes into contact with a gold inlay, the tin in the filling (the most easily oxidized of the major amalgam components) is oxidized-creating an unpleasant metallic taste in the mouth. A simplified, unbalanced equation for the redox reaction that takes place is

$$
\mathrm{Sn}(s)+\mathrm{O}_{2}(g) \longrightarrow \mathrm{Sn}^{2+}(a q)+\mathrm{H}_{2} \mathrm{O}(l)
$$

Gold inlay touching amalgam dental filling.

## Problems:

a) Balance (in acidic medium) the equation for the oxidation of tin from an amalgam filling. [ 144 Sample Problem 19.1]
b) Calculate the standard cell potential for the reaction in part (a). [144 Sample Problem 19.2]
c) Which of the components of dental amalgam (mercury, silver, tin, copper, or zinc) would be oxidized when a filling is brought into contact with lead? [14 Sample Problem 19.3]
d) Calculate the standard free-energy change for the reaction in part (a). [144 Sample Problem 19.4]
e) Calculate the equilibrium constant at $25^{\circ} \mathrm{C}$ for the reaction in part (a). [ 14 Sample Problem 19.5]

## Chapter Summary

## Section 19.1

- Redox reactions are those in which oxidation numbers change. Halfreactions are the separated oxidation and reduction reactions that make up the overall redox reaction.
- Redox equations can be balanced via the half-reaction method, which allows for the addition of $\mathrm{H}_{2} \mathrm{O}$ to balance $\mathrm{O}, \mathrm{H}^{+}$to balance H , and $\mathrm{OH}^{-}$for reactions taking place in basic solution.

## Section 19.2

- An electrochemical cell in which a spontaneous chemical reaction generates a flow of electrons through a wire is called a galvanic cell.
- Half-reactions in a galvanic cell take place in separate compartments called half-cells. Half-cells contain electrodes in solutions and are connected via an external wire and by a salt bridge.
- The electrode at which reduction occurs is called the cathode; the electrode at which oxidation occurs is called the anode.
- The difference in electric potential between the cathode and the anode is the cell potential $\left(\boldsymbol{E}_{\text {cell }}\right)$.

## Section 19.3

- We use standard reduction potentials $\left(\boldsymbol{E}^{\circ}\right)$ to calculate the standard cell voltage or standard cell potential ( $E_{\text {cell }}^{\circ}$ ).
- Half-cell potentials are measured relative to the standard hydrogen electrode (SHE), the half-reaction for which has an arbitrarily defined standard reduction potential of zero.

## Section 19.4

- $E_{\text {cell }}^{\circ}$ is related to the standard free-energy change $\left(\Delta G^{\circ}\right)$ and to the equilibrium constant, $K$. A positive $E_{\text {cell }}^{\circ}$ corresponds to a negative ( $\Delta G^{\circ}$ ) value and a large $K$ value.

## Section 19.5

- $E_{\text {cell }}$ under other than standard-state conditions is determined from $E_{\text {cell }}^{\circ}$ and the reaction quotient, $Q$, using the Nernst equation.
- A concentration cell has the same type of electrode and the same ion in solution (at different concentrations) in the anode and cathode compartments.

## Section 19.6

- Batteries are portable, self-contained sources of electric energy consisting of galvanic cells-or a series of galvanic cells.
- Fuel cells are not really batteries but also supply electric energy via a spontaneous redox reaction. Reactants must be supplied constantly for a fuel cell to operate.

## Section 19.7

- Electrolysis is the use of electric energy to drive a nonspontaneous redox reaction. An electrochemical cell used for this purpose is called an electrolytic cell.
- The voltage that must actually be supplied to drive a nonspontaneous redox reaction is greater than the calculated amount because of overvoltage.
- Electrolysis is used to recharge lead storage batteries, separate compounds into their constituent elements, and separate and purify metals.
- We can calculate the amount of a substance produced in electrolysis if we know the current applied to the cell and the length of time for which it is applied.

## Section 19.8

- Corrosion is the undesirable oxidation of metals.
- Corrosion can be prevented by coating the metal surface with paint, a less easily oxidized metal, or a more easily oxidized metal such as zinc.
- The use of a more easily oxidized metal is known as cathodic protection, wherein the metal being protected is made the cathode in a galvanic cell. Galvanization is the cathodic protection of iron or steel using zinc.

## Key Equations

$$
\begin{array}{ll}
19.1 & E_{\text {cell }}^{\circ}=E_{\text {cathode }}^{\circ}-E_{\text {anode }}^{\circ} \\
19.2 & \Delta G=-n F E_{\text {cell }} \\
19.3 & \Delta G^{\circ}=-n F E_{\text {cell }}^{\circ} \\
19.4 & E_{\text {cell }}^{\circ}=\frac{R T}{n F} \ln K \\
19.5 & E_{\text {cell }}^{\circ}=\frac{0.0592 \mathrm{~V}}{n} \log K \quad\left(\text { at } 25^{\circ} \mathrm{C}\right) \\
19.6 & E=E^{\circ}-\frac{R T}{n F} \ln Q \\
19.7 & E=E^{\circ}-\frac{0.0592 \mathrm{~V}}{n} \log Q
\end{array}
$$

## Questions and Problems

## Section 19.1: Balancing Redox Equations

## Problems

E19.1 Balance the following redox equations by the half-reaction method:
(a) $\mathrm{H}_{2} \mathrm{O}_{2}+\mathrm{Fe}^{2+} \longrightarrow \mathrm{Fe}^{3+}+\mathrm{H}_{2} \mathrm{O}$ (in acidic solution)
(b) $\mathrm{Cu}+\mathrm{HNO}_{3} \longrightarrow \mathrm{Cu}^{2+}+\mathrm{NO}+\mathrm{H}_{2} \mathrm{O}$ (in acidic solution)
(c) $\mathrm{CN}^{-}+\mathrm{MnO}_{4}^{-} \longrightarrow \mathrm{CNO}^{-}+\mathrm{MnO}_{2}$ (in basic solution)
(d) $\mathrm{Br}_{2} \longrightarrow \mathrm{BrO}_{3}^{-}+\mathrm{Br}^{-}$(in basic solution)
(e) $\mathrm{S}_{2} \mathrm{O}_{3}^{2-}+\mathrm{I}_{2} \longrightarrow \mathrm{I}^{-}+\mathrm{S}_{4} \mathrm{O}_{6}^{2-}$ (in acidic solution)

E19.2 Balance the following redox equations by the half-reaction method:
(a) $\mathrm{Mn}^{2+}+\mathrm{H}_{2} \mathrm{O}_{2} \longrightarrow \mathrm{MnO}_{2}+\mathrm{H}_{2} \mathrm{O}$ (in basic solution)
(b) $\mathrm{Bi}(\mathrm{OH})_{3}+\mathrm{SnO}_{2}^{2-} \longrightarrow \mathrm{SnO}_{3}^{2-}+\mathrm{Bi}$ (in basic solution)
(c) $\mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}+\mathrm{C}_{2} \mathrm{O}_{4}^{2-} \longrightarrow \mathrm{Cr}^{3+}+\mathrm{CO}_{2}$ (in acidic solution)
(d) $\mathrm{ClO}_{3}^{-}+\mathrm{Cl}^{-} \longrightarrow \mathrm{Cl}_{2}+\mathrm{ClO}_{2}$ (in acidic solution)
(e) $\mathrm{Mn}^{2+}+\mathrm{BiO}_{3}^{-} \longrightarrow \mathrm{Bi}^{3+}+\mathrm{MnO}_{4}^{-}$(in acidic solution)

## Section 19.2: Galvanic Cells

## Visualizing Chemistry

Figure 19.1
VC 19.1 In the first scene of the animation, when a zinc bar is immersed in an aqueous copper sulfate solution, solid copper deposits on the bar. What reaction would take place if a copper bar were immersed in an aqueous zinc sulfate solution?
a) No reaction would take place.
b) Solid copper would still deposit on the bar.
c) Solid zinc would deposit on the bar.

VC 19.2 What causes the change in the potential of the galvanic cell in Figure 19.1 as the cell operates?
a) Changes in the sizes of the zinc and copper electrodes.
b) Changes in the concentrations of zinc and copper ions.
c) Changes in the volumes of solutions in the half-cells.

VC 19.3 Why does the color of the blue solution in the galvanic cell (Figure 19.1) fade as the cell operates?
a) Blue $\mathrm{Cu}^{2+}$ ions are replaced by colorless $\mathrm{Zn}^{2+}$ ions solution.
b) Blue $\mathrm{Cu}^{2+}$ ions are removed from solution by reduction.
c) Blue $\mathrm{Cu}^{2+}$ ions are removed from solution by oxidation.

VC 19.4 What happens to the mass of the copper electrode in the galvanic cell in Figure 19.1 as the cell operates?
a) It increases.
b) It decreases.
c) It does not change.

## Review Questions

19.3 Define the following terms: anode, cathode, cell voltage, electromotive force, standard reduction potential.
19.4 Describe the basic features of a galvanic cell. Why are the two components of the cell separated from each other?
19.5 What is the function of a salt bridge? What kind of electrolyte should be used in a salt bridge?
19.6 What is a cell diagram? Write the cell diagram for a galvanic cell consisting of an Al electrode placed in a $1 \mathrm{M} \mathrm{Al}\left(\mathrm{NO}_{3}\right)_{3}$ solution and an Ag electrode placed in a $1 \mathrm{M} \mathrm{AgNO} \mathrm{Ag}_{3}$ solution.
19.7 What is the difference between the half-reactions discussed in redox processes in Chapter 4 and the half-cell reactions discussed in Section 19.2?

## Section 19.3: Standard Reduction Potentials

## Review Questions

19.8 Discuss the spontaneity of an electrochemical reaction in terms of its standard emf ( $E_{\text {cell }}^{\circ}$ ).
19.9 After operating a Daniell cell (see Figure 19.1) for a few minutes, the cell emf begins to drop. Explain.

## Problems

19.10 Calculate the standard emf of a cell that uses the $\mathrm{Mg} / \mathrm{Mg}^{2+}$ and $\mathrm{Cu} / \mathrm{Cu}^{2+}$ half-cell reactions at $25^{\circ} \mathrm{C}$. Write the equation for the cell reaction that occurs under standard-state conditions.
19.11 Calculate the standard emf of a cell that uses $\mathrm{Ag} / \mathrm{Ag}^{+}$and $\mathrm{Al} / \mathrm{Al}^{3+}$ half-cell reactions. Write the cell reaction that occurs under standard-state conditions.
19.12 Predict whether $\mathrm{Fe}^{3+}$ can oxidize $\mathrm{I}^{-}$to $\mathrm{I}_{2}$ under standard-state conditions.
19.13 Which of the following reagents can oxidize $\mathrm{H}_{2} \mathrm{O}$ to $\mathrm{O}_{2}(g)$ under standard-state conditions: $\mathrm{H}^{+}(a q), \mathrm{Cl}^{-}(a q), \mathrm{Cl}_{2}(g), \mathrm{Cu}^{2+}(a q)$, $\mathrm{Pb}^{2+}(a q), \mathrm{MnO}_{4}^{-}(a q)$ (in acid)?

EI 19.14 Consider the following half-reactions:

$$
\begin{gathered}
\mathrm{MnO}_{4}^{-}(a q)+8 \mathrm{H}^{+}(a q)+5 e^{-} \longrightarrow \mathrm{Mn}^{2+}(a q)+4 \mathrm{H}_{2} \mathrm{O}(l) \\
\mathrm{NO}_{3}^{-}(a q)+4 \mathrm{H}^{+}(a q)+3 e^{-} \longrightarrow \mathrm{NO}(g)+2 \mathrm{H}_{2} \mathrm{O}(l)
\end{gathered}
$$

Predict whether $\mathrm{NO}_{3}^{-}$ions will oxidize $\mathrm{Mn}^{2+}$ to $\mathrm{MnO}_{4}^{-}$under standard-state conditions.

E 19.15 Predict whether the following reactions would occur spontaneously in aqueous solution at $25^{\circ} \mathrm{C}$. Assume that the initial concentrations of dissolved species are all 1.0 M .
(a) $\mathrm{Ca}(s)+\mathrm{Cd}^{2+}(a q) \longrightarrow \mathrm{Ca}^{2+}(a q)+\mathrm{Cd}(s)$
(b) $2 \mathrm{Br}^{-}(a q)+\mathrm{Sn}^{2+}(a q) \longrightarrow \mathrm{Br}_{2}(l)+\mathrm{Sn}(s)$
(c) $2 \mathrm{Ag}(s)+\mathrm{Ni}^{2+}(a q) \longrightarrow 2 \mathrm{Ag}^{+}(a q)+\mathrm{Ni}(s)$
(d) $\mathrm{Cu}^{+}(a q)+\mathrm{Fe}^{3+}(a q) \longrightarrow \mathrm{Cu}^{2+}(a q)+\mathrm{Fe}^{2+}(a q)$

E19.16 Which species in each pair is a better oxidizing agent under standard-state conditions: (a) $\mathrm{Br}_{2}$ or $\mathrm{Au}^{3+}$, (b) $\mathrm{H}_{2}$ or $\mathrm{Ag}^{+}$, (c) $\mathrm{Cd}^{2+}$ or $\mathrm{Cr}^{3+}$, (d) $\mathrm{O}_{2}$ in acidic media or $\mathrm{O}_{2}$ in basic media?
19.17 Which species in each pair is a better reducing agent under standard-state conditions: (a) Na or Li , (b) $\mathrm{H}_{2}$ or $\mathrm{I}_{2}$, (c) $\mathrm{Fe}^{2+}$ or Ag , (d) $\mathrm{Br}^{-}$or $\mathrm{Co}^{2+}$ ?

## Section 19.4: Spontaneity of Redox Reactions Under Standard-State Conditions

## Review Questions

19.18 Use the information in Table 2.1, and calculate the Faraday constant.
19.19 Write the equations relating $\Delta G^{\circ}$ and $K$ to the standard emf of a cell. Define all the terms.
19.20 Compare the ease of measuring the equilibrium constant electrochemically with that by chemical means (see Equation 18.14).

## Problems

E19.21 What is the equilibrium constant for the following reaction at $25^{\circ} \mathrm{C}$ ?

$$
\mathrm{Mg}(s)+\mathrm{Zn}^{2+}(a q) \rightleftarrows \mathrm{Mg}^{2+}(a q)+\mathrm{Zn}(s)
$$

19.22 The equilibrium constant for the reaction

$$
\mathrm{Sr}(s)+\mathrm{Mg}^{2+}(a q) \rightleftarrows \mathrm{Sr}^{2+}(a q)+\mathrm{Mg}(s)
$$

is $2.69 \times 10^{12}$ at $25^{\circ} \mathrm{C}$. Calculate $E^{\circ}$ for a cell made up of $\mathrm{Sr} / \mathrm{Sr}^{2+}$ and $\mathrm{Mg} / \mathrm{Mg}^{2+}$ half-cells.

E19.23 Use the standard reduction potentials to find the equilibrium constant for each of the following reactions at $25^{\circ} \mathrm{C}$ :
(a) $\mathrm{Br}_{2}(l)+2 \mathrm{I}^{-}(a q) \rightleftarrows 2 \mathrm{Br}^{-}(a q)+\mathrm{I}_{2}(s)$
(b) $2 \mathrm{Ce}^{4+}(a q)+2 \mathrm{Cl}^{-}(a q) \rightleftarrows \mathrm{Cl}_{2}(g)+2 \mathrm{Ce}^{3+}(a q)$
(c) $5 \mathrm{Fe}^{2+}(a q)+\mathrm{MnO}_{4}^{-}(a q)+8 \mathrm{H}^{+}(a q) \rightleftarrows \mathrm{Mn}^{2+}(a q)+$ $4 \mathrm{H}_{2} \mathrm{O}+5 \mathrm{Fe}^{3+}(a q)$
19.24 Calculate $\Delta G^{\circ}$ and $K_{\mathrm{c}}$ for the following reactions at $25^{\circ} \mathrm{C}$ :
(a) $\mathrm{Mg}(s)+\mathrm{Pb}^{2+}(a q) \rightleftarrows \mathrm{Mg}^{2+}(a q)+\mathrm{Pb}(s)$
(b) $\mathrm{O}_{2}(g)+4 \mathrm{H}^{+}(a q)+4 \mathrm{Fe}^{2+}(a q) \rightleftarrows 2 \mathrm{H}_{2} \mathrm{O}(l)+4 \mathrm{Fe}^{3+}(a q)$
(c) $2 \mathrm{Al}(s)+3 \mathrm{I}_{2}(s) \rightleftarrows 2 \mathrm{Al}^{3+}(a q)+6 \mathrm{I}^{-}(a q)$

E 19.25 Under standard-state conditions, what spontaneous reaction will occur in aqueous solution among the ions $\mathrm{Ce}^{4+}, \mathrm{Ce}^{3+}, \mathrm{Fe}^{3+}$, and $\mathrm{Fe}^{2+}$ ? Calculate $\Delta G^{\circ}$ and $K_{\mathrm{c}}$ for the reaction.
19.26 Given that $E^{\circ}=0.52 \mathrm{~V}$ for the reduction $\mathrm{Cu}^{+}(a q)+e^{-}$ $\mathrm{Cu}(s)$, calculate $E^{\circ}, \Delta G^{\circ}$, and $K$ for the following reaction at $25^{\circ} \mathrm{C}$ :

$$
2 \mathrm{Cu}^{+}(a q) \rightleftarrows \mathrm{Cu}^{2+}(a q)+\mathrm{Cu}(s)
$$

## Section 19.5: Spontaneity of Redox Reactions Under Conditions Other Than Standard State

## Review Questions

19.27 Write the Nernst equation, and explain all the terms.
19.28 Write the Nernst equation for the following processes at some temperature $T$ :
(a) $\mathrm{Mg}(s)+\mathrm{Sn}^{2+}(a q) \rightleftarrows \mathrm{Mg}^{2+}(a q)+\mathrm{Sn}(s)$
(b) $2 \mathrm{Cr}(s)+3 \mathrm{~Pb}^{2+}(a q) \rightleftarrows 2 \mathrm{Cr}^{3+}(a q)+3 \mathrm{~Pb}(s)$

## Problems

E19.29 What is the potential of a cell made up of $\mathrm{Zn} / \mathrm{Zn}^{2+}$ and $\mathrm{Cu} / \mathrm{Cu}^{2+}$ half-cells at $25^{\circ} \mathrm{C}$ if $\left[\mathrm{Zn}^{2+}\right]=0.25 \mathrm{M}$ and $\left[\mathrm{Cu}^{2+}\right]=0.15 \mathrm{M}$ ?

I 19.30 Calculate $E^{\circ}, E$, and $\Delta G$ for the following cell reactions.
(a) $\mathrm{Mg}(s)+\mathrm{Sn}^{2+}(a q) \rightleftarrows \mathrm{Mg}^{2+}(a q)+\mathrm{Sn}(s)$
$\left[\mathrm{Mg}^{2+}\right]=0.045 \mathrm{M},\left[\mathrm{Sn}^{2+}\right]=0.035 \mathrm{M}$
(b) $3 \mathrm{Zn}(s)+2 \mathrm{Cr}^{3+}(a q) \rightleftarrows 3 \mathrm{Zn}^{2+}(a q)+2 \mathrm{Cr}(s)$ $\left[\mathrm{Cr}^{3+}\right]=0.010 \mathrm{M},\left[\mathrm{Zn}^{2+}\right]=0.0085 \mathrm{M}$
19.31 Calculate the standard potential of the cell consisting of the $\mathrm{Zn} / \mathrm{Zn}^{2+}$ half-cell and the SHE. What will the emf of the cell be if $\left[\mathrm{Zn}^{2+}\right]=0.45 \mathrm{M}, P_{\mathrm{H}_{2}}=2.0 \mathrm{~atm}$, and $\left[\mathrm{H}^{+}\right]=1.8 \mathrm{M}$ ?
19.32 What is the emf of a cell consisting of a $\mathrm{Pb}^{2+} / \mathrm{Pb}$ half-cell and a $\mathrm{Pt} / \mathrm{H}^{+} / \mathrm{H}_{2}$ half-cell if $\left[\mathrm{Pb}^{2+}\right]=0.10 \mathrm{M},[\mathrm{H}]=0.050 \mathrm{M}$, and $P_{\mathrm{H}_{2}}=1.0 \mathrm{~atm}$ ?

H19.33 Referring to the arrangement in Figure 19.1, calculate the $\left[\mathrm{Cu}^{2+}\right] /\left[\mathrm{Zn}^{2+}\right]$ ratio at which the following reaction is spontaneous at $25^{\circ} \mathrm{C}$ :

$$
\mathrm{Cu}(s)+\mathrm{Zn}^{2+}(a q) \longrightarrow \mathrm{Cu}^{2+}(a q)+\mathrm{Zn}(s)
$$

19.34 Calculate the emf of the following concentration cell:

$$
\mathrm{Mg}(s)\left|\mathrm{Mg}^{2+}(0.24 M) \| \mathrm{Mg}^{2+}(0.53 M)\right| \operatorname{Mg}(s)
$$

## Section 19.6: Batteries

## Review Questions

19.35 What is a battery? Describe several types of batteries.
19.36 Explain the differences between a primary galvanic cell-one that is not rechargeable-and a storage cell (for example, the lead storage battery), which is rechargeable.
19.37 Discuss the advantages and disadvantages of fuel cells over conventional power plants in producing electricity.

## Problems

E19.38 The hydrogen-oxygen fuel cell is described in Section 19.6. (a) What volume of $\mathrm{H}_{2}(\mathrm{~g})$, stored at $25^{\circ} \mathrm{C}$ at a pressure of 155 atm , would be needed to run an electric motor drawing a current of 8.5 A for 3.0 h ? (b) What volume (in liters) of air at $25^{\circ} \mathrm{C}$ and 1.00 atm will have to pass into the cell per minute to run the motor? Assume that air is 20 percent $\mathrm{O}_{2}$ by volume and that all the $\mathrm{O}_{2}$ is consumed in the cell. The other components of air do not affect the fuel-cell reactions. Assume ideal gas behavior.
19.39 Calculate the standard emf of the propane fuel cell discussed on page 841 at $25^{\circ} \mathrm{C}$, given that $\Delta G_{\mathrm{f}}^{\circ}$ for propane is $-23.5 \mathrm{~kJ} / \mathrm{mol}$.

## Section 19.7: Electrolysis

## Review Questions

19.40 What is the difference between a galvanic cell (such as a Daniell cell) and an electrolytic cell?
19.41 What is Faraday's contribution to quantitative electrolysis?
19.42 Define the term overvoltage. How does overvoltage affect electrolytic processes?

## Problems

E19.43 The half-reaction at an electrode is

$$
\mathrm{Mg}^{2+}(\text { molten })+2 e^{-} \longrightarrow \operatorname{Mg}(s)
$$

Calculate the number of grams of magnesium that can be produced by supplying 1.00 F to the electrode.

Ef 19.44 Consider the electrolysis of molten barium chloride $\left(\mathrm{BaCl}_{2}\right)$. (a) Write the half-reactions. (b) How many grams of barium metal can be produced by supplying 0.50 A for 30 min ?
19.45 Considering only the cost of electricity, would it be cheaper to produce a ton of sodium or a ton of aluminum by electrolysis?
f19.46 If the cost of electricity to produce magnesium by the electrolysis of molten magnesium chloride is $\$ 155$ per ton of metal, what is the cost (in dollars) of the electricity necessary to produce (a) 10.0 tons of aluminum, (b) 30.0 tons of sodium, and (c) 50.0 tons of calcium?

E119.47 One of the half-reactions for the electrolysis of water is

$$
2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{O}_{2}(g)+4 \mathrm{H}^{+}(a q)+4 e^{-}
$$

If 0.076 L of $\mathrm{O}_{2}$ is collected at $25^{\circ} \mathrm{C}$ and 755 mmHg , how many faradays of electricity had to pass through the solution?

I 19.48 How many faradays of electricity are required to produce (a) 0.84 L of $\mathrm{O}_{2}$ at exactly 1 atm and $25^{\circ} \mathrm{C}$ from aqueous $\mathrm{H}_{2} \mathrm{SO}_{4}$ solution, (b) 1.50 L of $\mathrm{Cl}_{2}$ at 750 mmHg and $20^{\circ} \mathrm{C}$ from molten NaCl , and (c) 6.0 g of Sn from molten $\mathrm{SnCl}_{2}$ ?
19.49 Calculate the amounts of Cu and $\mathrm{Br}_{2}$ produced in 1.0 h at inert electrodes in a solution of $\mathrm{CuBr}_{2}$ by a current of 4.50 A .

E19.50 In the electrolysis of an aqueous $\mathrm{AgNO}_{3}$ solution, 0.67 g of Ag is deposited after a certain period of time. (a) Write the half-reaction for the reduction of $\mathrm{Ag}^{+}$. (b) What is the probable oxidation half-reaction? (c) Calculate the quantity of electricity used (in coulombs).

I19.51 A steady current was passed through molten $\mathrm{CoSO}_{4}$ until 2.35 g of metallic cobalt was produced. Calculate the number of coulombs of electricity used.

I 19.52 A constant electric current flows for 3.75 h through two electrolytic cells connected in series. One contains a solution of $\mathrm{AgNO}_{3}$ and the second a solution of $\mathrm{CuCl}_{2}$. During this time, 2.00 g of silver is deposited in the first cell. (a) How many grams of copper are deposited in the second cell? (b) What is the current flowing (in amperes)?

- 19.53 What is the hourly production rate of chlorine gas (in kg ) from an electrolytic cell using aqueous NaCl electrolyte and carrying a current of $1.500 \times 10^{3} \mathrm{~A}$ ? The anode efficiency for the oxidation of $\mathrm{Cl}^{-}$is 93.0 percent.
19.54 Chromium plating is applied by electrolysis to objects suspended in a dichromate solution, according to the following (unbalanced) half-reaction:

$$
\mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}(a q)+e^{-}+\mathrm{H}^{+}(a q) \longrightarrow \mathrm{Cr}(s)+\mathrm{H}_{2} \mathrm{O}(l)
$$

How long (in hours) would it take to apply a chromium plating $1.0 \times 10^{-2} \mathrm{~mm}$ thick to a car bumper with a surface area of $0.25 \mathrm{~m}^{2}$ in an electrolytic cell carrying a current of 25.0 A ? (The density of chromium is $7.19 \mathrm{~g} / \mathrm{cm}^{3}$.)

G19.55 The passage of a current of 0.750 A for 25.0 min deposited 0.369 g of copper from a $\mathrm{CuSO}_{4}$ solution. From this information, calculate the molar mass of copper.
19.56 A quantity of 0.300 g of copper was deposited from a $\mathrm{CuSO}_{4}$ solution by passing a current of 3.00 A through the solution for 304 s. Calculate the value of the Faraday constant.

G19.57 In a certain electrolysis experiment, 1.44 g of Ag were deposited in one cell (containing an aqueous $\mathrm{AgNO}_{3}$ solution), while 0.120 g of an unknown metal X was deposited in another cell (containing an aqueous $\mathrm{XCl}_{3}$ solution) in series with the $\mathrm{AgNO}_{3}$ cell. Calculate the molar mass of X .

H 19.58 One of the half-reactions for the electrolysis of water is

$$
2 \mathrm{H}^{+}(a q)+2 e^{-} \longrightarrow \mathrm{H}_{2}(g)
$$

If 0.845 L of $\mathrm{H}_{2}$ is collected at $25^{\circ} \mathrm{C}$ and 782 mmHg , how many faradays of electricity had to pass through the solution?

## Section 19.8: Corrosion

## Review Questions

19.59 Steel hardware, including nuts and bolts, is often coated with a thin plating of cadmium. Explain the function of the cadmium layer.
19.60 "Galvanized iron" is steel sheet that has been coated with zinc; "tin" cans are made of steel sheet coated with tin. Discuss the functions of these coatings and the electrochemistry of the corrosion reactions that occur if an electrolyte contacts the scratched surface of a galvanized iron sheet or a tin can.

E 19.61 Tarnished silver contains $\mathrm{Ag}_{2} \mathrm{~S}$. The tarnish can be removed by placing silverware in an aluminum pan containing an inert electrolyte solution, such as NaCl . Explain the electrochemical principle for this procedure. [The standard reduction potential for the half-cell reaction $\mathrm{Ag}_{2} \mathrm{~S}(s)+2 e^{-} \longrightarrow 2 \mathrm{Ag}(s)+\mathrm{S}^{2-}(a q)$ is -0.71 V .]
19.62 How does the tendency of iron to rust depend on the pH of the solution?

## Additional Problems

E119.63 For each of the following redox reactions, (i) write the halfreactions, (ii) write a balanced equation for the whole reaction, (iii) determine in which direction the reaction will proceed spontaneously under standard-state conditions:
(a) $\mathrm{H}_{2}(g)+\mathrm{Ni}^{2+}(a q) \longrightarrow \mathrm{H}^{+}(a q)+\mathrm{Ni}(s)$
(b) $\mathrm{MnO}_{4}^{-}(a q)+\mathrm{Cl}^{-}(a q) \longrightarrow \mathrm{Mn}^{2+}(a q)+\mathrm{Cl}_{2}(g)$ (in acid solution)
(c) $\mathrm{Cr}(s)+\mathrm{Zn}^{2+}(a q) \longrightarrow \mathrm{Cr}^{3+}(a q)+\mathrm{Zn}(s)$
19.64 The oxidation of 25.0 mL of a solution containing $\mathrm{Fe}^{2+}$ requires 26.0 mL of $0.0250 M \mathrm{~K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$ in acidic solution. Balance the following equation, and calculate the molar concentration of $\mathrm{Fe}^{2+}$ :

$$
\mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}+\mathrm{Fe}^{2+}+\mathrm{H}^{+} \longrightarrow \mathrm{Cr}^{3+}+\mathrm{Fe}^{3+}
$$

E19.65 The $\mathrm{SO}_{2}$ present in air is mainly responsible for the phenomenon of acid rain. The concentration of $\mathrm{SO}_{2}$ can be determined by titrating against a standard permanganate solution as follows:

$$
5 \mathrm{SO}_{2}+2 \mathrm{MnO}_{4}^{-}+2 \mathrm{H}_{2} \mathrm{O} \longrightarrow 5 \mathrm{SO}_{4}^{2-}+2 \mathrm{Mn}^{2+}+4 \mathrm{H}^{+}
$$

Calculate the number of grams of $\mathrm{SO}_{2}$ in a sample of air if 7.37 mL of $0.00800 \mathrm{M} \mathrm{KnO}_{4}$ solution is required for the titration.

E 19.66 A sample of iron ore weighing 0.2792 g was dissolved in an excess of a dilute acid solution. All the iron was first converted to Fe (II) ions. The solution then required 23.30 mL of 0.0194 M $\mathrm{KMnO}_{4}$ for oxidation to Fe (III) ions. Calculate the percent by mass of iron in the ore.

EI 19.67 The concentration of a hydrogen peroxide solution can be conveniently determined by titration against a standardized potassium permanganate solution in an acidic medium according to the following unbalanced equation:

$$
\mathrm{MnO}_{4}^{-}+\mathrm{H}_{2} \mathrm{O}_{2} \longrightarrow \mathrm{O}_{2}+\mathrm{Mn}^{2+}
$$

(a) Balance this equation. (b) If 36.44 mL of a $0.01652 M \mathrm{KMnO}_{4}$ solution is required to completely oxidize 25.00 mL of an $\mathrm{H}_{2} \mathrm{O}_{2}$ solution, calculate the molarity of the $\mathrm{H}_{2} \mathrm{O}_{2}$ solution.
19.68 Oxalic acid $\left(\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}\right)$ is present in many plants and vegetables. (a) Balance the following equation in acid solution:

$$
\mathrm{MnO}_{4}^{-}+\mathrm{C}_{2} \mathrm{O}_{4}^{2-} \longrightarrow \mathrm{Mn}^{2+}+\mathrm{CO}_{2}
$$

(b) If a $1.00-\mathrm{g}$ sample of plant matter requires 24.0 mL of $0.0100 \mathrm{M} \mathrm{KMnO}_{4}$ solution to reach the equivalence point, what is the percent by mass of $\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}$ in the sample?
19.69 Calcium oxalate $\left(\mathrm{CaC}_{2} \mathrm{O}_{4}\right)$ is insoluble in water. This property has been used to determine the amount of $\mathrm{Ca}^{2+}$ ions in blood. The calcium oxalate isolated from blood is dissolved in acid and titrated against a standardized $\mathrm{KMnO}_{4}$ solution as described in Problem 19.68. In one test it is found that the calcium oxalate isolated from a $10.0-\mathrm{mL}$ sample of blood requires 24.2 mL of $9.56 \times 10^{-4} M \mathrm{KMnO}_{4}$ for titration. Calculate the number of milligrams of calcium per milliliter of blood.
19.70 Complete the following table. State whether the cell reaction is spontaneous, nonspontaneous, or at equilibrium.

| $\boldsymbol{E}$ | $\Delta \boldsymbol{G}$ | Cell Reaction |
| :---: | :---: | :---: |
| $>0$ |  |  |
|  | $>0$ |  |
| $=0$ |  |  |

19.71 From the following information, calculate the solubility product of AgBr :

$$
\begin{array}{ll}
\mathrm{Ag}^{+}(a q)+e^{-} \longrightarrow \mathrm{Ag}(s) & E^{\circ}=0.80 \mathrm{~V} \\
\mathrm{AgBr}(s)+e^{-} \longrightarrow \mathrm{Ag}(s)+\mathrm{Br}^{-}(a q) & E^{\circ}=0.07 \mathrm{~V}
\end{array}
$$

$\boldsymbol{Y}$ 19.72 Consider a galvanic cell composed of the SHE and a half-cell using the reaction $\mathrm{Ag}^{+}(a q)+e^{-} \longrightarrow \mathrm{Ag}(s)$. (a) Calculate the standard cell potential. (b) What is the spontaneous cell reaction under standard-state conditions? (c) Calculate the cell potential when $\left[\mathrm{H}^{+}\right]$in the hydrogen electrode is changed to (i) $1.0 \times$ $10^{-2} \mathrm{M}$ and (ii) $1.0 \times 10^{-5} \mathrm{M}$, all other reagents being held at standard-state conditions. (d) Based on this cell arrangement, suggest a design for a pH meter.
$\boldsymbol{\Psi}$ 19.73 A galvanic cell consists of a silver electrode in contact with 346 mL of $0.100 \mathrm{M} \mathrm{AgNO}_{3}$ solution and a magnesium electrode in contact with 288 mL of $0.100 \mathrm{M} \mathrm{Mg}\left(\mathrm{NO}_{3}\right)_{2}$ solution. (a) Calculate $E$ for the cell at $25^{\circ} \mathrm{C}$. (b) A current is drawn from the cell until 1.20 g of silver has been deposited at the silver electrode. Calculate $E$ for the cell at this stage of operation.
19.74 Explain why chlorine gas can be prepared by electrolyzing an aqueous solution of NaCl but fluorine gas cannot be prepared by electrolyzing an aqueous solution of NaF .
19.75 Calculate the emf of the following concentration cell at $25^{\circ} \mathrm{C}$ :

$$
\mathrm{Cu}(s)\left|\mathrm{Cu}^{2+}(0.080 M) \| \mathrm{Cu}^{2+}(1.2 M)\right| \mathrm{Cu}(s)
$$

G19.76 The cathode reaction in the Leclanché cell is given by

$$
2 \mathrm{MnO}_{2}(s)+\mathrm{Zn}^{2+}(a q)+2 e^{-} \longrightarrow \mathrm{ZnMn}_{2} \mathrm{O}_{4}(s)
$$

If a Leclanché cell produces a current of 0.0050 A , calculate how many hours this current supply will last if there is initially 4.0 g of $\mathrm{MnO}_{2}$ present in the cell. Assume that there is an excess of $\mathrm{Zn}^{2+}$ ions.
19.77 For a number of years, it was not clear whether mercury(I) ions existed in solution as $\mathrm{Hg}^{+}$or as $\mathrm{Hg}_{2}^{2+}$. To distinguish between these two possibilities, we could set up the following system:

$$
\mathrm{Hg}(l) \mid \text { soln } \mathrm{A} \| \text { soln } \mathrm{B} \mid \mathrm{Hg}(l)
$$

where soln A contained 0.263 g mercury(I) nitrate per liter and soln $B$ contained 2.63 g mercury $(\mathrm{I})$ nitrate per liter. If the measured emf of such a cell is 0.0289 V at $18^{\circ} \mathrm{C}$, what can you deduce about the nature of the mercury(I) ions?
19.78 An aqueous KI solution to which a few drops of phenolphthalein have been added is electrolyzed using an apparatus like the one shown here:

Describe what you would observe at the anode and the cathode. (Hint: Molecular iodine is only slightly soluble in water, but in the presence of $\mathrm{I}^{-}$ions, it forms the brown color of $\mathrm{I}_{3}^{-}$ions. See Problem 13.114.)
19.79 A piece of magnesium metal weighing 1.56 g is placed in 100.0 mL of $0.100 \mathrm{M} \mathrm{AgNO}_{3}$ at $25^{\circ} \mathrm{C}$. Calculate $\left[\mathrm{Mg}^{2+}\right]$ and $\left[\mathrm{Ag}^{+}\right]$in solution at equilibrium. What is the mass of the magnesium left? The volume remains constant.
19.80 Describe an experiment that would enable you to determine which is the cathode and which is the anode in a galvanic cell using copper and zinc electrodes.

I 19.81 An acidified solution was electrolyzed using copper electrodes. A constant current of 1.18 A caused the anode to lose 0.584 g after $1.52 \times 10^{3}$ s. (a) What is the gas produced at the cathode, and what is its volume at STP? (b) Given that the charge of an electron is $1.6022 \times 10^{-19} \mathrm{C}$, calculate Avogadro's number. Assume that copper is oxidized to $\mathrm{Cu}^{2+}$ ions.
19.82 In a certain electrolysis experiment involving $\mathrm{Al}^{3+}$ ions, 60.2 g of Al is recovered when a current of 0.352 A is used. How many minutes did the electrolysis last?
19.83 Consider the oxidation of ammonia:

$$
4 \mathrm{NH}_{3}(g)+3 \mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{~N}_{2}(g)+6 \mathrm{H}_{2} \mathrm{O}(l)
$$

(a) Calculate the $\Delta G^{\circ}$ for the reaction. (b) If this reaction were used in a fuel cell, what would the standard cell potential be?

E 19.84 When an aqueous solution containing gold(III) salt is electrolyzed, metallic gold is deposited at the cathode and oxygen gas is generated at the anode. (a) If 9.26 g of Au is deposited at the cathode, calculate the volume (in liters) of $\mathrm{O}_{2}$ generated at $23^{\circ} \mathrm{C}$ and 747 mmHg . (b) What is the current used if the electrolytic process took 2.00 h ?
19.85 In an electrolysis experiment, a student passes the same quantity of electricity through two electrolytic cells, one containing a silver salt and the other a gold salt. Over a certain period of time, the student finds that 2.64 g of Ag and 1.61 g of Au are deposited at the cathodes. What is the oxidation state of gold in the gold salt?
19.86 People living in cold-climate countries where there is plenty of snow are advised not to heat their garages in the winter. What is the electrochemical basis for this recommendation?
\& 19.87 Given that

$$
\begin{aligned}
2 \mathrm{Hg}^{2+}(a q)+2 e^{-} \longrightarrow \mathrm{Hg}_{2}^{2+}(a q) & E^{\circ}=0.92 \mathrm{~V} \\
\operatorname{Hg}_{2}^{2+}(a q)+2 e^{-} \longrightarrow 2 \mathrm{Hg}(l) & E^{\circ}=0.85 \mathrm{~V}
\end{aligned}
$$

calculate $\Delta G^{\circ}$ and $K$ for the following process at $25^{\circ} \mathrm{C}$ :

$$
\mathrm{Hg}_{2}^{2+}(a q) \longrightarrow \mathrm{Hg}^{2+}(a q)+\mathrm{Hg}(l)
$$

(The preceding reaction is an example of a disproportionation reaction in which an element in one oxidation state is both oxidized and reduced.)
$\boldsymbol{\Psi} 19.88$ Fluorine $\left(\mathrm{F}_{2}\right)$ is obtained by the electrolysis of liquid hydrogen fluoride (HF) containing potassium fluoride (KF). (a) Write the half-cell reactions and the overall reaction for the process. (b) What is the purpose of KF? (c) Calculate the volume of $\mathrm{F}_{2}$ (in liters) collected at $24.0^{\circ} \mathrm{C}$ and 1.2 atm after electrolyzing the solution for 15 h at a current of 502 A .
G119.89 A $300-\mathrm{mL}$ solution of NaCl was electrolyzed for 6.00 min . If the pH of the final solution was 12.24 , calculate the average current used.
19.90 Industrially, copper is purified by electrolysis. The impure copper acts as the anode, and the cathode is made of pure copper. The electrodes are immersed in a $\mathrm{CuSO}_{4}$ solution. During electrolysis, copper at the anode enters the solution as $\mathrm{Cu}^{2+}$ while $\mathrm{Cu}^{2+}$ ions are reduced at the cathode. (a) Write half-cell reactions and the overall reaction for the electrolytic process. (b) Suppose the anode was contaminated with Zn and Ag. Explain what happens to these impurities during electrolysis. (c) How many hours will it take to obtain 1.00 kg of Cu at a current of 18.9 A ?
$\boldsymbol{\Perp}$ 19.91 An aqueous solution of a platinum salt is electrolyzed at a current of 2.50 A for 2.00 h . As a result, 9.09 g of metallic Pt is formed at the cathode. Calculate the charge on the Pt ions in this solution.
19.92 Consider a galvanic cell consisting of a magnesium electrode in contact with $1.0 \mathrm{M} \mathrm{Mg}\left(\mathrm{NO}_{3}\right)_{2}$ and a cadmium electrode in contact with $1.0 \mathrm{M} \mathrm{Cd}\left(\mathrm{NO}_{3}\right)_{2}$. Calculate $E^{\circ}$ for the cell, and draw a diagram showing the cathode, anode, and direction of electron flow.
19.93 A current of 6.00 A passes through an electrolytic cell containing dilute sulfuric acid for 3.40 h . If the volume of $\mathrm{O}_{2}$ gas generated at the anode is 4.26 L (at STP), calculate the charge (in coulombs) on an electron.
19.94 Gold will not dissolve in either concentrated nitric acid or concentrated hydrochloric acid. However, the metal does dissolve in a mixture of the acids (one part $\mathrm{HNO}_{3}$ and three parts HCl by volume), called aqua regia. (a) Write a balanced equation for this reaction. (Hint: Among the products are $\mathrm{HAuCl}_{4}$ and $\mathrm{NO}_{2}$.) (b) What is the function of HCl ?
19.95 Explain why most useful galvanic cells give voltages of no more than 1.5 to 2.5 V . What are the prospects for developing practical galvanic cells with voltages of 5 V or more?

Ef 19.96 A silver rod and a SHE are dipped into a saturated aqueous solution of silver oxalate $\left(\mathrm{Ag}_{2} \mathrm{C}_{2} \mathrm{O}_{4}\right)$, at $25^{\circ} \mathrm{C}$. The measured potential difference between the rod and the SHE is 0.589 V , the rod being positive. Calculate the solubility product constant for silver oxalate.
19.97 Zinc is an amphoteric metal; that is, it reacts with both acids and bases. The standard reduction potential is -1.36 V for the reaction

$$
\mathrm{Zn}(\mathrm{OH})_{4}^{2-}(a q)+2 e^{-} \longrightarrow \mathrm{Zn}(s)+4 \mathrm{OH}^{-}(a q)
$$

Calculate the formation constant $\left(K_{\mathrm{f}}\right)$ for the reaction

$$
\mathrm{Zn}^{2+}(a q)+4 \mathrm{OH}^{-}(a q) \rightleftarrows \mathrm{Zn}(\mathrm{OH})_{4}^{2-}(a q)
$$

19.98 Use the data in Table 19.1 to determine whether or not hydrogen peroxide will undergo disproportionation in an acid medium: $2 \mathrm{H}_{2} \mathrm{O}_{2} \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}+\mathrm{O}_{2}$.
19.99 The magnitudes (but not the signs) of the standard reduction potentials of two metals X and Y are

$$
\begin{array}{ll}
\mathrm{Y}^{2+}+2 e^{-} \longrightarrow \mathrm{Y} & \left|E^{\circ}\right|=0.34 \mathrm{~V} \\
\mathrm{X}^{2+}+2 e^{-} \longrightarrow \mathrm{X} & \left|E^{\circ}\right|=0.25 \mathrm{~V}
\end{array}
$$

where the $\|$ notation denotes that only the magnitude (but not the sign) of the $E^{\circ}$ value is shown. When the half-cells of X and Y are connected, electrons flow from X to Y . When X is connected to a SHE, electrons flow from X to SHE. (a) Are the $E^{\circ}$ values of the half-reactions positive or negative? (b) What is the standard emf of a cell made up of $X$ and $Y$ ?

E19.100 A galvanic cell is constructed as follows. One half-cell consists of a platinum wire immersed in a solution containing $1.0 \mathrm{M} \mathrm{Sn}^{2+}$ and $1.0 \mathrm{M} \mathrm{Sn}^{4+}$; the other half-cell has a thallium rod immersed in a solution of $1.0 \mathrm{M} \mathrm{Tl}^{+}$. (a) Write the half-cell reactions and the overall reaction. (b) What is the equilibrium constant at $25^{\circ} \mathrm{C}$ ? (c) What is the cell voltage if the $\mathrm{Tl}^{+}$concentration is increased 10-fold? $\left(E^{\circ}{ }_{\mathrm{Tl}}{ }^{+} / \mathrm{Tl}=-0.34 \mathrm{~V}\right.$. $)$
19.101 Given the standard reduction potential for $\mathrm{Au}^{3+}$ in Table 19.1 and

$$
\mathrm{Au}^{+}(a q)+e^{-} \longrightarrow \mathrm{Au}(s) \quad E^{\circ}=1.69 \mathrm{~V}
$$

answer the following questions. (a) Why does gold not tarnish in air? (b) Will the following disproportionation occur spontaneously?

$$
3 \mathrm{Au}^{+}(a q) \longrightarrow \mathrm{Au}^{3+}(a q)+2 \mathrm{Au}(s)
$$

(c) Predict the reaction between gold and fluorine gas.
19.102 The ingestion of a very small quantity of mercury is not considered too harmful. Would this statement still hold if the gastric juice in your stomach were mostly nitric acid instead of hydrochloric acid?

E 19.103 When 25.0 mL of a solution containing both $\mathrm{Fe}^{2+}$ and $\mathrm{Fe}^{3+}$ ions is titrated with 23.0 mL of $0.0200 \mathrm{M} \mathrm{KMO}_{4}$ (in dilute sulfuric acid), all the $\mathrm{Fe}^{2+}$ ions are oxidized to $\mathrm{Fe}^{3+}$ ions. Next, the solution is treated with Zn metal to convert all the $\mathrm{Fe}^{3+}$ ions to $\mathrm{Fe}^{2+}$ ions. Finally, 40.0 mL of the same $\mathrm{KMnO}_{4}$ solution is added to the solution to oxidize the $\mathrm{Fe}^{2+}$ ions to $\mathrm{Fe}^{3+}$. Calculate the molar concentrations of $\mathrm{Fe}^{2+}$ and $\mathrm{Fe}^{3+}$ in the original solution.
19.104 Consider the Daniell cell in Figure 19.1. When viewed externally, the anode appears negative and the cathode positive (electrons are flowing from the anode to the cathode). Yet in solution anions are moving toward the anode, which means that it must appear positive to the anions. Because the anode cannot simultaneously be negative and positive, give an explanation for this apparently contradictory situation.
19.105 Use the data in Table 19.1 to show that the decomposition of $\mathrm{H}_{2} \mathrm{O}_{2}$ (a disproportionation reaction) is spontaneous at $25^{\circ} \mathrm{C}$ :

$$
2 \mathrm{H}_{2} \mathrm{O}_{2}(a q) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{O}_{2}(g)
$$

E19.106 The concentration of sulfuric acid in the lead-storage battery of an automobile over a period of time has decreased from 38.0 percent by mass (density $=1.29 \mathrm{~g} / \mathrm{mL}$ ) to 26.0 percent by mass $(1.19 \mathrm{~g} / \mathrm{mL})$. Assume the volume of the acid remains constant at 724 mL . (a) Calculate the total charge in coulombs supplied by the battery. (b) How long (in hours) will it take to recharge the battery back to the original sulfuric acid concentration using a current of 22.4 A ?
19.107 Consider a Daniell cell operating under non-standard-state conditions. Suppose that the cell's reaction is multiplied by 2 . What effect does this have on each of the following quantities in the Nernst equation: (a) $E$, (b) $E^{\circ}$, (c) $Q$, (d) $\ln Q$, (e) $n$ ?
19.108 A spoon was silver-plated electrolytically in an $\mathrm{AgNO}_{3}$ solution. (a) Sketch a diagram for the process. (b) If 0.884 g of Ag was deposited on the spoon at a constant current of 18.5 mA , how long (in min) did the electrolysis take?
19.109 Comment on whether $\mathrm{F}_{2}$ will become a stronger oxidizing agent with increasing $\mathrm{H}^{+}$concentration.
19.110 In recent years there has been much interest in electric cars. List some advantages and disadvantages of electric cars compared to automobiles with internal combustion engines.
19.111 Calculate the pressure of $\mathrm{H}_{2}$ (in atm) required to maintain equilibrium with respect to the following reaction at $25^{\circ} \mathrm{C}$,

$$
\mathrm{Pb}(s)+2 \mathrm{H}^{+}(a q) \rightleftarrows \mathrm{Pb}^{2+}(a q)+\mathrm{H}_{2}(g)
$$

given that $\left[\mathrm{Pb}^{2+}\right]=0.035 M$ and the solution is buffered at pH 1.60 .
19.112 A piece of magnesium ribbon and a copper wire are partially immersed in a 0.1 M HCl solution in a beaker. The metals are joined externally by another piece of metal wire. Bubbles are seen to evolve at both the Mg and Cu surfaces. (a) Write equations representing the reactions occurring at the metals.
(b) What visual evidence would you seek to show that Cu is not oxidized to $\mathrm{Cu}^{2+}$ ? (c) At some stage, NaOH solution is added to the beaker to neutralize the HCl acid. Upon further addition of NaOH , a white precipitate forms. What is it?
19.113 The zinc-air battery shows much promise for electric cars because it is lightweight and rechargeable:

The net transformation is $\mathrm{Zn}(s)+\frac{1}{2} \mathrm{O}_{2}(g) \longrightarrow \mathrm{ZnO}(s)$. (a) Write the half-reactions at the zinc-air electrodes, and calculate the standard emf of the battery at $25^{\circ} \mathrm{C}$. (b) Calculate the emf under actual operating conditions when the partial pressure of oxygen is 0.21 atm . (c) What is the energy density (measured as the energy in kilojoules that can be obtained from 1 kg of the metal) of the zinc electrode? (d) If a current of $2.1 \times 10^{5} \mathrm{~A}$ is to be drawn from a zinc-air battery system, what volume of air (in liters) would need to be supplied to the battery every second? Assume that the temperature is $25^{\circ} \mathrm{C}$ and the partial pressure of oxygen is 0.21 atm .
19.114 Calculate $E^{\circ}$ for the reactions of mercury with (a) $1 M \mathrm{HCl}$ and (b) $1 M \mathrm{HNO}_{3}$. Which acid will oxidize Hg to $\mathrm{Hg}_{2}^{2+}$ under standard-state conditions? Can you identify which pictured test tube contains $\mathrm{HNO}_{3}$ and Hg and which contains HCl and Hg ?

19.115 Because all alkali metals react with water, it is not possible to measure the standard reduction potentials of these metals directly as in the case of, say, zinc. An indirect method is to consider the following hypothetical reaction:

$$
\mathrm{Li}^{+}(a q)+\frac{1}{2} \mathrm{H}_{2}(g) \longrightarrow \mathrm{Li}(s)+\mathrm{H}^{+}(a q)
$$

Using the appropriate equation presented in this chapter and the thermodynamic data in Appendix 2, calculate $E^{\circ}$ for $\mathrm{Li}^{+}(a q)+$ $e^{-} \longrightarrow \mathrm{Li}(s)$ at 298 K . Use $96,485.338 \mathrm{C} / \mathrm{mol} e^{-}$for the Faraday constant. Compare your result with that listed in Table 19.1.

H19.116 A galvanic cell using $\mathrm{Mg} / \mathrm{Mg}^{2+}$ and $\mathrm{Cu} / \mathrm{Cu}^{2+}$ half-cells operates under standard-state conditions at $25^{\circ} \mathrm{C}$, and each compartment has a volume of 218 mL . The cell delivers 0.22 A for 31.6 h . (a) How many grams of Cu are deposited? (b) What is the $\left[\mathrm{Cu}^{2+}\right]$ remaining?
19.117 Given the following standard reduction potentials, calculate the ion-product, $K_{\mathrm{w}}$, for water at $25^{\circ} \mathrm{C}$ :

| $2 \mathrm{H}^{+}(a q)+2 e^{-} \longrightarrow \mathrm{H}_{2}(\mathrm{~g})$ | $E^{\circ}=0.00 \mathrm{~V}$ |
| :--- | :--- |
| $2 \mathrm{H}_{2} \mathrm{O}(l)+2 e^{-} \longrightarrow \mathrm{H}_{2}(g)+2 \mathrm{OH}^{-}(a q)$ | $E^{\circ}=-0.83 \mathrm{~V}$ |

19.118 Compare the pros and cons of a fuel cell, such as the hydrogenoxygen fuel cell, and a coal-fired power station for generating electricity.
19.119 Lead storage batteries are rated by ampere-hours, that is, the number of amperes they can deliver in an hour. (a) Show that $1 \mathrm{Ah}=3600 \mathrm{C}$. (b) The lead anodes of a certain lead-storage battery have a total mass of 406 g . Calculate the maximum theoretical capacity of the battery in ampere-hours. Explain why in practice we can never extract this much energy from the battery. (Hint: Assume all the lead will be used up in the electrochemical reaction, and refer to the electrode reactions on page 839.) (c) Calculate $E_{\text {cell }}^{\circ}$ and $\Delta G^{\circ}$ for the battery.
19.120 Use Equations 18.10 and 19.3 to calculate the emf values of the Daniell cell at $25^{\circ} \mathrm{C}$ and $80^{\circ} \mathrm{C}$. Comment on your results. What assumptions are used in the derivation? (Hint: You need the thermodynamic data in Appendix 2.)
$\boldsymbol{\Psi}$ 19.121 A construction company is installing an iron culvert (a long cylindrical tube) that is 40.0 m long with a radius of 0.900 m . To prevent corrosion, the culvert must be galvanized. This process is carried out by first passing an iron sheet of appropriate dimensions through an electrolytic cell containing $\mathrm{Zn}^{2+}$ ions, using graphite as the anode and the iron sheet as the cathode. If the voltage is 3.26 V , what is the cost of electricity for depositing a layer 0.200 mm thick if the efficiency of the process is 95 percent? The electricity rate is $\$ 0.12$ per kilowatt hour $(\mathrm{kWh})$, where $1 \mathrm{~W}=1 \mathrm{~J} / \mathrm{s}$ and the density of Zn is $7.14 \mathrm{~g} / \mathrm{cm}^{3}$.

GI 19.122 A $9.00 \times 10^{2} \mathrm{~mL}$ amount of $0.200 \mathrm{M} \mathrm{MgI}_{2}$ solution was electrolyzed. As a result, hydrogen gas was generated at the cathode and iodine was formed at the anode. The volume of hydrogen collected at $26^{\circ} \mathrm{C}$ and 779 mmHg was $1.22 \times 10^{3} \mathrm{~mL}$.
(a) Calculate the charge in coulombs consumed in the process.
(b) How long (in min) did the electrolysis last if a current of 7.55 A was used? (c) A white precipitate was formed in the process. What was it, and what was its mass in grams? Assume the volume of the solution was constant.

E19.123 Based on the following standard reduction potentials,

$$
\begin{aligned}
\mathrm{Fe}^{2+}(a q)+2 e^{-} \longrightarrow \mathrm{Fe}(s) & E_{1}^{\circ}=-0.44 \mathrm{~V} \\
\mathrm{Fe}^{3+}(a q)+e^{-} \longrightarrow \mathrm{Fe}^{2+}(a q) & E_{2}^{\circ}=0.77 \mathrm{~V}
\end{aligned}
$$

calculate the standard reduction potential for the half-reaction

$$
\mathrm{Fe}^{3+}(a q)+3 e^{-} \longrightarrow \mathrm{Fe}(s) \quad E_{3}^{\circ}=?
$$

19.124 To remove the tarnish $\left(\mathrm{Ag}_{2} \mathrm{~S}\right)$ on a silver spoon, a student carried out the following steps. First, she placed the spoon in a large pan filled with water so the spoon was totally immersed. Next, she added a few tablespoonfuls of baking soda (sodium bicarbonate), which readily dissolved. Finally, she placed some
aluminum foil at the bottom of the pan in contact with the spoon and then heated the solution to about $80^{\circ} \mathrm{C}$. After a few minutes, the spoon was removed and rinsed with cold water. The tarnish was gone, and the spoon regained its original shiny appearance. (a) Describe with equations the electrochemical basis for the procedure. (b) Adding NaCl instead of $\mathrm{NaHCO}_{3}$ would also work because both compounds are strong electrolytes. What is the added advantage of using $\mathrm{NaHCO}_{3}$ ? (Hint: Consider the pH of the solution.) (c) What is the purpose of heating the solution? (d) Some commercial tarnish removers contain a fluid (or paste) that is a dilute HCl solution. Rubbing the spoon with the fluid will also remove the tarnish. Name two disadvantages of using this procedure compared to the one described previously.
19.125 Calculate the equilibrium constant for the following reaction at 298 K :

$$
\mathrm{Zn}(s)+\mathrm{Cu}^{2+}(a q) \rightleftarrows \mathrm{Zn}^{2+}(a q)+\mathrm{Cu}(s)
$$

19.126 Cytochrome-c is a protein involved in biological electron transfer processes. The redox half-reaction is shown by the reduction of the $\mathrm{Fe}^{3+}$ ion to the $\mathrm{Fe}^{2+}$ ion:

$$
\operatorname{cyt~c}\left(\mathrm{Fe}^{3+}\right)+e^{-} \longrightarrow \operatorname{cyt~c}\left(\mathrm{Fe}^{2+}\right) \quad E^{\circ}=0.254 \mathrm{~V}
$$

Calculate the number of moles of cyt $\mathrm{c}\left(\mathrm{Fe}^{3+}\right)$ formed from cyt $\mathrm{c}\left(\mathrm{Fe}^{2+}\right)$ with the Gibbs free energy derived from the oxidation of 1 mole of glucose.
19.127 The nitrite ion $\left(\mathrm{NO}_{2}^{-}\right)$in soil is oxidized to the nitrate ion $\left(\mathrm{NO}_{3}^{-}\right)$ by the bacterium Nitrobacter agilis in the presence of oxygen. The half-reactions are

$$
\begin{aligned}
\mathrm{NO}_{3}^{-}+2 \mathrm{H}^{+}+2 e^{-} \longrightarrow \mathrm{NO}_{2}^{-}+\mathrm{H}_{2} \mathrm{O} & E^{\circ}=0.42 \mathrm{~V} \\
\mathrm{O}_{2}+4 \mathrm{H}^{+}+4 e^{-} \longrightarrow 2 \mathrm{H}_{2} \mathrm{O} & E^{\circ}=1.23 \mathrm{~V}
\end{aligned}
$$

Calculate the yield of ATP synthesis per mole of nitrite oxidized. (Hint: Refer to Section 18.7.)
19.128 Fluorine is a highly reactive gas that attacks water to form HF and other products. Follow the procedure in Problem 19.115 to show how you can determine indirectly the standard reduction potential for fluorine. Compare your result with the value in Table 19.1.
19.129 As discussed in Section 19.5, the potential of a concentration cell diminishes as the cell operates and the concentrations in the two compartments approach each other. When the concentrations in both compartments are the same, the cell ceases to operate. At this stage, is it possible to generate a cell potential by adjusting a parameter other than concentration? Explain.

## Pre-Professional Practice Exam Problems: Physical and Biological Sciences

A galvanic cell is constructed by immersing a piece of copper wire in 25.0 mL of a $0.20 \mathrm{M} \mathrm{CuSO}_{4}$ solution and a zinc strip in 25.0 mL of a 0.20 M ZnSO 4 solution. $\mathrm{Cu}^{2+}$ ions react with aqueous $\mathrm{NH}_{3}$ to form the complex ion $\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}^{2+}$ :

$$
\mathrm{Cu}^{2+}(a q)+4 \mathrm{NH}_{3}(a q) \longrightarrow \mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}^{2+}(a q)
$$

1. Using the equation

$$
E=E^{\circ}-\frac{0.0592 \mathrm{~V}}{n} \log Q
$$

calculate the emf of the cell at $25^{\circ} \mathrm{C}$.
a) 0.0 V
b) 1.10 V
c) 0.90 V
d) 1.30 V
2. What would happen if a small amount of concentrated $\mathrm{NH}_{3}$ solution were added to the $\mathrm{CuSO}_{4}$ solution?
a) Nothing.
b) Emf would increase.
c) Emf would decrease.
d) Not enough information to determine.
3. What would happen if a small amount of concentrated $\mathrm{NH}_{3}$ solution were added to the $\mathrm{ZnSO}_{4}$ solution?
a) Nothing.
b) Emf would increase.
c) Emf would decrease.
d) Not enough information to determine.
4. In a separate experiment, 25.0 mL of $3.00 \mathrm{MH}_{3}$ is added to the $\mathrm{CuSO}_{4}$ solution. If the emf of the cell is 0.68 V at equilibrium, calculate the formation constant $\left(K_{\mathrm{f}}\right)$ of $\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}^{2+}$.
a) $9.4 \times 10^{22}$
b) $1.1 \times 10^{-23}$
c) $1.5 \times 10^{-14}$
d) $1.5 \times 10^{14}$

## Answers to In-Chapter Materials

## Answers to Practice Problems

19.1A $2 \mathrm{MnO}_{4}^{-}+\mathrm{H}_{2} \mathrm{O}+3 \mathrm{CN}^{-} \longrightarrow 2 \mathrm{MnO}_{2}+2 \mathrm{OH}^{-}+3 \mathrm{CNO}^{-}$. 19.1B $\mathrm{MnO}_{4}^{-}+5 \mathrm{Fe}^{2+}+8 \mathrm{H}^{+} \longrightarrow \mathrm{Mn}^{2+}+5 \mathrm{Fe}^{3+}+4 \mathrm{H}_{2} \mathrm{O}$.
19.2 $\mathrm{A} \mathrm{Cd}+\mathrm{Pb}^{2+} \longrightarrow \mathrm{Cd}^{2+}+\mathrm{Pb}, E_{\text {cell }}^{\circ}=0.27 \mathrm{~V}$. 19.2B In one cell, the iron electrode is the anode and the overall reaction is $\mathrm{Fe}(s)+$ $\mathrm{Sn}^{2+}(a q) \longrightarrow \mathrm{Fe}^{2+}(a q)+\mathrm{Sn}(s) . E_{\text {cell }}^{\circ}=E_{\mathrm{Sn}^{2+} / \mathrm{Sn}}^{\circ}-E_{\mathrm{Fe}^{2+} / \mathrm{Fe}}^{\circ}=$ $(-0.14 \mathrm{~V})-(-0.44 \mathrm{~V})=0.30 \mathrm{~V}$. In the other cell, the iron electrode is the cathode and the overall reaction is $3 \mathrm{Fe}^{2+}(a q)+2 \mathrm{Cr}(s) \longrightarrow$ $3 \mathrm{Fe}(s)+2 \mathrm{Cr}^{3+}(a q) \cdot E_{\mathrm{cell}}^{\circ}=E_{\mathrm{Fe}^{2+} / \mathrm{Fe}}^{\circ}-E_{\mathrm{Cr}^{3+} / \mathrm{Cr}}^{\circ}=(-0.44 \mathrm{~V})-(-0.74 \mathrm{~V})$ $=0.30 \mathrm{~V} .19 .3 \mathrm{~A}$ (a) No reaction, (b) $2 \mathrm{H}^{+}+\mathrm{Pb} \longrightarrow \mathrm{H}_{2}+\mathrm{Pb}^{2+}$.
19.3B Cobalt has a more positive reduction potential than iron. Cobalt ion would, therefore, be reduced in the presence of iron metal; and the iron in an iron container would oxidize to $\mathrm{Fe}^{2+}$. Metal that is oxidized goes from the solid phase to the aqueous phase, meaning that the container would effectively dissolve. Cobalt has a less positive reduction potential than tin. Tin metal would not be oxidized by $\mathrm{Co}^{2+}$ ion, and the container would remain intact. A cobalt(II) chloride solution would be more safely stored in a tin container than in an iron container. 19.4A $-411 \mathrm{~kJ} / \mathrm{mol}$.
19.4B $23.2 \mathrm{~kJ} / \mathrm{mol}$. 19.5A $1 \times 10^{-42}$. 19.5B $1.4 \times 10^{5}$. 19.6A Yes, the reaction is spontaneous. $19.6 \mathrm{~B} 18 \mathrm{~atm} .19 .7 \mathrm{~A}\left[\mathrm{Cu}^{+}\right]=1.11 \times 10^{-3} M$, $K_{\text {sp }}=1.2 \times 10^{-6}$. 19.7B 0.16 V .19 .8 A 7.44 g Mg .19 .8 B 0.96 A .

## Answers to Checkpoints

## How Nuclear Chemistry Is Used to Treat Cancer

Brain tumors are some of the most difficult cancers to treat because the site of the malignant growth makes surgical excision difficult or impossible. Likewise, conventional radiation therapy using X rays or $\gamma$ rays from outside the skull is usually not effective. An ingenious approach to this problem is boron neutron capture therapy (BNCT). This technique involves first administering a boron-10 compound that is selectively taken up by tumor cells and then applying a beam of low-energy neutrons to the tumor site. ${ }^{10} \mathrm{~B}$ captures a neutron to produce ${ }^{11} \mathrm{~B}$, which disintegrates via the following nuclear reaction:

$$
{ }_{5}^{10} \mathrm{~B}+{ }_{0}^{1} \mathrm{n} \longrightarrow{ }_{3}^{7} \mathrm{Li}+{ }_{2}^{4} \alpha
$$

The highly energetic particles produced by this reaction destroy the tumor cells in which the ${ }^{10} \mathrm{~B}$ is concentrated. Because the particles are confined to just a few micrometers, they preferentially destroy tumor cells without damaging neighboring normal cells.
BNCT is a highly promising treatment and is an active area of research. One of the major goals of the research is to develop suitable compounds to deliver ${ }^{10} \mathrm{~B}$ to the desired site. For such a compound to be effective, it must meet several criteria. It must have a high affinity for tumor cells, be able to pass through membrane barriers to reach the tumor site, and have minimal toxic effects on the human body.

This is one example of how nuclear chemistry is important in the treatment of cancer.

At the end of this chapter, you will be able to answer questions about isotopes used in nuclear medicine [ $\quad$ Mage 885].

## In This Chapter, You Will Learn:

Some of the fundamentals of nuclear chemistry and how nuclear reactions are important to living systems and to society.

## Before you begin, you should review

- Radioactivity [l/ Section 2.2]
- Atomic number, mass number, and isotopes [l/4 Section 2.3]
- First-order kinetics [ 14 Section 14.3]

### 20.1 Nuclei and Nuclear Reactions

With the exception of hydrogen $\left({ }_{1}^{1} \mathrm{H}\right)$, all nuclei contain protons and neutrons. Some nuclei are unstable and undergo radioactive decay, emitting particles and/or electromagnetic radiation [144 Section 2.2]. Spontaneous emission of particles or electromagnetic radiation is known as radioactivity. All elements having an atomic number greater than 83 are unstable and are therefore radioactive. Polonium-210 $\left({ }_{84}^{210} \mathrm{Po}\right)$, for example, decays spontaneously to Pb by emitting an $\alpha$ particle.

Another type of nuclear process, known as nuclear transmutation, results from the bombardment of nuclei by neutrons, protons, or other nuclei. An example of a nuclear transmutation is the conversion of atmospheric ${ }_{7}^{14} \mathrm{~N}$ to ${ }_{6}^{14} \mathrm{C}$ and ${ }_{1}^{1} \mathrm{H}$, which results when the nitrogen isotope is bombarded by neutrons (from the sun). In some cases, heavier elements are synthesized from lighter elements. This type of transmutation occurs naturally in outer space, but it can also be achieved artificially, as we will see in Section 20.4.

Radioactive decay and nuclear transmutation are nuclear reactions, which differ significantly from ordinary chemical reactions. Table 20.1 summarizes the differences.

To discuss nuclear reactions in any depth, we must understand how to write and balance nuclear equations. Writing a nuclear equation differs somewhat from writing equations for chemical reactions. In addition to writing the symbols for the various chemical elements, we must also explicitly indicate the number of subatomic particles in every species involved in the reaction.

The symbols for subatomic particles are as follows:

$$
{ }_{1}^{1} \mathrm{H} \underset{\text { proton }}{\text { or }}{ }_{1}^{1} \mathrm{p} \underset{{ }_{0}^{1} \mathrm{n}}{{ }_{\text {neutron }}^{1}} \quad{ }_{-1}^{0} e \underset{\text { electron }}{\text { or }}{ }_{-1}^{0} \beta \quad{ }_{+1}^{0} e \underset{\text { positron }}{\text { or }}{ }_{+1}^{0} \beta \quad{ }_{2}^{4} \alpha \underset{\alpha \text { particle }}{\text { or }}{ }_{2}^{4} \mathrm{He}
$$

In accordance with the notation introduced in Section 2.3, the superscript in each case denotes the mass number (the total number of neutrons and protons present) and the subscript is the atomic number (the number of protons). Thus, the "atomic number" of a proton is 1 , because there is one proton present, and the "mass number" is also 1 , because there is one proton but no neutrons present. On the other hand, the mass number of a neutron is 1 , but its atomic number is zero, because there are no protons present. For the electron, the mass number is zero (there are neither protons nor neutrons present), but the atomic number is -1 , because the electron possesses a unit negative charge.

The symbol ${ }_{-1}^{0} e$ represents an electron in or from an atomic orbital. The symbol ${ }_{-1}^{0} \beta$, on the other hand, represents an electron that, although physically identical to any other electron, comes from a nucleus (in a decay process in which a neutron is converted to a proton and an electron) and not from an atomic orbital. The positron has the same mass as the electron, but bears a charge of +1 . The $\alpha$ particle has two protons and two neutrons, so its atomic number is 2 and its mass number is 4 .

In balancing any nuclear equation, we must balance the total of all atomic numbers and the total of all mass numbers for the products and reactants. If we know the atomic numbers and mass numbers of all but one of the species in a nuclear equation, we can identify the unknown species by applying these rules, as shown in Sample Problem 20.1.

## TABLE 20.1 Comparison of Chemical Reactions and Nuclear Reactions

## Chemical Reactions

1. Atoms are rearranged by the breaking and forming of chemical bonds.
2. Only electrons in atomic or molecular orbitals are involved in the reaction.
3. Reactions are accompanied by the absorption or release of relatively small amounts of energy.
4. Rates of reaction are influenced by temperature, pressure, concentration, and catalysts.

## Nuclear Reactions

1. Elements are converted to other elements (or isotopes).
2. Protons, neutrons, electrons, and other subatomic particles such as $\alpha$ particles may be involved.
3. Reactions are accompanied by the absorption or release of tremendous amounts of energy.
4. Rates of reaction normally are not affected by temperature, pressure, or catalysts.

## Sample Problem 20.1

Identify the missing species X in each of the following nuclear equations:
(a) ${ }_{84}^{212} \mathrm{Po} \longrightarrow{ }_{82}^{208} \mathrm{~Pb}+\mathrm{X}$
(b) ${ }_{38}^{90} \mathrm{Sr} \longrightarrow \mathrm{X}+{ }_{-1}^{0} \beta$
(c) $\mathrm{X} \longrightarrow{ }_{8}^{18} \mathrm{O}+{ }_{+1}^{0} \beta$

Strategy Determine the mass number for the unknown species, X , by summing the mass numbers on both sides of the equation:

$$
\Sigma \text { reactant mass numbers }=\Sigma \text { product mass numbers }
$$

Similarly, determine the atomic number for the unknown species:

$$
\Sigma \text { reactant atomic numbers }=\Sigma \text { product atomic numbers }
$$

Use the mass number and atomic number to determine the identity of the unknown species.
Setup (a) $212=(208+$ mass number of $X)$; mass number of $X=4.84=(82+$ atomic number of X ); atomic number of $\mathrm{X}=2$.
(b) $90=$ (mass number of $X+0$ ); mass number of $X=90.38=[$ atomic number of $X+(-1)]$; atomic number of $X=39$.
(c) Mass number of $X=(18+0)$; mass number of $X=18$. Atomic number of $X=(8+1)$; atomic number of $X=9$.

Solution (a) $\mathrm{X}={ }_{2}^{4} \alpha:{ }_{82}^{208} \mathrm{Po} \longrightarrow{ }_{82}^{208} \mathrm{~Pb}+{ }_{2}^{4} \alpha$
(b) $\mathrm{X}={ }_{39}^{90} \mathrm{Y}:{ }_{38}^{90} \mathrm{Sr} \longrightarrow{ }_{39}^{90} \mathrm{Y}+{ }_{-1}^{0} \beta$
(c) $\mathrm{X}={ }_{9}^{18} \mathrm{~F}:{ }_{9}^{18} \mathrm{~F} \longrightarrow{ }_{8}^{18} \mathrm{O}+{ }_{+1}^{0} \beta$

Think About It The rules of summation that we apply to balance nuclear equations can be thought of as the conservation of mass number and the conservation of atomic number.

Practice Problem A Identify X in each of the following nuclear equations:
(a) ${ }_{33}^{78} \mathrm{As} \longrightarrow \mathrm{X}+{ }_{-1}^{0} \beta$
(b) ${ }_{1}^{1} \mathrm{H}+{ }_{2}^{4} \mathrm{He} \longrightarrow \mathrm{X}$
(c) ${ }_{100}^{258} \mathrm{Fm} \longrightarrow{ }_{100}^{257} \mathrm{Fm}+\mathrm{X}$
$\leftrightarrows$ Practice Problem $B$ Identify $X$ in each of the following nuclear equations:
(a) $\mathrm{X}+{ }_{-1}^{0} \beta \longrightarrow{ }_{94}^{244} \mathrm{Pu}$
(b) ${ }_{92}^{238} \mathrm{U} \longrightarrow \mathrm{X}+{ }_{2}^{4} \mathrm{He}$
(c) $\mathrm{X} \longrightarrow{ }_{7}^{14} \mathrm{~N}+{ }_{-1}^{0} e$

## Checkpoint 20.1 Nuclei and Nuclear Reactions

20.1.1 Identify the species X in the following nuclear equation:

$$
{ }_{86}^{222} \mathrm{Rn} \longrightarrow \mathrm{X}+{ }_{2}^{4} \alpha
$$

a) ${ }_{84}^{226} \mathrm{Po}$
b) ${ }_{88}^{226} \mathrm{Ra}$
c) ${ }_{84}^{212} \mathrm{Po}$
d) ${ }_{84}^{218} \mathrm{Po}$
e) ${ }_{88}^{218} \mathrm{Ra}$
20.1.2 Identify the species X in the following nuclear equation:

$$
{ }_{8}^{15} \mathrm{O} \longrightarrow \mathrm{X}+{ }_{-1}^{0} \beta
$$

a) ${ }_{9}^{15} \mathrm{~F}$
b) ${ }_{8}^{14} \mathrm{O}$
c) ${ }_{9}^{16} \mathrm{~F}$
d) ${ }_{7}^{15} \mathrm{~N}$
e) ${ }_{7}^{14} \mathrm{~N}$

### 20.2 Nuclear Stability

The nucleus occupies a very small portion of the total volume of an atom, but it contains most of the atom's mass because both the protons and the neutrons reside there. In studying the stability of the atomic nucleus, it is helpful to know something about its density, because it tells us how tightly the particles are packed together. As a sample calculation, let us assume that a nucleus has

Student Annotation: The significance of these numbers for nuclear stability is similar to the numbers of electrons associated with the very stable noble gases (i.e., $2,10,18,36,54$, and 86 electrons).

Student Annotation: Of the two stable isotopes of antimony mentioned in rule 1 , both have even numbers of neutrons: ${ }_{51}^{121} \mathrm{Sb}$ and ${ }_{51}^{123} \mathrm{Sb}$.
a radius of $5 \times 10^{-3} \mathrm{pm}$ and a mass of $1 \times 10^{-22} \mathrm{~g}$. These figures correspond roughly to a nucleus containing 30 protons and 30 neutrons. Density is mass/volume, and we can calculate the volume from the known radius (the volume of a sphere is $\frac{4}{3} \pi r^{3}$, where $r$ is the radius of the sphere). First we convert the picometer units to centimeters. Then, we calculate the density in $\mathrm{g} / \mathrm{cm}^{3}$ :

$$
\begin{aligned}
r & =\left(5 \times 10^{-3} \mathrm{pm}\right)\left(\frac{1 \times 10^{-12} \mathrm{~m}}{1 \mathrm{pm}}\right)\left(\frac{100 \mathrm{~cm}}{1 \mathrm{~m}}\right)=5 \times 10^{-13} \mathrm{~cm} \\
\text { density } & =\frac{\text { mass }}{\text { volume }}=\frac{1 \times 10^{-22} \mathrm{~g}}{\frac{4}{3} \pi r^{3}}=\frac{1 \times 10^{-22} \mathrm{~g}}{\frac{4}{3} \pi\left(5 \times 10^{-13} \mathrm{~cm}\right)^{3}} \\
& =2 \times 10^{14} \mathrm{~g} / \mathrm{cm}^{3}
\end{aligned}
$$

This is an exceedingly high density. The highest density known for an element is $22.6 \mathrm{~g} / \mathrm{cm}^{3}$, for osmium (Os). Thus, the average atomic nucleus is roughly $9 \times 10^{12}$ (or 9 trillion) times as dense as the densest element known!

The enormously high density of the nucleus means that some very strong force is needed to hold the particles together so tightly. From Coulomb's law we know that like charges repel and unlike charges attract one another. We would thus expect the protons to repel one another strongly, particularly when we consider how close they must be to each other. This indeed is so. However, in addition to the repulsion, there are also short-range attractions between proton and proton, proton and neutron, and neutron and neutron. The stability of any nucleus is determined by the difference between coulombic repulsion and the short-range attraction. If repulsion outweighs attraction, the nucleus disintegrates, emitting particles and/or radiation. If attractive forces prevail, the nucleus is stable.

## Patterns of Nuclear Stability

The principal factor that determines whether a nucleus is stable is the neutron-to-proton ratio $(n / p)$. For stable atoms of elements having low atomic number $(\leq 20)$, the $n / p$ value is close to 1 . As the atomic number increases, the neutron-to-proton ratios of the stable nuclei also increase. This deviation at higher atomic numbers arises because more neutrons are needed to counteract the strong repulsion among the protons and stabilize the nucleus. The following rules are useful in gauging whether or not a particular nucleus is expected to be stable:

1. There are more stable nuclei containing $2,8,20,50,82$, or 126 protons or neutrons than there are containing other numbers of protons or neutrons. For example, there are 10 stable isotopes of $\operatorname{tin}(\mathrm{Sn})$ with the atomic number 50 and only 2 stable isotopes of antimony $(\mathrm{Sb})$ with the atomic number 51 . The numbers $2,8,20,50,82$, and 126 are called magic numbers.
2. There are many more stable nuclei with even numbers of both protons and neutrons than with odd numbers of these particles (Table 20.2).
3. All isotopes of the elements with atomic numbers higher than 83 are radioactive.
4. All isotopes of technetium $(\mathrm{Tc}, Z=43)$ and promethium $(\mathrm{Pm}, Z=61)$ are radioactive.

Figure 20.1 shows a plot of the number of neutrons versus the number of protons in various isotopes. The stable nuclei are located in an area of the graph known as the belt of stability. Most radioactive nuclei lie outside this belt. Above the belt of stability, the nuclei have higher neutron-to-proton ratios than those within the belt (for the same number of protons). To lower this ratio (and hence move down toward the belt of stability), these nuclei undergo the following process, called $\beta$-particle emission:

$$
{ }_{0}^{1} \mathrm{n} \longrightarrow{ }_{1}^{1} \mathrm{p}+{ }_{-1}^{0} \beta
$$

## TABLE 20.2

Even

Neutrons
Odd
Even
Odd
Even

Number of Stable Isotopes
4
50164

Beta-particle emission leads to an increase in the number of protons in the nucleus and a simultaneous decrease in the number of neutrons. Some examples are

$$
\begin{gathered}
{ }_{6}^{14} \mathrm{C} \longrightarrow{ }_{7}^{14} \mathrm{~N}+{ }_{-1}^{0} \beta \\
{ }_{19}^{40} \mathrm{~K} \longrightarrow{ }_{20}^{40} \mathrm{Ca}+{ }_{-1}^{0} \beta \\
{ }_{40}^{97} \mathrm{Zr} \longrightarrow{ }_{41}^{9} \mathrm{Nb}+{ }_{-1}^{0} \beta
\end{gathered}
$$

Below the belt of stability, the nuclei have lower neutron-to-proton ratios than those in the belt (for the same number of protons). To increase this ratio (and hence move up toward the belt of stability), these nuclei may emit a positron,

$$
{ }_{1}^{1} \mathrm{p} \longrightarrow{ }_{0}^{1} \mathrm{n}+{ }_{1}^{0} \beta
$$

An example of positron emission is

$$
{ }_{19}^{38} \mathrm{~K} \longrightarrow{ }_{18}^{38} \mathrm{Ar}+{ }_{+1}^{0} \beta
$$

Alternatively, a nucleus may undergo electron capture,

$$
{ }_{1}^{1} \mathrm{p}+{ }_{-1}^{0} e \longrightarrow{ }_{0}^{1} \mathrm{n}
$$

Electron capture is the capture of an electron-usually a $1 s$ electron-by the nucleus. The captured electron combines with a proton in the nucleus to form a neutron so that the atomic number decreases by 1 while the mass number remains the same. Electron capture has the same net effect on the nucleus as positron emission. Examples of electron capture are

$$
\begin{aligned}
& { }_{18}^{37} \mathrm{Ar}+{ }_{-1}^{0} e \longrightarrow{ }_{17}^{37} \mathrm{Cl} \\
& { }_{26}^{55} \mathrm{Fe}+{ }_{-1}^{0} e \longrightarrow{ }_{25}^{55} \mathrm{Mn}
\end{aligned}
$$

## Nuclear Binding Energy

A quantitative measure of nuclear stability is the nuclear binding energy, which is the energy required to break up a nucleus into its component protons and neutrons. This quantity represents the conversion of mass to energy that occurs during an exothermic nuclear reaction.

Figure 20.1 Plot of neutrons versus protons for various stable isotopes, represented by dots. The straight line represents the points at which the neutron-to-proton ratio is 1 . The shaded area represents the belt of stability.

The concept of nuclear binding energy evolved from studies of nuclear properties showing that the masses of nuclei are always less than the sum of the masses of the nucleons, which is a general term for the protons and neutrons in a nucleus. For example, the ${ }_{9}^{19} \mathrm{~F}$ isotope has an atomic mass of 18.99840 amu . The nucleus has 9 protons and 10 neutrons and therefore a total of 19 nucleons. Using the known masses of the ${ }_{1}^{1} \mathrm{H}$ atom ( 1.007825 amu ) and the neutron ( 1.008665 amu ), we can carry out the following analysis. The mass of $9{ }_{1}^{1} \mathrm{H}$ atoms (i.e., the mass of 9 protons and 9 electrons) is

$$
9 \times 1.007825 \mathrm{amu}=9.070425 \mathrm{amu}
$$

and the mass of 10 neutrons is

$$
10 \times 1.008665 \mathrm{amu}=10.08665 \mathrm{amu}
$$

Therefore, the atomic mass of an ${ }_{9}^{19} \mathrm{~F}$ atom calculated from the known numbers of electrons, protons, and neutrons is

$$
9.070425 \mathrm{amu}+10.08665 \mathrm{amu}=19.15708 \mathrm{amu}
$$

This value is larger than 18.99840 amu (the measured mass of ${ }_{9}^{19} \mathrm{~F}$ ) by 0.15868 amu .
The difference between the mass of an atom and the sum of the masses of its protons, neutrons, and electrons is called the mass defect. According to relativity theory, the loss in mass shows up as energy (heat) given off to the surroundings. Thus, the formation of ${ }_{9}^{19} \mathrm{~F}$ is exothermic. According to Einstein's mass-energy equivalence relationship ( $E=m c^{2}$, where $E$ is energy, $m$ is mass, and $c$ is the velocity of light), we can calculate the amount of energy released. We start by writing

Equation 20.1

$$
\Delta E=(\Delta m) c^{2}
$$

where $\Delta E$ and $\Delta m$ are defined as follows:

$$
\begin{aligned}
\Delta E & =\text { energy of product }- \text { energy of reactants } \\
\Delta m & =\text { mass of product }- \text { mass of reactants }
\end{aligned}
$$

Thus, the change in mass is

$$
\begin{aligned}
\Delta m & =18.99840 \mathrm{amu}-19.15708 \mathrm{amu} \\
& =-0.15868 \mathrm{amu}
\end{aligned}
$$

or

$$
\begin{aligned}
\Delta m & =(-0.15868 \mathrm{amu})\left(\frac{1 \mathrm{~kg}}{6.0221418 \times 10^{26} \mathrm{amu}}\right) \\
& =-2.6349 \times 10^{-28} \mathrm{~kg}
\end{aligned}
$$

Because ${ }_{9}^{19} \mathrm{~F}$ has a mass that is less than the mass calculated from the number of electrons and nucleons present, $\Delta m$ is a negative quantity. Consequently, $\Delta E$ is also a negative quantity; that is, energy is released to the surroundings as a result of the formation of the fluorine-19 nucleus. We calculate $\Delta E$ as follows:

$$
\begin{aligned}
\Delta E & =\left(-2.6349 \times 10^{-28} \mathrm{~kg}\right)\left(2.99792458 \times 10^{8} \mathrm{~m} / \mathrm{s}\right)^{2} \\
& =-2.3681 \times 10^{-11} \mathrm{~kg} \cdot \mathrm{~m}^{2} / \mathrm{s}^{2} \\
& =-2.3681 \times 10^{-11} \mathrm{~J}
\end{aligned}
$$

This is the amount of energy released when one fluorine-19 nucleus is formed from 9 protons and 10 neutrons. The nuclear binding energy of the nucleus is $2.3682 \times 10^{-11} \mathrm{~J}$, which is the amount of energy needed to decompose the nucleus into separate protons and neutrons. In the formation of 1 mole of fluorine nuclei, for instance, the energy released is

$$
\begin{aligned}
\Delta E & =\left(-2.3681 \times 10^{-11} \mathrm{~J}\right)\left(6.0221418 \times 10^{23} / \mathrm{mol}\right) \\
& =-1.4261 \times 10^{13} \mathrm{~J} / \mathrm{mol} \\
& =-1.4261 \times 10^{10} \mathrm{~kJ} / \mathrm{mol}
\end{aligned}
$$

The nuclear binding energy, therefore, is $1.4261 \times 10^{10} \mathrm{~kJ}$ for 1 mole of fluorine-19 nuclei, which is a tremendously large quantity when we consider that the enthalpies of ordinary chemical reactions are on the order of only 200 kJ . The procedure we have followed can be used to calculate the nuclear binding energy of any nucleus.

As we have noted, nuclear binding energy is an indication of the stability of a nucleus. When comparing the stability of any two nuclei, however, we must account for the fact that they have different numbers of nucleons. It makes more sense, therefore, to compare nuclei using the nuclear binding energy per nucleon:

$$
\text { nuclear binding energy per nucleon }=\frac{\text { nuclear binding energy }}{\text { number of nucleons }}
$$

For the fluorine-19 nucleus,

$$
\begin{aligned}
\text { nuclear binding energy per nucleon } & =\frac{2.3681 \times 10^{-11} \mathrm{~J}}{19 \text { nucleons }} \\
& =1.2464 \times 10^{-12} \mathrm{~J} / \text { nucleon }
\end{aligned}
$$

The nuclear binding energy per nucleon makes it possible to compare the stability of all nuclei on a common basis. Figure 20.2 shows the variation of nuclear binding energy per nucleon plotted against mass number. As you can see, the curve rises rather steeply. The highest binding energies per nucleon belong to elements with intermediate mass numbers-between 40 and 100-and are greatest for elements in the iron, cobalt, and nickel region (the Group 8B elements) of the periodic table. This means that the net attractive forces among the particles (protons and neutrons) are greatest for the nuclei of these elements.

Nuclear binding energy and nuclear binding energy per nucleon are calculated for an iodine nucleus in Sample Problem 20.2.

## Sample Problem 20.2

The atomic mass of ${ }_{53}^{127}$ I is 126.904473 amu . Calculate the nuclear binding energy of this nucleus and the corresponding nuclear binding energy per nucleon.

Strategy To calculate the nuclear binding energy, we first determine the difference between the mass of the nucleus and the mass of all the protons and neutrons, which yields the mass defect. Next, we must apply Einstein's mass-energy relationship $\left[\Delta E=(\Delta m) c^{2}\right]$.

Solution There are 53 protons and 74 neutrons in the iodine nucleus. The mass of $53{ }_{1}^{1} \mathrm{H}$ atoms is

$$
53 \times 1.007825 \mathrm{amu}=53.41473 \mathrm{amu}
$$

and the mass of 74 neutrons is

$$
74 \times 1.008665 \mathrm{amu}=74.64121 \mathrm{amu}
$$

Figure 20.2 Plot of nuclear binding energy per nucleon versus mass number.

Student Annotation: Note that when we report a nuclear binding energy per mole, we give just the magnitude without the negative sign.

Student Annotation: In general, the greater the nuclear binding energy per nucleon, the more stable the nucleus.

Therefore, the predicted mass for ${ }_{53}^{127} \mathrm{I}$ is $53.41473+74.64121=128.05594 \mathrm{amu}$, and the mass defect is

$$
\begin{aligned}
\Delta m & =126.904473 \mathrm{amu}-128.05594 \mathrm{amu} \\
& =-1.15147 \mathrm{amu} \\
& =(-1.15147 \mathrm{amu})\left(\frac{1 \mathrm{~kg}}{6.0221418 \times 10^{26} \mathrm{amu}}\right) \\
& =-1.91206 \times 10^{-27} \mathrm{~kg}
\end{aligned}
$$

The energy released is

$$
\begin{aligned}
\Delta E & =(\Delta m) c^{2} \\
& =\left(-1.91206 \times 10^{-27} \mathrm{~kg}\right)\left(2.99792458 \times 10^{8} \mathrm{~m} / \mathrm{s}\right)^{2} \\
& =1.71847 \times 10^{-10} \mathrm{~kg} \cdot \mathrm{~m}^{2} / \mathrm{s}^{2} \\
& =1.71847 \times 10^{-10} \mathrm{~J}
\end{aligned}
$$

Thus the nuclear binding energy is $1.71847 \times 10^{-10} \mathrm{~J}$. The nuclear binding energy per nucleon is obtained as follows:

$$
\frac{1.71847 \times 10^{-10} \mathrm{~J}}{127 \text { nucleons }}=1.35313 \times 10^{-12} \mathrm{~J} / \text { nucleon }
$$

Practice Problem A Calculate the nuclear binding energy (in joules) and the nuclear binding energy per nucleon of ${ }_{83}^{209} \mathrm{Bi}(208.980374 \mathrm{amu})$.
$\boldsymbol{\xi} \boldsymbol{P}$ Practice Problem B The nuclear binding energy for ${ }_{79}^{197} \mathrm{Au}$ is $1.2683 \times 10^{-12} \mathrm{~J} /$ nucleon. Determine the mass of a ${ }_{79}^{197} \mathrm{Au}$ atom.

## Checkpoint 20.2 Nuclear Stability

20.2.1 Determine the binding energy per nucleon in a ${ }^{238} \mathrm{U}$ nucleus (238.0507847 amu).
a) $2.891 \times 10^{-10} \mathrm{~J} /$ nucleon
b) $1.215 \times 10^{-12} \mathrm{~J} /$ nucleon
c) $1.186 \times 10^{-12} \mathrm{~J} /$ nucleon
d) $2.823 \times 10^{-10} \mathrm{~J} /$ nucleon
e) $3.212 \times 10^{-24} \mathrm{~J} /$ nucleon
20.2.2 What is the energy associated with a mass defect of 2.000 amu ?
a) $3.321 \times 10^{-27} \mathrm{~J}$
b) $2.989 \times 10^{-7} \mathrm{~J}$
c) $1.800 \times 10^{17} \mathrm{~J}$
d) $2.989 \times 10^{-10} \mathrm{~J}$
e) $3.309 \times 10^{-45} \mathrm{~J}$
20.2.3 What is the change in mass (in kg ) for the following reaction? $\Delta H^{\circ}$ for the reaction is $-890.4 \mathrm{~kJ} / \mathrm{mol}$.

a) $1.479 \times 10^{-21} \mathrm{~kg}$
b) $1.479 \times 10^{-24} \mathrm{~kg}$
c) $1.645 \times 10^{-35} \mathrm{~kg}$
d) $4.932 \times 10^{-33} \mathrm{~kg}$
e) $9.907 \times 10^{-15} \mathrm{~kg}$
20.2.4 What type of radioactive decay will the isotopes ${ }^{13} \mathrm{~B}$ and ${ }^{188} \mathrm{Au}$ most likely undergo?
a) Beta emission, positron emission
b) Beta emission, beta emission
c) Positron emission, beta emission
d) Positron emission, positron emission

### 20.3 Natural Radioactivity

Nuclei that do not lie within the belt of stability, as well as nuclei with more than 83 protons, tend to be unstable. The spontaneous emission by unstable nuclei of particles or electromagnetic radiation, or both, is known as radioactivity. The main types of radioactivity are the emission of $\alpha$

particles (doubly charged helium nuclei, $\mathrm{He}^{2+}$ ); the emission of $\beta$ particles (electrons of nuclear origin); the emission of $\gamma$ rays, which are very-short-wavelength ( 0.1 nm to 104 nm ) electromagnetic waves; the emission of positrons; and electron capture.

The disintegration of a radioactive nucleus often is the beginning of a radioactive decay series, which is a sequence of nuclear reactions that ultimately result in the formation of a stable isotope. Figure 20.3 shows the decay series of naturally occurring uranium-238, which involves 14 steps. This decay scheme, known as the uranium decay series, also shows the half-lives of all the nuclei involved.

It is important to be able to balance the nuclear reaction for each of the steps in a radioactive decay series. For example, the first step in the uranium decay series is the decay of uranium- 238 to thorium-234, with the emission of an $\alpha$ particle. Hence, the reaction is represented by

$$
{ }_{92}^{238} \mathrm{U} \longrightarrow{ }_{90}^{234} \mathrm{Th}+{ }_{2}^{4} \alpha
$$

The next step is represented by

$$
{ }_{90}^{234} \mathrm{Th} \longrightarrow{ }_{91}^{234} \mathrm{~Pa}+{ }_{-1}^{0} \beta
$$

and so on. In a discussion of radioactive decay steps, the beginning radioactive isotope is called the parent and the product isotope is called the daughter. Thus, ${ }_{92}^{238} \mathrm{U}$ is the parent in the first step of the uranium decay series, and ${ }_{90}^{234} \mathrm{Th}$ is the daughter.

Figure 20.3 Decay series for uranium-238. (Times shown are half-lives.)

Student Annotation: Most nuclear scientists (and some general chemistry books) use the symbol $\lambda$ instead of $k$ for the rate constant of nuclear reactions.

Student Annotation: Although Equation 14.3 uses concentrations of a reactant at times $t$ and 0 , it is the ratio of the two that is important, so we can also use the number of radioactive nuclei in this equation.

## Multimedia

Nuclear Chemistry—radioactive half-life.

## Kinetics of Radioactive Decay

All radioactive decays obey first-order kinetics. Therefore, the rate of radioactive decay at any time $t$ is given by

$$
\text { rate of decay at time } t=k N
$$

where $k$ is the first-order rate constant and $N$ is the number of radioactive nuclei present at time $t$. According to Equation 14.3, the number of radioactive nuclei at time zero $\left(N_{0}\right)$ and time $t\left(N_{t}\right)$ is

$$
\ln \frac{N_{t}}{N_{0}}=-k t
$$

and the corresponding half-life of the reaction is given by Equation 14.5:

$$
t_{1 / 2}=\frac{0.693}{k}
$$

The half-lives and, therefore, the rate constants of radioactive isotopes vary greatly from nucleus to nucleus. Looking at Figure 20.3, for example, we find that ${ }_{92}^{238} \mathrm{U}$ and ${ }_{84}^{214} \mathrm{Po}$ are two extreme cases:

$$
\begin{aligned}
{ }_{92}^{238} \mathrm{U} \longrightarrow{ }_{90}^{234} \mathrm{Th}+{ }_{2}^{4} \alpha
\end{aligned} \quad \begin{aligned}
& t_{1 / 2}=4.51 \times 10^{9} \mathrm{yr} \\
& { }_{84}^{214} \mathrm{Po} \longrightarrow{ }_{82}^{210} \mathrm{~Pb}+{ }_{2}^{4} \alpha
\end{aligned} \quad \begin{aligned}
& t_{1 / 2}=1.6 \times 10^{-4} \mathrm{~s}
\end{aligned}
$$

These two rate constants, after conversion to the same time unit, differ by many orders of magnitude. Furthermore, the rate constants are unaffected by changes in environmental conditions such as temperature and pressure. These highly unusual features are not seen in ordinary chemical reactions (see Table 20.1).

## Dating Based on Radioactive Decay

The half-lives of radioactive isotopes have been used as "atomic clocks" to determine the ages of certain objects. Some examples of dating by radioactive decay measurements will be described here.

The carbon-14 isotope is produced when atmospheric nitrogen is bombarded by cosmic rays:

$$
{ }_{7}^{14} \mathrm{~N}+{ }_{0}^{1} \mathrm{n} \longrightarrow{ }_{6}^{14} \mathrm{C}+{ }_{1}^{1} \mathrm{H}
$$

The radioactive carbon-14 isotope decays according to the equation

$$
{ }_{6}^{14} \mathrm{C} \longrightarrow{ }_{7}^{14} \mathrm{~N}+{ }_{-1}^{0} \beta
$$

This reaction is the basis of radiocarbon or "carbon-14" dating. To determine the age of an object, we measure the activity (disintegrations per second) of ${ }^{14} \mathrm{C}$ and compare it to the activity of ${ }^{14} \mathrm{C}$ in living matter.

Sample Problem 20.3 shows how to use radiocarbon dating to determine the age of an artifact.

## Sample Problem 20.3

A wooden artifact is found to have a ${ }^{14} \mathrm{C}$ activity of 9.1 disintegrations per second. Given that the ${ }^{14} \mathrm{C}$ activity of an equal mass of fresh-cut wood has a constant value of 15.2 disintegrations per second, determine the age of the artifact. The half-life of carbon-14 is 5715 years.

Strategy The activity of a radioactive sample is proportional to the number of radioactive nuclei. Thus, we can use Equation 14.3 with activity in place of concentration:

$$
\ln \frac{{ }^{14} \mathrm{C} \text { activity in artifact }}{{ }^{14} \mathrm{C} \text { activity in fresh-cut wood }}=-k t
$$

To determine $k$, though, we must solve Equation 14.5, using the value of $t \frac{1}{2}$, for carbon-14 (5715 years) given in the problem statement.

Setup Solving Equation 14.5 for $k$ gives

$$
k=\frac{0.693}{5715 \mathrm{yr}}=1.21 \times 10^{-4} \mathrm{yr}^{-1}
$$

## Solution

$$
\begin{aligned}
\ln \frac{9.1 \text { disintegrations per second }}{15.2 \text { disintegrations per second }} & =-1.21 \times 10^{-4} \mathrm{yr}^{-1}(t) \\
t & =\frac{-0.513}{-1.21 \times 10^{-4} \mathrm{yr}^{-1}}=4240 \mathrm{yr}
\end{aligned}
$$

Therefore, the age of the artifact is $4.2 \times 10^{3}$ years.

Practice Problem A A piece of linen cloth found at an ancient burial site is found to have a ${ }^{14} \mathrm{C}$ activity of 4.8 disintegrations per minute. Determine the age of the cloth. Assume that the carbon-14 activity of an equal mass of living flax (the plant from which linen is made) is 14.8 disintegrations per minute.

GPractice Problem B What would be the ${ }^{14} \mathrm{C}$ activity in a 2500 -year-old wooden object? Assume that the ${ }^{14} \mathrm{C}$ activity of an equal mass of fresh-cut wood is 13.9 disintegrations per second.

Because some of the intermediate products in the uranium decay series have very long halflives (see Figure 20.3), this series is particularly suitable for estimating the age of rocks found on Earth and of extraterrestrial objects. The half-life for the first step $\left({ }_{92}^{238} \mathrm{U}\right.$ to $\left.{ }_{50}^{234} \mathrm{Th}\right)$ is $4.51 \times 10^{9}$ years. This is about 20,000 times the second largest value (i.e., $2.47 \times 10^{5}$ years), which is the half-life for ${ }_{92}^{234} \mathrm{U}$ to ${ }_{90}^{230} \mathrm{Th}$. As a good approximation, therefore, we can assume that the half-life for the overall process (i.e., from ${ }_{92}^{238} \mathrm{U}$ to ${ }_{82}^{206} \mathrm{~Pb}$ ) is equal to the half-life of the first step:

$$
{ }_{92}^{238} \mathrm{U} \longrightarrow{ }_{82}^{206} \mathrm{~Pb}+8_{2}^{4} \alpha+6_{-1}^{0} \beta \quad t_{1 / 2}=4.51 \times 10^{9} \mathrm{yr}
$$

In naturally occurring uranium minerals, we should and do find some lead- 206 formed by radioactive decay. Assuming that no lead was present when the mineral was formed and that the mineral has not undergone chemical changes that would allow the lead-206 isotope to be separated from the parent uranium-238, it is possible to estimate the age of the rocks from the mass ratio of ${ }_{82}^{206} \mathrm{~Pb}$ to ${ }_{92}^{238} \mathrm{U}$. According to the preceding nuclear equation, $1 \mathrm{~mol}(206 \mathrm{~g})$ of lead is formed for every $1 \mathrm{~mol}(238 \mathrm{~g})$ of uranium that undergoes complete decay. If only half a mole of uranium- 238 has undergone decay, the mass ratio ${ }^{206} \mathrm{~Pb} /{ }^{238} \mathrm{U}$ becomes

$$
\frac{206 \mathrm{~g} / 2}{238 \mathrm{~g} / 2}=0.866
$$

and the process would have taken a half-life of $4.51 \times 10^{9}$ years to complete (Figure 20.4). Ratios lower than 0.866 mean that the rocks are less than $4.51 \times 10^{9}$ years old, and higher ratios suggest a greater age. Interestingly, studies based on the uranium series, as well as other decay series, put the age of the oldest rocks and, therefore, probably the age of Earth itself, at $4.5 \times 10^{9}$, or 4.5 billion, years.

One of the most important dating techniques in geochemistry is based on the radioactive decay of potassium-40. Radioactive potassium-40 decays by several different modes, but the one relevant for dating is that of electron capture:

$$
{ }_{19}^{40} \mathrm{~K}+{ }_{-1}^{0} e \longrightarrow{ }_{18}^{40} \mathrm{Ar} \quad t_{1 / 2}=1.2 \times 10^{9} \mathrm{yr}
$$

The accumulation of gaseous argon-40 is used to gauge the age of a specimen. When a potassium-40 atom in a mineral decays, argon- 40 is trapped in the lattice of the mineral and can escape only if the material is melted. Melting, therefore, is the procedure for analyzing a mineral sample in the laboratory. The amount of argon-40 present can be conveniently measured with a mass spectrometer (see page 48). Knowing the ratio of argon-40 to potassium-40 in the mineral and the half-life of decay makes it possible to establish the ages of rocks ranging from millions to billions of years old.

Sample Problem 20.4 shows how to use radioisotopes to determine the age of a specimen.

## Sample Problem 20.4

A rock is found to contain 5.51 mg of ${ }^{238} \mathrm{U}$ and 1.63 mg of ${ }^{206} \mathrm{~Pb}$. Determine the age of the rock $\left(t_{1 / 2}\right.$ of $\left.{ }^{238} \mathrm{U}=4.51 \times 10^{9} \mathrm{yr}\right)$.

Figure 20.4 After one half-life, half of the original uranium- 238 has been converted to lead-206.

Strategy We must first determine what mass of ${ }^{238} \mathrm{U}$ decayed to produce the measured amount of ${ }^{206} \mathrm{~Pb}$ and then use it to determine the original mass of ${ }^{238} \mathrm{U}$. Knowing the initial and final masses of ${ }^{238} \mathrm{U}$, we can use Equation 14.3 to solve for $t$.

## Setup

$$
1.63 \mathrm{mg}{ }^{206} \mathrm{~Pb} \times \frac{238 \mathrm{mg}{ }^{238} \mathrm{U}}{206 \mathrm{mg}{ }^{206} \mathrm{~Pb}}=1.88 \mathrm{mg}{ }^{238} \mathrm{U}
$$

Thus, the original mass of ${ }^{238} \mathrm{U}$ was $5.51 \mathrm{mg}+1.88 \mathrm{mg}=7.39 \mathrm{mg}$. The rate constant, $k$, is determined using Equation 14.5 and $t \frac{1}{2}$ for ${ }^{238} \mathrm{U}$ :

$$
k=\frac{0.693}{4.51 \times 10^{9}}=1.54 \times 10^{-10} \mathrm{yr}^{-1}
$$

## Solution

Think About It This is slightly more complicated than the radiocarbon problem. We cannot use the measured masses of the two isotopes in Equation 14.3 because they are masses of different elements.

$$
\begin{aligned}
\ln \frac{5.51 \mathrm{mg}}{7.39 \mathrm{mg}} & =-1.54 \times 10^{-10} \mathrm{yr}^{-1}(t) \\
t & =\frac{-0.294}{-1.54 \times 10^{-10} \mathrm{yr}^{-1}}=1.91 \times 10^{9} \mathrm{yr}
\end{aligned}
$$

The rock is 1.9 billion years old.

Practice Problem A Determine the age of a rock that contains 12.75 mg of ${ }^{238} \mathrm{U}$ and 1.19 mg of ${ }^{206} \mathrm{~Pb}$.
EPPractice Problem B How much ${ }^{206} \mathrm{~Pb}$ will be in a rock sample that is $1.3 \times 10^{8}$ years old and that contains 3.25 mg of ${ }^{238} \mathrm{U}$ ?

## Checkpoint 20.3 Natural Radioactivity

20.3.1 Determine the age of a rock found to contain $4.31 \mathrm{mg}^{238} \mathrm{U}$ and 2.47 mg of ${ }^{206} \mathrm{~Pb}$.
a) $7.19 \times 10^{9}$ years
b) $3.62 \times 10^{9}$ years
c) $1.18 \times 10^{8}$ years
d) $3.30 \times 10^{9}$ years
e) $1.78 \times 10^{8}$ years
20.3.2 Determine the ${ }^{14} \mathrm{C}$ activity in disintegrations per second (dps) of a wooden artifact that is 23,000 years old. (Assume that freshcut wood of equal mass has an activity of 15.2 dps .)
a) 16.3 dps
b) 15.2 dps
c) 0.935 dps
d) 11.5 dps
e) 4.31 dps
20.3.3 Iron-59 decays to cobalt via beta emission with a half-life of 45.1 days. From the diagram, determine how many half-lives have elapsed since the sample was pure iron-59.
a) 2
b) 3
c) 0.25
d) 8
e) 14

20.3.4 Isotope X decays to isotope Y with a half-life of 45 days. Which diagram most closely represents the sample of X after 105 days?

### 20.4 Nuclear Transmutation

The scope of nuclear chemistry would be rather narrow if study were limited to natural radioactive elements. An experiment performed by Rutherford in 1919, however, suggested the possibility of producing radioactivity artificially. When he bombarded a sample of nitrogen with $\alpha$ particles, the following reaction took place:

$$
{ }_{7}^{14} \mathrm{~N}+{ }_{2}^{4} \alpha \longrightarrow{ }_{8}^{17} \mathrm{O}+{ }_{1}^{1} \mathrm{p}
$$

An oxygen-17 isotope was produced with the emission of a proton. This reaction demonstrated for the first time the feasibility of converting one element into another, by the process of nuclear transmutation. Nuclear transmutation differs from radioactive decay in that transmutation is brought about by the collision of two particles.

The preceding reaction can be abbreviated as ${ }_{7}^{14} \mathrm{~N}(\alpha, \mathrm{p}){ }_{8}^{17} \mathrm{O}$. In the parentheses the bombarding particle is written first, followed by the emitted particle.

Sample Problem 20.5 shows how to use this notation to represent nuclear transmutations.

## Sample Problem 20.5

Write the balanced nuclear equation for the reaction represented by ${ }_{26}^{56} \mathrm{Fe}(\mathrm{d}, \alpha){ }_{25}^{54} \mathrm{Mn}$, where d represents a deuterium nucleus.

Strategy The species written first is a reactant. The species written last is a product. Within the parentheses, the bombarding particle (a reactant) is written first, followed by the emitted particle (a product).

Setup The bombarding and emitted particles are represented by ${ }_{1}^{2} \mathrm{H}$ and ${ }_{2}^{4} \alpha$, respectively.
Solution

$$
{ }_{26}^{56} \mathrm{Fe}+{ }_{1}^{2} \mathrm{H} \longrightarrow{ }_{25}^{54} \mathrm{Mn}+{ }_{2}^{4} \alpha
$$

Practice Problem A Write an equation for the process represented by ${ }_{46}^{106} \mathrm{Pd}(\alpha, \mathrm{p}){ }_{47}^{109} \mathrm{Ag}$.
GIPractice Problem B Write the abbreviated form of the following process:

$$
{ }_{17}^{33} \mathrm{Cl}+{ }_{0}^{1} \mathrm{n} \longrightarrow{ }_{15}^{31} \mathrm{P}+{ }_{2}^{3} \mathrm{He}
$$

Particle accelerators made it possible to synthesize the so-called transuranium elements, elements with atomic numbers greater than 92 . Neptunium $(Z=93)$ was first prepared in 1940. Since then, 24 other transuranium elements have been synthesized. All isotopes of these elements are radioactive. Table 20.3 lists the transuranium elements that have been reported and some of the reactions by which they have been produced.

Although light elements are generally not radioactive, they can be made so by bombarding their nuclei with appropriate particles. As we saw in the previous section, the radioactive carbon14 isotope can be prepared by bombarding nitrogen-14 with neutrons. Tritium $\left({ }_{1}^{3} \mathrm{H}\right)$ is prepared according to the following bombardment:

$$
{ }_{3}^{6} \mathrm{Li}+{ }_{0}^{1} \mathrm{n} \longrightarrow{ }_{1}^{3} \mathrm{H}+{ }_{2}^{4} \alpha
$$

Tritium decays with the emission of $\beta$ particles:

$$
{ }_{1}^{3} \mathrm{H} \longrightarrow{ }_{2}^{3} \mathrm{He}+{ }_{-1}^{0} \beta \quad t_{1 / 2}=12.5 \mathrm{yr}
$$

Many synthetic isotopes are prepared by using neutrons as projectiles. This approach is particularly convenient because neutrons carry no charges and therefore are not repelled by the targets-the nuclei. In contrast, when the projectiles are positively charged particles (e.g., protons or $\alpha$ particles), they must have considerable kinetic energy to overcome the electrostatic repulsion between themselves and the target nuclei. The synthesis of phosphorus from aluminum is one example:

$$
{ }_{13}^{27} \mathrm{Al}+{ }_{2}^{4} \alpha \longrightarrow{ }_{15}^{30} \mathrm{P}+{ }_{0}^{1} \mathrm{n}
$$

Think About It Check your work by summing the mass numbers and the atomic numbers on both sides of the equation.

TABLE 20.3
Preparation of the Transuranium Elements

| Atomic Number | Name | Symbol | Preparation* |
| :---: | :---: | :---: | :---: |
| 93 | Neptunium | Np | ${ }_{92}^{238} \mathrm{U}+{ }_{0}^{1} \mathrm{n} \longrightarrow{ }^{239} \mathrm{~Np}+{ }_{-1}^{0} \beta$ |

*Some of the transuranium elements have been prepared by more than one method.

Figure 20.5 Schematic diagram of a cyclotron particle accelerator. The particle (an ion) to be accelerated starts at the center and is forced to move in a spiral path through the influence of electric and magnetic fields until it emerges at a high velocity. The magnetic fields are perpendicular to the plane of the dees (so-called because of their shape), which are hollow and serve as electrodes.

A particle accelerator uses electric and magnetic fields to increase the kinetic energy of charged species so that a reaction will occur (Figure 20.5). Alternating the polarity (i.e., + and - ) on specially constructed plates causes the particles to accelerate along a spiral path. When they have the energy necessary to initiate the desired nuclear reaction, they are guided out of the accelerator into a collision with a target substance.

Various designs have been developed for particle accelerators, one of which accelerates particles along a linear path of about 3 km (Figure 20.6). It is now possible to accelerate particles to a speed well above 90 percent of the speed of light. (According to Einstein's theory of relativity, it is impossible for a particle to move at the speed of light. The only exception is the photon, which has a zero rest mass.) The extremely energetic particles produced in accelerators are employed by physicists to smash atomic nuclei to fragments. Studying the debris from such disintegrations provides valuable information about nuclear structure and binding forces.

## Checkpoint 20.4 Nuclear Transmutation

20.4.1 Identify the balanced nuclear equation for the reaction represented by ${ }_{42}^{98} \mathrm{Mo}(\mathrm{d}, \mathrm{n}){ }_{43}^{99} \mathrm{Tc}$.
a) ${ }_{42}^{98} \mathrm{Mo}+{ }_{1}^{1} \mathrm{H} \longrightarrow{ }_{43}^{99} \mathrm{Tc}$
b) ${ }_{42}^{98} \mathrm{Mo} \longrightarrow{ }_{43}^{99} \mathrm{Tc}+{ }_{1}^{2} \mathrm{H}+{ }_{0}^{1} \mathrm{n}$
c) ${ }_{42}^{98} \mathrm{Mo}+{ }_{0}^{1} \mathrm{n} \longrightarrow{ }_{43}^{99} \mathrm{Tc}+{ }_{1}^{2} \mathrm{H}$
d) ${ }_{42}^{98} \mathrm{Mo}+{ }_{1}^{2} \mathrm{H}+{ }_{0}^{1} \mathrm{n} \longrightarrow{ }_{43}^{99} \mathrm{Tc}$
e) ${ }_{42}^{98} \mathrm{Mo}+{ }_{1}^{2} \mathrm{H} \longrightarrow{ }_{43}^{99} \mathrm{Tc}+{ }_{0}^{1} \mathrm{n}$
20.4.2 Identify the correct abbreviated form of the equation

$$
{ }_{53}^{125} \mathrm{I}+{ }_{-1}^{0} \beta \longrightarrow{ }_{52}^{125} \mathrm{Te}+\gamma
$$

a) ${ }_{53}^{125} \mathrm{I}(\gamma, \beta){ }_{52}^{125} \mathrm{Te}$
b) ${ }_{53}^{125}(\beta, \gamma){ }_{52}^{125} \mathrm{Te}$
c) ${ }_{52}^{125} \mathrm{Te}(\beta, \gamma){ }_{53}^{125} \mathrm{I}$
d) ${ }_{52}^{125} \mathrm{I}(\beta, \gamma){ }_{53}^{125} \mathrm{Te}$
e) ${ }_{52}^{125} \mathrm{I}(\gamma, \beta){ }_{53}^{125} \mathrm{Te}$

### 20.5 Nuclear Fission

Nuclear fission is the process in which a heavy nucleus (mass number $>200$ ) divides to form smaller nuclei of intermediate mass and one or more neutrons. Because the heavy nucleus is less stable than its products (see Figure 20.2), this process releases a large amount of energy.

The first nuclear fission reaction to be studied was that of uranium- 235 bombarded with slow neutrons, whose speed is comparable to that of air molecules at room temperature. Under these conditions, uranium-235 undergoes fission, as shown in Figure 20.7. Actually, this reaction is very complex: more than 30 different elements have been found among the fission products (Figure 20.8). A representative reaction is

$$
{ }_{92}^{235} \mathrm{U}+{ }_{0}^{1} \mathrm{n} \longrightarrow{ }_{38}^{90} \mathrm{Sr}+{ }_{54}^{143} \mathrm{Xe}+3{ }_{0}^{1} \mathrm{n}
$$

Media Player/MPEG Animation: Figure 20.7, Nuclear Fission and Fusion, pp. 874-875.

Figure 20.7
Nuclear Fission and Fusion

The ${ }^{2} \mathrm{H}$ and ${ }^{3} \mathrm{H}$ nuclei have the following nuclear binding energies per nucleon:

$$
\begin{aligned}
& { }^{2} \mathrm{H}: 0.185 \times 10^{-12} \mathrm{~J} \\
& { }^{3} \mathrm{H}: 0.451 \times 10^{-12} \mathrm{~J}
\end{aligned}
$$

At very high temperatures, the ${ }^{2} \mathrm{H}$ and ${ }^{3} \mathrm{H}$ nuclei undergo fusion to produce a ${ }^{4} \mathrm{He}$ nucleus and a neutron. The ${ }^{4} \mathrm{He}$ nucleus has a significantly higher NBE per nucleon: $1.13 \times 10^{-12} \mathrm{~J}$

## What's the point?

Large nuclei, such as ${ }^{235} \mathrm{U}$, can achieve greater nuclear stability by splitting into smaller nuclei with greater NBE per nucleon. Small nuclei achieve stability by undergoing fusion to produce a larger nucleus with a greater NBE per nucleon. Note that different scales are used to show the change in NBE per nucleon for the two processes. There is a much greater change in NBE per nucleon in the fusion process than in the fission process. As with chemical reactions, nuclear reactions are favored when the products are more stable than the reactants.

Figure 20.8 Relative yields of the products resulting from the fission of ${ }^{235} \mathrm{U}$ as a function of mass number.

## TABLE 20.4

Nuclear
Binding
Energies of
${ }^{235} \mathrm{U}$ and
Its Fission Products

|  | Nuclear |
| :---: | :---: |
|  | Binding Energy |

Although many heavy nuclei can be made to undergo fission, only the fission of naturally occurring uranium- 235 and of the artificial isotope plutonium- 239 has any practical importance. Table 20.4 lists the nuclear binding energies of uranium- 235 and its fission products. As the table shows, the binding energy per nucleon for uranium- 235 is less than the sum of the binding energies for strontium- 90 and xenon-143. Therefore, when a uranium- 235 nucleus is split into two smaller nuclei, a certain amount of energy is released.

Let's estimate the magnitude of this energy. The difference between the binding energies of the reactants and products is $\left(1.23 \times 10^{-10}+1.92 \times 10^{-10}\right) \mathrm{J}-\left(2.82 \times 10^{-10}\right) \mathrm{J}$, or $3.3 \times$ $10^{-11} \mathrm{~J}$ per uranium-235 nucleus. For 1 mole of uranium-235, the energy released would be ( $3.3 \times$ $\left.10^{-11}\right)\left(6.02 \times 10^{23}\right)$, or $2.0 \times 10^{13} \mathrm{~J}$. This is an extremely exothermic reaction, considering that the heat of combustion of 1 ton of coal is only about $5 \times 10^{7} \mathrm{~J}$.

The significant feature of uranium- 235 fission is not just the enormous amount of energy released, but the fact that more neutrons are produced than are originally captured in the process. This property makes possible a nuclear chain reaction, which is a self-sustaining sequence of nuclear fission reactions. The neutrons generated during the initial stages of fission can induce fission in other uranium- 235 nuclei, which in turn produce more neutrons, and so on. In less than a second, the reaction can become uncontrollable, liberating a tremendous amount of heat to the surroundings. Figure 20.9 shows two types of fission reactions. For a chain reaction to occur, enough uranium-235 must be present in the sample to capture the neutrons. Otherwise, many of the neutrons will escape from the sample and the chain reaction will not occur. In this situation the mass of the sample is said to be subcritical. Figure 20.9 shows what happens when the amount of the fissionable material is equal to or greater than the critical mass, the minimum mass of fissionable material required to generate a self-sustaining nuclear chain reaction. In this case, most of the neutrons will be captured by uranium- 235 nuclei, and a chain reaction will occur.

The first application of nuclear fission was in the development of the atomic bomb. How is such a bomb made and detonated? The crucial factor in the bomb's design is the determination of the critical mass for the bomb. A small atomic bomb is equivalent to 20,000 tons of TNT (trinitrotoluene). Because 1 ton of TNT releases about $4 \times 10^{9} \mathrm{~J}$ of energy, 20,000 tons would produce $8 \times 10^{13} \mathrm{~J}$. Recall that 1 mole, or 235 g , of uranium- 235 liberates $2.0 \times 10^{13} \mathrm{~J}$ of energy when it undergoes fission. Thus, the mass of the isotope present in a small bomb must be at least

$$
(235 \mathrm{~g})\left(\frac{8 \times 10^{13} \mathrm{~J}}{2.0 \times 10^{13} \mathrm{~J}}\right) \approx 1 \mathrm{~kg}
$$

An atomic bomb is never assembled with the critical mass already present. Instead, the critical mass is formed by using a conventional explosive, such as TNT, to force the fissionable sections together, as shown in Figure 20.10. Neutrons from a source at the center of the device trigger the nuclear chain reaction. Uranium- 235 was the fissionable material in the bomb dropped

Figure 20.9 If a critical mass is present, many of the neutrons emitted during the fission process will be captured by other ${ }^{235} \mathrm{U}$ nuclei and a chain reaction will occur.
on Hiroshima, Japan, on August 6, 1945. Plutonium-239 was used in the bomb exploded over Nagasaki 3 days later. The fission reactions generated were similar in these two cases, as was the extent of the destruction.

A peaceful but controversial application of nuclear fission is the generation of electricity using heat from a controlled chain reaction in a nuclear reactor. Currently, nuclear reactors provide about 20 percent of the electric energy in the United States. This is a small but by no means negligible contribution to the nation's energy production. Several different types of nuclear reactors are in operation; we will briefly discuss the main features of three of them, along with their advantages and disadvantages.

Most of the nuclear reactors in the United States are light water reactors. Figure 20.11 is a schematic diagram of such a reactor, and Figure 20.12 shows the refueling process in the core of a nuclear reactor.

Figure 20.11 Schematic diagram of a nuclear fission reactor. The fission process is controlled by cadmium or boron rods. The heat generated by the process is used to produce steam for the generation of electricity via a heat exchange system.

Figure 20.12 Refueling the core of a nuclear reactor.

Figure 20.10 Schematic
diagram of an atomic bomb. The TNT explosives are set off first. The explosion forces the sections of fissionable material together to form an amount considerably larger than the critical mass.

Figure 20.13 Uranium oxide $\left(\mathrm{U}_{3} \mathrm{O}_{8}\right)$.

Figure 20.14 Radioactive plutonium oxide $\left(\mathrm{PuO}_{2}\right)$ has a red glow.

An important aspect of the fission process is the speed of the neutrons. Slow neutrons split uranium- 235 nuclei more efficiently than do fast ones. Because fission reactions are highly exothermic, the neutrons produced usually move at high velocities. For greater efficiency, they must be slowed down before they can be used to induce nuclear disintegration. To accomplish this goal, scientists use moderators, which are substances that can reduce the kinetic energy of neutrons. A good moderator must satisfy several requirements: It should be nontoxic and inexpensive (as very large quantities of it are necessary), and it should resist conversion into a radioactive substance by neutron bombardment. Furthermore, it is advantageous for the moderator to be a fluid so that it can also be used as a coolant. No substance fulfills all these requirements, although water comes closer than many others that have been considered. Nuclear reactors that use light water $\left(\mathrm{H}_{2} \mathrm{O}\right)$ as a moderator are called light water reactors because ${ }_{1}^{1} \mathrm{H}$ is the lightest isotope of the element hydrogen.

The nuclear fuel consists of uranium, usually in the form of its oxide, $\mathrm{U}_{3} \mathrm{O}_{8}$ (Figure 20.13). Naturally occurring uranium contains about 0.7 percent of the uranium- 235 isotope, which is too low a concentration to sustain a small-scale chain reaction. For effective operation of a light water reactor, uranium -235 must be enriched to a concentration of 3 or 4 percent. In principle, the main difference between an atomic bomb and a nuclear reactor is that the chain reaction that takes place in a nuclear reactor is kept under control at all times. The factor limiting the rate of the reaction is the number of neutrons present. This can be controlled by lowering cadmium or boron control rods between the fuel elements. These rods capture neutrons according to the equations

$$
\begin{aligned}
{ }_{48}^{113} \mathrm{Cd}+{ }_{0}^{1} \mathrm{n} \longrightarrow{ }_{48}^{114} \mathrm{Cd}+\gamma \\
{ }_{5}^{10} \mathrm{~B}+{ }_{0}^{1} \mathrm{n} \longrightarrow{ }_{3}^{7} \mathrm{Li}+{ }_{2}^{4} \alpha
\end{aligned}
$$

where $\gamma$ denotes gamma rays. Without the control rods, the reactor core would melt from the heat generated and release radioactive materials into the environment. Nuclear reactors have rather elaborate cooling systems that absorb the heat given off by the nuclear reaction and transfer it outside the reactor core, where it is used to produce enough steam to drive an electric generator. In this respect, a nuclear power plant is similar to a conventional power plant that burns fossil fuel. In both cases, large quantities of cooling water are needed to condense steam for reuse. Thus, most nuclear power plants are built near a river or a lake. Unfortunately, this method of cooling causes thermal pollution.

Another type of nuclear reactor uses $\mathrm{D}_{2} \mathrm{O}$, or heavy water, as the moderator, rather than $\mathrm{H}_{2} \mathrm{O}$. Deuterium absorbs neutrons much less efficiently than does ordinary hydrogen. Because fewer neutrons are absorbed, the reactor is more efficient and does not require enriched uranium. More neutrons leak out of the reactor, too, though this is not a serious disadvantage.

The main advantage of a heavy water reactor is that it eliminates the need for building expensive uranium enrichment facilities. However, $\mathrm{D}_{2} \mathrm{O}$ must be prepared by either fractional distillation or electrolysis of ordinary water, which can be very expensive considering the amount of water used in a nuclear reactor. In countries where hydroelectric power is abundant, the cost of producing $\mathrm{D}_{2} \mathrm{O}$ by electrolysis can be reasonably low. At present, Canada is the only nation successfully using heavy water nuclear reactors. The fact that no enriched uranium is required in a heavy water reactor allows a country to enjoy the benefits of nuclear power without undertaking work that is closely associated with weapons technology.

A breeder reactor uses uranium fuel, but unlike a conventional nuclear reactor, it produces more fissionable materials than it uses.

When uranium-238 is bombarded with fast neutrons, the following reactions take place:

$$
\begin{aligned}
{ }_{92}^{238} \mathrm{U}+{ }_{0}^{1} \mathrm{n} & \longrightarrow{ }_{92}^{239} \mathrm{U} \\
{ }_{92}^{239} \mathrm{U} & \longrightarrow{ }_{93}^{239} \mathrm{~Np}+{ }_{-1}^{0} \beta
\end{aligned} \begin{aligned}
& t_{1 / 2}=23.4 \mathrm{~min} \\
& { }_{93}^{239} \mathrm{~Np}
\end{aligned} \longrightarrow{ }_{94}^{239} \mathrm{Pu}+{ }_{-1}^{0} \beta \quad t_{1 / 2}=2.35 \text { days } .
$$

In this manner, the nonfissionable uranium-238 is transmuted into the fissionable isotope plutonium-239 (Figure 20.14).

In a typical breeder reactor, nuclear fuel containing uranium- 235 or plutonium-239 is mixed with uranium-238 so that breeding takes place within the core. For every uranium-235 (or plutonium-239) nucleus undergoing fission, more than one neutron is captured by uranium-238 to generate plutonium-239. Thus, the stockpile of fissionable material can be steadily increased as the starting nuclear fuels are consumed. It takes about 7 to 10 years to regenerate the sizable amount of material needed to refuel the original reactor and to fuel another reactor of comparable size. This interval is called the doubling time.

Another fertile isotope is ${ }_{90}^{232} \mathrm{Th}$. Upon capturing slow neutrons, thorium is transmuted to uranium-233, which, like uranium-235, is a fissionable isotope:

$$
\begin{aligned}
{ }_{90}^{232} \mathrm{Th}+{ }_{0}^{1} \mathrm{n} & \longrightarrow{ }_{90}^{233} \mathrm{Th} \\
{ }_{90}^{233} \mathrm{Th} & \longrightarrow{ }_{91}^{233} \mathrm{~Pa}+{ }_{-1}^{0} \beta
\end{aligned} \begin{aligned}
& t / 1 / 2=22 \mathrm{~min} \\
& { }_{91}^{23} \mathrm{~Pa}
\end{aligned} \longrightarrow{ }_{92}^{233} \mathrm{U}+{ }_{-1}^{0} \beta \quad \begin{aligned}
& 1 / 2
\end{aligned}=27.4 \text { days } .
$$

Uranium-233 ( $t_{1 / 2}=1.6 \times 10^{5}$ years) is stable enough for long-term storage.
Although the amounts of uranium-238 and thorium-232 in Earth's crust are relatively plentiful ( 4 ppm and 12 ppm by mass, respectively), the development of breeder reactors has been very slow. To date, the United States does not have a single operating breeder reactor, and only a few have been built in other countries, such as France and Russia. One problem is economics; breeder reactors are more expensive to build than conventional reactors. There are also more technical difficulties associated with the construction of such reactors. As a result, the future of breeder reactors, in the United States at least, is rather uncertain.

Many people, including environmentalists, regard nuclear fission as a highly undesirable method of energy production. Many fission products such as strontium- 90 are dangerous radioactive isotopes with long half-lives. Plutonium-239, used as a nuclear fuel and produced in breeder reactors, is one of the most toxic substances known. It is an $\alpha$-emitter with a half-life of 24,400 years.

Accidents, too, present many dangers. An accident at the Three Mile Island reactor in Pennsylvania in 1979 first brought the potential hazards of nuclear plants to public attention. In this instance, very little radiation escaped the reactor, but the plant remained closed for more than a decade while repairs were made and safety issues addressed. Only a few years later, on April 26, 1986, a reactor at the Chernobyl nuclear plant in Ukraine surged out of control. The fire and explosion that followed released much radioactive material into the environment. People working near the plant died within weeks as a result of the exposure to the intense radiation. The long-term effect of the radioactive fallout from this incident has not yet been clearly assessed, although agriculture and dairy farming were affected by the fallout. The number of potential cancer deaths attributable to the radiation contamination is estimated to be between a few thousand and more than 100,000.

In addition to the risk of accidents, the problem of radioactive waste disposal has not been satisfactorily resolved even for safely operated nuclear plants. Many suggestions have been made as to where to store or dispose of nuclear waste, including burial underground, burial beneath the ocean floor, and storage in deep geologic formations. But none of these sites has proved absolutely safe in the long run. Leakage of radioactive wastes into underground water, for example, can endanger nearby communities. The ideal disposal site would seem to be the sun, where a bit more radiation would make little difference, but this kind of operation requires space technology that is 100 percent reliable.

Because of the hazards, the future of nuclear reactors is clouded. What was once hailed as the ultimate solution to our energy needs in the twenty-first century is now being debated and questioned by both the scientific community and the general public. It seems likely that the controversy will continue for some time.

### 20.6 Nuclear Fusion

In contrast to the nuclear fission process, nuclear fusion, the combining of small nuclei into larger ones, is largely exempt from the waste disposal problem.

Figure 20.2 showed that for the lightest elements, nuclear stability increases with increasing mass number. This behavior suggests that if two light nuclei combine or fuse together to form a larger, more stable nucleus, an appreciable amount of energy will be released in the process. This is the basis for ongoing research into the harnessing of nuclear fusion for the production of energy.

Nuclear fusion occurs constantly in the sun. The sun is made up mostly of hydrogen and helium. In its interior, where temperatures reach about 15 million degrees Celsius, the following fusion reactions are believed to take place:

$$
\begin{aligned}
&{ }_{1}^{1} \mathrm{H}+{ }_{1}^{2} \mathrm{H} \longrightarrow{ }_{2}^{3} \mathrm{He} \\
&{ }_{2}^{3} \mathrm{He}+{ }_{2}^{3} \mathrm{He} \longrightarrow{ }_{2}^{4} \mathrm{He}+2{ }_{1}^{1} \mathrm{H} \\
&{ }_{1}^{1} \mathrm{H}+{ }_{1}^{1} \mathrm{H} \longrightarrow{ }_{1}^{2} \mathrm{H}+{ }_{-1}^{0} \beta
\end{aligned}
$$

Because fusion reactions take place only at very high temperatures, they are often called thermonuclear reactions.

A major concern in choosing the proper nuclear fusion process for energy production is the temperature necessary to carry out the process. Some promising reactions are listed here:

| Reaction | Energy Released |
| :--- | :--- |
| ${ }_{1}^{2} \mathrm{H}+{ }_{1}^{2} \mathrm{H} \longrightarrow{ }_{1}^{3} \mathrm{H}+{ }_{1}^{1} \mathrm{H}$ | $6.3 \times 10^{-13} \mathrm{~J}$ |
| ${ }_{1}^{2} \mathrm{H}+{ }_{1}^{3} \mathrm{H} \longrightarrow{ }_{2}^{3} \mathrm{He}+2{ }_{0}^{1} \mathrm{n}$ | $2.8 \times 10^{-12} \mathrm{~J}$ |
| ${ }_{3}^{6} \mathrm{Li}+{ }_{1}^{2} \mathrm{H} \longrightarrow{ }_{2}^{4} \mathrm{He}$ | $3.6 \times 10^{-12} \mathrm{~J}$ |

These reactions must take place at extremely high temperatures, on the order of 100 million degrees Celsius, to overcome the repulsive forces between the nuclei. The first reaction is particularly attractive because the world's supply of deuterium is virtually inexhaustible. The total volume of water on Earth is about $1.5 \times 10^{21} \mathrm{~L}$. Because the natural abundance of deuterium is 0.015 percent, the total amount of deuterium present is roughly $4.5 \times 10^{21} \mathrm{~g}$, or $5.0 \times 10^{15}$ tons. Although it is expensive to prepare deuterium, the cost is minimal compared to the value of the energy released by the reaction.

In contrast to the fission process, nuclear fusion looks like a very promising energy source, at least on paper. Although thermal pollution would be a problem, fusion has the following advantages: (1) the fuels are cheap and almost inexhaustible and (2) the process produces little radioactive waste. If a fusion machine were turned off, it would shut down completely and instantly, without any danger of a meltdown.

If nuclear fusion is so great, why isn't there even one fusion reactor producing energy? Although we possess the scientific knowledge to design such a reactor, the technical difficulties have not yet been solved. The basic problem is finding a way to hold the nuclei together long enough, and at the appropriate temperature, for fusion to occur. At temperatures of about 100 million degrees Celsius, molecules cannot exist, and most or all of the atoms are stripped of their electrons. This state of matter, a gaseous mixture of positive ions and electrons, is called plasma. The problem of containing this plasma is a formidable one. No solid container can exist at such temperatures, unless the amount of plasma is small, but then the solid surface would immediately cool the sample and quench the fusion reaction. One approach to solving this problem is to use magnetic confinement. Because plasma consists of charged particles moving at high speeds, a magnetic field will exert a force on it. As Figure 20.15 shows, the plasma moves through a doughnut-shaped tunnel, confined by a complex magnetic field. Thus, the plasma never comes in contact with the walls of the container.

Another promising design employs high-power lasers to initiate the fusion reaction. In test runs, a number of laser beams transfer energy to a small fuel pellet, heating it and causing it to implode - that is, to collapse inward from all sides and compress into a small volume (Figure 20.16). Consequently, fusion occurs. Like the magnetic confinement approach, laser fusion presents a number of technical difficulties that still need to be overcome before it can be put to practical use on a large scale.

The technical problems inherent in the design of a nuclear fusion reactor do not affect the production of a hydrogen bomb, also called a thermonuclear bomb. In this case, the objective is all power and no control. Hydrogen bombs do not contain gaseous hydrogen or gaseous deuterium; they contain solid lithium deuteride (LiD), which can be packed very tightly. The detonation of a hydrogen bomb occurs in two stages-first a fission reaction and then a fusion reaction. The required temperature for fusion is achieved with an atomic bomb. Immediately after the

Figure 20.15 A magnetic plasma confinement design called a tokamak.

atomic bomb explodes, the following fusion reactions occur, releasing vast amounts of energy (Figure 20.17):

$$
\begin{aligned}
& { }_{3}^{6} \mathrm{Li}+{ }_{1}^{2} \mathrm{H} \longrightarrow 2{ }_{2}^{4} \alpha \\
& { }_{1}^{2} \mathrm{H}+{ }_{1}^{2} \mathrm{H} \longrightarrow{ }_{1}^{3} \mathrm{H}+{ }_{1}^{1} \mathrm{H}
\end{aligned}
$$

There is no critical mass in a fusion bomb, and the force of the explosion is limited only by the quantity of reactants present. Thermonuclear bombs are described as being "cleaner" than atomic bombs because the only radioactive isotopes they produce are tritium, which is a weak $\beta$-particle emitter $\left(t_{1 / 2}=12.5\right.$ years $)$, and the products of the fission starter. Their damaging effects on the environment can be aggravated, however, by incorporating in the construction some nonfissionable material such as cobalt. Upon bombardment by neutrons, cobalt-59 is converted to cobalt-60, which is a very strong $\gamma$-ray emitter with a half-life of 5.2 years. The presence of radioactive cobalt isotopes in the debris or fallout from a thermonuclear explosion would be fatal to those who survived the initial blast.

### 20.7 Uses of Isotopes

Radioactive and stable isotopes alike have many applications in science and medicine. We have previously described the use of isotopes in the study of reaction mechanisms [ 14 Section 14.5] and in dating artifacts (page 868). In this section we will discuss a few more examples.

## Chemical Analysis

The formula of the thiosulfate ion is $\mathrm{S}_{2} \mathrm{O}_{3}^{2-}$. For some years, chemists were uncertain as to whether the two sulfur atoms occupied equivalent positions in the ion. The thiosulfate ion is prepared by treating the sulfite ion with elemental sulfur:

$$
\mathrm{SO}_{3}^{2-}(a q)+\mathrm{S}(s) \longrightarrow \mathrm{S}_{2} \mathrm{O}_{3}^{2-}(a q)
$$

When thiosulfate is treated with dilute acid, the reaction is reversed. The sulfite ion is re-formed, and elemental sulfur precipitates:

$$
\mathrm{S}_{2} \mathrm{O}_{3}^{2-}(a q) \xrightarrow{\mathrm{H}^{+}} \mathrm{SO}_{3}^{2-}(a q)+\mathrm{S}(s)
$$

If this sequence is started with elemental sulfur enriched with the radioactive sulfur- 35 isotope, the isotope acts as a "label" for S atoms. All the labels are found in the sulfur precipitate; none of them appears in the final sulfite ions. As a result, the two atoms of sulfur in $\mathrm{S}_{2} \mathrm{O}_{3}^{2-}$ are not structurally equivalent, as would be the case if the structure were

$$
[: \ddot{O}-\ddot{S}-\ddot{O}-\ddot{S}-\ddot{O}:]^{2-}
$$

If the sulfur atoms were equivalent, the radioactive isotope would be present in both the elemental sulfur precipitate and the sulfite ion. Based on spectroscopic studies, we now know that the structure of the thiosulfate ion is

The study of photosynthesis is also rich with isotope applications. The overall photosynthesis reaction can be represented as

$$
6 \mathrm{CO}_{2}+6 \mathrm{H}_{2} \mathrm{O} \longrightarrow \mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}+6 \mathrm{O}_{2}
$$

In Section 14.5 we learned that the ${ }^{18} \mathrm{O}$ isotope was used to determine the source of $\mathrm{O}_{2}$. The radioactive ${ }^{14} \mathrm{C}$ isotope helped to determine the path of carbon in photosynthesis. Starting with ${ }^{14} \mathrm{CO}_{2}$, it was possible to isolate the intermediate products during photosynthesis and measure the amount of radioactivity of each carbon-containing compound. In this manner the path from $\mathrm{CO}_{2}$ through various intermediate compounds to carbohydrate could be clearly charted. Isotopes, especially radioactive isotopes that are used to trace the path of the atoms of an element in a chemical or biological process, are called tracers.

Figure 20.16 This small-scale fusion reaction was carried out at the Lawrence Livermore National Laboratory using one of the world's most powerful lasers, Nova.

Multimedia
Nuclear chemistry—nuclear medical techniques.

Figure $20.18{ }^{123}$ I image of a normal brain (top) and the brain of an Alzheimer's victim (bottom).

## Isotopes in Medicine

Tracers are also used for diagnosis in medicine. Sodium-24 (a $\beta$-emitter with a half-life of 14.8 h ) injected into the bloodstream as a salt solution can be monitored to trace the flow of blood and detect possible constrictions or obstructions in the circulatory system. Iodine-131 (a $\beta$-emitter with a half-life of 8 days) has been used to test the activity of the thyroid gland. A malfunctioning thyroid can be detected by giving the patient a drink of a solution containing a known amount of $\mathrm{Na}^{131} \mathrm{I}$ and measuring the radioactivity just above the thyroid to see if the iodine is absorbed at the normal rate. Another radioactive isotope of iodine, iodine-123 (a $\gamma$-ray emitter), is used to image the brain (Figure 20.18). In each of these cases, though, the amount of radioisotope used must be kept small to prevent the patient from suffering permanent damage from the high-energy radiation.

Technetium, the first artificially prepared element, is one of the most useful elements in nuclear medicine. Although technetium is a transition metal, all its isotopes are radioactive. In the laboratory it is prepared by the nuclear reactions

$$
\begin{aligned}
& { }_{42}^{98} \mathrm{Mo}+{ }_{0}^{1} \mathrm{n} \longrightarrow{ }_{42}^{99} \mathrm{Mo} \\
& { }_{42}^{99} \mathrm{Mo} \longrightarrow{ }_{43}^{99 \mathrm{~m}} \mathrm{Tc}+{ }_{-1}^{0} \beta
\end{aligned}
$$

where the superscript " $m$ " denotes that the technetium- 99 isotope is produced in its excited nuclear state. This isotope has a half-life of about 6 hours, decaying by $\gamma$ radiation to technetium- 99 in its nuclear ground state. Thus, it is a valuable diagnostic tool. The patient either drinks or is injected with a solution containing ${ }^{99 \mathrm{~m}} \mathrm{Tc}$. By detecting the $\gamma$ rays emitted by ${ }^{99 \mathrm{~m}} \mathrm{Tc}$, doctors can obtain images of organs such as the heart, liver, and lungs.

A major advantage of using radioactive isotopes as tracers is that they are easy to detect. Their presence even in very small amounts can be detected by photographic techniques or by devices known as counters. Figure 20.19 is a diagram of a Geiger counter, an instrument widely used in scientific work and medical laboratories to detect radiation.

### 20.8 Biological Effects of Radiation

In this section we will examine briefly the effects of radiation on biological systems. But first we must define the quantitative measures of radiation. The fundamental unit of radioactivity is the curie $(\mathrm{Ci}) ; 1 \mathrm{Ci}$ corresponds to exactly $3.70 \times 10^{10}$ nuclear disintegrations per second. This decay rate is equivalent to that of 1 g of radium. A millicurie ( mCi ) is one-thousandth of a curie. Thus, 10 mCi of a carbon-14 sample is the quantity that undergoes $\left(10 \times 10^{-3}\right)\left(3.70 \times 10^{10}\right)=3.70 \times$ $10^{8}$ disintegrations per second.

The intensity of radiation depends on the number of disintegrations as well as on the energy and type of radiation emitted. One common unit for the absorbed dose of radiation is the rad (radiation $a$ bsorbed dose), which is the amount of radiation that results in the absorption of $1 \times 10^{-5} \mathrm{~J}$ per gram of irradiated material. The biological effect of radiation depends on the part of the body

Figure 20.19 Schematic diagram of a Geiger counter. Radiation ( $\alpha, \beta$, or $\gamma$ rays) entering through the window ionizes the argon gas to generate a small current flow between the electrodes. This current is amplified and is used to flash a light or operate a counter with a clicking sound.
irradiated and the type of radiation. For this reason, the rad is often multiplied by a factor called the RBE (relative biological effectiveness). The product is called a rem (roentgen equivalent for man):

$$
\text { number of rems }=\text { number of rads } \times 1 \text { RBE }
$$

Of the three types of nuclear radiation, $\alpha$ particles usually have the least-penetrating power. Beta particles are more penetrating than $\alpha$ particles, but less so than $\gamma$ rays.

Gamma rays have very short wavelengths and high energies. Furthermore, because they carry no charge, they cannot be stopped by shielding materials as easily as $\alpha$ and $\beta$ particles. If $\alpha$ - or $\beta$-emitters are ingested or inhaled, however, their damaging effects are greatly aggravated because the organs will be constantly subject to damaging radiation at close range. For example, strontium-90, a $\beta$-emitter, can replace calcium in bones, where it does the greatest damage.

Table 20.5 lists the average amounts of radiation an American receives every year. For shortterm exposures to radiation, a dosage of 50 to 200 rems will cause a decrease in white blood cell counts and other complications, while a dosage of 500 rems or greater may result in death within weeks. Current safety standards permit nuclear workers to be exposed to no more than 5 rems per year and specify a maximum of 0.5 rem of human-made radiation per year for the general public.

The chemical basis of radiation damage is that of ionizing radiation. Radiation (of either particles or $\gamma$ rays) can remove electrons from atoms and molecules in its path, leading to the formation of ions and radicals. Radicals (also called free radicals) are molecular fragments having one or more unpaired electrons; they are usually short lived and highly reactive. When water is irradiated with $\gamma$ rays, for example, the following reactions take place:

$$
\begin{gathered}
\mathrm{H}_{2} \mathrm{O} \xrightarrow{\text { radiation }} \mathrm{H}_{2} \mathrm{O}^{+}+e^{-} \\
\mathrm{H}_{2} \mathrm{O}^{+}+\mathrm{H}_{2} \mathrm{O} \longrightarrow \mathrm{H}_{3} \mathrm{O}^{+}+\cdot \mathrm{OH} \\
\text { hydroxyl radical }
\end{gathered}
$$

The electron (in the hydrated form) can subsequently react with water or with a hydrogen ion to form atomic hydrogen, and with oxygen to produce the superoxide ion ( $\mathrm{O}_{2}^{-}$) (a radical):

$$
e^{-}+\mathrm{O}_{2} \longrightarrow \cdot \mathrm{O}_{2}^{-}
$$

In the tissues the superoxide ions and other free radicals attack cell membranes and a host of organic compounds, such as enzymes and DNA molecules. Organic compounds can themselves be directly ionized and destroyed by high-energy radiation.

It has long been known that exposure to high-energy radiation can induce cancer in humans and other animals. Cancer is characterized by uncontrolled cellular growth. On the other hand, it is also well established that cancer cells can be destroyed by proper radiation treatment. In radiation therapy, a compromise is sought. The radiation to which the patient is exposed must be sufficient to destroy cancer cells without killing too many normal cells and, it is hoped, without inducing another form of cancer.

Radiation damage to living systems is generally classified as somatic or genetic. Somatic injuries are those that affect the organism during its own lifetime. Sunburn, skin rash, cancer, and cataracts are examples of somatic damage. Genetic damage means inheritable changes or gene mutations. For example, a person whose chromosomes have been damaged or altered by radiation may have deformed offspring.

## TABLE 20.5 Average Yearly Radiation Doses for Americans

| Source | Dose $(\mathbf{m r e m} / \mathbf{y r}$ )* |
| :--- | :---: |
| Cosmic rays | $20-50$ |
| Ground and surroundings | 25 |
| Human body ${ }^{\dagger}$ | 26 |
| Medical and dental X rays | $50-75$ |
| Air travel | 5 |
| Fallout from weapons tests | 5 |
| Nuclear waste | $\frac{2}{133-188}$ |
| Total |  |

## Bringing Chemistry to Life

## Radioactivity in Tobacco

"surgeon general's warning: Smoking Is Hazardous to Your Health." Warning labels such as this appear on every package of cigarettes sold in the United States. The link between cigarette smoke and cancer has long been established. There is, however, another cancer-causing mechanism in smokers. The culprit in this case is a radioactive environmental pollutant present in the tobacco leaves from which cigarettes are made.

The soil in which tobacco is grown is heavily treated with phosphate fertilizers, which are rich in uranium and its decay products. Consider a particularly important step in the uranium- 238 decay series:

$$
{ }_{88}^{226} \mathrm{Ra} \longrightarrow{ }_{86}^{222} \mathrm{Rn}+{ }_{2}^{4} \alpha
$$

The product formed, radon-222, is an unreactive gas. (Radon is the only gaseous species in the uranium-238 decay series.) Radon-222 emanates from radium-226 and is present at high concentrations in soil gas and in the surface air layer under the vegetation canopy provided by the field of growing tobacco. In this layer some of the daughters of radon-222, such as polonium-218 and lead-214, become firmly attached to the surface and interior of tobacco leaves. As Figure 20.3 shows, the next few decay reactions leading to the formation of lead- 210 proceed rapidly. Gradually, the concentration of radioactive lead- 210 can build to quite a high level.

During the combustion of a cigarette, tiny insoluble smoke particles are inhaled and deposited in the respiratory tract of the smoker and are eventually transported and stored at sites in the liver, spleen, and bone marrow. Measurements indicate a high lead-210 content in these particles. The lead- 210 content is not high enough to be hazardous chemically (it is insufficient to cause lead poisoning), but it is hazardous because it is radioactive. Because of its long half-life (20.4 years), lead-210 and its radioactive daughters-bismuth-210 and polonium-210-continue to build up in the body of a smoker over the years. Constant exposure of the organs and bone marrow to $\alpha$ - and $\beta$-particle radiation increases the probability the smoker will develop cancer. The overall impact on health is similar to that caused by indoor radon gas.

## Applying What You've Learned

In addition to BNCT, another promising treatment for brain tumors is brachytherapy using iodine-125. In brachytherapy, "seeds" containing ${ }^{125} \mathrm{I}$ are implanted directly into the tumor. As the radioisotope decays, $\gamma$ rays destroy the tumor cells. Careful implantation prevents the radiation from harming nearby healthy cells.

## Problems:

a) ${ }^{125} \mathrm{I}$ is produced by a two-step process in which ${ }^{124} \mathrm{Xe}$ nuclei are bombarded with neutrons to produce ${ }^{125} \mathrm{Xe}$-a process called neutron activation. ${ }^{125} \mathrm{Xe}$ then decays by electron capture to produce ${ }^{125} \mathrm{I}$, which also decays by electron capture. Write nuclear equations for the two steps that produce ${ }^{125} \mathrm{I}$ from ${ }^{124} \mathrm{Xe}$, and identify the product of the electron-capture decay of ${ }^{125}$ I. [144 Sample Problem 20.1]
b) The mass of an ${ }^{125}$ I nucleus is 124.904624 amu . Calculate the nuclear binding energy and the nuclear binding energy per nucleon. [ 144 Sample Problem 20.2]
c) The half-life of ${ }^{125}$ I is 59.4 days. How long will it take for the activity of implanted ${ }^{125}$ I seeds to fall to 5.00 percent of its original value? [ 14 Sample Problem 20.3]
d) Iridium-192 is another isotope used in brachytherapy. It is produced by a nuclear transmutation. Identify the target nucleus X , and write the balanced nuclear equation for the reaction represented by ${ }^{191} \mathrm{X}(\mathrm{n}, \gamma){ }^{192} \mathrm{Ir}$. [|/4 Sample Problem 20.5]

Brachytherapy seeds (shown with a penny to illustrate their size).

## Chapter Summary

## Section 20.1

- Spontaneous emission of particles or radiation from unstable nuclei is known as radioactivity. Unstable nuclei emit $\alpha$ particles, $\beta$ particles, positrons, or $\gamma$ rays.
- Nuclear transmutation is the conversion of one nucleus to another. Nuclear reactions are balanced by summing the mass numbers and the atomic numbers.

## Section 20.2

- Stable nuclei with low atomic numbers have neutron-to-proton ratios close to 1 . Heavier stable nuclei have higher ratios. Nuclear stability is favored by certain numbers of nucleons including even numbers and "magic" numbers.
- The difference between the actual mass of a nucleus and the mass calculated by summing the masses of the individual nucleons is the mass defect.
- Nuclear binding energy, determined by using Einstein's equation $E=m c^{2}$, is a measure of nuclear stability.

## Section 20.3

- Uranium-238 is the parent of a natural radioactive decay series that can be used to determine the ages of rocks. Radiocarbon dating is done using carbon-14.

## Section 20.4

- Transuranium elements are created by bombarding other elements with accelerated neutrons, protons, $\alpha$ particles, or other nuclei.

## Section 20.5

- Nuclear fission is the splitting of a large nucleus into two smaller nuclei and one or more neutrons. When the free neutrons are captured efficiently by other nuclei, a nuclear chain reaction can occur in which the fission process is sustained. The minimum amount of fissionable material required to sustain the reaction is known as the critical mass.
- Nuclear reactors use the heat from a controlled nuclear fission reaction to produce power. Fission is controlled, in part, by moderatorsmaterials that limit the speed of liberated neutrons but that do not themselves undergo fission when bombarded with neutrons. The three important types of reactors are light water reactors, heavy water reactors, and breeder reactors. Breeder reactors produce more fissionable material than they consume.

## Section 20.6

- Nuclear fusion, the type of reaction that occurs in the sun, is the combination of two light nuclei to form one heavier nucleus. Fusion reactions are sometimes referred to as thermonuclear reactions because they take place only at very high temperatures.

## Section 20.7

- Radioactive isotopes are easy to detect and thus make excellent tracers in chemical reactions and in medical procedures.

## Section 20.8

- High-energy radiation damages living systems by causing ionization and the formation of radicals, or free radicals, which are chemical species with unpaired electrons.

## Section 20.2: Nuclear Stability

## Review Questions

20.7 State the general rules for predicting nuclear stability.
20.8 What is the belt of stability?
20.9 Why is it impossible for the isotope ${ }_{2}^{2} \mathrm{He}$ to exist?
20.10 Define nuclear binding energy, mass defect, and nucleon.
20.11 How does Einstein's equation, $E=m c^{2}$, enable us to calculate nuclear binding energy?
20.12 Why is it preferable to use nuclear binding energy per nucleon for a comparison of the stabilities of different nuclei?

Problems
H20.13 The radius of a uranium- 235 nucleus is about $7.0 \times 10^{-3} \mathrm{pm}$. Calculate the density of the nucleus in $\mathrm{g} / \mathrm{cm}^{3}$. (Assume the atomic mass is 235 amu .)
$\leftrightarrows 20.14$ For each pair of isotopes listed, predict which one is less stable: (a) ${ }_{3}^{6} \mathrm{Li}$ or ${ }_{3}^{9} \mathrm{Li}$, (b) ${ }_{11}^{23} \mathrm{Na}$ or ${ }_{11}^{25} \mathrm{Na}$, (c) ${ }_{20}^{48} \mathrm{Ca}$ or ${ }_{21}^{48} \mathrm{Sc}$.

E20.15 For each pair of elements listed, predict which one has more stable isotopes: (a) Co or Ni , (b) F or Se , (c) Ag or Cd .

- 20.16 In each pair of isotopes shown, indicate which one you would expect to be radioactive: (a) ${ }_{10}^{20} \mathrm{Ne}$ or ${ }_{10}^{17} \mathrm{Ne}$, (b) ${ }_{20}^{40} \mathrm{Ca}$ or ${ }_{20}^{45} \mathrm{Ca}$, (c) ${ }_{42}^{95} \mathrm{Mo}$ or ${ }_{43}^{92} \mathrm{Tc}$, (d) ${ }_{80}^{195} \mathrm{Hg}$ or ${ }_{80}^{196} \mathrm{Hg}$, (e) ${ }_{83}^{209} \mathrm{Bi}$ or ${ }_{96}^{242} \mathrm{Cm}$.

E 20.17 Given that

$$
\mathrm{H}(g)+\mathrm{H}(g) \longrightarrow \mathrm{H}_{2}(g) \quad \Delta H^{\circ}=-436.4 \mathrm{~kJ} / \mathrm{mol}
$$

calculate the change in mass (in kg ) per mole of $\mathrm{H}_{2}$ formed.
E 20.18 Estimates show that the total energy output of the sun is $5 \times 10^{26} \mathrm{~J} / \mathrm{s}$. What is the corresponding mass loss in $\mathrm{kg} / \mathrm{s}$ of the sun?
20.19 Calculate the nuclear binding energy (in joules) and the binding energy per nucleon of the following isotopes: (a) ${ }_{3}^{7} \mathrm{Li}$ (7.01600 amu) and (b) ${ }_{17}^{35} \mathrm{Cl}$ (34.96885 amu).

E 20.20 Calculate the nuclear binding energy (in joules) and the binding energy per nucleon of the following isotopes: (a) ${ }_{2}^{4} \mathrm{He}$ (4.002603 amu) and (b) ${ }_{74}^{184} \mathrm{~W}(183.950928 \mathrm{amu})$.

GI20.21 Given that the nuclear binding energy of ${ }^{48} \mathrm{Cr}$ is $1.37340 \times$ $10^{-12} \mathrm{~J} /$ nucleon, calculate the mass of a single ${ }^{48} \mathrm{Cr}$ atom.
20.22 Given that the nuclear binding energy of ${ }^{192} \mathrm{Ir}$ is $1.27198 \times$ $10^{-12} \mathrm{~J} /$ nucleon, calculate the mass of a single ${ }^{192} \mathrm{Ir}$ atom.

## Section 20.3: Natural Radioactivity

## Review Questions

20.23 Discuss factors that lead to nuclear decay.
20.24 Outline the principle for dating materials using radioactive isotopes.

## Problems

$\boldsymbol{G} \mathbf{2 0 . 2 5}$ Fill in the blanks in the following radioactive decay series:

$\leftrightarrows$ 20.26 A radioactive substance undergoes decay as follows:

| Time (days) | Mass (g) |
| :---: | :---: |
| 0 | 500 |
| 1 | 389 |
| 2 | 303 |
| 3 | 236 |
| 4 | 184 |
| 5 | 143 |
| 6 | 112 |

Calculate the first-order decay constant and the half-life of the reaction.

H20.27 The radioactive decay of T1-206 to $\mathrm{Pb}-206$ has a half-life of 4.20 min . Starting with $5.00 \times 10^{22}$ atoms of T1-206, calculate the number of such atoms left after 42.0 min .

E20.28 A freshly isolated sample of ${ }^{90} \mathrm{Y}$ was found to have an activity of $9.8 \times 10^{5}$ disintegrations per minute at 1:00 P.M. on December 3, 2006. At 2:15 P.M. on December 17, 2006, its activity was measured again and found to be $2.6 \times 10^{4}$ disintegrations per minute. Calculate the half-life of ${ }^{90} \mathrm{Y}$.
420.29 A wooden artifact has a ${ }^{14} \mathrm{C}$ activity of 18.9 disintegrations per minute, compared to 27.5 disintegrations per minute for live wood. Given that the half-life of ${ }^{14} \mathrm{C}$ is 5715 years, determine the age of the artifact.
$\$ 20.30$ In the thorium decay series, thorium- 232 loses a total of six $\alpha$ particles and four $\beta$ particles in a 10 -stage process. What is the final isotope produced?
$\boldsymbol{H} 20.31$ Consider the decay series $\mathrm{A} \longrightarrow \mathrm{B} \longrightarrow \mathrm{C} \longrightarrow \mathrm{D}$ where A, B, and C are radioactive isotopes with half-lives of $4.50 \mathrm{~s}, 15.0$ days, and 1.00 s , respectively, and D is nonradioactive. Starting with 1.00 mole of A, and none of B, C, or D, calculate the number of moles of A, B, C, and D left after 30 days.
\$20.32 The activity of radioactive carbon-14 decay of a piece of charcoal found at a volcanic site is 11.2 disintegrations per second. If the activity of carbon- 14 decay in an equal mass of living matter is 18.3 disintegrations per second, what is the age of the charcoal? (See Problem 20.29 for the half-life of carbon-14.)
$\$$ 20.33 The age of some animal bones was determined by carbon-14 dating to be $8.4 \times 10^{3}$ years old. Calculate the activity of the carbon-14 in the bones in disintegrations per minute per gram, given that the original activity was 15.3 disintegrations per minute per gram. (See Problem 20.29 for the half-life of carbon-14.)

S 20.34 Given that the half-life of ${ }^{238} \mathrm{U}$ is $4.51 \times 10^{9}$ years, determine the age of a rock found to contain $1.09 \mathrm{mg}{ }^{238} \mathrm{U}$ and $0.08 \mathrm{mg}{ }^{206} \mathrm{~Pb}$.
20.35 Determine the ratio of ${ }^{238} \mathrm{U}$ to ${ }^{206} \mathrm{~Pb}$ in a rock that is $1.7 \times 10^{8}$ years old. (See Problem 20.34 for the half-life of ${ }^{238} \mathrm{U}$.)

## Section 20.4: Nuclear Transmutation

## Review Questions

20.36 What is the difference between radioactive decay and nuclear transmutation?
20.37 How is nuclear transmutation achieved in practice?

## Problems

\& 20.38 Write balanced nuclear equations for the following reactions, and identify X : (a) $\mathrm{X}(\mathrm{p}, \alpha){ }_{6}^{12} \mathrm{C}$, (b) ${ }_{13}^{27} \mathrm{Al}(\mathrm{d}, \alpha) \mathrm{X}$, (c) ${ }_{25}^{55} \mathrm{Mn}(\mathrm{n}, \gamma) \mathrm{X}$.
20.39 Write the abbreviated forms for the following reactions:
(a) ${ }_{7}^{14} \mathrm{~N}+{ }_{2}^{4} \alpha \longrightarrow{ }_{8}^{17} \mathrm{O}+{ }_{1}^{1} \mathrm{p}$
(b) ${ }_{4}^{9} \mathrm{Be}+{ }_{2}^{4} \alpha \longrightarrow{ }_{6}^{12} \mathrm{C}+{ }_{0}^{1} \mathrm{n}$
(c) ${ }_{92}^{238} \mathrm{U}+{ }_{1}^{2} \mathrm{H} \longrightarrow{ }_{93}^{238} \mathrm{~Np}+2{ }_{0}^{1} \mathrm{n}$

Ef 20.40 Write balanced nuclear equations for the following reactions, and identify X : (a) ${ }_{34}^{80} \mathrm{Se}(\mathrm{d}, \mathrm{p}) \mathrm{X}$, (b) $\mathrm{X}(\mathrm{d}, 2 \mathrm{p}){ }_{3}^{9} \mathrm{Li}$, (c) ${ }_{5}^{10} \mathrm{~B}(\mathrm{n}, \alpha) \mathrm{X}$.
20.41 Write the abbreviated forms for the following reactions:
(a) ${ }_{20}^{40} \mathrm{Ca}+{ }_{12}^{2} \mathrm{H} \longrightarrow{ }_{20}^{41} \mathrm{Ca}+{ }_{1}^{1} \mathrm{p}$
(b) ${ }_{16}^{32} \mathrm{~S}+{ }_{0}^{1} \mathrm{n} \longrightarrow{ }_{15}^{32} \mathrm{P}+{ }_{1}^{1} \mathrm{p}$
(c) ${ }_{94}^{239} \mathrm{Pu}+{ }_{2}^{4} \alpha \longrightarrow{ }_{96}^{242} \mathrm{Cm}+{ }_{0}^{1} \mathrm{n}$
20.42 Describe how you would prepare astatine-211, starting with bismuth-209.

G 20.43 A long-cherished dream of alchemists was to produce gold from cheaper and more abundant elements. This dream was finally realized when ${ }_{80}^{198} \mathrm{Hg}$ was converted into gold by neutron bombardment. Write a balanced equation for this reaction.

## Section 20.5: Nuclear Fission

## Visualizing Chemistry

Figure 20.7
VC 20.1 The fission of ${ }^{235} \mathrm{U}$ can result in a variety of products, including those shown in Figure 20.7. Which of the following equations does not represent another possible fission process?
a) ${ }_{0}^{1} \mathrm{n}+{ }_{92}^{235} \mathrm{U} \longrightarrow{ }_{52}^{137} \mathrm{Te}+{ }_{40}^{97} \mathrm{Zr}+2{ }_{0}^{1} \mathrm{n}$
b) ${ }_{0}^{1} \mathrm{n}+{ }_{92}^{235} \mathrm{U} \longrightarrow{ }_{56}^{142} \mathrm{Ba}+{ }_{36}^{91} \mathrm{Kr}+3{ }_{0}^{1} \mathrm{n}$
c) ${ }_{0}^{1} \mathrm{n}+{ }_{92}^{235} \mathrm{U} \longrightarrow{ }_{55}^{137} \mathrm{Cs}+{ }_{37}^{90} \mathrm{Rb}+3{ }_{0}^{1} \mathrm{n}$

VC 20.2 How many neutrons are produced in the fission reaction shown?

$$
{ }_{0}^{1} \mathrm{n}+{ }_{94}^{239} \mathrm{Pu} \longrightarrow{ }_{44}^{109} \mathrm{Ru}+{ }_{50}^{129} \mathrm{Sn}+\ldots{ }_{0}^{1} \mathrm{n}
$$

a) 1
b) 2
c) 3

VC 20.3 The fission of ${ }^{235} \mathrm{U}$ shown in Figure 20.7 is represented by the equation

$$
{ }_{0}^{1} \mathrm{n}+{ }_{92}^{235} \mathrm{U} \longrightarrow{ }_{54}^{143} \mathrm{Xe}+{ }_{38}^{90} \mathrm{Sr}+3{ }_{0}^{1} \mathrm{n}
$$

How does the combined mass of products compare to the combined mass of reactants for this process?
a) The combined mass of products is smaller than the combined mass of reactants.
b) The combined mass of products is larger than the combined mass of reactants.
c) The combined mass of products is equal to the combined mass of reactants.
VC 20.4 The fusion of ${ }_{1}^{2} \mathrm{H}$ and ${ }_{1}^{3} \mathrm{H}$ shown in Figure 20.7 is represented by the equation

$$
{ }_{1}^{2} \mathrm{H}+{ }_{1}^{3} \mathrm{H} \longrightarrow{ }_{2}^{4} \mathrm{He}+{ }_{0}^{1} \mathrm{n}
$$

How does the combined mass of products compare to the combined mass of reactants for this process?
a) The combined mass of products is smaller than the combined mass of reactants.
b) The combined mass of products is larger than the combined mass of reactants.
c) The combined mass of products is equal to the combined mass of reactants.

## Review Questions

20.44 Define nuclear fission, nuclear chain reaction, and critical mass.
20.45 Which isotopes can undergo nuclear fission?
20.46 Explain how an atomic bomb works.
20.47 Explain the functions of a moderator and a control rod in a nuclear reactor.
20.48 Discuss the differences between a light water and a heavy water nuclear fission reactor. What are the advantages of a breeder reactor over a conventional nuclear fission reactor?
20.49 No form of energy production is without risk. Make a list of the risks to society involved in fueling and operating a conventional coal-fired electric power plant, and compare them with the risks of fueling and operating a nuclear fission-powered electric plant.

## Section 20.6: Nuclear Fusion

## Review Questions

$\Psi 20.50$ Define nuclear fusion, thermonuclear reaction, and plasma.
20.51 Why do heavy elements such as uranium undergo fission whereas light elements such as hydrogen and lithium undergo fusion?
20.52 How does a hydrogen bomb work?
20.53 What are the advantages of a fusion reactor over a fission reactor? What are the practical difficulties in operating a large-scale fusion reactor?

## Section 20.7: Uses of Isotopes

## Problems

20.54 Describe how you would use a radioactive iodine isotope to demonstrate that the following process is in dynamic equilibrium:

$$
\mathrm{PbI}_{2}(s) \rightleftarrows \mathrm{Pb}^{2+}(a q)+2 \mathrm{I}^{-}(a q)
$$

20.55 Consider the following redox reaction:

$$
\mathrm{IO}_{4}^{-}(a q)+2 \mathrm{I}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow
$$

$$
\mathrm{I}_{2}(s)+\mathrm{IO}_{3}^{-}(a q)+2 \mathrm{OH}^{-}(a q)
$$

When $\mathrm{KIO}_{4}$ is added to a solution containing iodide ions labeled with radioactive iodine-128, all the radioactivity appears in $\mathrm{I}_{2}$ and none in the $\mathrm{IO}_{3}^{-}$ion. What can you deduce about the mechanism for the redox process?
20.56 Explain how you might use a radioactive tracer to show that ions are not completely motionless in crystals.
20.57 Each molecule of hemoglobin, the oxygen carrier in blood, contains four Fe atoms. Explain how you would use the radioactive ${ }_{26}^{59} \mathrm{Fe}\left(t_{1 / 2}=46\right.$ days $)$ to show that the iron in a certain food is converted into hemoglobin.

## Section 20.8: Biological Effects of Radiation

## Review Questions

20.58 List the factors that affect the intensity of radiation from a radioactive element.
20.59 What are rad and rem, and how are they related?
20.60 Explain, with examples, the difference between somatic and genetic radiation damage.
20.61 Compare the extent of radiation damage done by $\alpha, \beta$, and $\gamma$ sources.

## Additional Problems

20.62 How does a Geiger counter work?

H20.63 Strontium-90 is one of the products of the fission of uranium-235. This strontium isotope is radioactive, with a half-life of 28.1 years. Calculate how long (in years) it will take for 1.00 g of the isotope to be reduced to 0.200 g by decay.
20.64 Nuclei with an even number of protons and an even number of neutrons are more stable than those with an odd number of protons and/or an odd number of neutrons. What is the significance of the even numbers of protons and neutrons in this case?

G20.65 Tritium $\left({ }^{3} \mathrm{H}\right)$ is radioactive and decays by electron emission. Its half-life is 12.5 years. In ordinary water the ratio of ${ }^{1} \mathrm{H}$ to ${ }^{3} \mathrm{H}$
atoms is $1.0 \times 10^{17}$ to 1 . (a) Write a balanced nuclear equation for tritium decay. (b) How many disintegrations will be observed per minute in a $1.00-\mathrm{kg}$ sample of water?
$\leftrightarrows 20.66$ (a) What is the activity, in millicuries, of a $0.500-\mathrm{g}$ sample of ${ }_{93}^{237} \mathrm{~Np}$ ? (This isotope decays by $\alpha$-particle emission and has a halflife of $2.20 \times 10^{6}$ years.) (b) Write a balanced nuclear equation for the decay of ${ }_{93}^{237} \mathrm{~Np}$.

G 20.67 The following equations are for nuclear reactions that are known to occur in the explosion of an atomic bomb. Identify X .
(a) ${ }_{92}^{235} \mathrm{U}+{ }_{0}^{1} \mathrm{n} \longrightarrow{ }_{56}^{140} \mathrm{Ba}+3{ }_{0}^{1} \mathrm{n}+\mathrm{X}$
(b) ${ }_{92}^{235} \mathrm{U}+{ }_{0}^{1} \mathrm{n} \longrightarrow{ }_{55}^{144} \mathrm{Cs}+{ }_{37}^{90} \mathrm{Rb}+2 \mathrm{X}$
(c) ${ }_{92}^{235} \mathrm{U}+{ }_{0}^{1} \mathrm{n} \longrightarrow{ }_{35}^{87} \mathrm{Br}+3{ }_{0}^{1} \mathrm{n}+\mathrm{X}$
(d) ${ }_{92}^{235} \mathrm{U}+{ }_{0}^{1} \mathrm{n} \longrightarrow{ }_{62}^{160} \mathrm{Sm}+{ }_{30}^{72} \mathrm{Zn}+4 \mathrm{X}$
20.68 Calculate the nuclear binding energies (in $\mathrm{J} /$ nucleon) for the following species: (a) ${ }^{10} \mathrm{~B}(10.0129 \mathrm{amu})$, (b) ${ }^{11} \mathrm{~B}(11.009305 \mathrm{amu})$, (c) ${ }^{14} \mathrm{~N}(14.003074 \mathrm{amu})$, (d) ${ }^{56} \mathrm{Fe}(55.93494 \mathrm{amu})$.
$\boldsymbol{H}$ 20.69 Write complete nuclear equations for the following processes: (a) tritium ( ${ }^{3} \mathrm{H}$ ) undergoes $\beta$ decay, (b) ${ }^{242} \mathrm{Pu}$ undergoes $\alpha$-particle emission, (c) ${ }^{131}$ I undergoes $\beta$ decay, (d) ${ }^{251} \mathrm{Cf}$ emits an $\alpha$ particle.
20.70 The nucleus of nitrogen-18 lies above the stability belt. Write the equation for a nuclear reaction by which nitrogen-18 can achieve stability.
20.71 Why is strontium-90 a particularly dangerous isotope for humans? The half-life of strontium-90 is 29.1 years. Calculate the radioactivity in millicuries of 15.6 mg of ${ }^{90} \mathrm{Sr}$.
20.72 How are scientists able to tell the age of a fossil?
20.73 After the Chernobyl accident, people living close to the nuclear reactor site were urged to take large amounts of potassium iodide as a safety precaution. What is the chemical basis for this action?
$\leftrightarrows$ 20.74 To detect bombs that may be smuggled onto airplanes, the Federal Aviation Administration (FAA) will soon require all major airports in the United States to install thermal neutron analyzers. The thermal neutron analyzer will bombard baggage with lowenergy neutrons, converting some of the nitrogen-14 nuclei to nitrogen-15, with simultaneous emission of $\gamma$ rays. Because nitrogen content is usually high in explosives, detection of a high dosage of $\gamma$ rays will suggest that a bomb may be present. (a) Write an equation for the nuclear process. (b) Compare this technique with the conventional X-ray detection method.
20.75 Astatine, the last member of Group 7A, can be prepared by bombarding bismuth-209 with $\alpha$ particles. (a) Write an equation for the reaction. (b) Represent the equation in the abbreviated form as discussed in Section 20.4.
20.76 Explain why achievement of nuclear fusion in the laboratory requires a temperature of about 100 million degrees Celsius, which is much higher than that in the interior of the sun (15 million degrees Celsius).

E 20.77 The carbon-14 decay rate of a sample obtained from a young tree is 0.260 disintegration per second per gram of the sample. Another wood sample prepared from an object recovered at an archaeological excavation gives a decay rate of 0.186 disintegration per second per gram of the sample. What is the age of the object?
20.78 Tritium contains one proton and two neutrons. There is no significant proton-proton repulsion present in the nucleus. Why, then, is tritium radioactive?
20.79 The usefulness of radiocarbon dating is limited to objects no older than 60,000 years. What percent of the carbon-14, originally present in the sample, remains after this period of time?

E 20.80 The radioactive potassium-40 isotope decays to argon-40 with a half-life of $1.2 \times 10^{9}$ years. (a) Write a balanced equation for the reaction. (b) A sample of moon rock is found to contain 18 percent potassium-40 and 82 percent argon by mass. Calculate the age of the rock in years. (Assume that all the argon in the sample is the result of potassium decay.)
$\boldsymbol{\Psi} \boldsymbol{2 0 . 8 1}$ Nuclear waste disposal is one of the major concerns of the nuclear industry. In choosing a safe and stable environment to store nuclear wastes, consideration must be given to the heat released during nuclear decay. As an example, consider the $\beta$ decay of ${ }^{90} \mathrm{Sr}$ (89.907738 amu):

$$
{ }_{38}^{90} \mathrm{Sr} \longrightarrow{ }_{39}^{90} \mathrm{Y}+{ }_{-1}^{0} \beta \quad t \frac{1}{2}=28.1 \mathrm{yr}
$$

The ${ }^{90} \mathrm{Y}$ (89.907152 amu) further decays as follows:

$$
{ }_{39}^{90} \mathrm{Y} \longrightarrow{ }_{40}^{90} \mathrm{Zr}+{ }_{-1}^{0} \beta \quad t \frac{1}{2}=64 \mathrm{~h}
$$

Zirconium-90 (89.904703 amu) is a stable isotope. (a) Use the mass defect to calculate the energy released (in joules) in each of the preceding two decays. (The mass of the electron is $5.4857 \times$ $10^{-4}$ amu.) (b) Starting with 1 mole of ${ }^{90} \mathrm{Sr}$, calculate the number of moles of ${ }^{90} \mathrm{Sr}$ that will decay in a year. (c) Calculate the amount of heat released (in kJ ) corresponding to the number of moles of ${ }^{90} \mathrm{Sr}$ decayed to ${ }^{90} \mathrm{Zr}$ in part (b).
20.82 Both barium ( Ba ) and radium ( Ra ) are members of Group 2A and are expected to exhibit similar chemical properties. However, Ra is not found in barium ores. Instead, it is found in uranium ores. Explain.
$\leftrightarrows \mathbb{2 0 . 8 3}$ As a result of being exposed to the radiation released during the Chernobyl nuclear accident, the dose of iodine-131 in a person's body is $7.4 \mathrm{mC}\left(1 \mathrm{mC}=1 \times 10^{-3} \mathrm{Ci}\right)$. Use the relationship rate $=\lambda N$ to calculate the number of atoms of iodine- 131 to which this radioactivity corresponds. (The half-life of ${ }^{131} \mathrm{I}$ is 8.1 days.)
20.84 Which of the following poses a greater health hazard: a radioactive isotope with a short half-life or a radioactive isotope with a long half-life? Explain. [Assume the same type of radiation ( $\alpha$ or $\beta$ ) and comparable energetics per particle emitted.]

E20.85 From the definition of curie, calculate Avogadro's number, given that the molar mass of ${ }^{226} \mathrm{Ra}$ is $226.03 \mathrm{~g} / \mathrm{mol}$ and that it decays with a half-life of $1.6 \times 10^{3}$ years.

El 20.86 Since 1994, elements $110,111,112$, and 114 have been synthesized. Element 110 was created by bombarding ${ }^{208} \mathrm{~Pb}$ with ${ }^{62} \mathrm{Ni}$, element 111 was created by bombarding ${ }^{209} \mathrm{Bi}$ with ${ }^{64} \mathrm{Ni}$, element 112 was created by bombarding ${ }^{208} \mathrm{~Pb}$ with ${ }^{66} \mathrm{Zn}$, and element 114 was created by bombarding ${ }^{244} \mathrm{Pu}$ with ${ }^{48} \mathrm{Ca}$. Write an equation for each synthesis. Predict the chemical properties of these elements. Use W for element 110, X for element 111, Y for element 112, and Z for element 114.
$\leftrightarrows 20.87$ (a) Calculate the energy released when a U-238 isotope decays to Th-234. The atomic masses are as follows: U-238: 238.05078 amu ; Th-234: 234.03596 amu ; and He-4: 4.002603 amu . (b) The energy released in part (a) is transformed into the kinetic energy of the recoiling Th- 234 nucleus and the $\alpha$ particle. Which of the two will move away faster? Explain.
20.88 A person received an anonymous gift of a decorative cube, which he placed on his desk. A few months later he became ill and died shortly afterward. After investigation, the cause of his death
was linked to the box. The box was air-tight and had no toxic chemicals on it. What might have killed the man?
20.89 Identify two of the most abundant radioactive elements that exist on Earth. Explain why they are still present. (You may wish to consult a website such as that of the University of Sheffield and WebElements Ltd, UK, webelements.com.)
20.90 Sources of energy on Earth include fossil fuels, geothermal power, gravity, hydroelectric power, nuclear fission, nuclear fusion, the sun, and wind. Which of these have a "nuclear origin," either directly or indirectly?

Y 20.91 Cobalt-60 is an isotope used in diagnostic medicine and cancer treatment. It decays with $\gamma$-ray emission. Calculate the wavelength of the radiation in nanometers if the energy of the $\gamma$ ray is $2.4 \times 10^{-13} \mathrm{~J} /$ photon.
20.92 Americium-241 is used in smoke detectors because it has a long half-life ( 458 years) and its emitted $\alpha$ particles are energetic enough to ionize air molecules. Using the given schematic diagram of a smoke detector, explain how it works.

20.93 The constituents of wine contain, among others, carbon, hydrogen, and oxygen atoms. A bottle of wine was sealed about 6 years ago. To confirm its age, which of the isotopes would you choose in a radioactive dating study? The half-lives of the isotopes are: ${ }^{13} \mathrm{C}: 5715$ years; ${ }^{15} \mathrm{O}: 124 \mathrm{~s} ;{ }^{3} \mathrm{H}: 12.5$ years. Assume that the activities of the isotopes were known at the time the bottle was sealed.
20.94 Name two advantages of a nuclear-powered submarine over a conventional submarine.
20.95 In 1997 a scientist at a nuclear research center in Russia placed a thin shell of copper on a sphere of highly enriched uranium- 235 . Suddenly, there was a huge burst of radiation, which turned the air blue. Three days later, the scientist died of radiation exposure. Explain what caused the accident. (Hint: Copper is an effective metal for reflecting neutrons.)

H20.96 A radioactive isotope of copper decays as follows:

$$
{ }^{64} \mathrm{Cu} \longrightarrow{ }^{64} \mathrm{Zn}+{ }_{-1}^{0} \beta \quad t \frac{1}{2}=12.8 \mathrm{~h}
$$

Starting with 84.0 g of ${ }^{64} \mathrm{Cu}$, calculate the quantity of ${ }^{64} \mathrm{Zn}$ produced after 18.4 h .

E 20.97 A $0.0100-\mathrm{g}$ sample of a radioactive isotope with a half-life of $1.3 \times 10^{9}$ years decays at the rate of $2.9 \times 10^{4}$ disintegrations per minute. Calculate the molar mass of the isotope.
$\$ 20.98$ The half-life of ${ }^{27} \mathrm{Mg}$ is 9.50 min . (a) Initially there were $4.20 \times 10^{12}{ }^{27} \mathrm{Mg}$ nuclei present. How many ${ }^{27} \mathrm{Mg}$ nuclei are left 30.0 min later? (b) Calculate the ${ }^{27} \mathrm{Mg}$ activities (in Ci) at $t=0$ and $t=30.0 \mathrm{~min}$. (c) What is the probability that any one ${ }^{27} \mathrm{Mg}$ nucleus decays during a $1-$ s interval? What assumption is made in this calculation?

EI 20.99 (a) Assuming nuclei are spherical in shape, show that the radius $(r)$ of a nucleus is proportional to the cube root of mass number (A). (b) In general, the radius of a nucleus is given by $r=r_{0} A^{1 / 3}$, where $r_{0}$, the proportionality constant, is given by $1.2 \times 10^{-15} \mathrm{~m}$. Calculate the volume of the ${ }^{238} \mathrm{U}$ nucleus.
20.100 Modern designs of atomic bombs contain, in addition to uranium or plutonium, small amounts of tritium and deuterium to boost the power of explosion. What is the role of tritium and deuterium in these bombs?
$\boldsymbol{H}$ 20.101 The quantity of a radioactive material is often measured by its activity (measured in curies or millicuries) rather than by its mass. In a brain scan procedure, a $70-\mathrm{kg}$ patient is injected with 20.0 mCi of ${ }^{99 \mathrm{~m}} \mathrm{Tc}$, which decays by emitting $\gamma$-ray photons with a half-life of 6.0 h . Given that the RBE of these photons is 0.98 and only two-thirds of the photons are absorbed by the body, calculate the rem dose received by the patient. Assume all the ${ }^{99 \mathrm{~m}} \mathrm{Tc}$ nuclei decay while in the body. The energy of a $\gamma$-ray photon is $2.29 \times 10^{-14} \mathrm{~J}$.

E 20.102 In 2006, an ex-KGB agent was murdered in London. The investigation following the agent's death revealed that he
was poisoned with the radioactive isotope ${ }^{210} \mathrm{Po}$, which had apparently been added to his food. (a) ${ }^{210} \mathrm{Po}$ is prepared by bombarding ${ }^{209} \mathrm{Bi}$ with neutrons. Write an equation for the reaction. (b) The half-life of ${ }^{210} \mathrm{Po}$ is 138 days. It decays by $\alpha$ particle emission. Write the equation for the decay process. (c) Calculate the energy of an emitted $\alpha$ particle. Assume both the parent and daughter nuclei have zero kinetic energy. The atomic masses of ${ }^{210} \mathrm{Po},{ }^{206} \mathrm{~Pb}$, and ${ }_{2}^{4} \alpha$ are 209.98286, 205.97444, and 4.00150 amu , respectively. (d) Ingestion of $1 \mu \mathrm{~g}$ of ${ }^{210} \mathrm{Po}$ could prove fatal. What is the total energy released by this quantity of ${ }^{210} \mathrm{Po}$ over the course of 138 days?
$\mathbb{Y}$ 20.103 Alpha particles produced by radioactive decay eventually pick up electrons from their surroundings to form helium atoms. Calculate the volume (in mL ) of He collected at STP when 1.00 g of pure ${ }^{226} \mathrm{Ra}$ is stored in a closed container for 125 years. (Assume that there are five $\alpha$ particles generated per ${ }^{226} \mathrm{Ra}$ as it decays to ${ }^{206} \mathrm{~Pb}$.)
20.104 An electron and a positron are accelerated to nearly the speed of light before colliding in a particle accelerator. The resulting collision produces an exotic particle having a mass many times that of a proton. Does this result violate the law of conservation of mass? Explain.

## Pre-Professional Practice Exam Problems: Physical and Biological Sciences

The radioactive isotope ${ }^{238} \mathrm{Pu}$, used in pacemakers, decays by emitting an $\alpha$ particle with a half-life of 86 years. The energy of the emitted $\alpha$ particle is $9.0 \times 10^{-13} \mathrm{~J}$, which is the energy per decay. After 10 years, the activity of the isotope decreases by 8.0 percent. (Power is measured in watts or J/s.)

1. What is the rate constant for the decay?
a) $2.6 \times 10^{-10} \mathrm{~s}^{-1}$
b) 86 year $^{-1}$
c) $2.7 \times 10^{-9} \mathrm{~s}^{-1}$
d) 0.012 year $^{-1}$
2. Identify the equation for the decay process.
a) ${ }^{238} \mathrm{Pu} \longrightarrow{ }^{236} \mathrm{Pu}+\alpha$
b) ${ }^{238} \mathrm{Pu}+\alpha \longrightarrow{ }^{234} \mathrm{U}$
c) ${ }^{238} \mathrm{Pu} \longrightarrow{ }^{234} \mathrm{U}+\alpha$
d) ${ }^{238} \mathrm{Pu} \longrightarrow{ }^{234} \mathrm{Pu}+\alpha$
3. Assuming that all the $\alpha$-particle energy is used to run the pacemaker, calculate the power output at $t=0$ and $t=10$ years. Initially, 1.0 mg of ${ }^{238} \mathrm{Pu}$ was present in the pacemaker.
a) $0.081 \mathrm{~mW}, 0.075 \mathrm{~mW}$
b) $2.6 \times 10^{-10} \mathrm{~mW}, 2.4 \times 10^{-10} \mathrm{~mW}$
c) $1.0 \mathrm{~mW}, 0.92 \mathrm{~mW}$
d) $0.58 \mathrm{~mW}, 0.53 \mathrm{~mW}$
4. How long will it take for the power output to fall to 80 percent of its original value?
a) 28 years
b) 69 years
c) 86 years
d) 43 years

## How Human-made Molecules Have Impacted the Environment

The presence of ozone $\left(\mathrm{O}_{3}\right)$ in the atmosphere is responsible for the absorption of light that otherwise would significantly alter life on Earth. The wavelengths of light that are absorbed by stratospheric ozone are known to cause cancer, genetic mutations, and the destruction of plant life. Ozone is destroyed naturally by the absorption of this shortwavelength light-and is regenerated by another solar process. The balance of ozone destruction and regeneration can be disrupted, however, by the presence of substances not found naturally in the atmosphere.

In 1973 F. Sherwood "Sherry" Rowland and Mario Molina, chemistry professors at the University of California-Irvine, began studying the chemical behavior of chlorofluorocarbons (CFCs) in the atmosphere. They discovered that although CFC molecules were extraordinarily stable in the troposphere, the very stability that made them attractive as coolants and propellants also allowed them to survive the gradual diffusion into the stratosphere where they would ultimately be broken down by high-energy ultraviolet radiation. Rowland and Molina proposed that chlorine atoms liberated in the breakdown of CFCs could potentially catalyze the destruction of large amounts of ozone in the stratosphere. The work of Rowland and Molina, along with other atmospheric scientists, provoked a debate among the scientific and international communities regarding the fate of the ozone layer-and the planet. The Montreal Protocol, once referred to by United Nations Secretary-General Kofi Annan as "perhaps the single most successful international agreement to date," is an international treaty designed to protect the ozone layer. Originally signed in 1987, it calls for a halt to the production of substances believed to contribute to the destruction of stratospheric ozone.

In 1995 Rowland and Molina, along with Dutch atmospheric chemist Paul Crutzen, were awarded the Nobel Prize in Chemistry for their elucidation of the role of human-made chemicals in the catalytic destruction of stratospheric ozone.

At the end of this chapter, you will be able to answer questions about an environmentally important molecule [ $\quad$ Page 913].

- Catalysis [ 14 Section 14.6]
- Molecular polarity [ KA Section 9.2]

### 21.1 Earth's Atmosphere

Earth is unique among the planets of our solar system in having an atmosphere that is chemically active and rich in oxygen. Mars, for example, has a much thinner atmosphere that is about 90 percent carbon dioxide. Jupiter has no solid surface; it is made up, instead, of 90 percent hydrogen, 9 percent helium, and 1 percent other substances.

It is generally believed that three billion or four billion years ago, Earth's atmosphere consisted mainly of ammonia, methane, and water. There was little, if any, free oxygen present. Ultraviolet (UV) radiation from the sun probably penetrated the atmosphere, rendering the surface of Earth sterile. However, the same UV radiation may have triggered the chemical reactions (perhaps beneath the surface) that eventually led to life on Earth. Primitive organisms used energy from the sun to break down carbon dioxide (produced by volcanic activity) to obtain carbon, which they incorporated in their own cells. The major by-product of this process, called photosynthesis, is oxygen. Another important source of oxygen is the photodecomposition of water vapor by UV light. Over time, the more reactive gases such as ammonia and methane have largely disappeared, and today our atmosphere consists

Figure 21.1 The nitrogen cycle. Although the supply of nitrogen in the atmosphere is virtually inexhaustible, it must be combined with hydrogen or oxygen before it can be assimilated by higher plants, which in turn are consumed by animals. Juvenile nitrogen is nitrogen that has not previously participated in the nitrogen cycle.
mainly of oxygen and nitrogen gases. Biological processes determine to a great extent the atmospheric concentrations of these gases, one of which is reactive (oxygen) and the other unreactive (nitrogen).

Table 21.1 shows the composition of dry air at sea level. The total mass of the atmosphere is about $5.3 \times 10^{18} \mathrm{~kg}$. Water is excluded from this table because its concentration in air can vary drastically from location to location.

Figure 21.1 shows the major processes involved in the cycle of nitrogen in nature. Molecular nitrogen, with its triple bond, is a very stable molecule. However, through biological and industrial nitrogen fixation (the conversion of molecular nitrogen into nitrogen compounds), atmospheric nitrogen gas is converted into nitrates and other compounds suitable for assimilation by algae and plants. Another important mechanism for producing nitrates from nitrogen gas is lightning. The steps are

$$
\begin{gathered}
\mathrm{N}_{2}(g)+\mathrm{O}_{2}(g) \xrightarrow{\text { electric energy }} 2 \mathrm{NO}(g) \\
2 \mathrm{NO}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{NO}_{2}(g) \\
2 \mathrm{NO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{HNO}_{2}(a q)+\mathrm{HNO}_{3}(a q)
\end{gathered}
$$

About 30 million tons of $\mathrm{HNO}_{3}$ are produced this way annually. Nitric acid is converted to nitrate salts in the soil. These nutrients are taken up by plants, which in turn are ingested by animals. Animals use the nutrients from plants to make proteins and other essential biomolecules. Denitrification reverses nitrogen fixation to complete the cycle. For example, certain anaerobic organisms decompose animal wastes as well as dead plants and animals to produce free molecular nitrogen from nitrates.

The main processes of the global oxygen cycle are shown in Figure 21.2. This cycle is complicated by the fact that oxygen takes so many different chemical forms. Atmospheric oxygen is

Composition of Dry Air at Sea Level

| Gas | Composition <br> (\% by Volume) |
| :--- | :---: |
| $\mathrm{N}_{2}$ | 78.03 |
| $\mathrm{O}_{2}$ | 20.99 |
| Ar | 0.94 |
| $\mathrm{CO}_{2}$ | 0.033 |
| Ne | 0.0015 |
| He | 0.000524 |
| Kr | 0.00014 |
| Xe | 0.000006 |

Figure 21.2 The oxygen cycle. The cycle is complicated because oxygen appears in so many chemical forms and combinations, primarily as molecular oxygen, in water, and in organic and inorganic compounds.

Figure 21.3 Regions of Earth's atmosphere. Notice the variation of temperature with altitude. Most of the phenomena shown here are discussed in the chapter.

removed through respiration and various industrial processes (mostly combustion), which produce carbon dioxide. Photosynthesis is the major mechanism by which molecular oxygen is regenerated from carbon dioxide and water.

Scientists divide the atmosphere into several different layers according to temperature variation and composition (Figure 21.3). As far as visible events are concerned, the most active region is the troposphere, the layer of the atmosphere closest to Earth's surface. The troposphere contains about 80 percent of the total mass of air and practically all the atmosphere's water vapor. The troposphere is the thinnest layer of the atmosphere $(10 \mathrm{~km})$, but it is where all the dramatic events of weather-rain, lightning, hurricanes-occur. Temperature decreases almost linearly with increasing altitude in this region.

Above the troposphere is the stratosphere, which consists of nitrogen, oxygen, and ozone. In the stratosphere, the air temperature increases with altitude. This warming effect is the result of exothermic reactions triggered by UV radiation from the sun (see Section 21.3). One of the products of this reaction sequence is ozone $\left(\mathrm{O}_{3}\right)$, which serves to prevent harmful UV rays from reaching Earth's surface.

In the mesosphere, which is above the stratosphere, the concentration of ozone and other gases is low, and the temperature decreases again with increasing altitude. The thermosphere, or ionosphere, is the uppermost layer of the atmosphere. The increase in temperature in this region is the result of the bombardment of molecular oxygen and nitrogen and atomic species by energetic particles, such as electrons and protons, from the sun. Typical reactions are

$$
\begin{array}{ll}
\mathrm{N}_{2} \longrightarrow 2 \mathrm{~N} & \Delta H^{\circ}=941.4 \mathrm{~kJ} / \mathrm{mol} \\
\mathrm{~N} \longrightarrow \mathrm{~N}^{+}+e^{-} & \Delta H^{\circ}=1400 \mathrm{~kJ} / \mathrm{mol} \\
\mathrm{O}_{2} \longrightarrow \mathrm{O}_{2}^{+}+e^{-} & \Delta H^{\circ}=1176 \mathrm{~kJ} / \mathrm{mol}
\end{array}
$$

In reverse, these processes liberate the equivalent amount of energy, mostly as heat. Ionized particles are responsible for the reflection of radio waves back toward Earth.

### 21.2 Phenomena in the Outer Layers of the Atmosphere

In this section we will discuss two dazzling phenomena that occur in the outer regions of the atmosphere. One is a natural event. The other is a curious by-product of human space travel.

## Aurora Borealis and Aurora Australis

Violent eruptions on the surface of the sun, called solar flares, result in the ejection of myriad electrons and protons into space, where they disrupt radio transmission and provide us with spectacular celestial light shows known as auroras (Figure 21.4). These electrons and protons collide with the molecules and atoms in Earth's upper atmosphere, causing them to become ionized and electronically excited. Eventually, the excited molecules and ions return to the ground state with the emission of light. For example, an excited oxygen atom emits photons at wavelengths of 558 nm (green) and between 630 and 636 nm (red):

$$
\mathrm{O}^{*} \longrightarrow \mathrm{O}+h v
$$

where the asterisk denotes an electronically excited species and $h v$ denotes the emitted photon [ IW Section 6.2]. Similarly, the blue and violet colors often observed in auroras result from the transition in the ionized nitrogen molecule:

$$
\mathrm{N}_{2}^{+} * \longrightarrow \mathrm{~N}_{2}^{+}+h v
$$

The wavelengths for this transition fall between 391 and 470 nm .
The incoming streams of solar protons and electrons are oriented by Earth's magnetic field so that most auroral displays occur in doughnut-shaped zones about 2000 km in diameter centered on the North and South Poles. Aurora borealis is the name given to this phenomenon in the Northern Hemisphere. In the Southern Hemisphere, it is called aurora australis. Sometimes, the number of solar particles is so immense that auroras are also visible from locations as far south as Olympia, Washington.

Sample Problem 21.1 shows how to determine the maximum wavelength capable of breaking a chemical bond.

## Sample Problem 21.1

The bond enthalpy of $\mathrm{O}_{2}$ is $498.7 \mathrm{~kJ} / \mathrm{mol}$. Calculate the maximum wavelength (in nm ) of a photon that can cause the dissociation of an $\mathrm{O}_{2}$ molecule.

Strategy We want to calculate the wavelength of a photon that will break an $\mathrm{O}=\mathrm{O}$ bond. Therefore, we need the amount of energy in one bond. The bond energy of $\mathrm{O}_{2}$ is given in units of $\mathrm{kJ} / \mathrm{mol}$. The units needed for the energy of one bond are $\mathrm{J} /$ molecule. Once we know the energy in one bond, we can calculate the minimum frequency and maximum wavelength needed to dissociate one $\mathrm{O}_{2}$ molecule.

Figure 21.4 Aurora borealis, commonly referred to as the northern lights.

Think About It In principle, any photon with a wavelength of 240 nm or shorter can dissociate an $\mathrm{O}_{2}$ molecule.

Setup The conversion steps are

$$
\mathrm{kJ} / \mathrm{mol} \longrightarrow \mathrm{~J} / \text { molecule } \longrightarrow \text { frequency of photon } \longrightarrow \text { wavelength of photon }
$$

Solution First we calculate the energy required to dissociate one $\mathrm{O}_{2}$ molecule:

$$
\text { energy per molecule }=\frac{498.7 \times 10^{3} \mathrm{~J}}{1 \mathrm{~mol}} \times \frac{1 \mathrm{~mol}}{6.022 \times 10^{23} \text { molecules }}=8.281 \times 10^{-19} \frac{\mathrm{~J}}{\text { molecule }}
$$

The energy of the photon is given by $E=h v$ (Equation 6.2). Therefore,

$$
\nu=\frac{E}{h}=\frac{8.281 \times 10^{-19} \wedge}{6.63 \times 10^{-34} \not \supset \cdot \mathrm{~s}}=1.25 \times 10^{15} \mathrm{~s}^{-1}
$$

Finally, we calculate the wavelength of the photon, given by $\lambda=c / v$ (Equation 6.1), as follows:

$$
\lambda=\frac{3.00 \times 10^{8} \mathrm{~m} / \mathrm{s}}{1.25 \times 10^{15} \mathrm{~s}^{-1}}=2.40 \times 10^{-7} \mathrm{~m}=240 \mathrm{~nm}
$$

Figure 21.5 The glowing tail section of the space shuttle viewed from inside the vehicle.

Practice Problem A Calculate the wavelength (in nm ) of a photon needed to dissociate an $\mathrm{O}_{3}$ molecule:

$$
\mathrm{O}_{3} \longrightarrow \mathrm{O}+\mathrm{O}_{2} \quad \Delta H^{\circ}=107.2 \mathrm{~kJ} / \mathrm{mol}
$$

$\leftrightarrow \nmid$ Practice Problem B Which of the following gaseous species is dissociated by visible light: $\mathrm{CS}_{2}, \mathrm{~F}_{2}$, HI, CIF, HCN? (See Table 8.6 on p. 326.)

## The Mystery Glow of Space Shuttles

A human-made light show that baffled scientists for several years is produced by space shuttles orbiting Earth. In 1983, astronauts first noticed an eerie orange glow on the outside surface of their spacecraft at an altitude about 300 km above Earth (Figure 21.5).

The light, which usually extends about 10 cm away from the protective silica heat tiles and other surface materials, is most pronounced on the parts of the shuttle facing its direction of travel. This fact led scientists to postulate that collision between oxygen atoms in the atmosphere and the fast-moving shuttle somehow produced the orange light. Spectroscopic measurements of the glow, as well as laboratory tests, strongly suggested that nitric oxide $(\mathrm{NO})$ and nitrogen dioxide $\left(\mathrm{NO}_{2}\right)$ also played a part. It is believed that oxygen atoms interact with nitric oxide adsorbed on (i.e., bound to) the shuttle's surface to form electronically excited nitrogen dioxide:

$$
\mathrm{O}+\mathrm{NO} \longrightarrow \mathrm{NO}_{2}^{*}
$$

As the $\mathrm{NO}_{2}^{*}$ leaves the shell of the spacecraft, it emits photons at a wavelength of 680 nm (orange):

$$
\mathrm{NO}_{2}^{*} \longrightarrow \mathrm{NO}_{2}+h v
$$

Support for this explanation came inadvertently in 1991, when astronauts aboard Discovery released various gases, including carbon dioxide, neon, xenon, and nitric oxide, from the cargo bay in the course of an unrelated experiment. Expelled one at a time, these gases scattered onto the surface of the shuttle's tail. The nitric oxide caused the normal shuttle glow to intensify markedly, but the other gases had no effect on it.

What is the source of the nitric oxide on the outside of the spacecraft? Scientists believe that some of it may come from the exhaust gases emitted by the shuttle's rockets and that some of it is present in the surrounding atmosphere. The shuttle glow does not harm the vehicle, but it does interfere with spectroscopic measurements on distant objects made from the spacecraft.

## Checkpoint 21.2 $\quad$ Phenomena in the Outer Layers of the Atmosphere

21.2.1 What maximum wavelength (in nm ) of light is necessary to break the bond in a nitrogen molecule $\left(\mathrm{N}_{2}\right)$ ? (The bond energy of $\mathrm{N}_{2}$ is $941.4 \mathrm{~kJ} / \mathrm{mol}$.)
a) 127 nm
b) 211 nm
c) 236 nm
d) 942 nm
e) 941 nm
21.2.2 What process gives rise to the aurora borealis and the aurora australis?
a) Formation of oxygen and nitrogen molecules
b) Collisions between nitrogen atoms
c) Collisions between oxygen atoms
d) Emission of photons of visible light
e) Absorption of photons of visible light

### 21.3 Depletion of Ozone in the Stratosphere

As mentioned earlier, ozone in the stratosphere prevents UV radiation emitted by the sun from reaching Earth's surface. The formation of ozone in this region begins with the photodissociation of oxygen molecules by solar radiation at wavelengths below 240 nm :

$$
\mathrm{O}_{2} \xrightarrow{\mathrm{UV}<240 \mathrm{~nm}} \mathrm{O}+\mathrm{O}
$$

Equation 21.1
The highly reactive O atoms combine with oxygen molecules to form ozone as follows:

$$
\mathrm{O}+\mathrm{O}_{2}+\mathrm{M} \longrightarrow \mathrm{O}_{3}+\mathrm{M}
$$

$$
\text { Equation } 21.2
$$

where $M$ is some inert substance such as $N_{2}$. The role of $M$ in this exothermic reaction is to absorb some of the excess energy released and prevent the spontaneous decomposition of the $\mathrm{O}_{3}$ molecule. The energy that is not absorbed by M is given off as heat. (As the M molecules themselves become de-excited, they release more heat to the surroundings.) In addition, ozone itself absorbs UV light between 200 and 300 nm :

$$
\mathrm{O}_{3} \xrightarrow{\mathrm{UV}} \mathrm{O}+\mathrm{O}_{2}
$$

Equation 21.3
The process continues when O and $\mathrm{O}_{2}$ recombine to form $\mathrm{O}_{3}$ as shown in Equation 21.2, further warming the stratosphere.

If all the stratospheric ozone were compressed into a single layer at STP on Earth, that layer would be only about 3 mm thick! Although the concentration of ozone in the stratosphere is very low, it is sufficient to filter out (i.e., absorb) solar radiation in the 200- to 300-nm range (see Equation 21.3). In the stratosphere, it acts as our protective shield against UV radiation, which can induce skin cancer, cause genetic mutations, and destroy crops and other forms of vegetation.

The formation and destruction of ozone by natural processes is a dynamic equilibrium that maintains a constant concentration of ozone in the stratosphere. Since the mid-1970s scientists have been concerned about the harmful effects of CFCs on the ozone layer. Generally known by the trade name Freons, CFCs were first synthesized in the 1930s. Some of the common ones are $\mathrm{CFCl}_{3}$ (Freon 11), $\mathrm{CF}_{2} \mathrm{Cl}_{2}$ (Freon 12), $\mathrm{C}_{2} \mathrm{~F}_{3} \mathrm{Cl}_{3}$ (Freon 113), and $\mathrm{C}_{2} \mathrm{~F}_{4} \mathrm{Cl}_{2}$ (Freon 114). Because these compounds are readily liquefied, relatively inert, nontoxic, noncombustible, and volatile, they have been used as coolants in refrigerators and air conditioners, in place of highly toxic liquid sulfur dioxide $\left(\mathrm{SO}_{2}\right)$ and ammonia $\left(\mathrm{NH}_{3}\right)$. Large quantities of CFCs are also used in the manufacture of disposable foam products such as cups and plates, as aerosol propellants in spray cans, and as solvents to clean newly soldered electronic circuit boards (Figure 21.6). In 1977, the peak year of production, nearly $1.5 \times 10^{6}$ tons of CFCs were produced in the United States. Most of the CFCs produced for commercial and industrial use are eventually discharged into the atmosphere.

Because of their relative inertness, the CFCs slowly diffuse unchanged up to the stratosphere, where UV radiation of wavelengths between 175 and 220 nm causes them to decompose:

$$
\begin{aligned}
\mathrm{CFCl}_{3} & \longrightarrow \mathrm{CFCl}_{2}+\mathrm{Cl} \\
\mathrm{CF}_{2} \mathrm{Cl}_{2} & \longrightarrow \mathrm{CF}_{2} \mathrm{Cl}+\mathrm{Cl}
\end{aligned}
$$

The reactive chlorine atoms then undergo the following reactions:

$$
\begin{aligned}
& \mathrm{Cl}+\mathrm{O}_{3} \longrightarrow \mathrm{ClO}+\mathrm{O}_{2} \\
& \mathrm{ClO}+\mathrm{O} \longrightarrow \mathrm{Cl}+\mathrm{O}_{2}
\end{aligned}
$$

Equation 21.4
Equation 21.5
The overall result (the sum of Equations 21.4 and 21.5) is the net removal of an $\mathrm{O}_{3}$ molecule from the stratosphere:

$$
\mathrm{O}_{3}+\mathrm{O} \longrightarrow 2 \mathrm{O}_{2}
$$

Equation 21.6
The oxygen atoms in Equation 21.5 are supplied by the photochemical decomposition of molecular oxygen and ozone described earlier. The Cl atom plays the role of a catalyst in the reaction mechanism scheme represented by Equations 21.4 and 21.5 because it is not used up and therefore can take part in many such reactions. In fact, one Cl atom can destroy up to $100,000 \mathrm{O}_{3}$ molecules

Figure 21.6 Uses of CFCs. Since 1978, the use of aerosol propellants has been banned in the United States.

Figure 21.7 The variations in concentrations of ClO and $\mathrm{O}_{3}$ with latitude.

before it is removed by some other reaction. The ClO (chlorine monoxide) species is an intermediate because it is produced in the first elementary step (Equation 21.4) and consumed in the second step (Equation 21.5). The preceding mechanism for the destruction of ozone has been supported by the detection of ClO in the stratosphere in recent years (Figure 21.7). As can be seen, the concentration of $\mathrm{O}_{3}$ decreases in regions that have high amounts of ClO .

Another group of compounds that can destroy stratospheric ozone are the nitrogen oxides, generally denoted as $\mathrm{NO}_{x}$. (Examples of $\mathrm{NO}_{x}$ are NO and $\mathrm{NO}_{2}$.) These compounds come from the exhausts of high-altitude supersonic aircraft and from human and natural activities on Earth. Solar radiation decomposes a substantial amount of the other nitrogen oxides to nitric oxide (NO), which participates in the destruction of ozone as follows:

$$
\begin{aligned}
& \mathrm{O}_{3} \longrightarrow \mathrm{O}_{2}+\mathrm{O} \\
& \mathrm{NO}+\mathrm{O}_{3} \longrightarrow \mathrm{NO}_{2}+\mathrm{O}_{2} \\
& \text { Overall: } \frac{\mathrm{NO}_{2}+\mathrm{O} \longrightarrow \mathrm{NO}+\mathrm{O}_{2}}{2} \longrightarrow 3 \mathrm{O}_{2}
\end{aligned}
$$

In this case, NO is the catalyst and $\mathrm{NO}_{2}$ is the intermediate. Nitrogen dioxide also reacts with chlorine monoxide to form chlorine nitrate:

$$
\mathrm{ClO}+\mathrm{NO}_{2} \longrightarrow \mathrm{ClONO}_{2}
$$

Chlorine nitrate is relatively stable and serves as a "chlorine reservoir," which plays a role in the depletion of the stratospheric ozone over the North and South Poles.

## Polar Ozone Holes

In the mid-1980s, evidence began to accumulate that an "Antarctic ozone hole" developed in late winter, depleting the stratospheric ozone over Antarctica by as much as 50 percent (Figure 21.8). In the stratosphere, a stream of air known as the "polar vortex" circles Antarctica in winter. Air trapped within this vortex becomes extremely cold during the polar night. This condition leads to the formation of ice particles known as polar stratospheric clouds (PSCs) (Figure 21.9). Acting as a heterogeneous catalyst, these PSCs provide a surface for reactions converting HCl (emitted from Earth) and chlorine nitrate to more reactive chlorine molecules:

$$
\mathrm{HCl}+\mathrm{ClONO}_{2} \longrightarrow \mathrm{Cl}_{2}+\mathrm{HNO}_{3}
$$

By early spring, the sunlight splits molecular chlorine into chlorine atoms,

$$
\mathrm{Cl}_{2}+h \nu \longrightarrow 2 \mathrm{Cl}
$$

which then attack ozone as shown earlier.

The situation is not as severe in the warmer Arctic region, where the vortex does not persist quite as long. Studies have shown that ozone levels in this region have declined between 4 and 8 percent in the past decade. Volcanic eruptions, such as that of Mount Pinatubo in the Philippines in 1991, inject large quantities of dust-sized particles and sulfuric acid aerosols into the atmosphere. These particles can perform the same catalytic function as the ice crystals at the South Pole. As a result, the Arctic hole is expected to grow larger for several years following an eruption.

Recognizing the serious implications of the loss of ozone in the stratosphere, nations throughout the world have acknowledged the need to drastically curtail or totally stop the production of CFCs. In 1978 the United States was one of the few countries to ban the use of CFCs in hair sprays and other aerosols. The Montreal protocol was signed by most industrialized nations in 1987, setting targets for cutbacks in CFC production and the complete elimination of these substances by the year 2000. Although progress has been made in this respect, many nations have not been able to abide by the treaty because of the importance of CFCs to their economies. Recycling could play a significant supplementary role in preventing CFCs already in appliances from escaping into the atmosphere. As Figure 21.6 shows, more than half of the CFCs in use are recoverable.

An intense effort is under way to find CFC substitutes that are not harmful to the ozone layer. One of the promising candidates is called hydrochlorofluorocarbon-123, or HCFC-123 $\left(\mathrm{CF}_{3} \mathrm{CHCl}_{2}\right)$. The presence of the hydrogen atom makes the compound more susceptible to oxidation in the lower atmosphere, so it never reaches the stratosphere. Specifically, it is attacked by the hydroxyl radical in the troposphere:

$$
\mathrm{CF}_{3} \mathrm{CHCl}_{2}+\mathrm{OH} \longrightarrow \mathrm{CF}_{3} \mathrm{CCl}_{2}+\mathrm{H}_{2} \mathrm{O}
$$

The $\mathrm{CF}_{3} \mathrm{CCl}_{2}$ fragment reacts with oxygen, eventually decomposing to $\mathrm{CO}_{2}$, water, and hydrogen halides that are removed by rainwater. Unfortunately, the same hydrogen atom also makes the compound more active biologically than the CFCs. Laboratory tests have shown that HCFC-123 can cause tumors in rats, although its toxic effect on humans is not known. Another promising group of compounds that can substitute for CFCs are the hydrofluorocarbons (HFCs). Because they do not contain chlorine, HFCs will not promote the destruction of ozone even if they diffuse to the stratosphere. Examples of these compounds are $\mathrm{CF}_{3} \mathrm{CFH}_{2}, \mathrm{CF}_{3} \mathrm{CF}_{2} \mathrm{H}, \mathrm{CF}_{3} \mathrm{CH}_{3}$, and $\mathrm{CF}_{2} \mathrm{HCH}_{3}$. In particular, $\mathrm{CF}_{3} \mathrm{CFH}_{2}$ is already widely used in place of CFCs in air conditioning and refrigeration applications.

Figure 21.8 In recent years, scientists have found that the ozone layer in the stratosphere over the South Pole has become thinner. This map, based on data collected over a number of years, shows the depletion of ozone in blue.

Figure 21.9 Polar stratospheric clouds containing ice particles can catalyze the formation of Cl atoms and lead to the destruction of ozone.

Figure 21.10 A volcanic eruption.

Although it is unclear whether the CFCs already released to the atmosphere will eventually result in catastrophic damage to life on Earth, it is conceivable that the depletion of ozone can be slowed by reducing the availability of Cl atoms. Indeed, some chemists have suggested sending a fleet of planes to spray 50,000 tons of ethane $\left(\mathrm{C}_{2} \mathrm{H}_{6}\right)$ or propane $\left(\mathrm{C}_{3} \mathrm{H}_{8}\right)$ high over the South Pole in an attempt to heal the hole in the ozone layer. Being a reactive species, the chlorine atom would react with the hydrocarbons as follows:

$$
\begin{aligned}
& \mathrm{Cl}+\mathrm{C}_{2} \mathrm{H}_{6} \longrightarrow \mathrm{HCl}+\mathrm{C}_{2} \mathrm{H}_{5} \\
& \mathrm{Cl}+\mathrm{C}_{3} \mathrm{H}_{8} \longrightarrow \mathrm{HCl}+\mathrm{C}_{3} \mathrm{H}_{7}
\end{aligned}
$$

The products of these reactions would not affect the ozone concentration. A less realistic plan is to rejuvenate the ozone layer by producing large quantities of ozone and releasing it into the stratosphere from airplanes. Technically this solution is feasible, but it would be enormously costly and it would require the collaboration of many nations.

Having discussed the chemistry in the outer regions of Earth's atmosphere, we will focus in Sections 21.4 through 21.8 on events closer to us-that is, in the troposphere.

### 21.4 Volcanoes

Volcanic eruptions, Earth's most spectacular natural displays of energy, are instrumental in forming large parts of Earth's crust. The upper mantle, immediately under the crust, is nearly molten. A slight increase in heat, such as that generated by the movement of one crustal plate under another, melts the rock. The molten rock, called magma, rises to the surface and generates some types of volcanic eruptions (Figure 21.10).

An active volcano emits gases, liquids, and solids. The gases spewed into the atmosphere include primarily $\mathrm{N}_{2}, \mathrm{CO}_{2}, \mathrm{HCl}, \mathrm{HF}, \mathrm{H}_{2} \mathrm{~S}$, and water vapor. It is estimated that volcanoes are the source of about two-thirds of the sulfur in the air. On the slopes of Mount St. Helens, which last erupted in 1980, deposits of elemental sulfur are visible near the eruption site. At high temperatures, the hydrogen sulfide gas given off by a volcano is oxidized by air:

$$
2 \mathrm{H}_{2} \mathrm{~S}(\mathrm{~g})+3 \mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{SO}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(g)
$$

Some of the $\mathrm{SO}_{2}$ is reduced by more $\mathrm{H}_{2} \mathrm{~S}$ from the volcano to elemental sulfur and water:

$$
2 \mathrm{H}_{2} \mathrm{~S}(g)+\mathrm{SO}_{2}(g) \longrightarrow 3 \mathrm{~S}(s)+2 \mathrm{H}_{2} \mathrm{O}(g)
$$

The rest of the $\mathrm{SO}_{2}$ is released into the atmosphere, where it reacts with water to form acid rain (see Section 21.6).

The tremendous force of a volcanic eruption carries a sizable amount of gas into the stratosphere. There $\mathrm{SO}_{2}$ is oxidized to $\mathrm{SO}_{3}$, which is eventually converted to sulfuric acid aerosols in a series of complex reactions. In addition to destroying ozone in the stratosphere (see page 901), these aerosols can also affect climate. Because the stratosphere is above the atmospheric weather patterns, the aerosol clouds often persist for more than a year. They absorb solar radiation and thereby cause a drop in temperature at Earth's surface. However, this cooling effect is local rather than global, because it depends on the site and frequency of volcanic eruptions.

### 21.5 The Greenhouse Effect

Although carbon dioxide is only a trace gas in Earth's atmosphere, with a concentration of about 0.033 percent by volume (see Table 21.1), it plays a critical role in controlling our climate. The socalled greenhouse effect describes the trapping of heat near Earth's surface by gases in the atmosphere, particularly carbon dioxide. The glass roof of a greenhouse transmits visible sunlight and absorbs some of the outgoing infrared (IR) radiation, thereby trapping the heat. Carbon dioxide acts somewhat like a glass roof, except that the temperature rise in the greenhouse is due mainly to the restricted air circulation inside. Calculations show that if the atmosphere did not contain carbon dioxide, Earth would be $30^{\circ} \mathrm{C}$ cooler!

Figure 21.11 shows the carbon cycle in our global ecosystem. The transfer of carbon dioxide to and from the atmosphere is an essential part of the carbon cycle. Carbon dioxide is produced

Figure 21.11 The carbon cycle.
when any form of carbon or a carbon-containing compound is burned in an excess of oxygen. Many carbonates give off $\mathrm{CO}_{2}$ when heated, and all give off $\mathrm{CO}_{2}$ when treated with acid:

$$
\begin{aligned}
\mathrm{CaCO}_{3}(s) & \longrightarrow \mathrm{CaO}(s)+\mathrm{CO}_{2}(g) \\
\mathrm{CaCO}_{3}(s)+2 \mathrm{HCl}(a q) & \longrightarrow \mathrm{CaCl}_{2}(a q)+\mathrm{H}_{2} \mathrm{O}(l)+\mathrm{CO}_{2}(g)
\end{aligned}
$$

Carbon dioxide is also a by-product of the fermentation of sugar:

$$
\underset{\text { glucose }}{\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}(a q)} \xrightarrow{\text { yeast }} \underset{\text { ethanol }}{2 \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(a q)}+2 \mathrm{CO}_{2}(g)
$$

Carbohydrates and other complex carbon-containing molecules are consumed by animals, which respire and release $\mathrm{CO}_{2}$ as an end product of metabolism:

$$
\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}(a q)+6 \mathrm{O}_{2}(g) \longrightarrow 6 \mathrm{CO}_{2}(g)+6 \mathrm{H}_{2} \mathrm{O}(l)
$$

Figure 21.12 The incoming radiation from the sun and the outgoing radiation from Earth's surface.

As mentioned earlier, another major source of $\mathrm{CO}_{2}$ is volcanic activity. Carbon dioxide is removed from the atmosphere by photosynthetic plants and certain microorganisms:

$$
6 \mathrm{CO}_{2}(g)+6 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}(a q)+6 \mathrm{O}_{2}(g)
$$

After plants and animals die, the carbon in their tissues is oxidized to $\mathrm{CO}_{2}$ and returns to the atmosphere. In addition, there is a dynamic equilibrium between atmospheric $\mathrm{CO}_{2}$ and carbonates in the oceans and lakes.

The solar radiant energy received by Earth is distributed over a band of wavelengths between 100 and 5000 nm , but much of it is concentrated in the 400 - to $700-\mathrm{nm}$ range, which is the visible region of the spectrum (Figure 21.12). By contrast, the thermal radiation emitted by Earth's surface is characterized by wavelengths longer than 4000 nm (the IR region) because of the much lower average surface temperature compared to that of the sun. The outgoing IR radiation can be absorbed by water and carbon dioxide, but not by nitrogen and oxygen.

All molecules vibrate, even at the lowest temperatures. The energy associated with molecular vibration is quantized, much like the electronic energies of atoms and molecules. To vibrate more energetically, a molecule must absorb a photon of a specific wavelength in the IR region. First, however, its dipole moment must change during the course of a vibration. [Recall that the dipole moment of a molecule is the product of the charge and the distance between charges (see page 311).] Figure 21.13 shows how a diatomic molecule can vibrate. If the molecule is homonuclear like $\mathrm{N}_{2}$ and $\mathrm{O}_{2}$, there can be no change in the dipole moment; the molecule has a zero dipole moment no matter how far apart or close together the two atoms are. We call such molecules IR-inactive because they cannot absorb IR radiation. On the other hand, all heteronuclear diatomic molecules are IR-active; that is, they all can absorb IR radiation because their dipole moments constantly change as the bond lengths change.

A polyatomic molecule can vibrate in more than one way. Water, for example, can vibrate in three different ways as shown in Figure 21.14. Because water is a polar molecule, any of these vibrations results in a change in dipole moment because there is a change in bond length. Therefore, an $\mathrm{H}_{2} \mathrm{O}$ molecule is IR-active. Carbon dioxide has a linear geometry and is nonpolar. Figure 21.15 shows two of the four ways a $\mathrm{CO}_{2}$ molecule can vibrate. One of them [Figure 21.15(a)] symmetrically displaces atoms from the center of gravity and will not create a dipole moment, but the other vibration [Figure 21.15(b)] is IR-active because the dipole moment changes from zero to a maximum value in one direction and then reaches the same maximum value when it changes to the other extreme position.

Upon receiving a photon in the IR region, a molecule of $\mathrm{H}_{2} \mathrm{O}$ or $\mathrm{CO}_{2}$ is promoted to a higher vibrational energy level:

$$
\begin{aligned}
& \mathrm{H}_{2} \mathrm{O}+h \nu \longrightarrow \mathrm{H}_{2} \mathrm{O}^{*} \\
& \mathrm{CO}_{2}+h \nu \longrightarrow \mathrm{CO}_{2}^{*}
\end{aligned}
$$

(the asterisk denotes a vibrationally excited molecule). These energetically excited molecules soon lose their excess energy either by collision with other molecules or by spontaneous emission of radiation. Part of this radiation is emitted to outer space and part returns to Earth's surface.

Although the total amount of water vapor in our atmosphere has not altered noticeably over the years, the concentration of $\mathrm{CO}_{2}$ has been rising steadily since the turn of the century as a result of the burning of fossil fuels (petroleum, natural gas, and coal). Figure 21.16 shows the percentages of $\mathrm{CO}_{2}$ emitted due to human activities in the United States in 1998, and Figure 21.17 shows the variation of carbon dioxide concentration over a period of years, as measured in Hawaii. In the Northern Hemisphere, the seasonal oscillations are caused by the removal of carbon dioxide by photosynthesis during the growing season and its buildup during the fall and winter months. The trend is toward an increase in $\mathrm{CO}_{2}$. The current rate of increase is about 1 ppm ( 1 part $\mathrm{CO}_{2}$ per million parts air) by volume per year, which is equivalent to $9 \times 10^{9}$ tons of $\mathrm{CO}_{2}$ ! Scientists have estimated that by the year 2010 the $\mathrm{CO}_{2}$ concentration will exceed preindustrial levels by about 25 percent.

In addition to $\mathrm{CO}_{2}$ and $\mathrm{H}_{2} \mathrm{O}$, other greenhouse gases, such as the $\mathrm{CFCs}, \mathrm{CH}_{4}, \mathrm{NO}_{x,}$ and $\mathrm{N}_{2} \mathrm{O}$ also contribute appreciably to the warming of the atmosphere. Figure 21.18 shows the gradual increase in temperature over the years, and Figure 21.19 shows the relative contributions of the greenhouse gases to global warming.

It is predicted by some meteorologists that should the buildup of greenhouse gases continue at its current rate, Earth's average temperature will increase by about $1^{\circ}$ to $3^{\circ} \mathrm{C}$ in the twenty-first century. Although a temperature increase of a few degrees may seem insignificant, it is actually large enough to disrupt the delicate thermal balance on Earth and could cause glaciers and ice caps to melt. Consequently, the sea level would rise and coastal areas would be flooded. Predicting weather trends is extremely difficult, though, and there are other potentially moderating factors

Figure 21.15 Two of the four ways a carbon dioxide molecule can vibrate. The vibration in (a) does not result in a change in dipole moment, but the vibration in (b) renders the molecule IR-active.

Figure 21.16 Sources of carbon dioxide emission in the United States. Note that not all the emitted $\mathrm{CO}_{2}$ enters the atmosphere. Some of it is taken up by carbon dioxide "sinks," such as the ocean.

Figure 21.17 Yearly variation of carbon dioxide concentration at Mauna Loa, Hawaii, the source of the longest running record of atmospheric $\mathrm{CO}_{2}$. The general trend clearly points to an increase of carbon dioxide in the atmosphere.

Figure 21.18 Temperature rise on Earth's surface from 1880 to 1992. Zero represents the average temperature for the years 1951-1980.

Figure 21.19 Contribution to global warming by various greenhouse gases. The concentrations of CFCs and methane are much lower than that of carbon dioxide. However, because they can absorb IR radiation much more effectively than $\mathrm{CO}_{2}$, they make a significant contribution to the overall warming effect.

Student Annotation: Global climate change is the subject of the Academy Award-winning 2006 documentary, An Inconvenient Truth, presented by former vice president Al Gore.

to take into account before concluding that global warming is inevitable and irreversible. For example, the ash from volcanic eruptions diffuses upward and can stay in the atmosphere for years. By reflecting incoming sunlight, volcanic ash can cause a cooling effect. Furthermore, the warming effect of CFCs in the troposphere is offset by its action in the stratosphere. Because ozone is a polar polyatomic molecule, it is also an effective greenhouse gas. A decrease in ozone brought about by CFCs actually produces a noticeable drop in temperature.

To combat the greenhouse effect, we must lower carbon dioxide emissions. This can be done by improving energy efficiency in automobiles and in household heating and lighting, and by developing nonfossil fuel energy sources, such as photovoltaic cells. Nuclear energy is a viable alternative, but its use is highly controversial due to the difficulty of disposing of radioactive waste and the fact that nuclear power stations are more prone to accidents than conventional power stations (see Chapter 20). The proposed phasing out of CFCs, the most potent greenhouse gas, will help to slow down the warming trend. The recovery of methane gas generated at landfills and the reduction of natural gas leakages are other steps we could take to control $\mathrm{CO}_{2}$ emissions. Finally, the preservation of the Amazon jungle, tropical forests in Southeast Asia, and other large forests is vital to maintaining the steady-state concentration of $\mathrm{CO}_{2}$ in the atmosphere. Converting forests to farmland for crops and grassland for cattle may do irreparable damage to the delicate ecosystem and permanently alter the climate pattern on Earth.

## Sample Problem 21.2

Which of the following qualify as greenhouse gases: $\mathrm{CO}, \mathrm{NO}, \mathrm{NO}_{2}, \mathrm{Cl}_{2}, \mathrm{H}_{2}, \mathrm{Ne}$ ?
Strategy To behave as a greenhouse gas, either the molecule must possess a dipole moment or some of its vibrational motions must generate a temporary dipole moment.

Setup The necessary conditions immediately rule out homonuclear diatomic molecules and atomic species.

Solution Only $\mathrm{CO}, \mathrm{NO}$, and $\mathrm{NO}_{2}$, which are all polar molecules, qualify as greenhouse gases. Both $\mathrm{Cl}_{2}$ and $\mathrm{H}_{2}$ are homonuclear diatomic molecules, and Ne is atomic. These three species are all IR-inactive.

Practice Problem A Which of the following is a more effective greenhouse gas: CO or $\mathrm{H}_{2} \mathrm{O}$ ? Explain.

GPractice Problem B Both $\mathrm{O}_{2}$ and $\mathrm{O}_{3}$ exhibit molecular vibration. Despite this, only $\mathrm{O}_{3}$ acts as a greenhouse gas. Explain.

## Checkpoint 21.5 The Greenhouse Effect

21.5.1 Which of the following can act as a greenhouse gas? (Select all that apply.)
a) $\mathrm{CH}_{4}$
b) $\mathrm{N}_{2}$
c) Rn
d) $\mathrm{O}_{3}$
e) Xe
21.5.2 The greenhouse effect is
a) caused by depletion of stratospheric ozone.
b) entirely the result of human activity.
c) a natural phenomenon that has been enhanced by human activity.
d) the absorption of the sun's energy by molecules and atoms in the upper atmosphere.
e) responsible for the aurora borealis and the aurora australis.

### 21.6 Acid Rain

Every year acid rain causes hundreds of millions of dollars' worth of damage to stone buildings and statues throughout the world. The term stone leprosy is used by some environmental chemists to describe the corrosion of stone by acid rain (Figure 21.20). Acid rain is also toxic to vegetation and aquatic life. Many well-documented cases show dramatically how acid rain has destroyed agricultural and forest lands and killed aquatic organisms.

Precipitation in the northeastern United States has an average pH of about 4.3 (Figure 21.21). Because atmospheric $\mathrm{CO}_{2}$ in equilibrium with rainwater would not be expected to result in a pH less than 5.5 , sulfur dioxide $\left(\mathrm{SO}_{2}\right)$ and, to a lesser extent, nitrogen oxides from auto emissions are believed to be responsible for the high acidity of rainwater. Acidic oxides, such as $\mathrm{SO}_{2}$, react with water to give the corresponding acids. There are several sources of atmospheric $\mathrm{SO}_{2}$. Nature itself contributes much $\mathrm{SO}_{2}$ in the form of volcanic eruptions. Also, many metals exist combined with sulfur in nature. Extracting the metals often entails smelting, or roasting, the ores-that is, heating the metal sulfide in air to form the metal oxide and $\mathrm{SO}_{2}$. For example,

$$
2 \mathrm{ZnS}(s)+3 \mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{ZnO}(s)+2 \mathrm{SO}_{2}(g)
$$

The metal oxide can be reduced more easily than the sulfide (by a more reactive metal or in some cases by carbon) to the free metal.

Although smelting is a major source of $\mathrm{SO}_{2}$, the burning of fossil fuels in industry, in power plants, and in homes accounts for most of the $\mathrm{SO}_{2}$ emitted to the atmosphere (Figure 21.22). The

Figure 21.21 Mean precipitation pH in the United States in 1994. Most $\mathrm{SO}_{2}$ comes from the midwestern states. Prevailing winds carry the acid droplets formed over the Northeast. Nitrogen oxides also contribute to acid rain formation.

Figure 21.20 The effect of acid rain on a marble statue. The photos were taken just a few decades apart.

Figure 21.22 Sulfur dioxide and other air pollutants being released into the atmosphere from a coal-burning power plant.

Figure 21.23 Common procedure for removing $\mathrm{SO}_{2}$ from burning fossil fuel. Powdered limestone decomposes into CaO , which reacts with $\mathrm{SO}_{2}$ to form $\mathrm{CaSO}_{3}$. The remaining $\mathrm{SO}_{2}$ is combined with an aqueous suspension of CaO to form $\mathrm{CaSO}_{3}$.
sulfur content of coal ranges from 0.5 to 5 percent by mass, depending on the source of the coal. The sulfur content of other fossil fuels is similarly variable. Oil from the Middle East, for instance, is low in sulfur, whereas that from Venezuela has a high sulfur content. To a lesser extent, the nitrogen-containing compounds in oil and coal are converted to nitrogen oxides, which can also acidify rainwater.

All in all, some 50 million to 60 million tons of $\mathrm{SO}_{2}$ are released into the atmosphere each year! In the troposphere, $\mathrm{SO}_{2}$ is almost all oxidized to $\mathrm{H}_{2} \mathrm{SO}_{4}$ in the form of aerosol, which ends up in wet precipitation or acid rain. The mechanism for the conversion of $\mathrm{SO}_{2}$ to $\mathrm{H}_{2} \mathrm{SO}_{4}$ is quite complex and not fully understood. The reaction is believed to be initiated by the hydroxyl radi$\mathrm{cal}(\mathrm{OH})$ :

$$
\mathrm{OH}+\mathrm{SO}_{2} \longrightarrow \mathrm{HOSO}_{2}
$$

The $\mathrm{HOSO}_{2}$ radical is further oxidized to $\mathrm{SO}_{3}$ :

$$
\mathrm{HOSO}_{2}+\mathrm{O}_{2} \longrightarrow \mathrm{HO}_{2}+\mathrm{SO}_{3}
$$

The sulfur trioxide formed would then rapidly react with water to form sulfuric acid:

$$
\mathrm{SO}_{3}+\mathrm{H}_{2} \mathrm{O} \longrightarrow \mathrm{H}_{2} \mathrm{SO}_{4}
$$

$\mathrm{SO}_{2}$ can also be oxidized to $\mathrm{SO}_{3}$ and then converted to $\mathrm{H}_{2} \mathrm{SO}_{4}$ on particles by heterogeneous catalysis. Eventually, the acid rain can corrode limestone and marble $\left(\mathrm{CaCO}_{3}\right)$. A typical reaction is

$$
\mathrm{CaCO}_{3}(s)+\mathrm{H}_{2} \mathrm{SO}_{4}(a q) \longrightarrow \mathrm{CaSO}_{4}(s)+\mathrm{H}_{2} \mathrm{O}(l)+\mathrm{CO}_{2}(g)
$$

Sulfur dioxide can also attack calcium carbonate directly:

$$
2 \mathrm{CaCO}_{3}(s)+2 \mathrm{SO}_{2}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{CaSO}_{4}(s)+2 \mathrm{CO}_{2}(g)
$$

There are two ways to minimize the effects of $\mathrm{SO}_{2}$ pollution. The most direct approach is to remove sulfur from fossil fuels before combustion, but this is technologically difficult to accomplish. A cheaper but less efficient way is to remove $\mathrm{SO}_{2}$ as it is formed. For example, in one process powdered limestone is injected into the power plant boiler or furnace along with the coal (Figure 21.23). At high temperatures, the following decomposition occurs:

$$
\underset{\text { limestone }}{\mathrm{CaCO}_{3}(s) \longrightarrow} \underset{\text { quicklime }}{\mathrm{CaO}(s)}+\mathrm{CO}_{2}(g)
$$

The quicklime reacts with $\mathrm{SO}_{2}$ to form calcium sulfite and some calcium sulfate:

$$
\begin{aligned}
\mathrm{CaO}(s)+\mathrm{SO}_{2}(g) & \longrightarrow \mathrm{CaSO}_{3}(s) \\
2 \mathrm{CaO}(s)+2 \mathrm{SO}_{2}(g)+\mathrm{O}_{2}(g) & \longrightarrow 2 \mathrm{CaSO}_{4}(s)
\end{aligned}
$$

To remove any remaining $\mathrm{SO}_{2}$, an aqueous suspension of quicklime is injected into a purification chamber prior to the gases' escape through the smokestack. Quicklime is also added to lakes and soils in a process called liming to reduce their acidity (Figure 21.24). Installing a sulfuric acid plant near a metal ore refining site is also an effective way to cut $\mathrm{SO}_{2}$ emission because the $\mathrm{SO}_{2}$ produced by roasting metal sulfides can be captured for use in the synthesis of sulfuric acid. This is a very sensible way to turn what is a pollutant in one process into a starting material for another process!

### 21.7 Photochemical Smog

The word smog was coined to describe the combination of smoke and fog that shrouded London during the 1950s. The primary cause of this noxious cloud was sulfur dioxide. Today, however, photochemical smog, which is formed by the reactions of automobile exhaust in the presence of sunlight, is much more common.

Automobile exhaust consists mainly of NO, CO, and various unburned hydrocarbons. These gases are called primary pollutants because they set in motion a series of photochemical reactions that produce secondary pollutants. It is the secondary pollutants-chiefly $\mathrm{NO}_{2}$ and $\mathrm{O}_{3}$ - that are responsible for the buildup of smog.

Nitric oxide is the product of the reaction between atmospheric nitrogen and oxygen at high temperatures inside an automobile engine:

$$
\mathrm{N}_{2}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{NO}(g)
$$

Once released into the atmosphere, nitric oxide is oxidized to nitrogen dioxide:

$$
2 \mathrm{NO}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{NO}_{2}(g)
$$

Sunlight causes the photochemical decomposition of $\mathrm{NO}_{2}$ (at a wavelength shorter than 400 nm ) into NO and O :

$$
\mathrm{NO}_{2}(g)+h \nu \longrightarrow \mathrm{NO}(g)+\mathrm{O}(g)
$$

Atomic oxygen is a highly reactive species that can initiate a number of important reactions, one of which is the formation of ozone:

$$
\mathrm{O}(g)+\mathrm{O}_{2}(g)+\mathrm{M} \longrightarrow \mathrm{O}_{3}(g)+\mathrm{M}
$$

where M is some inert substance such as $\mathrm{N}_{2}$. Ozone attacks the $\mathrm{C}=\mathrm{C}$ linkage in rubber:

where R represents groups of C and H atoms. In smog-ridden areas, this reaction can cause automobile tires to crack. Similar reactions are also damaging to lung tissues and other biological substances.

Ozone can be formed also by a series of very complex reactions involving unburned hydrocarbons, nitrogen oxides, and oxygen. One of the products of these reactions is peroxyacetyl nitrate (PAN):

PAN is a powerful lachrymator, or tear producer, and causes breathing difficulties.
Figure 21.25 shows typical variations with time of primary and secondary pollutants. Initially, the concentration of $\mathrm{NO}_{2}$ is quite low. As soon as solar radiation penetrates the atmosphere, though, more $\mathrm{NO}_{2}$ is formed from NO and $\mathrm{O}_{2}$. The concentration of ozone remains fairly constant at a low level in the early morning hours. As the concentration of unburned hydrocarbons and aldehydes increases in the air, the concentrations of $\mathrm{NO}_{2}$ and $\mathrm{O}_{3}$ also rise rapidly. The actual amounts depend on the location, traffic, and weather conditions, but their presence is always accompanied by haze (Figure 21.26). The oxidation of hydrocarbons produces various organic intermediates, such as alcohols and carboxylic acids, which are all less volatile than the hydrocarbons themselves. These substances eventually condense into small droplets of liquid. The dispersion of these droplets in air, called an aerosol, scatters sunlight and reduces visibility. This interaction also makes the air look hazy.

Figure 21.24 Spreading calcium oxide ( CaO ) over acidified soil. This process is called liming.

Figure 21.25 Typical variations with time in concentration of air pollutants on a smoggy day.

Figure 21.26 A smoggy day in a big city.

As the mechanism of photochemical smog formation has become better understood, major efforts have been made to reduce the buildup of primary pollutants. Most automobiles now are equipped with catalytic converters designed to oxidize CO and unburned hydrocarbons to $\mathrm{CO}_{2}$ and $\mathrm{H}_{2} \mathrm{O}$ and to reduce NO and $\mathrm{NO}_{2}$ to $\mathrm{N}_{2}$ and $\mathrm{O}_{2}$ [ 144 Section 14.6]. More efficient automobile engines and better public transportation systems would also help to decrease air pollution in urban areas. A recent technological innovation to combat photochemical smog is to coat automobile radiators and air conditioner compressors with a platinum catalyst. So equipped, a running car can purify the air that flows under the hood by converting ozone and carbon monoxide to oxygen and carbon dioxide:

$$
\mathrm{O}_{3}(\mathrm{~g})+\mathrm{CO}(\mathrm{~g}) \xrightarrow{\mathrm{Pt}} \mathrm{O}_{2}(\mathrm{~g})+\mathrm{CO}_{2}(\mathrm{~g})
$$

In a city like Los Angeles, where the number of miles driven in one day equals nearly 300 million, this approach would significantly improve the air quality and reduce the "high-ozone level" warnings frequently issued to its residents.

### 21.8 Indoor Pollution

Difficult as it is to avoid air pollution outdoors, it is no easier to avoid pollution indoors. The air quality in homes and in the workplace is affected by human activities, by construction materials, and by other factors in our immediate environment. The common indoor pollutants are radon, carbon monoxide, carbon dioxide, and formaldehyde.

## The Risk from Radon

In a highly publicized case about 35 years ago, an employee reporting for work at a nuclear power plant in Pennsylvania set off the plant's radiation monitor. Astonishingly, the source of his contamination turned out not to be the plant, but radon in his home!

A lot has been said and written about the potential dangers of radon as an air pollutant. Just what is radon? Where does it come from? And how does it affect our health?

Radon is a member of Group 8A (the noble gases). It is an intermediate product of the radioactive decay of uranium-238 (see Figure 20.3). All isotopes of radon are radioactive, but radon- 222 is the most hazardous because it has the longest half-life- 3.8 days. Radon, which accounts for slightly over half the background radioactivity on Earth, is generated mostly from the phosphate minerals of uranium (Figure 21.27).

Since the 1970s, high levels of radon have been detected in homes built on reclaimed land above uranium mill tailing deposits. The colorless, odorless, and tasteless radon gas enters a building through tiny cracks in the basement floor. It is slightly soluble in water, so it can be spread in different media. Radon-222 is an $\alpha$-emitter. When it decays, it produces radioactive polonium-214 and polonium-218, which can build up to high levels in an enclosed space. These solid radioactive particles can adhere to airborne dust and smoke, which are inhaled into the lungs and deposited in the respiratory tract. Over a long period of time, the $\alpha$ particles emitted by polonium and its decay products, which are also radioactive, can cause lung cancer.

What can be done to combat radon pollution indoors? The first step is to measure the radon level in the basement with a reliable test kit. Short-term and long-term kits are available (Figure 21.28). The short-term tests use activated charcoal to collect the decay products of radon over a period of several days. The container is sent to a laboratory where a technician measures the radioactivity ( $\gamma$ rays) from radon-decay products lead-214 and bismuth-214. Knowing the length of exposure, the lab technician back-calculates to determine radon concentration. The long-term test kits use a piece of special polymer film on which an $\alpha$ particle will leave a "track." After several months' exposure, the film is etched with a sodium hydroxide solution and the number of tracks counted. Knowing the length of exposure enables the technician to calculate the radon concentration. If the radon level is unacceptably high, then the house must be regularly ventilated. This precaution is particularly important in recently built houses, which are well insulated. A more effective way to prevent radon pollution is to reroute the gas before it gets into the house (e.g., by installing a ventilation duct to draw air from beneath the basement floor to the outside).

Currently there is considerable controversy regarding the health effects of radon. The first detailed studies of the effects of radon on human health were carried out in the 1950s when it was recognized that uranium miners suffered from an abnormally high incidence of lung cancer. Some scientists have challenged the validity of these studies because the miners were also smokers. It seems quite likely that there is a synergistic effect between radon and smoking on the development of lung cancer. Radon decay products will adhere not only to tobacco tar deposits in the lungs, but also to the solid particles in cigarette smoke, which can be inhaled by smokers and nonsmokers. More systematic studies are needed to evaluate the environmental impact of radon. In the meantime, the Environmental Protection Agency (EPA) has recommended remedial action where the radioactivity level due to radon exceeds 4 picocuries ( pCi ) per liter of air. [A curie corresponds to $3.70 \times 10^{10}$ disintegrations of radioactive nuclei per second; a picocurie is a trillionth of a curie, or $3.70 \times 10^{-2}$ disintegrations per second ( dps ).]

## Sample Problem 21.3

The half-life of Rn-222 is 3.8 days. Starting with 1.0 g of $\mathrm{Rn}-222$, how much will be left after 10 half-lives?

Strategy All radioactive decays obey first-order kinetics, making the half-life independent of the initial concentration.

Setup Because the question involves an integral number of half-lives, we can deduce the amount of Rn-222 remaining without using Equation 14.3.

Solution After one half-life, the amount of Rn left is $0.5 \times 1.0 \mathrm{~g}$, or 0.5 g . After two half-lives, only 0.25 g of Rn remains. Generalizing the fraction of the isotope left after $n$ half-lives as $(1 / 2)^{n}$, where $n=10$, we write

$$
\begin{aligned}
\text { quantity of Rn-222 left } & =1.0 \mathrm{~g} \times(1 / 2)^{10} \\
& =9.8 \times 10^{-4} \mathrm{~g}
\end{aligned}
$$

Practice Problem A The concentration of Rn-222 in the basement of a house is $1.8 \times 10^{-6} \mathrm{~mol} / \mathrm{L}$. Assume the air remains static, and calculate the concentration of the radon after 2.4 days.

Figure 21.27 (a) Sources of background radiation. (b) Radon occurrence in the United States.

Figure 21.28 Home radon detector.

Think About It An alternative solution is to calculate the firstorder rate constant from the halflife and use Equation 14.3:

$$
\ln \frac{N_{t}}{N_{0}}=-k t
$$

where $N$ is the mass of $\mathrm{Rn}-222$. Try this and verify that your answers are the same. (Since most of the kinetics problems we encounter do not involve an integral number of half-lives, we generally use Equation 14.3 as the first approach to solving them.)

HPractice Problem B How long will it take for the radioactivity due to radon to fall to a level considered acceptable by the EPA if the starting activity is $2.25 \times 10^{3} \mathrm{dps} / \mathrm{L}$ ?

## Carbon Dioxide and Carbon Monoxide

Both carbon dioxide $\left(\mathrm{CO}_{2}\right)$ and carbon monoxide $(\mathrm{CO})$ are products of combustion.
In the presence of an abundant supply of oxygen, $\mathrm{CO}_{2}$ is formed; in a limited supply of oxygen, both CO and $\mathrm{CO}_{2}$ are formed. The indoor sources of these gases are gas cooking ranges, woodstoves, space heaters, tobacco smoke, human respiration, and exhaust fumes from cars (in garages). Carbon dioxide is not a toxic gas, but it does have an asphyxiating effect. In airtight buildings, the concentration of $\mathrm{CO}_{2}$ can reach as high as 2000 ppm by volume (compared with 3 ppm outdoors). Workers exposed to high concentrations of $\mathrm{CO}_{2}$ in skyscrapers and other sealed environments become fatigued more easily and have difficulty concentrating. Adequate ventilation is the solution to $\mathrm{CO}_{2}$ pollution.

Like $\mathrm{CO}_{2}$, CO is a colorless and odorless gas, but it differs from $\mathrm{CO}_{2}$ in that it is highly poisonous. The toxicity of CO lies in its unusual ability to bind very strongly to hemoglobin, the oxygen carrier in blood. Both $\mathrm{O}_{2}$ and CO bind to the Fe (II) ion in hemoglobin, but the affinity of hemoglobin for CO is about 200 times greater than it is for $\mathrm{O}_{2}$. Hemoglobin molecules with tightly bound CO (called carboxyhemoglobin) cannot carry the oxygen needed for metabolic processes. At a concentration of $70 \mathrm{ppm}, \mathrm{CO}$ can cause drowsiness and headache; at higher concentrations, death may result when about half the hemoglobin molecules become complexed with CO. The best first-aid response to CO poisoning is to remove the victim immediately to an area with a plentiful oxygen supply or to give mouth-to-mouth resuscitation.

## Formaldehyde

Formaldehyde $\left(\mathrm{CH}_{2} \mathrm{O}\right)$ is a rather disagreeable-smelling liquid used as a preservative for laboratory specimens. Industrially, formaldehyde resins are used as bonding agents in building and furniture construction materials such as plywood and particle board. In addition, urea-formaldehyde insulation foams are used to fill wall cavities. The resins and foams slowly break down to release free formaldehyde, especially under acid and humid conditions. Low concentrations of formaldehyde in the air can cause drowsiness, nausea, headaches, and other respiratory ailments. Laboratory tests show that breathing high concentrations of formaldehyde can induce cancers in animals, but whether it has a similar effect in humans is unclear. The safe standard of formaldehyde in indoor air has been set at 0.1 ppm by volume.

Because formaldehyde is a reducing agent, devices have been constructed to remove it by means of a redox reaction. Indoor air is circulated through an air purifier containing an oxidant such as $\mathrm{Al}_{2} \mathrm{O}_{3} / \mathrm{KMnO}_{4}$, which converts formaldehyde to the less harmful and less volatile formic $\operatorname{acid}(\mathrm{HCOOH})$. Proper ventilation is the best way to remove formaldehyde. However, care should be taken not to remove the air from a room too quickly without replenishment, because a reduced pressure would cause the formaldehyde resins to decompose faster, resulting in the release of more formaldehyde.

## Checkpoint 21.8 Indoor Pollution

21.8.1 The risk posed by radon gas in homes is
a) respiratory distress
b) nausea
c) dizziness
d) coma
e) lung cancer
21.8.2 What mass of a $1.0-\mathrm{g}$ sample of radon remains after 30 days? (The half-life of radon is 3.8 days.)
a) 0.030 g
b) 0.0040 g
c) 0.99 g
d) 0.97 g
e) 0.0010 g

## Applying What You've Learned

The research of Paul Crutzen, the third recipient of the Nobel Prize for Chemistry in 1995, involved the effect of nitric oxide ( NO ) on the destruction of stratospheric ozone. Unlike CFCs, which may take 50 to 100 years to diffuse into the upper atmosphere, nitric oxide is introduced directly to the stratosphere in the exhaust of high-altitude aircraft. Early in the 1970s, the United States considered construction of a large fleet of supersonic transport airplanes (SSTs), similar to the Concorde. Environmentalists argued, based in part on the work of Paul Crutzen, that to do so would significantly endanger the ozone layer.

## Problems:

a) The bond enthalpy of NO is $630.6 \mathrm{~kJ} / \mathrm{mol}$. Determine the maximum wavelength of light required to break the bond in an NO molecule. [ 14 Sample Problem 21.1]
b) Can nitric oxide act as a greenhouse gas? Explain. [\$4 Sample Problem 21.2]

## Chapter Summary

## Section 21.1

- Earth's atmosphere is made up mainly of nitrogen and oxygen, plus a number of other trace gases. Molecular nitrogen in the atmosphere is incorporated into other compounds via nitrogen fixation.
- The regions of the atmosphere, from Earth's surface outward, are the troposphere, the stratosphere, the mesosphere, the thermosphere, and the ionosphere.
- The chemical processes that go on in the atmosphere are influenced by solar radiation, volcanic eruption, and human activities.

## Section 21.2

- In the outer regions of the atmosphere, the bombardment of molecules and atoms by solar particles gives rise to the aurora borealis in the Northern Hemisphere and the aurora australis in the Southern Hemisphere. The glow on a space shuttle is caused by excitation of molecules adsorbed on the shuttle's surface.

## Section 21.3

- Ozone in the stratosphere absorbs harmful UV radiation in the 200- to $300-\mathrm{nm}$ range and protects life underneath. For many years, chlorofluorocarbons have been destroying the ozone layer.

## Section 21.4

- Volcanic eruptions can lead to air pollution, deplete ozone in the stratosphere, and affect climate.

## Section 21.5

- Carbon dioxide's ability to absorb infrared radiation enables it to trap some of the outgoing heat from Earth, warming its surface-a phenomenon known as the greenhouse effect. Other gases such as the CFCs and methane also contribute to the greenhouse effect. Global warming refers to the result of the enhanced greenhouse effect caused by human activities.

## Section 21.6

- Sulfur dioxide, and to a lesser extent nitrogen oxides, generated mainly from the burning of fossil fuels and from the roasting of metal sulfides, causes acid rain.

## Section 21.7

- Photochemical smog is formed by the photochemical reaction of automobile exhaust in the presence of sunlight. It is a complex reaction involving nitrogen oxides, ozone, and hydrocarbons.

## Section 21.8

- Indoor air pollution is caused by radon, a radioactive gas formed during uranium decay; carbon monoxide and carbon dioxide, products of combustion; and formaldehyde, a volatile organic substance released from resins used in construction materials.

## Key Words

Greenhouse effect, 902
Ionosphere, 897

Mesosphere, 897
Nitrogen fixation, 895

Photochemical smog, 909
Stratosphere, 897

Thermosphere, 897
Troposphere, 896

## Questions and Problems

## Section 21.1: Earth's Atmosphere

## Review Questions

21.1 Describe the regions of Earth's atmosphere.
21.2 Briefly outline the main processes of the nitrogen and oxygen cycles.
21.3 Explain why, for maximum performance, supersonic airplanes need to fly at a high altitude (in the stratosphere).
21.4 Jupiter's atmosphere consists mainly of hydrogen ( 90 percent) and helium ( 9 percent). How does this mixture of gases contrast with the composition of Earth's atmosphere? Why does the composition differ?

## Problems

21.5 Referring to Table 21.1, calculate the mole fraction of $\mathrm{CO}_{2}$ and its concentration in parts per million by volume.

H21.6 Calculate the partial pressure of $\mathrm{CO}_{2}$ (in atm) in dry air when the atmospheric pressure is 754 mmHg .
21.7 Describe the processes that result in the warming of the stratosphere.
E 21.8 Calculate the mass (in kg ) of nitrogen, oxygen, and carbon dioxide gases in the atmosphere. Assume that the total mass of air in the atmosphere is $5.25 \times 10^{21} \mathrm{~g}$.

## Section 21.2: Phenomena in the Outer Layers of the Atmosphere

## Review Questions

21.9 What process gives rise to the aurora borealis and aurora australis?
21.10 Why can astronauts not release oxygen atoms to test the mechanism of shuttle glow?

## Problems

21.11 The highly reactive OH radical (a species with an unpaired electron) is believed to be involved in some atmospheric processes. Table 8.6 lists the bond enthalpy for the oxygen-to-hydrogen bond in OH as $460 \mathrm{~kJ} / \mathrm{mol}$. What is the longest wavelength (in nm ) of radiation that can bring about the following reaction?

$$
\mathrm{OH}(g) \longrightarrow \mathrm{O}(g)+\mathrm{H}(g)
$$

E 21.12 The green color observed in the aurora borealis is produced by the emission of a photon by an electronically excited oxygen atom at 558 nm . Calculate the energy difference between the two levels involved in the emission process.

## Section 21.3: Depletion of Ozone in the Stratosphere

## Review Questions

21.13 Briefly describe the absorption of solar radiation in the stratosphere by $\mathrm{O}_{2}$ and $\mathrm{O}_{3}$ molecules.
21.14 Explain the processes that have a warming effect on the stratosphere.
21.15 List the properties of CFCs, and name four major uses of these compounds.
21.16 How do CFCs and nitrogen oxides destroy ozone in the stratosphere?
21.17 What causes the polar ozone holes?
21.18 How do volcanic eruptions contribute to ozone destruction?
21.19 Describe ways to curb the destruction of ozone in the stratosphere.
21.20 Discuss the effectiveness of some of the CFC substitutes.

## Problems

$\boldsymbol{E}$ 21.21 Given that the quantity of ozone in the stratosphere is equivalent to a $3.0-\mathrm{mm}$-thick layer of ozone on Earth at STP, calculate the number of ozone molecules in the stratosphere and their mass in kilograms. (Hint: The radius of Earth is 6371 km and the surface area of a sphere is $4 \pi r^{2}$, where $r$ is the radius.)

H21.22 Referring to the answer in Problem 21.21, and assuming that the level of ozone in the stratosphere has already fallen 6.0 percent, calculate the number of kilograms of ozone that would have to be manufactured on a daily basis so that we could restore the ozone to the original level in 100 years. If ozone is made according to the process $3 \mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{O}_{3}(\mathrm{~g})$, how many kilojoules of energy would be required?
21.23 Both Freon-11 and Freon-12 are made by the reaction of carbon tetrachloride $\left(\mathrm{CCl}_{4}\right)$ with hydrogen fluoride. Write equations for these reactions.
21.24 Why are CFCs not decomposed by UV radiation in the troposphere?
21.25 The average bond enthalpies of the $\mathrm{C}-\mathrm{Cl}$ and $\mathrm{C}-\mathrm{F}$ bonds are 340 and $485 \mathrm{~kJ} / \mathrm{mol}$, respectively. Based on this information, explain why the $\mathrm{C}-\mathrm{Cl}$ bond in a CFC molecule is preferentially broken by solar radiation at 250 nm .

H21.26 Like CFCs, certain bromine-containing compounds such as $\mathrm{CF}_{3} \mathrm{Br}$ can also participate in the destruction of ozone by a similar mechanism starting with the Br atom:

$$
\mathrm{CF}_{3} \mathrm{Br} \longrightarrow \mathrm{CF}_{3}+\mathrm{Br}
$$

Given that the average $\mathrm{C}-\mathrm{Br}$ bond energy is $276 \mathrm{~kJ} / \mathrm{mol}$, estimate the longest wavelength required to break this bond. Will this compound be decomposed in the troposphere only or in both the troposphere and stratosphere?

H21.27 Draw Lewis structures for chlorine nitrate $\left(\mathrm{ClONO}_{2}\right)$ and chlorine monoxide ( ClO ).

G 21.28 Draw Lewis structures for $\mathrm{HCFC}-123\left(\mathrm{CF}_{3} \mathrm{CHCl}_{2}\right)$ and $\mathrm{CF}_{3} \mathrm{CFH}_{2}$.

## Section 21.4: Volcanoes

## Review Questions

21.29 What are the effects of volcanic eruptions on climate?
21.30 Classify the reaction between $\mathrm{H}_{2} \mathrm{~S}$ and $\mathrm{SO}_{2}$ that leads to the formation of sulfur at the site of a volcanic eruption.

## Section 21.5: The Greenhouse Effect

## Review Questions

21.31 What is the greenhouse effect? What is the criterion for classifying a gas as a greenhouse gas?
21.32 Why is more emphasis placed on the role of carbon dioxide in the greenhouse effect than on that of water?
21.33 Describe three human activities that generate carbon dioxide. List two major mechanisms for the uptake of carbon dioxide.
21.34 Deforestation contributes to the greenhouse effect in two ways. What are they?
21.35 How does an increase in world population enhance the greenhouse effect?
21.36 Is ozone a greenhouse gas? If so, sketch three ways an ozone molecule can vibrate.
21.37 What effects do CFCs and their substitutes have on Earth's temperature?
21.38 Why are CFCs more effective greenhouse gases than methane and carbon dioxide?

## Problems

21.39 The annual production of zinc sulfide $(\mathrm{ZnS})$ is $4.0 \times 10^{4}$ tons. Estimate the number of tons of $\mathrm{SO}_{2}$ produced by roasting it to extract zinc metal.
421.40 Calcium oxide or quicklime $(\mathrm{CaO})$ is used in steelmaking, cement manufacture, and pollution control. It is prepared by the thermal decomposition of calcium carbonate:

$$
\mathrm{CaCO}_{3}(s) \longrightarrow \mathrm{CaO}(s)+\mathrm{CO}_{2}(g)
$$

Calculate the yearly release of $\mathrm{CO}_{2}$ (in kg ) to the atmosphere if the annual production of CaO in the United States is $1.7 \times$ $10^{10} \mathrm{~kg}$.

- 21.41 The molar heat capacity of a diatomic molecule is $29.1 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$. Assuming the atmosphere contains only nitrogen gas and there is no heat loss, calculate the total heat intake (in kJ ) if the atmosphere warms up by $3^{\circ} \mathrm{C}$ during the next 50 years. Given that there are $1.8 \times 10^{20}$ moles of diatomic molecules present, how many kilograms of ice (at the North and South Poles) will this quantity of heat melt at $0^{\circ} \mathrm{C}$ ? (The molar heat of fusion of ice is $6.01 \mathrm{~kJ} / \mathrm{mol}$.)
21.42 As mentioned in the chapter, spraying the stratosphere with hydrocarbons such as ethane and propane should eliminate Cl atoms. What is the drawback of this procedure if used on a large scale for an extended period of time?

## Section 21.6: Acid Rain

## Review Questions

21.43 Name the gas that is largely responsible for the acid rain phenomenon.
21.44 List three detrimental effects of acid rain.
21.45 Briefly discuss two industrial processes that lead to acid rain.
21.46 Discuss ways to curb acid rain.
21.47 Water and sulfur dioxide are both polar molecules, and their geometry is similar. Why is $\mathrm{SO}_{2}$ not considered a major greenhouse gas?
21.48 Describe the removal of $\mathrm{SO}_{2}$ by CaO (to form $\mathrm{CaSO}_{3}$ ) in terms of a Lewis acid-base reaction.

## Problems

E 21.49 An electric power station annually burns $3.1 \times 10^{7} \mathrm{~kg}$ of coal containing 2.4 percent sulfur by mass. Calculate the volume of $\mathrm{SO}_{2}$ emitted at STP.
$\leftrightarrows 21.50$ The concentration of $\mathrm{SO}_{2}$ in the troposphere over a certain region is 0.16 ppm by volume. The gas dissolves in rainwater as follows:

$$
\mathrm{SO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{H}^{+}(a q)+\mathrm{HSO}_{3}^{-}(a q)
$$

Given that the equilibrium constant for the preceding reaction is $1.3 \times 10^{-2}$, calculate the pH of the rainwater. Assume that the reaction does not affect the partial pressure of $\mathrm{SO}_{2}$.

## Section 21.7: Photochemical Smog

## Review Questions

21.51 What is photochemical smog? List the factors that favor the formation of photochemical smog.
21.52 What are primary and secondary pollutants?
21.53 Identify the gas that is responsible for the brown color of photochemical smog.
21.54 The safety limits of ozone and carbon monoxide are 120 ppb by volume and 9 ppm by volume, respectively. Why does ozone have a lower limit?
21.55 Suggest ways to minimize the formation of photochemical smog.

H21.56 In which region of the atmosphere is ozone beneficial? In which region is it detrimental?

## Problems

EI21.57 Assume that the formation of nitrogen dioxide:

$$
2 \mathrm{NO}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{NO}_{2}(g)
$$

is an elementary reaction. (a) Write the rate law for this reaction. (b) A sample of air at a certain temperature is contaminated with 2.0 ppm of NO by volume. Under these conditions, can the rate law be simplified? If so, write the simplified rate law. (c) Under the conditions described in part (b), the half-life of the reaction has been estimated to be $6.4 \times 10^{3} \mathrm{~min}$. What would the half-life be if the initial concentration of NO were 10 ppm ?

EI 21.58 The gas-phase decomposition of peroxyacetyl nitrate (PAN) obeys first-order kinetics:

$$
\mathrm{CH}_{3} \mathrm{COOONO}_{2} \longrightarrow \mathrm{CH}_{3} \mathrm{COOO}+\mathrm{NO}_{2}
$$

with a rate constant of $4.9 \times 10^{-4} \mathrm{~s}^{-1}$. Calculate the rate of decomposition (in $\mathrm{M} / \mathrm{s}$ ) if the concentration of PAN is 0.55 ppm by volume. Assume STP conditions.
§ 21.59 On a smoggy day in a certain city, the ozone concentration was 0.42 ppm by volume. Calculate the partial pressure of ozone (in atm) and the number of ozone molecules per liter of air if the temperature and pressure were $20.0^{\circ} \mathrm{C}$ and 748 mmHg , respectively.
21.60 Which of the following settings is the most suitable for photochemical smog formation: (a) Gobi desert at noon in June, (b) New York City at 1 P.M. in July, (c) Boston at noon in January? Explain your choice.

## Section 21.8: Indoor Pollution

## Review Questions

21.61 List the major indoor pollutants and their sources.
21.62 What is the best way to deal with indoor pollution?
21.63 Why is it dangerous to idle a car's engine in a poorly ventilated place, such as the garage?
21.64 Describe the properties that make radon an indoor pollutant. Would radon be more hazardous if ${ }^{222} \mathrm{Rn}$ had a longer half-life?

## Problems

$\leftrightarrows 21.65$ A concentration of $8.00 \times 10^{2} \mathrm{ppm}$ by volume of CO is considered lethal to humans. Calculate the minimum mass of CO (in grams) that would become a lethal concentration in a closed room 17.6 m long, 8.80 m wide, and 2.64 m high. The temperature and pressure are $20.0^{\circ} \mathrm{C}$ and 756 mmHg , respectively.

E- 21.66 A volume of 5.0 L of polluted air at $18.0^{\circ} \mathrm{C}$ and 747 mmHg is passed through lime water [an aqueous suspension of $\mathrm{Ca}(\mathrm{OH})_{2}$ ], so that all the carbon dioxide present is precipitated as $\mathrm{CaCO}_{3}$. If the mass of the $\mathrm{CaCO}_{3}$ precipitate is 0.026 g , calculate the percentage by volume of $\mathrm{CO}_{2}$ in the air sample.

## Additional Problems

21.67 Briefly describe the harmful effects of the following substances: $\mathrm{O}_{3}, \mathrm{SO}_{2}, \mathrm{NO}_{2}, \mathrm{CO}, \mathrm{CH}_{3} \mathrm{COOONO}_{2}$ (PAN), Rn.
$\leftrightarrows 21.68$ The equilibrium constant $\left(K_{P}\right)$ for the reaction

$$
\mathrm{N}_{2}(g)+\mathrm{O}_{2}(g) \rightleftarrows 2 \mathrm{NO}(g)
$$

is $4.0 \times 10^{-31}$ at $25^{\circ} \mathrm{C}$ and $2.6 \times 10^{-6}$ at $1100^{\circ} \mathrm{C}$, the temperature of a running car's engine. Is this an endothermic or exothermic reaction?

E 21.69 As stated in the chapter, carbon monoxide has a much higher affinity for hemoglobin than oxygen does. (a) Write the equilibrium constant expression $\left(K_{\mathrm{c}}\right)$ for the following process:

$$
\mathrm{CO}(g)+\mathrm{HbO}_{2}(a q) \rightleftarrows \mathrm{O}_{2}(g)+\mathrm{HbCO}(a q)
$$

where $\mathrm{HbO}_{2}$ and HbCO are oxygenated hemoglobin and carboxyhemoglobin, respectively. (b) The composition of a breath of air inhaled by a person smoking a cigarette is $1.9 \times 10^{-6} \mathrm{~mol} / \mathrm{L}$ CO and $8.6 \times 10^{-3} \mathrm{~mol} / \mathrm{L} \mathrm{O}_{2}$. Calculate the ratio of $[\mathrm{HbCO}]$ to $\left[\mathrm{HbO}_{2}\right]$, given that $K_{\mathrm{c}}$ is 212 at $37^{\circ} \mathrm{C}$.
21.70 Instead of monitoring carbon dioxide, suggest another gas that scientists could study to substantiate the fact that $\mathrm{CO}_{2}$ concentration is steadily increasing in the atmosphere.

H21.71 In 1991 it was discovered that nitrous oxide $\left(\mathrm{N}_{2} \mathrm{O}\right)$ is produced in the synthesis of nylon. This compound, which is released into the atmosphere, contributes both to the depletion of ozone in the stratosphere and to the greenhouse effect. (a) Write equations representing the reactions between $\mathrm{N}_{2} \mathrm{O}$ and oxygen atoms in the stratosphere to produce nitric oxide (NO), which is then oxidized by ozone to form nitrogen dioxide. (b) Is $\mathrm{N}_{2} \mathrm{O}$ a more effective greenhouse gas than carbon dioxide? Explain. (c) One of the intermediates in nylon manufacture is adipic acid $\left[\mathrm{HOOC}\left(\mathrm{CH}_{2}\right)_{4} \mathrm{COOH}\right]$. About $2.2 \times 10^{9} \mathrm{~kg}$ of adipic acid is consumed every year. It is estimated that for every mole of adipic acid produced, 1 mole of $\mathrm{N}_{2} \mathrm{O}$ is generated. What is the maximum number of moles of $\mathrm{O}_{3}$ that can be destroyed as a result of this process per year?

G21.72 A glass of water initially at pH 7.0 is exposed to dry air at sea level at $20^{\circ} \mathrm{C}$. Calculate the pH of the water when equilibrium is reached between atmospheric $\mathrm{CO}_{2}$ and $\mathrm{CO}_{2}$ dissolved in the water, given that Henry's law constant for $\mathrm{CO}_{2}$ at $20^{\circ} \mathrm{C}$ is $0.032 \mathrm{~mol} / \mathrm{L} \cdot \mathrm{atm}$. (Hint: Assume no loss of water due to evaporation, and use Table 21.1 to calculate the partial pressure of $\mathrm{CO}_{2}$. Your answer should correspond roughly to the pH of rainwater.)

- 21.73 A $14-\mathrm{m}$ by $10-\mathrm{m}$ by $3.0-\mathrm{m}$ basement had a high radon content. On the day the basement was sealed off from its surroundings so that no exchange of air could take place, the partial pressure of ${ }^{222} \mathrm{Rn}$ was $1.2 \times 10^{-6} \mathrm{mmHg}$. Calculate the number of ${ }^{222} \mathrm{Rn}$ isotopes $\left(t_{1 / 2}=3.8\right.$ days $)$ at the beginning and end of 31 days. Assume STP conditions.
$\boldsymbol{\$}$ 21.74 Ozone in the troposphere is formed by the following steps:

$$
\begin{align*}
\mathrm{NO}_{2} & \longrightarrow \mathrm{NO}+\mathrm{O}  \tag{1}\\
\mathrm{O}+\mathrm{O}_{2} & \longrightarrow \mathrm{O}_{3} \tag{2}
\end{align*}
$$

The first step is initiated by the absorption of visible light $\left(\mathrm{NO}_{2}\right.$ is a brown gas). Calculate the longest wavelength required for step 1 at $25^{\circ} \mathrm{C}$. (Hint: You need to first calculate $\Delta H$ and hence $\Delta E$ for step 1. Next, determine the wavelength for decomposing $\mathrm{NO}_{2}$ from $\Delta E$.)

E 21.75 Although the hydroxyl radical $(\mathrm{OH})$ is present only in a trace amount in the troposphere, it plays a central role in its chemistry because it is a strong oxidizing agent and can react with many pollutants as well as some CFC substitutes. The hydroxyl radical is formed by the following reactions:

$$
\begin{aligned}
& \mathrm{O}_{3} \lambda=320 \mathrm{~nm} \\
& \mathrm{O}+\mathrm{H}_{2} \mathrm{O} \mathrm{O}^{*}+\mathrm{O}_{2} \\
& 2 \mathrm{OH}
\end{aligned}
$$

where $\mathrm{O}^{*}$ denotes an electronically excited atom. (a) Explain why the concentration of OH is so small even though the concentrations of $\mathrm{O}_{3}$ and $\mathrm{H}_{2} \mathrm{O}$ are quite large in the troposphere. (b) What property makes OH a strong oxidizing agent? (c) The reaction between OH and $\mathrm{NO}_{2}$ contributes to acid rain. Write an equation for this process. (d) The hydroxyl radical can oxidize $\mathrm{SO}_{2}$ to $\mathrm{H}_{2} \mathrm{SO}_{4}$. The first step is the formation of a neutral $\mathrm{HSO}_{3}$ species, followed by its reaction with $\mathrm{O}_{2}$ and $\mathrm{H}_{2} \mathrm{O}$ to form $\mathrm{H}_{2} \mathrm{SO}_{4}$ and the hydroperoxyl radical $\left(\mathrm{HO}_{2}\right)$. Write equations for these processes.
21.76 The equilibrium constant $\left(K_{P}\right)$ for the reaction $2 \mathrm{CO}(g)+$ $\mathrm{O}_{2}(\mathrm{~g}) \rightleftarrows 2 \mathrm{CO}_{2}(\mathrm{~g})$ is $1.4 \times 10^{90}$ at $25^{\circ} \mathrm{C}$. Given this enormous value, why doesn't CO convert totally to $\mathrm{CO}_{2}$ in the troposphere?
21.77 A person was found dead of carbon monoxide poisoning in a well-insulated cabin. Investigation showed that he had used a blackened bucket to heat water on a butane burner. The burner was found to function properly with no leakage. Explain, with an appropriate equation, the cause of his death.
21.78 The carbon dioxide level in the atmosphere today is often compared with that in preindustrial days. Explain how scientists use tree rings and air trapped in polar ice to arrive at the comparison.
21.79 What is ironic about the following cartoon?

E 21.80 Calculate the standard enthalpy of formation $\left(\Delta H_{\mathrm{f}}^{\circ}\right)$ of ClO from the following bond energies: $\mathrm{Cl}_{2}: 242.7 \mathrm{~kJ} / \mathrm{mol} ; \mathrm{O}_{2}: 498.7 \mathrm{~kJ} / \mathrm{mol}$; ClO: $206 \mathrm{~kJ} / \mathrm{mol}$.

H21.81 Methyl bromide $\left(\mathrm{CH}_{3} \mathrm{Br}\right.$, b.p. $\left.=3.6^{\circ} \mathrm{C}\right)$ is used as a soil fumigant to control insects and weeds. It is also a marine by-product. Photodissociation of the $\mathrm{C}-\mathrm{Br}$ bond produces Br atoms that can react with ozone similar to Cl , except more effectively. Do you expect $\mathrm{CH}_{3} \mathrm{Br}$ to be photolyzed in the troposphere? The bond enthalpy of the $\mathrm{C}-\mathrm{Br}$ bond is about $293 \mathrm{~kJ} / \mathrm{mol}$.

E 21.82 The effective incoming solar radiation per unit area on Earth is $342 \mathrm{~W} / \mathrm{m}^{2}$. Of this radiation, $6.7 \mathrm{~W} / \mathrm{m}^{2}$ is absorbed by $\mathrm{CO}_{2}$ at $14,993 \mathrm{~nm}$ in the atmosphere. How many photons at this wavelength are absorbed per second in $1 \mathrm{~m}^{2}$ by $\mathrm{CO}_{2} ?(1 \mathrm{~W}=1 \mathrm{~J} / \mathrm{s}$.

E 21.83 As stated in the chapter, about 50 million tons of sulfur dioxide is released into the atmosphere every year. (a) If 20 percent of the $\mathrm{SO}_{2}$ is eventually converted to $\mathrm{H}_{2} \mathrm{SO}_{4}$, calculate the number of 1000-lb marble statues the resulting acid rain can damage. As an estimate, assume that the acid rain only destroys the surface layer of each statue, which is made up of 5 percent of its total mass.
(b) What is the other undesirable result of the acid rain damage?

El 21.84 Peroxyacetyl nitrate (PAN) undergoes thermal decomposition as follows:

$$
\mathrm{CH}_{3}(\mathrm{CO}) \mathrm{OONO}_{2} \longrightarrow \mathrm{CH}_{3}(\mathrm{CO}) \mathrm{OO}+\mathrm{NO}_{2}
$$

The rate constant is $3.0 \times 10^{-4} \mathrm{~s}^{-1}$ at $25^{\circ} \mathrm{C}$. At the boundary between the troposphere and stratosphere, where the temperature is about $-40^{\circ} \mathrm{C}$, the rate constant is reduced to $2.6 \times 10^{-7} \mathrm{~s}^{-1}$.
(a) Calculate the activation energy for the decomposition of PAN.
(b) What is the half-life of the reaction (in min ) at $25^{\circ} \mathrm{C}$ ?
21.85 How are past temperatures determined from ice cores obtained from the Arctic or Antarctica? (Hint: Look up the stable isotopes of hydrogen and oxygen. How does energy required for vaporization depend on the masses of $\mathrm{H}_{2} \mathrm{O}$ molecules containing different isotopes? How would you determine the age of an ice core?)

H21.86 The balance between $\mathrm{SO}_{2}$ and $\mathrm{SO}_{3}$ is important in understanding acid rain formation in the troposphere. From the following information at $25^{\circ} \mathrm{C}$

$$
\begin{aligned}
\mathrm{S}(s)+\mathrm{O}_{2}(g) & \rightleftarrows \mathrm{SO}_{2}(g) \\
2 \mathrm{~S}(\mathrm{~s})+3 \mathrm{O}_{2}(g) & K_{1}=4.2 \times 10^{52} \\
2 \mathrm{SO}_{3}(g) & K_{2}=9.8 \times 10^{128}
\end{aligned}
$$

calculate the equilibrium constant for the reaction

$$
2 \mathrm{SO}_{2}(g)+\mathrm{O}_{2}(\mathrm{~g}) \rightleftarrows 2 \mathrm{SO}_{3}(\mathrm{~g})
$$

## Pre-Professional Practice Exam Problems: Physical and Biological Sciences

Indoor air pollutants, including radon gas, can pose significant health risks. Radon is a radioactive gas found in the soils and rocks of Earth's crust. It finds its way into homes through cracks in the foundation or basement, and sometimes through the water supply. Radon is invisible and odorless, and becomes a health hazard when it is allowed to build up inside the home. The isotope of radon commonly found in homes is radon-222, a product of the uranium-238 decay chain, formed by the $\alpha$ decay of radium-226. Radon-222, in turn, decays by $\alpha$ emission.

1. Select the equation that correctly represents the $\alpha$ decay of radium-226.
a) ${ }^{226} \mathrm{Ra} \longrightarrow{ }^{226} \mathrm{Rn}+\alpha$
b) ${ }^{226} \mathrm{Ra} \longrightarrow{ }^{222} \mathrm{Rn}+\alpha$
c) ${ }^{226} \mathrm{Ra}+\alpha \longrightarrow{ }^{226} \mathrm{Rn}$
d) ${ }^{226} \mathrm{Ra}+\alpha \longrightarrow{ }^{222} \mathrm{Rn}$
2. How many neutrons does a radium- 226 nucleus contain?
a) 226
b) 88
c) 113
d) 138
3. What is the product when radon- 222 decays by $\alpha$ emission?
a) Radon- 218
b) Radium- 218
c) Polonium-218
d) Polonium- 226
4. What would the product be if radon- 222 decayed by $\beta$ emission?
a) Francium- 222
b) Radon- 223
c) Radon- 221
d) Astatine-222

## How Coordination Chemistry Is Used to Treat Lead Poisoning

Although the Consumer Product Safety Commission (CPSC) banned the residential use of lead-based paint in 1978, millions of children remain at risk for exposure to lead from deteriorating paint in older homes. Lead poisoning is especially harmful to children under the age of 5 years because it interferes with growth and development and it has been shown to lower IQ. Symptoms of chronic exposure to lead include diminished appetite, nausea, malaise, and convulsions. Blood lead level (BLL), expressed as micrograms per deciliter ( $\mu \mathrm{g} / \mathrm{dL}$ ), is used to monitor the effect of chronic exposure. A BLL $\leq$ $10 \mu \mathrm{~g} / \mathrm{dL}$ is considered normal; a BLL $>45 \mu \mathrm{~g} / \mathrm{dL}$ requires medical and environmental intervention. At high levels ( $>70 \mu \mathrm{~g} / \mathrm{dL}$ ), lead can cause seizures, coma, and death.

Treatment for lead poisoning involves chelation therapy, in which a chelating agent is administered orally, intravenously, or intramuscularly. Chelating agents form strong coordinate-covalent bonds to metal ions, forming stable, water-soluble complex ions that are easily removed from the body via the urine. One of the drugs commonly used for this purpose is dimercaptosuccinic acid (DMSA), marketed under the name Chemet. Chelation therapy relies on coordination chemistry.

Dimercaptosuccinic acid (DMSA)

At the end of this chapter, you will be able to answer questions about some important coordination compounds [ $\quad$ Page 939].

## In This Chapter You, Will Learn:

About the properties of coordination compounds and how, through the use of chelates, coordination chemistry is used to solve a variety of medical and other societal problems.

## Before you begin, you should review

- Lewis acids and bases [ kt Section 16.12]
- The shapes of $d$ orbitals [ $/ 4$ Section 6.7]

Student Annotation: A complex ion is one in which a metal cation is covalently bound to one or more molecules or ions [ 14 Section 17.5].

Student Annotation: We can use the term coordination complex to refer to a compound, such as $\mathrm{Fe}(\mathrm{CO})_{5}$, or to a complex ion.

Student Annotation: The Group 2B metals$\mathrm{Zn}, \mathrm{Cd}$, and Hg -do not fit either of these criteria. As a result, they are $d$-block metals, but they are not actually transition metals.

Multimedia
Chemical Reactions—oxidation states of vanadium.

Figure 22.1 The transition metals (shown in green). Note that although the Group 2B elements $(\mathrm{Zn}, \mathrm{Cd}, \mathrm{Hg})$ are described as transition metals by some chemists, neither the metals nor their ions possess incompletely filled $d$ subshells.

### 22.1 Coordination Compounds

Coordination compounds contain coordinate covalent bonds [14 Section 8.8] formed by the reactions of metal ions with groups of anions or polar molecules. The metal ion in these kinds of reactions acts as a Lewis acid, accepting electrons, whereas the anions or polar molecules act as Lewis bases, donating pairs of electrons to form bonds to the metal ion. Thus, a coordinate covalent bond is a covalent bond in which one of the atoms donates both of the electrons that constitute the bond. Often a coordination compound consists of a complex ion and one or more counter ions. In writing formulas for such coordination compounds, we use square brackets to separate the complex ion from the counter ion.

$$
\mathrm{K}_{2}\left[\mathrm{PtCl}_{6}\right]
$$

This compound consists of the complex ion $\mathrm{PtCl}_{6}^{2-}$ and two $\mathrm{K}^{+}$counter ions.
Some coordination compounds, such as $\mathrm{Fe}(\mathrm{CO})_{5}$, do not contain complex ions. Most but not all of the metals in coordination compounds are transition metals. Our understanding of the nature of coordination compounds stems from the classic work of Alfred Werner, ${ }^{1}$ who prepared and characterized many coordination compounds. In 1893, at the age of 26, Werner proposed what is now commonly referred to as Werner's coordination theory.

Nineteenth-century chemists were puzzled by a certain class of reactions that seemed to violate valence theory. For example, the valences of the elements in cobalt(III) chloride and those in ammonia seem to be completely satisfied, and yet these two substances react to form a stable compound having the formula $\mathrm{CoCl}_{3} \cdot 6 \mathrm{NH}_{3}$. To explain this behavior, Werner postulated that most elements exhibit two types of valence: primary valence and secondary valence. In modern terminology, primary valence corresponds to the oxidation number and secondary valence to the coordination number of the element. In $\mathrm{CoCl}_{3} \cdot 6 \mathrm{NH}_{3}$, according to Werner, cobalt has a primary valence of 3 and a secondary valence of 6 .

Today we use the formula $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right] \mathrm{Cl}_{3}$ to indicate that the ammonia molecules and the cobalt atom form a complex ion; the chloride ions are not part of the complex but are counter ions, held to the complex ion by Coulombic attraction.

## Properties of Transition Metals

Transition metals are those that either have incompletely filled $d$ subshells or form ions with incompletely filled $d$ subshells (Figure 22.1). Incompletely filled $d$ subshells give rise to several notable properties, including distinctive colors, the formation of paramagnetic compounds, catalytic activity, and the tendency to form complex ions. The most common transition metals are scandium through copper, which occupy the fourth row of the periodic table. Table 22.1 lists the electron configurations and some of the properties of these metals.

Most of the transition metals exhibit a close-packed structure in which each atom has a coordination number of 12 . Furthermore, these elements have relatively small atomic radii. The combined effect of closest packing and small atomic size results in strong metallic bonds. Therefore,

transition metals have higher densities, higher melting points and boiling points, and higher heats of fusion and vaporization than the main group and Group 2B metals (Table 22.2).

Transition metals exhibit variable oxidation states in their compounds. Figure 22.2 shows the oxidation states of the first row of transition metals. Note that all these metals can exhibit the oxidation state +3 and nearly all can exhibit the oxidation state +2 . Of these two, the +2 oxidation state is somewhat more common for the heavier elements. The highest oxidation state for a transition metal is +7 , exhibited by manganese $\left(4 s^{2} 3 d^{5}\right)$. Transition metals exhibit their highest oxidation states in compounds that contain highly electronegative elements such as oxygen and fluorine-for example, $\mathrm{V}_{2} \mathrm{O}_{5}, \mathrm{CrO}_{3}$, and $\mathrm{Mn}_{2} \mathrm{O}_{7}$.

Student Annotation: The oxidation state of $O$ in each of these compounds is -2 , making those of $\mathrm{V}, \mathrm{Cr}$, and $\mathrm{Mn}+5,+6$, and +7 , respectively [ 14 Section 4.4].

Figure 22.2 Oxidation states of the first-row transition metals. The most stable oxidation numbers are shown in red. The zero oxidation state is encountered in some compounds, such as $\mathrm{Ni}(\mathrm{CO})_{4}$ and $\mathrm{Fe}(\mathrm{CO})_{5}$.

## Ligands

The molecules or ions that surround the metal in a complex ion are called ligands (Table 22.3). The formation of covalent bonds between ligands and a metal can be thought of as a Lewis acid-base reaction. (Recall that a Lewis base is a species that donates a pair of electrons [ $W 4$ Section 16.12].) To be a ligand, a molecule or ion must have at least one unshared pair of valence electrons, as these examples illustrate:

Therefore, ligands play the role of Lewis bases. The transition metal, on the other hand, acts as a Lewis acid, accepting (and sharing) pairs of electrons from the Lewis bases.

The atom in a ligand that is bound directly to the metal atom is known as the donor atom. For example, nitrogen is the donor atom in the $\left[\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}\right]^{2+}$ complex ion:

The coordination number in a coordination compound refers to the number of donor atoms surrounding the central metal atom in a complex ion. The coordination number of $\mathrm{Cu}^{2+}$ in $\left[\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}\right]^{2+}$ is 4 . The most common coordination numbers are 4 and 6 , although coordination numbers of 2 and 5 are also known.

Depending on the number of donor atoms a ligand possesses, it is classified as monodentate ( 1 donor atom), bidentate ( 2 donor atoms), or polydentate ( $>2$ donor atoms). Table 22.3 lists some common ligands. Figure 22.3 shows how ethylenediamine, sometimes abbreviated "en," forms two bonds to a metal atom.

Bidentate and polydentate ligands are also called chelating agents because of their ability to hold the metal atom like a claw (from the Greek chele, meaning "claw"). One example is EDTA (Figure 22.4), a polydentate ligand used to treat metal poisoning. Six donor atoms enable EDTA to form a very stable complex ion with lead. This stable complex enables the body to remove lead from the blood.

The oxidation state of a transition metal in a complex ion is determined using the known charges of the ligands and the known overall charge of the complex ion. In the complex ion $\left[\mathrm{PtCl}_{6}\right]^{2-}$, for example, each chloride ion ligand has an oxidation number of -1 . For the overall charge of the ion to be -2 , the Pt must have an oxidation number of +4 .

Sample Problem 22.1 shows how to determine transition metal oxidation states in coordination compounds.

## Sample Problem 22.1

Determine the oxidation state of the central metal atom in each of the following compounds: (a) $\left[\mathrm{Ru}\left(\mathrm{NH}_{3}\right)_{5}\left(\mathrm{H}_{2} \mathrm{O}\right)\right] \mathrm{Cl}_{2}$, (b) $\left[\mathrm{Cr}\left(\mathrm{NH}_{3}\right)_{6}\right]\left(\mathrm{NO}_{3}\right)_{3}$, and (c) $\mathrm{Fe}(\mathrm{CO})_{5}$.

Strategy Identify the components of each compound, and use known oxidation states and charges to determine the oxidation state of the metal.

Student Annotation: Remember that the oxidation number of a monoatomic ion is equal to the charge [ 14 Section 4.4].

Figure 22.4 (a) EDTA complex of lead. The complex bears a net charge of 2 - because each O donor atom has one negative charge and the lead ion carries two positive charges. Only the lone pairs that participate in bonding are shown. Note the octahedral geometry about the $\mathrm{Pb}^{2+}$ ion. (b) Molecular model of the $\mathrm{Pb}^{2+}$-EDTA complex. The light green sphere is the $\mathrm{Pb}^{2+}$ ion.
Figure 22.3 (a) Structure of a metal-ethylenediamine complex cation, such as $\left[\mathrm{Co}(\mathrm{en})_{3}\right]^{2+}$. Each ethylenediamine molecule provides two N donor atoms and is therefore a bidentate ligand. (b) Simplified structure of the same complex cation.

Think About It To solve a problem like this, you must be able to recognize the common polyatomic ions and you must know their charges.

Setup (a) $\left[\mathrm{Ru}\left(\mathrm{NH}_{3}\right)_{5}\left(\mathrm{H}_{2} \mathrm{O}\right)\right] \mathrm{Cl}_{2}$ consists of a complex ion (the part of the formula enclosed in square brackets) and two $\mathrm{Cl}^{-}$counter ions. Because the overall charge on the compound is zero, the complex ion is $\left[\mathrm{Ru}\left(\mathrm{NH}_{3}\right)_{5}\left(\mathrm{H}_{2} \mathrm{O}\right)\right]^{2+}$. There are six ligands: five ammonia molecules and one water molecule. Each molecule has a zero charge (i.e., each ligand is neutral), so the charge on the metal is equal to the overall charge on the complex ion.
(b) $\left[\mathrm{Cr}\left(\mathrm{NH}_{3}\right)_{6}\right]\left(\mathrm{NO}_{3}\right)_{3}$ consists of a complex ion and three $\mathrm{NO}_{3}{ }^{-}$ions, making the complex ion $\left[\mathrm{Cr}\left(\mathrm{NH}_{3}\right)_{6}\right]^{3+}$. Each of the six ammonia molecule ligands is neutral (i.e., each has a zero charge), making the charge on the metal equal to the overall charge on the complex ion.
(c) $\mathrm{Fe}(\mathrm{CO})_{5}$ does not contain a complex ion. The ligands are CO molecules, which have a zero charge, so the central metal also has a zero charge.

Solution (a) +2
(b) +3
(c) 0

Practice Problem A Give oxidation numbers for the metals in (a) $\mathrm{K}\left[\mathrm{Au}(\mathrm{OH})_{4}\right]$ and (b) $\mathrm{K}_{4}\left[\mathrm{Fe}(\mathrm{CN})_{6}\right]$.
$\$$ Practice Problem B The oxidation state of cobalt in each of the following species is +3 . Determine the overall charge on each complex: $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}_{2}\right]^{?},\left[\mathrm{Co}(\mathrm{CN})_{6}\right]^{7},\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{3} \mathrm{Br}_{3}\right]^{3},\left[\mathrm{Co}(\mathrm{en})_{2} \mathrm{Cl}_{2}\right]^{?}$, $\left[\mathrm{Co}(\mathrm{en})_{3}\right]^{7},\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right]^{?},\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{Cl}\right]^{?}$.

## Nomenclature of Coordination Compounds

Now that we have discussed the various types of ligands and the oxidation numbers of metals, our next step is to learn how to name coordination compounds. The rules for naming ionic coordination compounds are as follows:

1. The cation is named before the anion, as in other ionic compounds. The rule holds regardless of whether the complex ion bears a net positive or a net negative charge. In the compounds $\mathrm{K}_{2}\left[\mathrm{Fe}(\mathrm{CN})_{6}\right]$ and $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{4}\right] \mathrm{Cl}$, for example, we name the $\mathrm{K}^{+}$and $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{4}\right]^{+}$cations first, respectively.
2. Within a complex ion, the ligands are named first, in alphabetical order, and the metal ion is named last.
3. The names of anionic ligands end with the letter $o$, whereas neutral ligands are usually called by the names of the molecules. The exceptions are $\mathrm{H}_{2} \mathrm{O}$ (aqua), CO (carbonyl), and $\mathrm{NH}_{3}$ (ammine). Table 22.4 lists some common ligands and their nomenclature.

## TABLE 22.4 Names of Common Ligands in Coordination Compounds

## Ligand

Bromide ( $\mathrm{Br}^{-}$)
Chloride ( $\mathrm{Cl}^{-}$)
Cyanide ( $\mathrm{CN}^{-}$)
Hydroxide $\left(\mathrm{OH}^{-}\right)$
Oxide ( $\mathrm{O}^{2-}$ )
Carbonate $\left(\mathrm{CO}_{3}^{2-}\right)$
Nitrite $\left(\mathrm{NO}_{2}^{-}\right)$
Oxalate $\left(\mathrm{C}_{2} \mathrm{O}_{4}^{2-}\right)$
Ammonia $\left(\mathrm{NH}_{3}\right)$
Carbon monoxide (CO)
Water $\left(\mathrm{H}_{2} \mathrm{O}\right)$

TABLE 22.5 Names of Anions Containing Metal Atoms

## Metal

| Aluminum | Aluminate |
| :--- | :--- |
| Chromium | Chromate |
| Cobalt | Cobaltate |
| Copper | Cuprate |
| Gold | Aurate |
| Iron | Ferrate |
| Lead | Plumbate |
| Manganese | Manganate |
| Molybdenum | Molybdate |
| Nickel | Nickelate |
| Silver | Argentate |
| Tin | Stannate |
| Tungsten | Tungstate |
| Zinc | Zincate |

4. When two or more of the same ligand are present, use Greek prefixes di, tri, tetra, penta, and hexa, to specify their number. Thus, the ligands in the cation $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}_{2}\right]^{+}$are "tetraamminedichloro." (Note that prefixes are not used for the purpose of alphabetizing the ligands.)
5. The oxidation number of the metal is indicated in Roman numerals immediately following the name of the metal. For example, the Roman numeral III is used to indicate the +3 oxidation state of chromium in $\left[\mathrm{Cr}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}_{2}\right]^{+}$, which is called tetraamminedichlorochromium(III) ion.
6. If the complex is an anion, its name ends in -ate. In $\mathrm{K}_{4}\left[\mathrm{Fe}(\mathrm{CN})_{6}\right]$, for example, the anion $\left[\mathrm{Fe}(\mathrm{CN})_{6}\right]^{4-}$ is called hexacyanoferrate(II) ion. Note that the Roman numeral indicating the oxidation state of the metal follows the suffix -ate. Table 22.5 lists the names of anions containing metal atoms.
Sample Problems 22.2 and 22.3 apply these rules to the nomenclature of coordination compounds.

## Sample Problem 22.2

Write the names of the following coordination compounds: (a) $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}_{2}\right] \mathrm{Cl}$ and (b) $\mathrm{K}_{3}\left[\mathrm{Fe}(\mathrm{CN})_{6}\right]$.
Strategy For each compound, name the cation first and the anion second. Refer to Tables 22.4 and 22.5 for the names of ligands and anions containing metal atoms.

Setup (a) The cation is a complex ion containing four ammonia molecules and two chloride ions. The counter ion is chloride $\left(\mathrm{Cl}^{-}\right)$, so the charge on the complex cation is +1 , making the oxidation state of cobalt +3 .
(b) The cation is $\mathrm{K}^{+}$, and the anion is a complex ion containing six cyanide ions. The charge on the complex ion is -3 , making the oxidation state of iron +3 .

Solution (a) Tetraamminedichlorocobalt(III) chloride
(b) Potassium hexacyanoferrate(III)

Practice Problem A Give the correct name for (a) $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Br}_{2}\right] \mathrm{Cl}$, (b) $\left[\mathrm{Cr}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4} \mathrm{Cl}_{2}\right] \mathrm{Cl}$, and (c) $\mathrm{K}_{2}\left[\mathrm{CuCl}_{4}\right]$.
${ }_{\$} \boldsymbol{I}$ Practice Problem B Give the correct name for (a) $\mathrm{Na}_{3}\left[\mathrm{Fe}(\mathrm{CN})_{6}\right]$, (b) $\left[\mathrm{Cr}(\mathrm{en})_{2} \mathrm{Cl}_{2}\right] \mathrm{Br}$, and (c) $\left[\mathrm{Co}(\mathrm{en})_{3}\right] \mathrm{Cl}_{3}$. [Hint: For parts (b) and (c), read the Student Annotation above regarding the use of prefixes.]

Student Annotation: When the name of a ligand already contains a Greek prefix, a different set of prefixes is used to denote the number of the ligand:

2 bis
3 tris
4 tetrakis
Two ethylenediamine ligands, for example, would be specified by bis(ethylenediamine).

Student Annotation: Note that there is no space between the compound name and the parenthetical Roman numeral.

Think About It When the anion is a complex ion, its name must end in -ate, followed by the metal's oxidation state in Roman numerals. Also, do not use prefixes to denote numbers of counter ions.

Think About lt Although ligands are alphabetized in a compound's name, they do not necessarily appear in alphabetical order in the compound's formula.

## Sample Problem 22.3

Write formulas for the following compounds: (a) pentaamminechlorocobalt(III) chloride and (b) dichlorobis(ethylenediamine)platinum(IV) nitrate.

Strategy If you can't remember them yet, refer to Tables 22.4 and 22.5 for the names of ligands and anions containing metal atoms.

Setup (a) There are six ligands: five $\mathrm{NH}_{3}$ molecules and one $\mathrm{Cl}^{-}$ion. The oxidation state of cobalt is +3 , making the overall charge on the complex ion +2 . Therefore, there are two chloride ions as counter ions.
(b) There are four ligands: two bidentate ethylenediamines and two $\mathrm{Cl}^{-}$ions. The oxidation state of platinum is +4 , making the overall charge on the complex ion +2 . Therefore, there are two nitrate ions as counter ions.

Solution (a) $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{Cl}\right] \mathrm{Cl}_{2}$
(b) $\left[\mathrm{Pt}(\mathrm{en})_{2} \mathrm{Cl}_{2}\right]\left(\mathrm{NO}_{3}\right)_{2}$

Practice Problem A Write the formulas for (a) pentaaquabromoruthenium(II) nitrate, (b) potassium tetrabromodichloroplatinate(IV), and (c) sodium hexanitrocobaltate(III).

EPractice Problem B Write the formulas for (a) bis(ethylenediamine)oxalatovanadium(IV) chloride, (b) dibromobis(ethylenediamine)chromium(III) nitrate, and (c) tris(ethylenediamine)platinum(IV) sulfate. (Hint: Read the Student Annotation on page 927.)

## Checkpoint 22.1 Coordination Compounds

22.1.1 Select the correct name for the compound $\left[\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}\right] \mathrm{Cl}_{2}$.
a) Coppertetraammine dichloride
b) Tetraamminecopper(II) chloride
c) Tetraaminedichlorocuprate(II)
d) Dichlorotetraaminecopper(II)
e) Tetraaminedichlorocopper(II)
22.1.2 Select the correct name for the compound $\mathrm{K}_{3}\left[\mathrm{FeF}_{6}\right]$.
a) Tripotassiumironhexafluoride
b) Hexafluorotripotassiumferrate(III)
c) Hexafluoroiron(III) potassium
d) Potassium hexafluoroferrate(III)
e) Potassium ironhexafluorate
22.1.3 Select the correct formula for pentaamine nitrocobalt(III).
a) $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{NO}_{2}\right]^{3+}$
b) $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{NO}_{2}\right]^{2+}$
c) $\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{NO}_{2}$
d) $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{5}\right]\left(\mathrm{NO}_{2}\right)$
e) $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{5}\right]\left(\mathrm{NO}_{2}\right)_{2}$
22.1.4 Select the correct formula for tetraaquadichlorochromium(III) chloride.
a) $\left[\mathrm{Cr}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4} \mathrm{Cl}_{2}\right] \mathrm{Cl}_{3}$
b) $\left[\mathrm{Cr}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4} \mathrm{Cl}_{2}\right] \mathrm{Cl}_{2}$
c) $\left[\mathrm{Cr}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4} \mathrm{Cl}_{2}\right] \mathrm{Cl}$
d) $\left[\mathrm{Cr}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right] \mathrm{Cl}_{3}$
e) $\left[\mathrm{Cr}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right] \mathrm{Cl}_{2}$

### 22.2 Structure of Coordination Compounds

The geometry of a coordination compound often plays a significant role in determining its properties. Figure 22.5 shows four different geometric arrangements for metal atoms with monodentate ligands. In these diagrams we see that structure and the coordination number of the metal relate to each other as follows:

| Coordination Number | Structure |
| :---: | :--- |
| 2 | Linear |
| 4 | Tetrahedral or square planar |
| 6 | Octahedral |

(a)

(b)

(a)

(b)

In studying the geometry of coordination compounds, we sometimes find that there is more than one way to arrange the ligands around the central atom. Such compounds in which ligands are arranged differently, known as stereoisomers, have distinctly different physical and chemical properties. Coordination compounds may exhibit two types of stereoisomerism: geometric and optical.

Geometrical isomers are stereoisomers that cannot be interconverted without breaking chemical bonds. Geometric isomers come in pairs. We use the terms cis and trans to distinguish one geometric isomer of a compound from the other. Cis means that two particular atoms (or groups of atoms) are adjacent to each other, and trans means that the atoms (or groups of atoms) are on opposite sides in the structural formula. The cis and trans isomers of coordination compounds generally have quite different colors, melting points, dipole moments, and chemical reactivities. Figure 22.6 shows the cis and trans isomers of diamminedichloroplatinum(II). Note that although the types of bonds are the same in both isomers ( $\mathrm{two} \mathrm{Pt}-\mathrm{N}$ and two $\mathrm{Pt}-\mathrm{Cl}$ bonds), the spatial arrangements are different. Another example is the tetraamminedichlorocobalt(III) ion, shown in Figure 22.7.

Optical isomers are nonsuperimposable mirror images. (Superimposable means that if one structure is laid over the other, the positions of all the atoms will match.) Like geometric isomers, optical isomers come in pairs. However, the optical isomers of a compound have identical physical and chemical properties, such as melting point, boiling point, dipole moment, and chemical reactivity toward molecules that are not themselves optical isomers. Optical isomers differ from each other, though, in their interactions with plane-polarized light, as we will see.

The structural relationship between two optical isomers is analogous to the relationship between your left and right hands. If you place your left hand in front of a mirror, the image you see will look like your right hand (Figure 22.8). Your left hand and right hand are mirror images of each other. They are nonsuperimposable, however, because when you place your left hand over your right hand (with both palms facing down), they do not match. This is why a right-handed glove will not fit comfortably on your left hand.

Figure 22.9 shows the cis and trans isomers of dichlorobis(ethylenediamine)cobalt(III) ion and the mirror image of each. Careful examination reveals that the trans isomer and its mirror image are superimposable, but the cis isomer and its mirror image are not. Thus, the cis isomer and its mirror image are optical isomers.

Optical isomers are described as chiral (from the Greek word for "hand") because, like your left and right hands, chiral molecules are nonsuperimposable. Isomers that are superimposable

Figure 22.5 Common geometries of complex ions. In each case $M$ is a metal and L is a monodentate ligand.

Figure 22.6 The (a) cis and (b) trans isomers of diamminedichloroplatinum(II). Note that the two Cl atoms are adjacent to each other in the cis isomer and diagonally across from each other in the trans isomer.

Figure 22.7 The (a) cis and (b) trans isomers of tetraamminedichlorocobalt(III) ion, $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}_{2}\right]^{+}$. The ion has only two geometric isomers.

Student Annotation: In general, stereoisomers are compounds that are made up of the same types and numbers of atoms, bonded together in the same sequence, but with different spatial arrangements.

Figure 22.8 A left hand and its mirror image.

Figure 22.9 The (a) cis and (b) trans isomers of dichlorobis(ethylenediamine)cobalt(III) ion and their mirror images. If you could rotate the mirror image in (b) $90^{\circ}$ clockwise about the vertical position and place the ion over the trans isomer, you would find that the two are superimposable. No matter how you rotate the cis isomer and its mirror image in (a), however, you cannot superimpose one on the other.
with their mirror images are said to be achiral. Chiral molecules play a vital role in enzyme reactions in biological systems. Many drug molecules are chiral, although only one of a pair of chiral isomers is biologically effective [ $1 / 4$ Section 10.4].

Chiral molecules are said to be optically active because of their ability to rotate the plane of polarization of polarized light as it passes through them. Unlike ordinary light, which vibrates in all directions, plane-polarized light vibrates only in a single plane. We use a polarimeter to measure the rotation of polarized light by optical isomers (Figure 22.10). A beam of unpolarized light first passes through a Polaroid sheet, called the polarizer, and then through a sample tube containing a solution of an optically active, chiral compound. As the polarized light passes through the sample tube, its plane of polarization is rotated either to the right (clockwise) or to the left (counterclockwise). This rotation can be measured directly by turning the analyzer in the appropriate direction until minimal light transmission is achieved (Figure 22.11). If the plane of polarization is rotated to the right, the isomer is said to be dextrorotatory and the isomer is labeled $d$; if the rotation is to the left, the isomer is levorotatory and the isomer is labeled $l$. The $d$ and $l$ isomers of a chiral substance, called enantiomers, always rotate the plane of polarization by the same amount, but in opposite directions. Thus, in an equimolar mixture of two enantiomers, called a racemic mixture, the net rotation is zero.

Figure 22.10 Operation of a polarimeter. Initially, the tube is filled with an achiral compound. The analyzer is rotated so that its plane of polarization is perpendicular to that of the polarizer. Under this condition, no light reaches the observer. Next, a chiral compound is placed in the tube as shown. The plane of polarization of the polarized light is rotated as it travels through the tube so that some light reaches the observer. Rotating the analyzer (either to the left or to the right) until no light reaches the observer again allows the angle of optical rotation to be measured.

### 22.3 Bonding in Coordination Compounds: Crystal Field Theory

A satisfactory theory of bonding in coordination compounds must account for properties such as color and magnetism, as well as stereochemistry and bond strength. No single theory as yet does all this for us. Rather, several different approaches have been applied to transition metal complexes. We will consider only one of them here-crystal field theory-because it accounts for both the color and magnetic properties of many coordination compounds.

We will begin our discussion of crystal field theory with the most straightforward casenamely, complex ions with octahedral geometry. Then we will see how it is applied to tetrahedral and square-planar complexes.

## Crystal Field Splitting in Octahedral Complexes

Crystal field theory explains the bonding in complex ions purely in terms of electrostatic forces. In a complex ion, two types of electrostatic interaction come into play. One is the attraction between the positive metal ion and the negatively charged ligand or the negatively charged end of a polar ligand. This is the force that binds the ligands to the metal. The second type of interaction is the electrostatic repulsion between the lone pairs on the ligands and the electrons in the $d$ orbitals of the metals.

The $d$ orbitals have different orientations [ 14 Section 6.7], but in the absence of an external disturbance, they all have the same energy. In an octahedral complex, a central metal atom is surrounded by six lone pairs of electrons (on the six ligands), so all five $d$ orbitals experience electrostatic repulsion. The magnitude of this repulsion depends on the orientation of the $d$ orbital that is involved. Take the $d_{x^{2}}-y^{2}$ orbital as an example. In Figure 22.12, we see that the lobes of this orbital point toward the corners of the octahedron along the $x$ and $y$ axes, where the lone-pair electrons are positioned. Thus, an electron residing in this orbital would experience a greater repulsion from the ligands than an electron would in the $d_{x y}, d_{y z}$, or $d_{x z}$ orbitals. For this reason, the energy of the $d_{x^{2}}-y^{2}$ orbital is increased relative to the $d_{x y}, d_{y z}$, and $d_{x z}$ orbitals. The $d_{z^{2}}$ orbital's energy is also greater, because its lobes are pointed at the ligands along the $z$ axis. As a result of these metal-ligand interactions, the five $d$ orbitals in an octahedral complex are split between two sets of energy levels: a higher level with two orbitals $\left(d_{x^{2}}-y^{2}\right.$ and $\left.d_{z}{ }^{2}\right)$ having the same energy, and a lower level with three equal-energy orbitals ( $d_{x y}, d_{y z}$, and $d_{x z}$ ), as shown in Figure 22.13. The crystal field splitting $(\Delta)$ is the energy difference between two sets of $d$ orbitals in a metal atom when ligands are present. The magnitude of $\Delta$ depends on the metal and the nature of the ligands; it has a direct effect on the color and magnetic properties of complex ions.

Figure 22.11 Polarized lenses. No light passes through the lenses when they are rotated so that their planes of polarization are perpendicular.

Figure 22.12 The five $d$ orbitals in an octahedral environment. The metal atom (or ion) is at the center of the octahedron, and the six lone pairs on the donor atoms of the ligands are at the corners.

Figure 22.13 Crystal field splitting between $d$ orbitals in an octahedral complex.

Figure 22.14 A color wheel with appropriate wavelengths. Complementary colors, such as red and green, are on opposite sides of the wheel.

## Color

In Chapter 6 we learned that white light, such as sunlight, is a combination of all colors. A substance appears black if it absorbs all the visible light that strikes it. If it absorbs no visible light, it is white or colorless. An object appears green if it absorbs all light but reflects the green component. An object also looks green if it reflects all colors except red, the complementary color of green (Figure 22.14).

What has been said of reflected light also applies to transmitted light (i.e., the light that passes through the medium, such as a solution). Consider the hydrated cupric ion $\left(\left[\mathrm{Cu}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}\right)$; it absorbs light in the orange region of the spectrum, so a solution of $\mathrm{CuSO}_{4}$ appears blue to us. Recall from Chapter 6 that when the energy of a photon is equal to the difference between the ground state and an excited state, absorption occurs as the photon strikes the atom (or ion or compound), and an electron is promoted to a higher level. Using these concepts, we can calculate the energy change involved in the electron transition. The energy of a photon is given by

$$
E=h v
$$

where $h$ represents Planck's constant $\left(6.63 \times 10^{-34} \mathrm{~J} \cdot \mathrm{~s}\right)$ and $v$ is the frequency of the radiation, which is $5.00 \times 10^{14} \mathrm{~s}^{-1}$ for a wavelength of 600 nm . Here $E=\Delta$, so we have

$$
\begin{aligned}
\Delta & =h v \\
& =\left(6.63 \times 10^{-34} \mathrm{~J} \cdot \mathrm{~s}\right)\left(5.00 \times 10^{14} \mathrm{~s}\right) \\
& =3.32 \times 10^{-19} \mathrm{~J}
\end{aligned}
$$

This value is very small, but it is the energy absorbed by only one ion. If the wavelength of the photon absorbed by an ion lies outside the visible region, then the transmitted light looks the same (to us) as the incident light-white-and the ion appears colorless.

The best way to measure crystal field splitting is to use spectroscopy to determine the wavelength at which light is absorbed. The $\left[\mathrm{Ti}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}$ ion provides a straightforward example, because $\mathrm{Ti}^{3+}$ has only one $3 d$ electron (Figure 22.15). The $\left[\mathrm{Ti}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}$ ion absorbs light in the visible region of the spectrum (Figure 22.16). The wavelength corresponding to maximum

absorption is 498 nm [Figure 22.15(b)]. To calculate the crystal field splitting energy, we start by writing

$$
\Delta=h v
$$

Next, recall that

$$
v=\frac{c}{\lambda}
$$

where $c$ is the speed of light and $\lambda$ is the wavelength. Therefore,

$$
\Delta=\frac{h c}{\lambda}=\frac{\left(6.63 \times 10^{-34} \mathrm{~J} \cdot \mathrm{~s}\right)\left(3.00 \times 10^{8} \mathrm{~m} / \mathrm{s}\right)}{(498 \mathrm{~nm})\left(1 \times 10^{-9} \mathrm{~m} / \mathrm{nm}\right)}=3.99 \times 10^{-19} \mathrm{~J}
$$

This is the energy required to excite one $\left[\mathrm{Ti}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}$ ion. To express this energy difference in the more convenient units of $\mathrm{kJ} / \mathrm{mol}$, we write

$$
\begin{aligned}
\Delta & =\left(3.99 \times 10^{-19} \mathrm{~J} / \text { ion }\right)\left(6.02 \times 10^{23} \mathrm{ions} / \mathrm{mol}\right) \\
& =240,000 \mathrm{~J} / \mathrm{mol} \\
& =240 \mathrm{~kJ} / \mathrm{mol}
\end{aligned}
$$

Aided by spectroscopic data for a number of complexes, all having the same metal ion but different ligands, chemists calculated the crystal field splitting for each ligand and established the following spectrochemical series, which is a list of ligands arranged in increasing order of their abilities to split the $d$ orbital energy levels:

$$
\mathrm{I}^{-}<\mathrm{Br}^{-}<\mathrm{Cl}^{-}<\mathrm{OH}^{-}<\mathrm{F}^{-}<\mathrm{H}_{2} \mathrm{O}<\mathrm{NH}_{3}<\mathrm{en}<\mathrm{CN}^{-}<\mathrm{CO}
$$

These ligands are arranged in the order of increasing value of $\Delta$. CO and $\mathrm{CN}^{-}$are called strongfield ligands, because they cause a large splitting of the $d$ orbital energy levels. The halide ions and hydroxide ion are weak-field ligands, because they split the $d$ orbitals to a lesser extent.

## Magnetic Properties

The magnitude of the crystal field splitting also determines the magnetic properties of a complex ion. The $\left[\mathrm{Ti}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}$ ion, having only one $d$ electron, is always paramagnetic. However, for an ion with several $d$ electrons, the situation is less immediately clear. Consider, for example, the octahedral complexes $\left[\mathrm{FeF}_{6}\right]^{3-}$ and $\left[\mathrm{Fe}(\mathrm{CN})_{6}\right]^{3-}$ (Figure 22.17). The electron configuration of $\mathrm{Fe}^{3+}$ is $[\mathrm{Ar}] 3 d^{5}$, and there are two possible ways to distribute the five $d$ electrons among the $d$ orbitals. According to Hund's rule [144 Section 6.8], maximum stability is reached when the

Figure 22.15 (a) The process of photon absorption, and (b) a graph of the absorption spectrum of $\left[\mathrm{Ti}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}$. The energy of the incoming photon is equal to the crystal field splitting. The maximum absorption peak in the visible region occurs at 498 nm .

Figure 22.16 Colors of some of the first-row transition metal ions in solution. From left to right: $\mathrm{Ti}^{3+}, \mathrm{Cr}^{3+}$, $\mathrm{Mn}^{2+}, \mathrm{Fe}^{3+}, \mathrm{Co}^{2+}, \mathrm{Ni}^{2+}, \mathrm{Cu}^{2+}$. The $\mathrm{Sc}^{3+}$ and $\mathrm{V}^{5+}$ ions are colorless.

Figure 22.17 Energy-level diagrams for the $\mathrm{Fe}^{3+}$ ion and for the $\left[\mathrm{FeF}_{6}\right]^{3-}$ and $\left[\mathrm{Fe}(\mathrm{CN})_{6}\right]^{3-}$ complex ions.

Figure 22.18 Orbital diagrams for the high-spin and low-spin octahedral complexes corresponding to the electron configurations of (a) $d^{4}$, (b) $d^{5}$, (c) $d^{6}$, and (d) $d^{7}$.

electrons are placed in five separate orbitals with parallel spins. This arrangement can be achieved only at a cost, however, because two of the five electrons must be promoted to the higher-energy $d_{x^{2}-y^{2}}$ and $d_{z^{2}}$ orbitals. No such energy investment is needed if all five electrons enter the $d_{x y}, d_{y z}$, and $d_{x z}$ orbitals. According to Pauli's exclusion principle [ 14 Section 6.8], there will be only one unpaired electron present in this case.

Figure 22.18 shows the distribution of electrons among $d$ orbitals that results in low- and high-spin complexes. The actual arrangement of the electrons is determined by the amount of

(a)

(b)

(c)

(d)
stability gained by having maximum parallel spins versus the investment in energy required to promote electrons to higher $d$ orbitals. Because $\mathrm{F}^{-}$is a weak-field ligand, the five $d$ electrons enter five separate $d$ orbitals with parallel spins to create a high-spin complex. The cyanide ion is a strong-field ligand, though, so it is energetically preferable for all five electrons to be in the lower orbitals, thus forming a low-spin complex. High-spin complexes are more paramagnetic than lowspin complexes.

The actual number of unpaired electrons (or spins) in a complex ion can be found by magnetic measurements, and in general, experimental findings support predictions based on crystal field splitting. However, a distinction between low- and high-spin complexes can be made only if the metal ion contains more than three and fewer than eight $d$ electrons, as shown in Figure 22.18.

Sample Problem 22.4 shows how to determine the number of spins in an octahedral complex.

## Sample Problem 22.4

Predict the number of unpaired spins in the $\left[\mathrm{Cr}(\mathrm{en})_{3}\right]^{2+}$ ion.
Strategy The magnetic properties of a complex ion depend on the strength of the ligands. Strongfield ligands, which cause a high degree of splitting among the $d$ orbital energy levels, result in lowspin complexes. Weak-field ligands, which cause only a small degree of splitting among the $d$ orbital energy levels, result in high-spin complexes.

Setup The electron configuration of $\mathrm{Cr}^{2+}$ is $[\mathrm{Ar}] 3 d^{4}$; and en is a strong-field ligand.
Solution Because en is a strong-field ligand, we expect $\left[\mathrm{Cr}(\mathrm{en})_{3}\right]^{2+}$ to be a low-spin complex. According to Figure 22.18, all four electrons will be placed in the lower-energy $d$ orbitals ( $d_{x y}, d_{y z}$, and $d_{x z}$ ) and there will be a total of two unpaired spins.

Practice Problem A How many unpaired spins are in $\left[\mathrm{Mn}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}$ ? $\left(\right.$ Hint: $\mathrm{H}_{2} \mathrm{O}$ is a weak-field ligand.)

- Practice Problem B Transition metal ions can have as few as one $d$ electron or as many as nine $d$ electrons. Which numbers of $d$ electrons (1-9) result in the same number of unpaired spins in both the high-spin and low-spin states?

## Tetrahedral and Square-Planar Complexes

So far we have concentrated on octahedral complexes. The splitting of the $d$ orbital energy levels in tetrahedral and square-planar complexes, though, can also be accounted for satisfactorily by the crystal field theory. In fact, the splitting pattern for a tetrahedral ion is just the reverse of that for octahedral complexes. In this case, the $d_{x y}, d_{y z}$, and $d_{x z}$ orbitals are more closely directed at the ligands and therefore have more energy than the $d_{x^{2}-y^{2}}$ and $d_{z^{2}}$ orbitals (Figure 22.19). Most tetrahedral complexes are high-spin complexes. Presumably, the tetrahedral arrangement reduces the magnitude of the metal-ligand interactions, resulting in a smaller $\Delta$ value. This is a reasonable assumption because the number of ligands is smaller in a tetrahedral complex.

As Figure 22.20 shows, the splitting pattern for square-planar complexes is the most complicated. The $d_{x^{2}-y^{2}}$ orbital possesses the highest energy (as in the octahedral case), and the $d_{x y}$ orbital is the next highest. However, the relative placement of the $d_{z}{ }^{2}$ and the $d_{x z}$ and $d_{y z}$ orbitals cannot be determined simply by inspection and must be calculated.

Think About It It is easy to draw the wrong conclusion regarding high- and low-spin complexes. Remember that the term high spin refers to the number of spins (unpaired electrons), not to the energy levels of the $d$ orbitals. The greater the energy gap between the lower-energy and higher-energy $d$ orbitals, the greater the chance that the complex will be low spin.

Figure 22.19 Crystal field splitting between $d$ orbitals in a tetrahedral complex.

Figure 22.20 Energy-level diagram for a square-planar complex. Because there are more than two energy levels, we cannot define crystal field splitting as we can for octahedral and tetrahedral complexes.

## Checkpoint 22.3 Bonding in Coordination Compounds:

 Crystal Field Theory22.3.1 How many unpaired spins would you expect the $\left[\mathrm{Mn}(\mathrm{CO})_{6}\right]^{2+}$ ion to have?
a) 0
b) 1
c) 2
d) 3
e) 5
22.3.2 Which of the following metal ions can potentially form both low-spin and highspin complexes? (Select all that apply.)
a) $\mathrm{Ti}^{2+}$
b) $\mathrm{Cu}^{+}$
c) $\mathrm{Fe}^{2+}$
d) $\mathrm{Ni}^{2+}$
e) $\mathrm{Cr}^{3+}$

### 22.4 Reactions of Coordination Compounds

Complex ions undergo ligand exchange (or substitution) reactions in solution. The rates of these reactions vary widely, depending on the nature of the metal ion and the ligands.

In studying ligand exchange reactions, it is often useful to distinguish between the stability of a complex ion and its tendency to react, which we call kinetic lability. Stability in this context is a thermodynamic property, which is measured in terms of the species' formation constant $K_{\mathrm{f}}$ [14 Section 17.5]. For example, we say that the complex ion tetracyanonickelate(II) is stable because it has a large formation constant $\left(K_{\mathrm{f}}=1 \times 10^{30}\right)$ :

$$
\mathrm{Ni}^{2+}+4 \mathrm{CN}^{-} \rightleftarrows\left[\mathrm{Ni}(\mathrm{CN})_{4}\right]^{2-}
$$

By using cyanide ions labeled with the radioactive isotope carbon-14, chemists have shown that $\left[\mathrm{Ni}(\mathrm{CN})_{4}\right]^{2-}$ undergoes ligand exchange very rapidly in solution. The following equilibrium is established almost as soon as the species are mixed:

$$
\left[\mathrm{Ni}(\mathrm{CN})_{4}\right]^{2-}+4 * \mathrm{CN}^{-} \rightleftarrows\left[\mathrm{Ni}(* \mathrm{CN})_{4}\right]^{2-}+4 \mathrm{CN}^{-}
$$

where the asterisk denotes a ${ }^{14} \mathrm{C}$ atom. Complexes like the tetracyanonickelate(II) ion are termed labile complexes because they undergo rapid ligand exchange reactions. Thus, a thermodynamically stable species (i.e., one that has a large formation constant) is not necessarily unreactive.

A complex that is thermodynamically unstable in acidic solution is $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right]^{3+}$. The equilibrium constant for the following reaction is about $1 \times 10^{20}$ :

$$
\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right]^{3+}+6 \mathrm{H}^{+}+6 \mathrm{H}_{2} \mathrm{O} \rightleftarrows\left[\mathrm{Co}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}+6 \mathrm{NH}_{4}^{+}
$$

When equilibrium is reached, the concentration of the $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right]^{3+}$ ion is very low. This reaction requires several days to complete, however, because the $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right]^{3+}$ ion is so inert. This is an example of an inert complex - a complex ion that undergoes very slow exchange reactions (on the order of hours or even days). It shows that a thermodynamically unstable species is not necessarily chemically reactive. The rate of reaction is determined by the energy of activation, which is high in this case.

Most complex ions containing $\mathrm{Co}^{3+}, \mathrm{Cr}^{3+}$, and $\mathrm{Pt}^{2+}$ are kinetically inert. Because they exchange ligands very slowly, they are easy to study in solution. As a result, our knowledge of the bonding, structure, and isomerism of coordination compounds has come largely from studies of these compounds.

### 22.5 Applications of Coordination Compounds

Coordination compounds are found in living systems and have many uses in the home, in industry, and in medicine. We briefly describe a few examples in this section.

## Metallurgy

The extraction of silver and gold by the formation of cyanide complexes and the purification of nickel by converting the metal to the gaseous compound $\mathrm{Ni}(\mathrm{CO})_{4}$ are typical examples of the use of coordination compounds in metallurgical processes.

## Chelation Therapy

Earlier we mentioned that chelation therapy is used in the treatment of lead poisoning. Other metals, such as arsenic and mercury, can also be removed using chelating agents.

## Chemotherapy

Several platinum-containing coordination compounds, including cisplatin $\left[\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{2} \mathrm{Cl}_{2}\right]$ and carboplatin $\left[\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{2}(\mathrm{OCO})_{2} \mathrm{C}_{4} \mathrm{H}_{6}\right]$, can effectively inhibit the growth of cancerous cells. The mechanism for the action of cisplatin is the chelation of DNA, the molecule that contains the genetic code. During cell division, the double-stranded DNA unwinds into two single strands, which must be accurately copied for the new cells to be identical to their parent cell. X-ray studies show that cisplatin binds to DNA by forming cross-links in which the two chlorides on cisplatin are replaced by nitrogen atoms in the adjacent guanine bases on the same strand of the DNA. (Guanine is one of the four bases in DNA [ 14 Section 10.6, Figure 10.15].) This causes a bend in the double-stranded structure at the binding site. It is believed that this structural distortion is a key factor in inhibiting replication. The damaged cell is then destroyed by the body's immune system. Because the binding of cisplatin to DNA requires both Cl atoms to be on the same side of the complex, the trans isomer of the compound is totally ineffective as an anticancer drug.

## Chemical Analysis

Although EDTA has a great affinity for a large number of metal ions (especially $2+$ and $3+$ ions), other chelates are more selective in binding. Dimethylglyoxime, for example, forms an insoluble brick-red solid with $\mathrm{Ni}^{2+}$ and an insoluble bright-yellow solid with $\mathrm{Pd}^{2+}$. These characteristic colors are used in qualitative analysis to identify nickel and palladium. Furthermore, the quantities of ions present can be determined by gravimetric analysis [ 14 Section 4.6] as follows: To a solution containing $\mathrm{Ni}^{2+}$ ions, say, we add an excess of dimethylglyoxime reagent, and a brick-red precipitate forms. The precipitate is then filtered, dried, and weighed. Knowing the formula of the complex (Figure 22.21), we can readily calculate the amount of nickel in the original solution.

Figure 22.21 Structure of nickel dimethylglyoxime. Note that the overall structure is stabilized by hydrogen bonds.

Organic and Biochemistry-oxygen binding in hemoglobin.

## Detergents

The cleansing action of soap in hard water is hampered by the reaction of the $\mathrm{Ca}^{2+}$ ions in the water with the soap molecules to form insoluble salts or curds. In the late 1940s the detergent industry introduced a "builder," usually sodium tripolyphosphate, to circumvent this problem. The tripolyphosphate ion is an effective chelating agent that forms stable, soluble complexes with $\mathrm{Ca}^{2+}$ ions. Sodium tripolyphosphate revolutionized the detergent industry. Because phosphates are plant nutrients, however, wastewater containing phosphates discharged into rivers and lakes causes algae to grow, resulting in oxygen depletion. Under these conditions, most or all aquatic life eventually succumbs. This process is called eutrophication. Consequently, many states have banned phosphate detergents since the 1970s, and manufacturers have reformulated their products to eliminate phosphates.

## Sequestrants

In addition to its use in medicine and chemical analysis, EDTA is used as a food additive to sequester metal ions. EDTA sequesters copper, iron, and nickel ions that would otherwise catalyze the oxidation reactions that cause food to spoil. EDTA is a common preservative in a wide variety of consumer products.

## Bringing Chemistry to Life

## The Coordination Chemistry of Oxygen Transport

Because of its central function as an oxygen carrier for metabolic processes, hemoglobin is probably the most studied of all the proteins. The molecule contains four folded long chains called subunits. Hemoglobin carries oxygen in the blood from the lungs to the tissues, where it delivers the oxygen molecules to myoglobin. Myoglobin, which is made up of only one subunit, stores oxygen for metabolic processes in the muscle.

The porphine molecule forms an important part of the hemoglobin structure. Upon coordination to a metal, the $\mathrm{H}^{+}$ions that are bonded to two of the four nitrogen atoms in porphine are displaced. Complexes derived from porphine are called porphyrins, and the iron-porphyrin combination is called the heme group. The iron in the heme group has an oxidation state of +2 ; it is coordinated to the four nitrogen atoms in the porphine group and also to a nitrogen donor atom in a ligand that is attached to the protein. The sixth ligand is a water molecule, which binds to the $\mathrm{Fe}^{2+}$ ion on the other side of the ring to complete the octahedral complex. This hemoglobin molecule is called deoxyhemoglobin and imparts a bluish tinge to venous blood. The water ligand can be replaced readily by molecular oxygen (in the lungs) to form red oxyhemoglobin, which is found in arterial blood. Each subunit contains a heme group, so each hemoglobin molecule can bind up to four $\mathrm{O}_{2}$ molecules.

Porphine

Protein

## Applying What You've Learned

Elevated BLL and other heavy metal poisoning can be treated with one of several chelating agents, including DMSA and EDTA. EDTA is administered intravenously as either the sodium salt (Endrate) or as the calcium disodium salt (Versenate). Endrate is not approved for the treatment of lead poisoning because of its high affinity for calcium. It is approved, however, for treating hypercalcemia, a condition in which there is excess calcium in the blood-usually as a result of bone cancer. The accidental use of Endrate during treatment for lead poisoning resulted in the death of a 2 -year-old girl in February of 2005. The girl's death was attributed to sudden cardiac arrest caused by the removal of too much calcium from her blood.

Chelation therapy works by the administration of a ligand, which binds to metal ions already in the body. Many drugs, including cisplatin [ $\mathrm{KA}^{4}$ Chapter 3, Applying What You've Learned], are themselves coordination compounds in which the central metal ion binds to electron-rich sites (such as oxygen or sulfur atoms) in biological molecules.

## Problems:

a) Determine the oxidation state of platinum in cisplatin, $\left[\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{2} \mathrm{Cl}_{2}\right]$. [14 Sample Problem 22.1]
b) Give the systematic name for cisplatin. [ 1 Kt Sample Problem 22.2]
c) Write the formula for the compound potassium hexachloroplatinate(IV). [ 144 Sample Problem 22.3]

## Chapter Summary

## Section 22.1

- Coordination compounds contain coordinate covalent bonds between a metal ion (often a transition metal ion) and two or more polar molecules or ions.
- The molecules or anions that surround a metal in a coordination complex are called ligands.
- Many coordination compounds consist of a complex ion and a counter ion.
- Transition metals are those that have incompletely filled $d$ subshellsor that give rise to ions with incompletely filled $d$ subshells.
- Transition metals exhibit variable oxidation states ranging from +1 to +7 .
- To act as a ligand, a molecule or ion must have at least one unshared pair of electrons. The atom that bears the unshared pair of electrons is the donor atom.
- Ligands are classified as monodentate, bidentate, or polydentate, based on the number of donor atoms they contain. Bidentate and polydentate ions are also known as chelating agents.
- The coordination number is the number of donor atoms surrounding a metal in a complex.
- Ionic coordination compounds are named by first naming the cation and then the anion. Complex ions are named by listing the ligands in alphabetical order, followed by the metal and its oxidation state (as a Roman numeral). When the complex ion is the anion, the anion's name ends in -ate.

## Section 22.2

- The coordination number largely determines the geometry of a coordination complex.
- Coordination compounds containing different arrangements of the same ligands are stereoisomers. The two types of stereoisomerism are geometric and optical.
- Geometrical isomers contain the same atoms and bonds arranged differently in space.
- Optical isomers are nonsuperimposable mirror images. We call a pair of optical isomers enantiomers. The rotation of polarized light is measured with a polarimeter.
- Enantiomers rotate the plane of plane-polarized light in opposite directions. The enantiomer that rotates it to the right is called dextrorotatory and is labeled $d$. The enantiomer that rotates it to the left is called levorotatory and is labeled $l$. An equal mixture of a pair of enantiomers, called a racemic mixture, does not cause any net rotation of plane-polarized light.

## Section 22.3

- Ligands in a coordination complex cause the energy levels of the $d$ orbitals on a metal to split. The difference in energy between the lower and higher $d$ orbital energy levels is called the crystal field splitting ( $\Delta$ ).
- The magnitude of $\Delta$ depends on the nature of the ligands in the complex. The spectrochemical series orders some common ligands in order of increasing field strength.
- Strong-field ligands give rise to a larger $\Delta$ value; weak-field ligands yield a smaller $\Delta$ value.
- Crystal field splitting sometimes changes the number of unpaired electrons, and therefore the magnetic properties, of a metal.
- Complexes containing transition metals with $d^{4}, d^{5}, d^{6}$, or $d^{7}$ configurations may be high spin or low spin. In high-spin complexes, the number of unpaired electrons is maximized because $\Delta$ is small; in low-spin complexes, the number of unpaired electrons is minimized because $\Delta$ is large.

## Section 22.4

- Complex ions undergo ligand exchange in solution. The rate at which ligand exchange occurs is a measure of a complex's kinetic lability and does not necessarily correspond directly to the complex's thermodynamic stability.

## Section 22.5

- Coordination chemistry is important in many biological, medical, and industrial processes.

## Questions and Problems

## Section 22.1: Coordination Compounds

## Review Questions

22.1 What distinguishes a transition metal from a main group metal?
22.2 Why is zinc not considered a transition metal?
22.3 Explain why atomic radii decrease very gradually from scandium to copper.
El 22.4 Without referring to the text, write the ground-state electron configurations of the first-row transition metals. Explain any irregularities.

E 22.5 Write the electron configurations of the following ions: $\mathrm{V}^{5+}, \mathrm{Cr}^{3+}$, $\mathrm{Mn}^{2+}, \mathrm{Fe}^{3+}, \mathrm{Cu}^{2+}, \mathrm{Sc}^{3+}, \mathrm{Ti}^{4+}$.
22.6 Why do transition metals have more oxidation states than other elements?
22.7 Give the highest oxidation states for scandium to copper.
22.8 Define the following terms: coordination compound, ligand, donor atom, coordination number, chelating agent.
22.9 Describe the interaction between a donor atom and a metal atom in terms of a Lewis acid-base reaction.

## Problems

- 22.10 Complete the following statements for the complex ion $\left[\mathrm{Co}(\mathrm{en})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right) \mathrm{CN}\right]^{2+}$. (a) en is the abbreviation for $\qquad$ -. (b) The oxidation number of Co is _._. (c) The coord
number of Co is ___ (d) ___ is a bidentate ligand.
22.11 Complete the following statements for the complex ion $\left[\mathrm{Cr}\left(\mathrm{C}_{2} \mathrm{O}_{4}\right)_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]^{-}$. (a) The oxidation number of Cr is $\qquad$ -. (b) The coordination number of Cr is $\qquad$ (c) $\qquad$ is a bidentate ligand.
\$22.12 Give the oxidation numbers of the metals in the following species: (a) $\mathrm{K}_{3}\left[\mathrm{Fe}(\mathrm{CN})_{6}\right]$, (b) $\mathrm{K}_{3}\left[\mathrm{Cr}\left(\mathrm{C}_{2} \mathrm{O}_{4}\right)_{3}\right]$, (c) $\left[\mathrm{Ni}(\mathrm{CN})_{4}\right]^{2-}$.
$\boldsymbol{\$ 2 2 . 1 3}$ Give the oxidation numbers of the metals in the following species: (a) $\mathrm{Na}_{2} \mathrm{MoO}_{4}$, (b) $\mathrm{MgWO}_{4}$, (c) $\mathrm{Fe}(\mathrm{CO})_{5}$.

H22.14 What are the systematic names for the following ions and compounds?
(a) $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}_{2}\right]^{+}$
(c) $\left[\mathrm{Co}(\mathrm{en})_{2} \mathrm{Br}_{2}\right]^{+}$
(b) $\left[\mathrm{Cr}\left(\mathrm{NH}_{3}\right)_{3} \mathrm{Cl}_{3}\right]$
(d) $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right] \mathrm{Cl}_{3}$

H22.15 What are the systematic names for the following ions and compounds?
(a) $\left[\text { cis- } \mathrm{Co}(\mathrm{en})_{2} \mathrm{Cl}_{2}\right]^{+}$
(c) $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{Cl}\right] \mathrm{Cl}_{2}$
(b) $\left[\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{Cl}\right] \mathrm{Cl}_{3}$
$\$ 22.16$ Write the formulas for each of the following ions and compounds: (a) tetrahydroxozincate(II), (b) pentaaquachlorochromium(III) chloride, (c) tetrabromocuprate(II), (d) ethylenediaminetetraacetatoferrate(II).
$\$ 22.17$ Write the formulas for each of the following ions and compounds: (a) dichlorobis(ethylenediamine)chromium(III), (b) pentacarbonyliron(0), (c) potassium tetracyanocuprate(II), (d) tetraammineaquachlorocobalt(III) chloride.

## Section 22.2: Structure of Coordination Compounds

## Review Questions

22.18 Define the following terms: stereoisomers, geometric isomers, optical isomers, plane-polarized light.

E/22.19 Specify which of the following structures can exhibit geometric isomerism: (a) linear, (b) square planar, (c) tetrahedral, (d) octahedral.
22.20 What determines whether a molecule is chiral? How does a polarimeter measure the chirality of a molecule?
22.21 Explain the following terms: enantiomers, racemic mixtures.

Problems
$\boldsymbol{\xi}$ 22.22 The complex ion $\left[\mathrm{Ni}(\mathrm{CN})_{2} \mathrm{Br}_{2}\right]^{2-}$ has a square-planar geometry. Draw the structures of the geometric isomers of this complex.
$\leftrightarrows \mathbf{2 2 . 2 3}$ How many geometric isomers are in the following species:
(a) $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{2} \mathrm{Cl}_{4}\right]^{-}$,
(b) $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{3} \mathrm{Cl}_{3}\right]$ ?
$\$ 22.24$ Draw structures of all the geometric and optical isomers of each of the following cobalt complexes:
(a) $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right]^{3+}$
(b) $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{Cl}\right]^{2+}$
(c) $\left[\mathrm{Co}\left(\mathrm{C}_{2} \mathrm{O}_{4}\right)_{3}\right]^{3-}$
§22.25 Draw structures of all the geometric and optical isomers of each of the following cobalt complexes: (a) $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}_{2}\right]^{+}$, (b) $\left[\mathrm{Co}(\mathrm{en})_{3}\right]^{3+}$.

## Section 22.3: Bonding in Coordination Compounds: Crystal Field Theory

## Review Questions

22.26 Briefly describe crystal field theory.
22.27 Define the following terms: crystal field splitting, high-spin complex, low-spin complex, spectrochemical series.
22.28 What is the origin of color in a coordination compound?
22.29 Compounds containing the $\mathrm{Sc}^{3+}$ ion are colorless, whereas those containing the $\mathrm{Ti}^{3+}$ ion are colored. Explain.
22.30 For the same type of ligands, explain why the crystal field splitting for an octahedral complex is always greater than that for a tetrahedral complex.

## Problems

22.31 Transition metal complexes containing $\mathrm{CN}^{-}$ligands are often yellow in color, whereas those containing $\mathrm{H}_{2} \mathrm{O}$ ligands are often green or blue. Explain.
$\$ 22.32$ Predict the number of unpaired electrons in the following complex ions: (a) $\left[\mathrm{Cr}(\mathrm{CN})_{6}\right]^{4-}$, (b) $\left[\mathrm{Cr}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}$.
H22.33 The absorption maximum for the complex ion $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right]^{3+}$ occurs at 470 nm . (a) Predict the color of the complex, and (b) calculate the crystal field splitting in $\mathrm{kJ} / \mathrm{mol}$.

GI22.34 From each of the following pairs, choose the complex that absorbs light at a longer wavelength: (a) $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right]^{2+},\left[\mathrm{Co}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}$; (b) $\left[\mathrm{FeF}_{6}\right]^{3-},\left[\mathrm{Fe}(\mathrm{CN})_{6}\right]^{3-}$; (c) $\left[\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}\right]^{2+},\left[\mathrm{CuCl}_{4}\right]^{2-}$.
$\mathbf{H 2 2 . 3 5}$ A solution made by dissolving 0.875 g of $\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}_{3}$ in 25.0 g of water freezes at $-0.56^{\circ} \mathrm{C}$. Calculate the number of moles of ions produced when 1 mole of $\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}_{3}$ is dissolved in water, and suggest a structure for the complex ion present in this compound.
22.36 In biological systems, the $\mathrm{Cu}^{2+}$ ions coordinated with S atoms tend to form tetrahedral complexes, whereas those coordinated with N atoms tend to form octahedral complexes. Explain.
22.37 Plastocyanin, a copper-containing protein found in photosynthetic systems, is involved in electron transport, with the copper ion switching between the +1 and +2 oxidation states. The copper ion is coordinated with two histidine residues, a cysteine residue, and a methionine residue in a tetrahedral configuration. How does the crystal field splitting $(\Delta)$ change between these two oxidation states?

## Section 22.4: Reactions of Coordination Compounds

## Review Questions

22.38 Define the terms labile complex and inert complex.
22.39 Explain why a thermodynamically stable species may be chemically reactive and a thermodynamically unstable species may be unreactive.

## Problems

22.40 Oxalic acid $\left(\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}\right)$ is sometimes used to clean rust stains from sinks and bathtubs. Explain the chemistry underlying this cleaning action.
22.41 The $\left[\mathrm{Fe}(\mathrm{CN})_{6}\right]^{3-}$ complex is more labile than the $\left[\mathrm{Fe}(\mathrm{CN})_{6}\right]^{4-}$ complex. Suggest an experiment that would prove that $\left[\mathrm{Fe}(\mathrm{CN})_{6}\right]^{3-}$ is a labile complex.
22.42 Aqueous copper(II) sulfate solution is blue in color. When aqueous potassium fluoride is added, a green precipitate is formed. When aqueous potassium chloride is added instead, a bright-green solution is formed. Explain what is happening in these two cases.
22.43 When aqueous potassium cyanide is added to a solution of copper(II) sulfate, a white precipitate, soluble in an excess of potassium cyanide, is formed. No precipitate is formed when hydrogen sulfide is bubbled through the solution at this point. Explain.
22.44 A concentrated aqueous copper(II) chloride solution is bright green in color. When diluted with water, the solution becomes light blue. Explain.
-122.45 In a dilute nitric acid solution, $\mathrm{Fe}^{3+}$ reacts with thiocyanate ion ( $\mathrm{SCN}^{-}$) to form a dark-red complex:

$$
\left[\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}+\mathrm{SCN}^{-} \rightleftarrows \mathrm{H}_{2} \mathrm{O}+\left[\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{5} \mathrm{NCS}\right]^{2+}
$$

The equilibrium concentration of $\left[\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{5} \mathrm{NCS}\right]^{2+}$ may be determined by how darkly colored the solution is (measured by a spectrometer). In one such experiment, 1.0 mL of 0.20 M $\mathrm{Fe}\left(\mathrm{NO}_{3}\right)_{3}$ was mixed with 1.0 mL of $1.0 \times 10^{-3} M \mathrm{KSCN}$ and 8.0 mL of dilute $\mathrm{HNO}_{3}$. The color of the solution quantitatively indicated that the $\left[\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{5} \mathrm{NCS}\right]^{2+}$ concentration was $7.3 \times$ $10^{-5} M$. Calculate the formation constant for $\left[\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{5} \mathrm{NCS}\right]^{2+}$.

## Section 22.5: Applications of Coordination Compounds

## Review Question

22.46 Describe and give examples of the applications of coordination compounds.

## Additional Problems

22.47 Suffocation victims usually look purple, but a person poisoned by carbon monoxide often has rosy cheeks. Explain.
22.48 As we read across the first-row transition metals from left to right, the +2 oxidation state becomes more stable in comparison with the +3 state. Why is this so?
22.49 Which is a stronger oxidizing agent in aqueous solution, $\mathrm{Mn}^{3+}$ or $\mathrm{Cr}^{3+}$ ? Explain your choice.
22.50 Carbon monoxide binds to Fe in hemoglobin some 200 times more strongly than oxygen. This is the reason why CO is a toxic substance. The metal-to-ligand sigma bond is formed by donating a lone pair from the donor atom to an empty $s p^{3} d^{2}$ orbital on Fe . (a) On the basis of electronegativities, would you expect the C or O atom to form the bond to Fe ? (b) Draw a diagram illustrating the overlap of the orbitals involved in the bonding.
22.51 What are the oxidation states of Fe and Ti in the ore ilmenite $\left(\mathrm{FeTiO}_{3}\right)$ ? (Hint: Look up the ionization energies of Fe and Ti in Table 22.1; the fourth ionization energy of Ti is $4180 \mathrm{~kJ} / \mathrm{mol}$.)
22.52 A student has prepared a cobalt complex that has one of the following three structures: $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right] \mathrm{Cl}_{3},\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{Cl}\right] \mathrm{Cl}_{2}$, or $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}_{2}\right] \mathrm{Cl}$. Explain how the student would distinguish between these possibilities by an electrical conductance experiment. At the student's disposal are three strong electrolytes- NaCl , $\mathrm{MgCl}_{2}$, and $\mathrm{FeCl}_{3}$ - which may be used for comparison purposes.
22.53 Chemical analysis shows that hemoglobin contains 0.34 percent of Fe by mass. What is the minimum possible molar mass of hemoglobin? The actual molar mass of hemoglobin is about $65,000 \mathrm{~g}$. How do you account for the discrepancy between your minimum value and the actual value?
22.54 Explain the following facts: (a) Copper and iron have several oxidation states, whereas zinc has only one. (b) Copper and iron form colored ions, whereas zinc does not.

G22.55 A student in 1895 prepared three coordination compounds containing chromium, with the following properties:

| Formula | Color | $\mathbf{C l}^{-}$Ions in Solution <br> per Formula Unit |
| :--- | :--- | :---: |
| (a) $\mathrm{CrCl}_{3} \cdot 6 \mathrm{H}_{2} \mathrm{O}$ | Violet | 3 |
| (b) $\mathrm{CrCl}_{3} \cdot 6 \mathrm{H}_{2} \mathrm{O}$ | Light green | 2 |
| (c) $\mathrm{CrCl}_{3} \cdot 6 \mathrm{H}_{2} \mathrm{O}$ | Dark green | 1 |

Write modern formulas for these compounds, and suggest a method for confirming the number of $\mathrm{Cl}^{-}$ions present in solution in each case. (Hint: Some of the compounds may exist as hydrates.)
$\leftrightarrows 22.56$ The formation constant for the reaction $\mathrm{Ag}^{+}+2 \mathrm{NH}_{3} \rightleftarrows$ $\left[\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}\right]^{+}$is $1.5 \times 10^{7}$, and that for the reaction $\mathrm{Ag}^{+}+$
$2 \mathrm{CN}^{-} \rightleftarrows\left[\mathrm{Ag}(\mathrm{CN})_{2}\right]^{-}$is $1.0 \times 10^{21}$ at $25^{\circ} \mathrm{C}$ (see Table 17.5).
Calculate the equilibrium constant and $\Delta G^{\circ}$ at $25^{\circ} \mathrm{C}$ for the reaction

$$
\left[\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}\right]^{+}+2 \mathrm{CN}^{-} \rightleftarrows\left[\mathrm{Ag}(\mathrm{CN})_{2}\right]^{-}+2 \mathrm{NH}_{3}
$$

22.57 From the standard reduction potentials listed in Table 19.1 for $\mathrm{Zn} / \mathrm{Zn}^{2+}$ and $\mathrm{Cu} / \mathrm{Cu}^{2+}$, calculate $\Delta G^{\circ}$ and the equilibrium constant for the reaction

$$
\mathrm{Zn}(s)+2 \mathrm{Cu}^{2+}(a q) \longrightarrow \mathrm{Zn}^{2+}(a q)+2 \mathrm{Cu}^{+}(a q)
$$

EI22.58 Using the standard reduction potentials listed in Table 19.1 and the Handbook of Chemistry and Physics, show that the following reaction is favorable under standard-state conditions:

$$
2 \mathrm{Ag}(s)+\mathrm{Pt}^{2+}(a q) \longrightarrow 2 \mathrm{Ag}^{+}(a q)+\operatorname{Pt}(s)
$$

What is the equilibrium constant of this reaction at $25^{\circ} \mathrm{C}$ ?
22.59 The $\mathrm{Co}^{2+}$-porphyrin complex is more stable than the $\mathrm{Fe}^{2+}$ porphyrin complex. Why, then, is iron the metal ion in hemoglobin (and other heme-containing proteins)?
22.60 What are the differences between geometric isomers and optical isomers?
22.61 Oxyhemoglobin is bright red, whereas deoxyhemoglobin is purple. Show that the difference in color can be accounted for qualitatively on the basis of high-spin and low-spin complexes. (Hint: $\mathrm{O}_{2}$ is a strong-field ligand. See the Bringing Chemistry to Life box on page 938.)
22.62 Hydrated $\mathrm{Mn}^{2+}$ ions are practically colorless (see Figure 22.16) even though they possess five $3 d$ electrons. Explain. (Hint: Electronic transitions in which there is a change in the number of unpaired electrons do not occur readily.)
22.63 Which of the following hydrated cations are colorless: $\mathrm{Fe}^{2+}(a q)$, $\mathrm{Zn}^{2+}(a q), \mathrm{Cu}^{+}(a q), \mathrm{Cu}^{2+}(a q), \mathrm{V}^{5+}(a q), \mathrm{Ca}^{2+}(a q), \mathrm{Co}^{2+}(a q)$, $\mathrm{Sc}^{3+}(a q), \mathrm{Pb}^{2+}(a q)$ ? Explain your choice.
22.64 Aqueous solutions of $\mathrm{CoCl}_{2}$ are generally either light pink or blue. Low concentrations and low temperatures favor the pink form, whereas high concentrations and high temperatures favor the blue form. Adding hydrochloric acid to a pink solution of $\mathrm{CoCl}_{2}$ causes the solution to turn blue; the pink color is restored by the addition of $\mathrm{HgCl}_{2}$. Account for these observations.
22.65 Suggest a method that would allow you to distinguish between cis $-\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{2} \mathrm{Cl}_{2}$ and trans $-\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{2} \mathrm{Cl}_{2}$.
\&22.66 You are given two solutions containing $\mathrm{FeCl}_{2}$ and $\mathrm{FeCl}_{3}$ at the same concentration. One solution is light yellow, and the other one is brown. Identify these solutions based only on color.
22.67 The label of a certain brand of mayonnaise lists EDTA as a food preservative. How does EDTA prevent the spoilage of mayonnaise?
22.68 The compound 1,1,1-trifluoroacetylacetone (tfa) is a bidentate ligand:

It forms a tetrahedral complex with $\mathrm{Be}^{2+}$ and a square-planar complex with $\mathrm{Cu}^{2+}$. Draw structures of these complex ions, and identify the type of isomerism exhibited by these ions.
22.69 How many geometric isomers can the following square-planar complex have?

$22.70\left[\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{2} \mathrm{Cl}_{2}\right]$ is found to exist in two geometric isomers designated I and II, which react with oxalic acid as follows:

$$
\begin{aligned}
\mathrm{I}+\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4} & \longrightarrow\left[\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{2} \mathrm{C}_{2} \mathrm{O}_{4}\right] \\
\mathrm{II}+\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4} & \longrightarrow\left[\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{2}\left(\mathrm{HC}_{2} \mathrm{O}_{4}\right)_{2}\right]
\end{aligned}
$$

Comment on the structures of I and II.
\$22.71 Commercial silver-plating operations frequently use a solution containing the complex $\operatorname{Ag}(\mathrm{CN})_{2}^{-}$ion. Because the formation constant $\left(K_{\mathrm{f}}\right)$ is quite large, this procedure ensures that the free $\mathrm{Ag}^{+}$concentration in solution is low for uniform electrodeposition. In one process, a chemist added 9.0 L of 5.0 M NaCN to 90.0 L of $0.20 \mathrm{M} \mathrm{AgNO}_{3}$. Calculate the concentration of free $\mathrm{Ag}^{+}$ions at equilibrium. See Table 17.5 for $K_{\mathrm{f}}$ value.
22.72 Draw qualitative diagrams for the crystal field splittings in (a) a linear complex ion $\mathrm{ML}_{2}$, (b) a trigonal-planar complex ion $\mathrm{ML}_{3}$, and (c) a trigonal-bipyramidal complex ion $\mathrm{ML}_{5}$.
$\leftrightarrows 22.73$ (a) The free $\mathrm{Cu}(\mathrm{I})$ ion is unstable in solution and has a tendency to disproportionate:

$$
2 \mathrm{Cu}^{+}(a q) \rightleftarrows \mathrm{Cu}^{2+}(a q)+\mathrm{Cu}(s)
$$

Use the information in Table 19.1 (page 827) to calculate the equilibrium constant for the reaction. (b) Based on your results in part (a), explain why most $\mathrm{Cu}(\mathrm{I})$ compounds are insoluble.
$\boldsymbol{H}$ 22.74 Consider the following two ligand exchange reactions:

$$
\begin{aligned}
{\left[\mathrm{Co}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}+6 \mathrm{NH}_{3} } & \rightleftarrows\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right]^{3+}+6 \mathrm{H}_{2} \mathrm{O} \\
{\left[\mathrm{Co}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}+3 \mathrm{en} } & \left.\rightleftarrows \mathrm{Co}(\mathrm{en})_{3}\right]^{3+}+6 \mathrm{H}_{2} \mathrm{O}
\end{aligned}
$$

(a) Which of the reactions should have a larger $\Delta S^{\circ}$ ? (b) Given that the $\mathrm{Co}-\mathrm{N}$ bond strength is approximately the same in both complexes, which reaction will have a larger equilibrium constant? Explain your choices.
22.75 The $\mathrm{Cr}^{3+}$ ion forms octahedral complexes with two neutral ligands X and Y . The color of $\mathrm{CrX}_{6}^{3+}$ is blue while that of $\mathrm{CrY}_{6}^{3+}$ is yellow. Which is a stronger field ligand, X or Y ?
22.76 Explain the difference between these two compounds: $\mathrm{CrCl}_{3} \cdot 6 \mathrm{H}_{2} \mathrm{O}$ and $\left[\mathrm{Cr}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right] \mathrm{Cl}_{3}$.

H22.77 The $K_{\mathrm{f}}$ for the formation of the complex ion between $\mathrm{Pb}^{2+}$ and EDTA $^{4-}$,

$$
\mathrm{Pb}^{2+}+\mathrm{EDTA}^{4-} \rightleftarrows[\mathrm{Pb}(\mathrm{EDTA})]^{2-}
$$

is $1.0 \times 10^{18}$ at $25^{\circ} \mathrm{C}$. Calculate $\left[\mathrm{Pb}^{2+}\right]$ at equilibrium in a solution containing $1.0 \times 10^{-3} \mathrm{M} \mathrm{Pb}^{2+}$ and $2.0 \times 10^{-3} M$ EDTA $^{4-}$.
22.78 Locate the transition metal atoms and ions in the periodic table shown here. Atoms: (a) $[\mathrm{Kr}] 5 s^{2} 4 d^{5}$. (b) $[\mathrm{Xe}] 6 s^{2} 4 f^{14} 5 d^{4}$. Ions: (c) $[\mathrm{Ar}] 3 d^{3}$ (ion with charge $4+$ ). (d) $[\mathrm{Xe}] 4 f^{14} 5 d^{8}$ (ion with charge $3+$ ).

Manganese forms three low-spin complex ions with the cyanide ion with the formulas $\left[\mathrm{Mn}(\mathrm{CN})_{6}\right]^{5-},\left[\mathrm{Mn}(\mathrm{CN})_{6}\right]^{4-}$, and $\left[\mathrm{Mn}(\mathrm{CN})_{6}\right]^{3-}$. For each complex ion, determine the oxidation number of Mn and the number of unpaired $d$ electrons.
22.80 Copper is known to exist in the +3 oxidation state, which is believed to be involved in some biological electron-transfer reactions. (a) Would you expect this oxidation state of copper to be stable? Explain. (b) Name the compound $\mathrm{K}_{3} \mathrm{CuF}_{6}$ and predict the geometry and magnetic properties of the complex ion. (c) Most of the known $\mathrm{Cu}(\mathrm{III})$ compounds have square planar geometry. Are these compounds diamagnetic or paramagnetic?

## Pre-Professional Practice Exam Problems: Physical and Biological Sciences

The following questions are not based on a passage.

1. What are the correct names for the complex ions $\left[\mathrm{Ni}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}$ and $\left[\mathrm{Ni}\left(\mathrm{NH}_{3}\right)_{6}\right]^{2+}$ ?
a) Hexaaquanickel(VI) ion and hexaamminenickel(VI) ion
b) Nickel(II) hexaaqua ion and nickel(II) hexaammine ion
c) Hexaaquanickel(II) ion and hexaamminenickel(II) ion
d) Hexaaquanickelate and hexaamminenickelate
2. One of the complex ions in Question 1 is green, and the other is purple. Based on the spectrochemical series, which is which?
$\mathrm{I}^{-}<\mathrm{Br}^{-}<\mathrm{Cl}^{-}<\mathrm{OH}^{-}<\mathrm{F}^{-}<\mathrm{H}_{2} \mathrm{O}<\mathrm{NH}_{3}<$ en $<\mathrm{CN}^{-}<\mathrm{CO}$
a) $\left[\mathrm{Ni}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}$ is green and $\left[\mathrm{Ni}\left(\mathrm{NH}_{3}\right)_{6}\right]^{2+}$ is purple.
b) $\left[\mathrm{Ni}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}$ is purple and $\left[\mathrm{Ni}\left(\mathrm{NH}_{3}\right)_{6}\right]^{2+}$ is green.
c) Both ions should be the same color because they contain the same metal.
d) There is not enough information to determine which is which.
3. How many geometric isomers are possible for the complex ion $\left[\mathrm{Ni}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\left(\mathrm{NH}_{3}\right)_{2}\right]^{2+}$ ?
a) 1
b) 2
c) 4
d) 6
4. How many ions in solution would result from dissolving $\left[\mathrm{Ni}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\left(\mathrm{NH}_{3}\right)_{2}\right] \mathrm{Cl}_{2}$ ?
a) 2
b) 3
c) 8
d) 11

## Answers to In-Chapter Materials

## The Importance of Metals in Human Biology

Calcium, potassium, and sodium are the three most abundant metals in the human body. Present in a much smaller amount, copper is nonetheless vitally important to human health. Copper-dependent enzymes known as cuproenzymes play a critical role in a host of biochemical processes, including cellular energy production, connective tissue formation, and reactions essential to normal functioning of the brain and central nervous system. Two hereditary diseases that involve errors of copper metabolism are Menkes disease and Wilson's disease.

In Menkes disease, copper is not absorbed in the intestine and is not available for distribution throughout the body. Consequently, cuproenzymes such as cytochrome c oxidase, lysyl oxidase, and dopamine beta hydroxylase cannot function normally. Sufferers exhibit severe developmental delay; subnormal body temperature; kinky, steel-colored hair; seizures; and ultimately the degeneration of muscle, bone, and organs. Baby boys born with the most severe form of Menkes disease typically do not live beyond their third year of life.

Wilson's disease causes the body to retain copper. Although people with Wilson's disease are able to absorb copper in the intestine, the liver of a person with Wilson's disease does not release copper into the bile as it should. Eventually, damaged by the buildup of copper, the liver releases copper directly into the blood, where it is carried throughout the body. Excess copper causes damage to the kidneys, brain, and eyes. Unlike Menkes disease, Wilson's disease can be managed and treated. Sufferers must follow a strict lowcopper diet, avoiding such foods as mushrooms, nuts, and chocolate. In addition, they must undergo lifelong periodic chelation therapy.

Menkes and Wilson's diseases illustrate the importance of metals to living systems.

Student Annotation: Menkes disease is an X-linked recessive condition and nearly all victims are male.

At the end of this chapter, you will have an appreciation for the importance of metals and the many roles they play in human health [ $\quad$ M Page 962].

## In This Chapter, You Will Learn:

How some metals are produced and about their chemistry.
Before you begin, you should review

## Minerals

$\mathrm{Ag}, \mathrm{Au}, \mathrm{Bi}, \mathrm{Cu}, \mathrm{Pd}, \mathrm{Pt}$
$\mathrm{BaCO}_{3}$ (witherite), $\mathrm{CaCO}_{3}$ (calcite, limestone), $\mathrm{MgCO}_{3}$ (magnesite), $\mathrm{CaCO}_{3} \cdot \mathrm{MgCO}_{3}$ (dolomite), $\mathrm{PbCO}_{3}$ (cerussite), $\mathrm{ZnCO}_{3}$ (smithsonite)
$\mathrm{CaF}_{2}$ (fluorite), NaCl (halite), KCl (sylvite), $\mathrm{Na}_{3} \mathrm{AlF}_{6}$ (cryolite)
$\mathrm{Al}_{2} \mathrm{O}_{3} \cdot 2 \mathrm{H}_{2} \mathrm{O}$ (bauxite), $\mathrm{Al}_{2} \mathrm{O}_{3}$ (corundum), $\mathrm{Fe}_{2} \mathrm{O}_{3}$ (hematite), $\mathrm{Fe}_{3} \mathrm{O}_{4}$ (magnetite), $\mathrm{Cu}_{2} \mathrm{O}$ (cuprite), $\mathrm{MnO}_{2}$ (pyrolusite), $\mathrm{SnO}_{2}$ (cassiterite), $\mathrm{TiO}_{2}$ (rutile), ZnO (zincite)
$\mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}$ (phosphate rock), $\mathrm{Ca}_{5}\left(\mathrm{PO}_{4}\right)_{3} \mathrm{OH}$ (hydroxyapatite)
$\mathrm{Be}_{3} \mathrm{Al}_{2} \mathrm{Si}_{6} \mathrm{O}_{18}$ (beryl), $\mathrm{ZrSiO}_{4}$ (zircon), $\mathrm{NaAlSi}_{3} \mathrm{O}_{8}$ (albite), $\mathrm{Mg}_{3}\left(\mathrm{Si}_{4} \mathrm{O}_{10}\right)(\mathrm{OH})_{2}$ (talc)
$\mathrm{Ag}_{2} \mathrm{~S}$ (argentite), CdS (greenockite), $\mathrm{Cu}_{2} \mathrm{~S}$ (chalcocite), $\mathrm{FeS}_{2}$ (pyrite), HgS (cinnabar), PbS (galena), ZnS (sphalerite) (celestite), $\mathrm{MgSO}_{4} \cdot 7 \mathrm{H}_{2} \mathrm{O}$ (epsomite)

Figure 23.1 Metals and their best-known minerals. Lithium is found in spodumene $\left(\mathrm{LeAlSi}_{2} \mathrm{O}_{6}\right)$, and beryllium in beryl (see Table 23.1). The rest of the alkaline earth metals are found in minerals that are carbonates and sulfates. The minerals for $\mathrm{Sc}, \mathrm{Y}$, and La are the phosphates. Some metals have more than one type of important mineral. For example, in addition to the sulfide, iron is found as the oxides hematite $\left(\mathrm{Fe}_{2} \mathrm{O}_{3}\right)$ and magnetite $\left(\mathrm{Fe}_{3} \mathrm{O}_{4}\right)$; and aluminum, in addition to the oxide, is found in beryl $\left(\mathrm{Be}_{3} \mathrm{Al}_{2} \mathrm{Si}_{6} \mathrm{O}_{18}\right)$. Technetium (Tc) is a synthetic element.

### 23.1 Occurrence of Metals

Most metals come from minerals. A mineral is a naturally occurring substance with a range of chemical composition. A mineral deposit concentrated enough to allow economical recovery of a desired metal is known as ore. Table 23.1 lists the principal types of minerals, and Figure 23.1 shows a classification of metals according to their minerals.

The most abundant metals, which exist as minerals in Earth's crust, are aluminum, iron, calcium, magnesium, sodium, potassium, titanium, and manganese (see page 47). Seawater is a rich source of some metal ions, including $\mathrm{Na}^{+}, \mathrm{Mg}^{2+}$, and $\mathrm{Ca}^{2+}$. Furthermore, vast areas of the ocean floor are covered with manganese nodules, which are made up mostly of manganese, along with iron, nickel, copper, and cobalt in a chemically combined state (Figure 23.2).

## Bringing Chemistry to Life

## The Importance of Molybdenum

Molybdenum is one of the less abundant metals in Earth's crust. Its importance to human health was recognized relatively recently. Like copper, it is essential in trace amounts for proper enzyme function, and it is toxic in large amounts. Molybdenum deficiency in humans has been described and is known to cause visual problems, rapid heart rate, and coma. However, the number of people affected by a lack of dietary molybdenum is very small. A deficiency that has affected a large group of people is molybdenum deficiency in the soil. In the north China province of Honan, there is a small region (Lin Xian) where for generations the incidence of esophageal cancer has been one of the highest in the world. It turns out that the soil in this region is naturally low in molybdenum. Without molybdenum, the enzyme nitrate reductase, found in nitrogen-fixing bacteria, was inactive. Thus, instead of being converted to amines, nitrates in the soil were converted to nitrosamines, compounds that are known to cause cancer. The addition of molybdenum to the soil may result in lower levels of nitrosamines in the diets of Lin Xian residents and, it is hoped, a lower incidence of esophageal cancer.

### 23.2 Metallurgical Processes

Metallurgy is the science and technology of separating metals from their ores and of compounding alloys. An alloy is a solid solution either of two or more metals, or of a metal or metals with one or more nonmetals. The three principal steps in the recovery of a metal from its ore are (1) preparation of the ore, (2) production of the metal, and (3) purification of the metal.

## Preparation of the Ore

In the preliminary treatment of an ore, the desired mineral is separated from waste materialsusually clay and silicate minerals-which are collectively called the gangue. One very useful method for carrying out such a separation is called flotation.

In this process, the ore is finely ground and added to water containing oil and detergent. The liquid mixture is then beaten or blown to form a froth. The oil preferentially wets the mineral particles, which are then carried to the top in the froth, while the gangue settles to the bottom. The froth is skimmed off, allowed to collapse, and dried to recover the mineral particles.

Another physical separation process makes use of the magnetic properties of certain minerals. Ferromagnetic metals are strongly attracted to magnets. The mineral magnetite $\left(\mathrm{Fe}_{3} \mathrm{O}_{4}\right)$, in particular, can be separated from the gangue by using a strong electromagnet. Cobalt is another ferromagnetic metal.

Mercury forms amalgams with a number of metals. An amalgam is an alloy of mercury with another metal or metals [ $1 / 4$ Chapter 19]. Mercury can therefore be used to extract metal from ore. Mercury dissolves the silver and gold in an ore to form a liquid amalgam, which is easily separated from the remaining ore. The gold or silver is recovered by distilling off the mercury.

## Production of Metals

Because metals in their combined forms always have positive oxidation numbers, the production of a free metal is a reduction process. Preliminary operations may be necessary to convert the ore to a chemical state more suitable for reduction. For example, an ore may be roasted to drive off volatile impurities and at the same time to convert the carbonates and sulfides to the corresponding oxides, which can be reduced more conveniently to yield the pure metals:

$$
\begin{aligned}
\mathrm{CaCO}_{3}(s) & \longrightarrow \mathrm{CaO}(s)+\mathrm{CO}_{2}(g) \\
2 \mathrm{PbS}(s)+3 \mathrm{O}_{2}(g) & \longrightarrow 2 \mathrm{PbO}(s)+2 \mathrm{SO}_{2}(g)
\end{aligned}
$$

This last equation demonstrates that the conversion of sulfides to oxides is a major source of sulfur dioxide, a notorious air pollutant.

How a pure metal is obtained by reduction from its combined form depends on the standard reduction potential of the metal. Table 23.2 outlines the reduction processes for several metals.

Lin Xian in the Honan province in China.

## TABLE 23.2 Reduction Processes for Some Common Metals

## Metal

## Reduction Process

Electrolytic reduction of the molten chloride

Electrolytic reduction of anhydrous oxide (in molten cryolite)
Reduction of the metal oxide with a more electropositive metal, or reduction with coke and carbon monoxide

These metals occur in the free (uncombined) state, or they can be obtained by roasting their sulfides

Most major metallurgical processes now in use involve pyrometallurgy, procedures carried out at high temperatures. The reduction in these procedures may be accomplished either chemically or electrolytically.

## Chemical Reduction

A more electropositive metal can be used as a reducing agent to separate a less electropositive metal from its compound at high temperatures:

$$
\begin{aligned}
\mathrm{V}_{2} \mathrm{O}_{5}(s)+5 \mathrm{Ca}(l) & \longrightarrow 2 \mathrm{~V}(l)+5 \mathrm{CaO}(s) \\
\mathrm{TiCl}_{4}(g)+2 \mathrm{Mg}(l) & \longrightarrow \mathrm{Ti}(s)+2 \mathrm{MgCl}_{2}(l) \\
\mathrm{Cr}_{2} \mathrm{O}_{3}(s)+2 \mathrm{Al}(s) & \longrightarrow 2 \mathrm{Cr}(l)+\mathrm{Al}_{2} \mathrm{O}_{3}(s) \\
3 \mathrm{Mn}_{3} \mathrm{O}_{4}(s)+8 \mathrm{Al}(s) & \longrightarrow 9 \mathrm{Mn}(l)+4 \mathrm{Al}_{2} \mathrm{O}_{3}(s)
\end{aligned}
$$

In some cases, even molecular hydrogen can be used as a reducing agent, as in the preparation of tungsten (used as filaments in lightbulbs) from tungsten(VI) oxide:

$$
\mathrm{WO}_{3}(s)+3 \mathrm{H}_{2}(g) \longrightarrow \mathrm{W}(s)+3 \mathrm{H}_{2} \mathrm{O}(g)
$$

## Electrolytic Reduction

Electrolytic reduction is suitable for very electropositive metals, such as sodium, magnesium, and aluminum. The process is usually carried out on the anhydrous molten oxide or halide of the metal:

$$
\begin{gathered}
2 \mathrm{MO}(l) \longrightarrow 2 \mathrm{M} \text { (at cathode) }+\mathrm{O}_{2} \text { (at anode) } \\
2 \mathrm{MCl}(l) \longrightarrow 2 \mathrm{M} \text { (at cathode) }+\mathrm{Cl}_{2} \text { (at anode) }
\end{gathered}
$$

We will describe the specific procedures later in this section.

## The Metallurgy of Iron

Multimedia
Chemical Reactions-smelting of iron.

Iron exists in Earth's crust in many different minerals, such as iron pyrite $\left(\mathrm{FeS}_{2}\right)$, siderite $\left(\mathrm{FeCO}_{3}\right)$, hematite $\left(\mathrm{Fe}_{2} \mathrm{O}_{3}\right)$, and magnetite $\left(\mathrm{Fe}_{3} \mathrm{O}_{4}\right.$, often represented as $\left.\mathrm{FeO} \cdot \mathrm{Fe}_{2} \mathrm{O}_{3}\right)$. Of these, hematite and magnetite are particularly suitable for the extraction of iron. The metallurgical processing of iron involves the chemical reduction of the minerals by carbon (in the form of coke) in a blast furnace (Figure 23.3). The concentrated iron ore, limestone $\left(\mathrm{CaCO}_{3}\right)$, and coke are introduced into the furnace from the top. A blast of hot air is forced up the furnace from the bottom-hence, the name blast furnace. The oxygen gas reacts with the carbon in the coke to form mostly carbon monoxide and some carbon dioxide. These reactions are highly exothermic, and as the hot CO and $\mathrm{CO}_{2}$ gases rise, they react with the iron oxides in different temperature zones as shown in Figure 23.3. The key steps in the extraction of iron are

$$
\begin{aligned}
3 \mathrm{Fe}_{2} \mathrm{O}_{3}(s)+\mathrm{CO}(g) & \longrightarrow 2 \mathrm{Fe}_{3} \mathrm{O}_{4}(s)+\mathrm{CO}_{2}(g) \\
\mathrm{Fe}_{3} \mathrm{O}_{4}(s)+\mathrm{CO}(g) & \longrightarrow 3 \mathrm{FeO}(s)+\mathrm{CO}_{2}(g) \\
\mathrm{FeO}(s) & +\mathrm{CO}(g)
\end{aligned} \longrightarrow \mathrm{Fe}(l)+\mathrm{CO}_{2}(g) \text { 號 }
$$

The limestone decomposes in the furnace as follows:

$$
\mathrm{CaCO}_{3}(s) \longrightarrow \mathrm{CaO}(s)+\mathrm{CO}_{2}(g)
$$

The calcium oxide then reacts with the impurities in the iron, which are mostly sand $\left(\mathrm{SiO}_{2}\right)$ and aluminum oxide $\left(\mathrm{Al}_{2} \mathrm{O}_{3}\right)$ :

$$
\begin{aligned}
\mathrm{CaO}(s)+\mathrm{SiO}_{2}(s) & \mathrm{CaSiO}_{3}(l) \\
\mathrm{CaO}(s)+\mathrm{Al}_{2} \mathrm{O}_{3}(s) & \mathrm{Ca}\left(\mathrm{AlO}_{2}\right)_{2}(l)
\end{aligned}
$$

The mixture of calcium silicate and calcium aluminate that remains molten at the furnace temperature is known as slag.

By the time the ore works its way down to the bottom of the furnace, most of it has already been reduced to iron. The temperature of the lower part of the furnace is above the melting point of impure iron, and so the molten iron at the lower level can be run off to a receiver. The slag, because it is less dense, forms the top layer above the molten iron and can be run off at that level, as shown in Figure 23.3.

Iron extracted in this way contains many impurities and is called pig iron; it may contain up to 5 percent carbon and some silicon, phosphorus, manganese, and sulfur. Some of the impurities stem from the silicate and phosphate minerals, while carbon and sulfur come from coke. Pig iron is granular and brittle. It has a relatively low melting point (about $1180^{\circ} \mathrm{C}$ ), so it can be cast in various forms; for this reason it is also called cast iron.

## Steelmaking

Steel manufacturing is one of the most important metal industries. In the United States, the annual consumption of steel is well above 100 million tons. Steel is an iron alloy that contains from 0.03 to 1.4 percent carbon plus various amounts of other elements. The wide range of useful mechanical properties associated with steel is primarily a function of the chemical composition and heat treatment of a particular type of steel.

Whereas the production of iron is basically a reduction process (converting iron oxides to metallic iron), the conversion of iron to steel is essentially an oxidation process in which the unwanted impurities are removed from the iron by reaction with oxygen gas. One of several methods used in steelmaking is the basic oxygen process. Because of its ease of operation

Figure 23.3 A blast furnace. Iron ore, limestone, and coke are introduced at the top of the furnace. Iron is obtained from the ore by reduction with carbon.

Figure 23.4 The basic oxygen process of steelmaking. The capacity of a typical vessel is 100 tons of cast iron.

and the relatively short time (about 20 minutes) required for each large-scale (hundreds of tons) conversion, the basic oxygen process is by far the most common means of producing steel today.

Figure 23.4 shows the basic oxygen process. Molten iron from the blast furnace is poured into an upright cylindrical vessel. Pressurized oxygen gas is introduced via a water-cooled tube above the molten metal. Under these conditions, manganese, phosphorus, and silicon, as well as excess carbon, react with oxygen to form oxides. These oxides are then reacted with the appropriate fluxes (e.g., CaO or $\mathrm{SiO}_{2}$ ) to form slag. The type of flux chosen depends on the composition of the iron. If the main impurities are silicon and phosphorus, a basic flux such as CaO is added to the iron:

$$
\begin{aligned}
\mathrm{SiO}_{2}(s)+\mathrm{CaO}(s) & \longrightarrow \mathrm{CaSiO}_{3}(l) \\
\mathrm{P}_{4} \mathrm{O}_{10}(l)+6 \mathrm{CaO}(s) & \longrightarrow 2 \mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}(l)
\end{aligned}
$$

On the other hand, if manganese is the main impurity, then an acidic flux such as $\mathrm{SiO}_{2}$ is needed to form the slag:

$$
\mathrm{MnO}(s)+\mathrm{SiO}_{2}(s) \longrightarrow \mathrm{MnSiO}_{3}(l)
$$

The molten steel is sampled at intervals. When the desired blend of carbon and other impurities has been reached, the vessel is rotated to a horizontal position so that the molten steel can be tapped off (Figure 23.5).

The properties of steel depend not only on its chemical composition but also on the heat treatment. At high temperatures, iron and carbon in steel combine to form iron carbide $\left(\mathrm{Fe}_{3} \mathrm{C}\right)$, called cementite:

$$
3 \mathrm{Fe}(s)+\mathrm{C}(s) \longrightarrow \mathrm{Fe}_{3} \mathrm{C}(s)
$$

The forward reaction is endothermic, so the formation of cementite is favored at high temperatures. When steel containing cementite is cooled slowly, the preceding equilibrium shifts to the left and the carbon separates as small particles of graphite, which give the steel a grey color. (Very slow decomposition of cementite also takes place at room temperature.) If the steel is cooled rapidly, equilibrium is not attained and the carbon remains largely in the form of cementite $\left(\mathrm{Fe}_{3} \mathrm{C}\right)$. Steel containing cementite is light in color, and it is harder and more brittle than that containing graphite.

Heating the steel to some appropriate temperature for a short time and then cooling it rapidly to give it the desired mechanical properties is known as "tempering." In this way, the ratio of carbon present as graphite and as cementite can be varied within rather wide limits. Table 23.3 lists the composition, properties, and uses of various types of steel.

## TABLE 23.3 Types of Steel

|  | Composition (Percent by Mass)* |  |  |  |  |  |  |  |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Type | $\mathbf{C}$ | $\mathbf{M n}$ | $\mathbf{P}$ | $\mathbf{S}$ | $\mathbf{S i}$ | $\mathbf{N i}$ | $\mathbf{C r}$ | Others | Uses |
| Plain | 1.35 | 1.65 | 0.04 | 0.05 | 0.06 | - | - | $\mathrm{Cu}(0.2-0.6)$ | Sheet products, tools |
| High-strength | 0.25 | 1.65 | 0.04 | 0.05 | $0.15-0.9$ | $0.4-1.0$ | $0.3-1.3$ | $\mathrm{Cu}(0.01-0.08)$ | Construction, steam <br> turbines |
| Stainless | $0.03-1.2$ | $1.0-10$ | $0.04-0.06$ | 0.03 | $1-3$ | $1-22$ | $4.0-27$ | - | Kitchen utensils, <br> razor blades |

*A single number indicates the maximum amount of the substance present.

## Purification of Metals

Metals prepared by reduction usually need further treatment to remove impurities. The extent of purification depends on how the metal will be used. Three common purification procedures are distillation, electrolysis, and zone refining.

## Distillation

Metals that have low boiling points, such as mercury, magnesium, and zinc, can be separated from other metals by fractional distillation. One well-known method of fractional distillation is the Mond ${ }^{1}$ process for the purification of nickel. Carbon monoxide gas is passed over the impure nickel metal at about $70^{\circ} \mathrm{C}$ to form the volatile tetracarbonylnickel (b.p. $43^{\circ} \mathrm{C}$ ), a highly toxic substance, which is separated from the less volatile impurities by distillation:

$$
\mathrm{Ni}(s)+4 \mathrm{CO}(g) \longrightarrow \mathrm{Ni}(\mathrm{CO})_{4}(g)
$$

Pure metallic nickel is recovered from $\mathrm{Ni}(\mathrm{CO})_{4}$ by heating the gas at $200^{\circ} \mathrm{C}$ :

$$
\mathrm{Ni}(\mathrm{CO})_{4}(g) \longrightarrow \mathrm{Ni}(s)+4 \mathrm{CO}(g)
$$

The carbon monoxide that is released is recycled back into the process.

## Electrolysis

Electrolysis is another important purification technique. The copper metal obtained by roasting copper sulfide usually contains impurities such as zinc, iron, silver, and gold. The more electropositive metals are removed by an electrolysis process in which the impure copper acts as the anode and pure copper acts as the cathode in a sulfuric acid solution containing $\mathrm{Cu}^{2+}$ ions (Figure 23.6). The reactions are

$$
\begin{array}{lrl}
\text { Anode (oxidation): } & \mathrm{Cu}(s) \longrightarrow \mathrm{Cu}^{2+}(a q)+2 e^{-} \\
\text {Cathode (reduction): } & \mathrm{Cu}^{2+}(a q)+2 e^{-} \longrightarrow \mathrm{Cu}(s)
\end{array}
$$

[^47]Figure 23.6 Electrolytic purification of copper.

Figure 23.7 Copper cathodes used in the electrorefining process.

Figure 23.8 Zone-refining technique for purifying metals. Top to bottom: An impure metal rod is moved slowly through a heating coil. As the metal rod moves forward, the impurities dissolve in the molten portion of the metal while pure metal crystallizes out in front of the molten zone.

Reactive metals in the copper anode, such as iron and zinc, are also oxidized at the anode and enter the solution as $\mathrm{Fe}^{2+}$ and $\mathrm{Zn}^{2+}$ ions. They are not reduced at the cathode, however. The less electropositive metals, such as gold and silver, are not oxidized at the anode. Eventually, as the copper anode dissolves, these metals fall to the bottom of the cell. Thus, the net result of this electrolysis process is the transfer of copper from the anode to the cathode. Copper prepared this way has a purity greater than 99.5 percent (Figure 23.7).

## Zone Refining

Another often-used method of obtaining extremely pure metals is zone refining. In this process, a metal rod containing a few impurities is drawn through an electric heating coil that melts the metal (Figure 23.8). Most impurities dissolve in the molten metal. As the metal rod emerges from the heating coil, it cools and the pure metal crystallizes, leaving the impurities in the molten metal portion that is still in the heating coil. (This is analogous to the freezing of seawater, in which the solid that separates is mostly pure solvent-water. In zone refining, the liquid metal acts as the solvent and the impurities act as the solutes.) When the molten zone carrying the impurities, now at increased concentration, reaches the end of the rod, it is allowed to cool and is then cut off. Repeating this procedure a number of times results in metal with a purity greater than 99.99 percent.

### 23.3 Band Theory of Conductivity

To gain a better understanding of the conductivity properties of metals, we must also apply our knowledge of quantum mechanics. The model we will use to study metallic bonding is band theory, so called because it states that delocalized electrons move freely through "bands" formed by overlapping molecular orbitals. We will also apply band theory to certain elements that are semiconductors.

## Conductors

Metals are characterized by high electrical conductivity. Consider magnesium, for example. The electron configuration of Mg is $[\mathrm{Ne}] 3 s^{2}$, so each atom has two valence electrons in the $3 s$ orbital. In a metallic crystal, the atoms are packed closely together, so the energy levels of each magnesium atom are affected by the immediate neighbors of the atom as a result of orbital overlaps. According to molecular orbital theory [ 144 Section 9.6], the interaction between two atomic orbitals leads to the formation of a bonding and an antibonding molecular orbital. Because the number of atoms in even a small piece of magnesium is enormously large (on the order of $10^{20}$ atoms), the number of molecular orbitals they form is also very large. These molecular orbitals are so closely spaced on the energy scale that they are more appropriately described as a "band" (Figure 23.9). The closely spaced filled energy levels make up the valence band. The upper half of the energy

Figure 23.10 Comparison of the energy gaps between the valence band and the conduction band in a metal, a semiconductor, and an insulator. In a metal the energy gap is virtually nonexistent; in a semiconductor the energy gap is small; and in an insulator the energy gap is very large, thus making the promotion of an electron from the valence band to the conduction band difficult.
levels corresponds to the empty, delocalized molecular orbitals formed by the overlap of the $3 p$ orbitals. This set of closely spaced empty levels is called the conduction band.

We can imagine a metallic crystal as an array of positive ions immersed in a sea of delocalized valence electrons. The great cohesive force resulting from the delocalization is partly responsible for the strength noted in most metals. Because the valence band and the conduction band are adjacent to each other, the amount of energy needed to promote a valence electron to the conduction band is negligible. There the electron can travel freely through the metal, because the conduction band is void of electrons. This freedom of movement explains why metals are good conductors-that is, they are capable of conducting an electric current.

Why don't substances like wood and glass conduct electricity as metals do? Figure 23.10 provides an answer to this question. Basically, the electrical conductivity of a solid depends on the spacing of the energy bands and the extent to which they are occupied. In magnesium and other metals, the valence bands are adjacent to the conduction bands, so these metals readily act as conductors. In wood and glass, on the other hand, the gap between the valence band and the conduction band is considerably greater than it is in a metal. Consequently, much more energy is needed to excite an electron into the conduction band. Lacking this energy, electrons cannot move freely. Therefore, glass and wood are insulators, ineffective conductors of electricity.

## Semiconductors

Semiconductors are elements that normally are not conductors, but will conduct electricity at elevated temperatures or when combined with a small amount of certain other elements. The Group 4A elements silicon and germanium are especially suited for this purpose. The use of semiconductors in transistors and solar cells, to name two applications, has revolutionized the electronic industry in recent decades, leading to the increased miniaturization of electronic equipment.

The energy gap between the filled and empty bands of these solids is much smaller than it is for insulators (see Figure 23.10). If the energy needed to excite electrons from the valence band into the conduction band is provided, the solid becomes a conductor. This behavior is opposite that of the metals. A metal's ability to conduct electricity decreases with increasing temperature, because the enhanced vibration of atoms at higher temperatures tends to disrupt the flow of electrons.

The ability of a semiconductor to conduct electricity can also be enhanced by adding small amounts of certain impurities to the element, a process called doping. Consider what happens, for

Figure 23.9 Formation of conduction bands in magnesium. The electrons in the $1 s, 2 s$, and $2 p$ orbitals are localized on each Mg atom. However, the $3 s$ and $3 p$ orbitals overlap to form delocalized molecular orbitals. Electrons in these orbitals can travel throughout the metal, and this accounts for the electrical conductivity of the metal.

Figure 23.11 (a) Silicon crystal doped with phosphorus. (b) Silicon crystal doped with boron. Note the formation of a negative center in (a) and a positive center in (b).

(a)

(b)
example, when a trace amount of boron or phosphorus is added to solid silicon. (Only about five out of every million Si atoms are replaced by B or P atoms.) The structure of solid silicon is similar to that of diamond; that is, each Si atom is covalently bonded to four other Si atoms. Phosphorus $\left([\mathrm{Ne}] 3 s^{2} 3 p^{3}\right)$ has one more valence electron than silicon $\left([\mathrm{Ne}] 3 s^{2} 3 p^{2}\right)$, so there is a valence electron left over after four of them are used to form covalent bonds with silicon (Figure 23.11).

This extra electron can be removed from the phosphorus atom by applying a voltage across the solid. The free electron can move through the structure and function as a conduction electron. Impurities of this type are known as donor impurities, because they provide conduction electrons. Solids containing donor impurities are called n-type semiconductors, where $n$ stands for negative (the charge of the "extra" electron).

The opposite effect occurs if boron is added to silicon. A boron atom has three valence electrons ( $1 s^{2} 2 s^{2} 2 p^{1}$ ), one less than silicon. Thus, for every boron atom in the silicon crystal, there is a single vacancy in a bonding orbital. It is possible, though, to excite a valence electron from a nearby Si into this vacant orbital. A vacancy created at that Si atom can then be filled by an electron from a neighboring Si atom, and so on. In this manner, electrons can move through the crystal in one direction while the vacancies, or "positive holes," move in the opposite direction, and the solid becomes an electrical conductor. Impurities that are electron deficient are called acceptor impurities. Semiconductors that contain acceptor impurities are called p-type semiconductors, where $p$ stands for positive.

In both the $p$-type and $n$-type semiconductors, the energy gap between the valence band and the conduction band is effectively reduced, so only a small amount of energy is needed to excite the electrons. Typically, the conductivity of a semiconductor is increased by a factor of 100,000 or so by the presence of impurity atoms.

The growth of the semiconductor industry since the early 1960s has been truly remarkable. Today semiconductors are essential components of nearly all electronic equipment, ranging from radios and television sets to pocket calculators and computers. One of the main advantages of solid-state devices over vacuum-tube electronics is that the former can be made on a single "chip" of silicon no larger than the cross section of a pencil eraser. Consequently, much more equipment can be packed into a small volume-a point of particular importance in space travel, as well as in handheld calculators and microprocessors (computers-on-a-chip).

### 23.4 Periodic Trends in Metallic Properties

Metals are lustrous in appearance, solid at room temperature (with the exception of mercury), good conductors of heat and electricity, malleable (can be hammered flat), and ductile (can be drawn into wires). Figure 23.12 shows the positions of the representative metals and the Group

2B metals in the periodic table. (The transition metals are discussed in Chapter 22.) As we saw in Chapter 8, the electronegativity of elements increases from left to right across a period and from bottom to top in a group [ 14 Section 8.4, Figure 8.6]. The metallic character of metals increases in just the opposite directions-that is, from right to left across a period and from top to bottom in a group. Because metals generally have low electronegativities, they tend to form cations and almost always have positive oxidation numbers in their compounds. However, beryllium and magnesium in Group 2A and the metals in Group 3A and beyond also form covalent compounds.

In Sections 23.5 through 23.7 we will study the chemistry of selected metals from Group 1A (the alkali metals), Group 2A (the alkaline earth metals), and Group 3A (aluminum).

### 23.5 The Alkali Metals

As a group, the alkali metals (the Group 1A elements) are the most electropositive (or the least electronegative) elements known. They exhibit many similar properties, some of which are listed in Table 23.4. Based on their electron configurations, we expect the oxidation number of these elements in their compounds to be +1 because the cations would be isoelectronic with the preceding noble gases. This is indeed the case.

The alkali metals have low melting points and are soft enough to be sliced with a knife. These metals all possess a body-centered crystal structure with low packing efficiency. This accounts for their low densities among metals. In fact, lithium is the lightest metal known. Because of their great chemical reactivity, the alkali metals never occur naturally in elemental form; instead, they are found combined with halide, sulfate, carbonate, and silicate ions. In this section we will describe the chemistry of two members of Group 1A-sodium and potassium. The chemistry of lithium, rubidium, and cesium is less important; all isotopes of francium, the last member of the group, are radioactive.

Sodium and potassium are about equally abundant in nature. They occur in silicate minerals such as albite $\left(\mathrm{NaAlSi}_{3} \mathrm{O}_{8}\right)$ and orthoclase $\left(\mathrm{KAlSi}_{3} \mathrm{O}_{8}\right)$. Over long periods of time (on a geologic scale), silicate minerals are slowly decomposed by wind and rain, and their sodium and potassium ions are converted to more soluble compounds. Eventually rain leaches these compounds out of the soil and carries them to the sea. Yet when we look at the composition of seawater, we find that the concentration ratio of sodium to potassium is about 28 to 1 . The reason for this uneven distribution is that potassium is essential to plant growth, while sodium is not. Thus, plants take up many of the potassium ions along the way, while sodium ions are free to move on to the sea. Other minerals that contain sodium or potassium are halite ( NaCl ), shown in Figure 23.13, Chile saltpeter $\left(\mathrm{NaNO}_{3}\right)$, and sylvite $(\mathrm{KCl})$. Sodium chloride is also obtained from rock salt.

Metallic sodium is most conveniently obtained from molten sodium chloride by electrolysis in the Downs cell (review Figure 19.10). The melting point of sodium chloride is rather high $\left(801^{\circ} \mathrm{C}\right)$, and much energy is needed to keep large amounts of the substance molten. Adding a suitable substance, such as $\mathrm{CaCl}_{2}$, lowers the melting point to about $600^{\circ} \mathrm{C}$-a more convenient temperature for the electrolysis process.

## Multimedia

Periodic Table-properties of the alkali and alkaline earth metals.

Figure 23.14 Self-contained breathing apparatus.

Metallic potassium cannot be easily prepared by the electrolysis of molten KCl because it is too soluble in the molten KCl to float to the top of the cell for collection. Moreover, it vaporizes readily at the operating temperatures, creating hazardous conditions. Instead, it is usually obtained by the distillation of molten KCl in the presence of sodium vapor at $892^{\circ} \mathrm{C}$. The reaction that takes place at this temperature is

$$
\mathrm{Na}(g)+\mathrm{KCl}(l) \longrightarrow \mathrm{NaCl}(l)+\mathrm{K}(g)
$$

This reaction may seem strange given that potassium is a stronger reducing agent than sodium (see Table 23.4). Potassium has a lower boiling point $\left(770^{\circ} \mathrm{C}\right)$ than sodium $\left(892^{\circ} \mathrm{C}\right)$, however, so it is more volatile at $892^{\circ} \mathrm{C}$ and distills off more easily. According to Le Châtelier's principle, constantly removing the potassium vapor drives the reaction to the right, ensuring metallic potassium is recovered.

Sodium and potassium are both extremely reactive, but potassium is the more reactive of the two. Both react with water to form the corresponding hydroxides. In a limited supply of oxygen, sodium burns to form sodium oxide $\left(\mathrm{Na}_{2} \mathrm{O}\right)$. In the presence of excess oxygen, however, sodium forms the pale-yellow peroxide:

$$
2 \mathrm{Na}(s)+\mathrm{O}_{2}(g) \longrightarrow \mathrm{Na}_{2} \mathrm{O}_{2}(s)
$$

Sodium peroxide reacts with water to give an alkaline solution and hydrogen peroxide:

$$
\mathrm{Na}_{2} \mathrm{O}_{2}(s)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{NaOH}(a q)+\mathrm{H}_{2} \mathrm{O}_{2}(a q)
$$

Like sodium, potassium forms the peroxide. In addition, potassium also forms the superoxide when it burns in air:

$$
\mathrm{K}(s)+\mathrm{O}_{2}(g) \longrightarrow \mathrm{KO}_{2}(s)
$$

When potassium superoxide reacts with water, oxygen gas is evolved:

$$
2 \mathrm{KO}_{2}(s)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{KOH}(a q)+\mathrm{O}_{2}(g)+\mathrm{H}_{2} \mathrm{O}_{2}(a q)
$$

This reaction is utilized in breathing equipment (Figure 23.14). Exhaled air contains both moisture and carbon dioxide. The moisture reacts with $\mathrm{KO}_{2}$ in the apparatus to generate oxygen gas as shown in the preceding reaction. Furthermore, $\mathrm{KO}_{2}$ also reacts with exhaled $\mathrm{CO}_{2}$, which produces more oxygen gas:

$$
4 \mathrm{KO}_{2}(s)+2 \mathrm{CO}_{2}(g) \longrightarrow 2 \mathrm{~K}_{2} \mathrm{CO}_{3}(s)+3 \mathrm{O}_{2}(g)
$$

Thus, a person using the apparatus can continue to breathe oxygen without being exposed to toxic fumes outside.

Sodium and potassium metals dissolve in liquid ammonia to produce beautiful blue solutions:

$$
\begin{aligned}
\mathrm{Na} \xrightarrow{\mathrm{NH}_{3}} \mathrm{Na}^{+}+e^{-} \\
\mathrm{K} \xrightarrow{\mathrm{NH}_{3}} \mathrm{~K}^{+}+e^{-}
\end{aligned}
$$

Both the cation and the electron exist in the solvated form, and the solvated electrons are responsible for the characteristic blue color of such solutions. Metal-ammonia solutions are powerful reducing agents (because they contain free electrons); they are useful in synthesizing both organic and inorganic compounds. It was discovered that the hitherto unknown alkali metal anions, $\mathrm{M}^{-}$, are also formed in such solutions. This means that an ammonia solution of an alkali metal contains ion pairs such as $\mathrm{Na}^{+} \mathrm{Na}^{-}$and $\mathrm{K}^{+} \mathrm{K}^{-}$! (In each case, the metal cation exists as a complex ion with crown ether, an organic compound with a high affinity for cations.) In fact, these "salts" are so stable that they can be isolated in crystalline form. This finding is of considerable theoretical interest, because it shows clearly that the alkali metals can have an oxidation number of -1 , although -1 is not found in ordinary compounds.

Sodium and potassium are essential elements of living matter. Sodium ions and potassium ions are present in intracellular and extracellular fluids, and they are essential for osmotic balance and enzyme functions. We now describe the preparations and uses of several of the important compounds of sodium and potassium.

## Sodium Chloride

The source, properties, and uses of sodium chloride were discussed in Chapter 7.

## Sodium Carbonate

Sodium carbonate (called soda ash) is used in all kinds of industrial processes, including water treatment and the manufacture of soaps, detergents, medicines, and food additives. Today about half of all $\mathrm{Na}_{2} \mathrm{CO}_{3}$ produced is used in the glass industry. Sodium carbonate ranks eleventh among the chemicals produced in the United States. For many years, $\mathrm{Na}_{2} \mathrm{CO}_{3}$ was produced by the Solvay ${ }^{2}$ process, in which ammonia is first dissolved in a saturated solution of sodium chloride. Bubbling carbon dioxide into the solution precipitates sodium bicarbonate as follows:

$$
\mathrm{NH}_{3}(a q)+\mathrm{NaCl}(a q)+\mathrm{H}_{2} \mathrm{CO}_{3}(a q) \longrightarrow \mathrm{NaHCO}_{3}(s)+\mathrm{NH}_{4} \mathrm{Cl}(a q)
$$

Sodium bicarbonate is then separated from the solution and heated to give sodium carbonate:

$$
2 \mathrm{NaHCO}_{3}(s) \longrightarrow \mathrm{Na}_{2} \mathrm{CO}_{3}(s)+\mathrm{CO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(g)
$$

However, the rising cost of ammonia and the pollution problem resulting from the by-products have prompted chemists to look for other sources of sodium carbonate. One is the mineral trona $\left[\mathrm{Na}_{5}\left(\mathrm{CO}_{3}\right)_{2}\left(\mathrm{HCO}_{3}\right) \cdot 2 \mathrm{H}_{2} \mathrm{O}\right]$, large deposits of which have been found in Wyoming. When trona is crushed and heated, it decomposes as follows:

$$
2 \mathrm{Na}_{5}\left(\mathrm{CO}_{3}\right)_{2}\left(\mathrm{HCO}_{3}\right)+2 \mathrm{H}_{2} \mathrm{O}(s) \longrightarrow 5 \mathrm{Na}_{2} \mathrm{CO}_{3}(s)+\mathrm{CO}_{2}(g)+3 \mathrm{H}_{2} \mathrm{O}(g)
$$

The sodium carbonate obtained this way is dissolved in water, the solution is filtered to remove the insoluble impurities, and the sodium carbonate is crystallized as $\mathrm{Na}_{2} \mathrm{CO}_{3} \cdot 10 \mathrm{H}_{2} \mathrm{O}$. Finally, the hydrate is heated to give pure, anhydrous sodium carbonate.

## Sodium Hydroxide and Potassium Hydroxide

The properties of sodium hydroxide and potassium hydroxide are very similar. These hydroxides are prepared by the electrolysis of aqueous NaCl and KCl solutions; both hydroxides are strong bases and very soluble in water. Sodium hydroxide is used in the manufacture of soap and many organic and inorganic compounds. Potassium hydroxide is used as an electrolyte in some storage batteries, and aqueous potassium hydroxide is used to remove carbon dioxide and sulfur dioxide from air.

## Sodium Nitrate and Potassium Nitrate

Large deposits of sodium nitrate (Chile saltpeter) are found in Chile. It decomposes with the evolution of oxygen at about $500^{\circ} \mathrm{C}$ :

$$
2 \mathrm{NaNO}_{3}(s) \longrightarrow 2 \mathrm{NaNO}_{2}(s)+\mathrm{O}_{2}(g)
$$

Potassium nitrate (saltpeter) is prepared beginning with the "reaction"

$$
\mathrm{KCl}(a q)+\mathrm{NaNO}_{3}(a q) \longrightarrow \mathrm{KNO}_{3}(a q)+\mathrm{NaCl}(a q)
$$

This process is carried out just below $100^{\circ} \mathrm{C}$. Because $\mathrm{KNO}_{3}$ is the least soluble salt at room temperature, it is separated from the solution by fractional crystallization. Like $\mathrm{NaNO}_{3}, \mathrm{KNO}_{3}$ decomposes when heated.

Gunpowder consists of potassium nitrate, wood charcoal, and sulfur in the approximate proportions of 6:1:1 by mass. When gunpowder is heated, the reaction is

$$
2 \mathrm{KNO}_{3}(s)+\mathrm{S}(l)+3 \mathrm{C}(s) \longrightarrow \mathrm{K}_{2} \mathrm{~S}(s)+\mathrm{N}_{2}(g)+3 \mathrm{CO}_{2}(g)
$$

The sudden formation of hot nitrogen and carbon dioxide gases causes an explosion.

### 23.6 The Alkaline Earth Metals

The alkaline earth metals are somewhat less electropositive and less reactive than the alkali metals. Except for the first member of the family, beryllium, which resembles aluminum (a Group 3A metal) in some respects, the alkaline earth metals have similar chemical properties. Because their $\mathrm{M}^{2+}$ ions attain the stable electron configuration of the preceding noble gas, the oxidation number

[^49]

$\dagger$ The half-reaction is $\mathrm{M}^{2+}(a q)+2 e^{-} \longrightarrow \mathrm{M}(s)$.
of alkaline earth metals in the combined form is almost always +2 . Table 23.5 lists some common properties of these metals. Radium is not included in the table because all radium isotopes are radioactive and it is difficult and expensive to study the chemistry of this Group 2A element.

## Magnesium

Magnesium is the sixth most plentiful element in Earth's crust (about 2.5 percent by mass). Among the principal magnesium ores are brucite $\left[\mathrm{Mg}(\mathrm{OH})_{2}\right]$, dolomite $\left(\mathrm{CaCO}_{3} \cdot \mathrm{MgCO}_{3}\right)$ (Figure 23.15), and epsomite $\left(\mathrm{MgSO}_{4} \cdot 7 \mathrm{H}_{2} \mathrm{O}\right)$. Seawater is a good source of magnesium - there are about 1.3 g of magnesium in each kilogram of seawater. As is the case with most alkali and alkaline earth metals, metallic magnesium is obtained by electrolysis, in this case from its molten chloride, $\mathrm{MgCl}_{2}$ (obtained from seawater).

The chemistry of magnesium is intermediate between that of beryllium and the heavier Group 2A elements. Magnesium does not react with cold water but does react slowly with steam:

$$
\mathrm{Mg}(s)+\mathrm{H}_{2} \mathrm{O}(g) \longrightarrow \mathrm{MgO}(s)+\mathrm{H}_{2}(g)
$$

It burns brilliantly in air to produce magnesium oxide and magnesium nitride:

$$
\begin{aligned}
& 2 \mathrm{Mg}(s)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{MgO}(s) \\
& 3 \mathrm{Mg}(s)+\mathrm{N}_{2}(g) \longrightarrow \mathrm{Mg}_{3} \mathrm{~N}_{2}(s)
\end{aligned}
$$

This property makes magnesium (in the form of thin ribbons or fibers) useful in flash photography and flares.

Magnesium oxide reacts very slowly with water to form magnesium hydroxide, a white solid suspension called milk of magnesia, which is used to treat acid indigestion:

$$
\mathrm{MgO}(s)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{Mg}(\mathrm{OH})_{2}(s)
$$

Magnesium is a typical alkaline earth metal in that its hydroxide is a strong base. [The only alkaline earth hydroxide that is not a strong base is $\mathrm{Be}(\mathrm{OH})_{2}$, which is amphoteric.]

The major uses of magnesium are in lightweight structural alloys, for cathodic protection; in organic synthesis; and in batteries. Magnesium is essential to plant and animal life, and $\mathrm{Mg}^{2+}$ ions are not toxic. It is estimated that the average adult ingests about 0.3 g of magnesium ions daily. Magnesium plays several important biological roles. It is present, for instance, in intracellular and extracellular fluids, and magnesium ions are essential for the proper functioning of a number of enzymes. Magnesium is also present in the green plant pigment chlorophyll, which plays an important part in photosynthesis.

## Calcium

Earth's crust contains about 3.4 percent calcium by mass. Calcium occurs in limestone, calcite, chalk, and marble as $\mathrm{CaCO}_{3}$; in dolomite as $\mathrm{CaCO}_{3} \cdot \mathrm{MgCO}_{3}$ (see Figure 23.15); in gypsum as
$\mathrm{CaSO}_{4} \cdot 2 \mathrm{H}_{2} \mathrm{O}$; and in fluorite as $\mathrm{CaF}_{2}$ (Figure 23.16). Metallic calcium is best prepared by the electrolysis of molten calcium chloride $\left(\mathrm{CaCl}_{2}\right)$.

As we read down Group 2A from beryllium to barium, metallic properties increase. Unlike beryllium and magnesium, calcium (like strontium and barium) reacts with cold water to yield the corresponding hydroxide, although the rate of reaction is much slower than those involving the alkali metals:

$$
\mathrm{Ca}(s)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{Ca}(\mathrm{OH})_{2}(a q)+\mathrm{H}_{2}(g)
$$

Calcium hydroxide $\left[\mathrm{Ca}(\mathrm{OH})_{2}\right]$ is commonly known as slaked lime or hydrated lime. Lime $(\mathrm{CaO})$, which is also referred to as quicklime, is one of the oldest materials known to humankind. Quicklime is produced by the thermal decomposition of calcium carbonate:

$$
\mathrm{CaCO}_{3}(s) \longrightarrow \mathrm{CaO}(s)+\mathrm{CO}_{2}(g)
$$

whereas slaked lime is produced by the reaction between quicklime and water:

$$
\mathrm{CaO}(s)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{Ca}(\mathrm{OH})_{2}(a q)
$$

Quicklime is used in metallurgy (see Section 23.2) and in the removal of $\mathrm{SO}_{2}$ when fossil fuel is burned. Slaked lime is used in water treatment. For many years, farmers have used lime to lower the acidity of the soil for their crops (a process called liming). Nowadays lime is also applied to lakes affected by acid rain.

Metallic calcium has rather limited uses. It serves mainly as an alloying agent for metals like aluminum and copper and in the preparation of beryllium metal from its compounds. It is also used as a dehydrating agent for organic solvents.

Calcium is an essential element in living matter. It is the major component of bones and teeth; the calcium ion is present in a complex phosphate salt called hydroxyapatite $\left[\mathrm{Ca}_{5}\left(\mathrm{PO}_{4}\right)_{3} \mathrm{OH}\right]$. A characteristic function of $\mathrm{Ca}^{2+}$ ions in living systems is the activation of a variety of metabolic processes, including a vital role in heart action, blood clotting, muscle contraction, and nerve impulse transmission.

### 23.7 Aluminum

Aluminum is the most abundant metal and the third most plentiful element in Earth's crust ( 7.5 percent by mass). The elemental form does not occur in nature; instead, its principal ore is bauxite $\left(\mathrm{Al}_{2} \mathrm{O}_{3} \cdot 2 \mathrm{H}_{2} \mathrm{O}\right)$. Other minerals containing aluminum are orthoclase ( $\mathrm{KAlSi}_{3} \mathrm{O}_{8}$ ), beryl $\left(\mathrm{Be}_{3} \mathrm{Al}_{2} \mathrm{Si}_{6} \mathrm{O}_{18}\right)$, cryolite $\left(\mathrm{Na}_{3} \mathrm{AlF}_{6}\right)$, and corundum $\left(\mathrm{Al}_{2} \mathrm{O}_{3}\right)$ (Figure 23.17).

Aluminum is usually prepared from bauxite, which is frequently contaminated with silica $\left(\mathrm{SiO}_{2}\right)$, iron oxides, and titanium(IV) oxide. The ore is first heated in sodium hydroxide solution to convert the silica into soluble silicates:

$$
\mathrm{SiO}_{2}(s)+2 \mathrm{OH}^{-}(a q) \longrightarrow \mathrm{SiO}_{3}^{2-}(a q)+\mathrm{H}_{2} \mathrm{O}(l)
$$

At the same time, aluminum oxide is converted to the aluminate ion $\left(\mathrm{AlO}_{2}^{-}\right)$:

$$
\mathrm{Al}_{2} \mathrm{O}_{3}(s)+2 \mathrm{OH}^{-}(a q) \longrightarrow 2 \mathrm{AlO}_{2}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l)
$$

Iron oxide and titanium oxide are unaffected by this treatment and are filtered off. Next, the solution is treated with acid to precipitate the insoluble aluminum hydroxide:

$$
\mathrm{AlO}_{2}^{-}(a q)+\mathrm{H}_{3} \mathrm{O}^{+}(a q) \longrightarrow \mathrm{Al}(\mathrm{OH})_{3}(s)
$$

After filtration, the aluminum hydroxide is heated to obtain aluminum oxide:

$$
2 \mathrm{Al}(\mathrm{OH})_{3}(s) \longrightarrow \mathrm{Al}_{2} \mathrm{O}_{3}(\mathrm{~s})+3 \mathrm{H}_{2} \mathrm{O}(\mathrm{~g})
$$

Anhydrous aluminum oxide, or corundum, is reduced to aluminum by the Hall ${ }^{3}$ process. Figure 23.18 shows a Hall electrolytic cell, which contains a series of carbon anodes. The cathode is also made of carbon and constitutes the lining inside the cell. The key to the Hall process is the use of

[^50]

Figure 23.16 Fluorite $\left(\mathrm{CaF}_{2}\right)$.

Figure 23.17 Corundum $\left(\mathrm{Al}_{2} \mathrm{O}_{3}\right)$.

Figure 23.18 Electrolytic production of aluminum based on the Hall process.

cryolite $\left(\mathrm{Na}_{3} \mathrm{AlF}_{6}\right.$; m.p. $1000^{\circ} \mathrm{C}$ ) as the solvent for aluminum oxide (m.p. $2045^{\circ} \mathrm{C}$ ). The mixture is electrolyzed to produce aluminum and oxygen gas:

$$
\begin{array}{lrl}
\text { Anode (oxidation): } & 3\left[2 \mathrm{O}^{2-}\right. & \left.\longrightarrow \mathrm{O}_{2}(g)+4 e^{-}\right] \\
\text {Cathode (reduction): } & 4\left[\mathrm{Al}^{3+}+3 e^{-} \longrightarrow \mathrm{Al}(l)\right] \\
\text { Overall: } & 2 \mathrm{Al}_{2} \mathrm{O}_{3} \longrightarrow 4 \mathrm{Al}(l)+3 \mathrm{O}_{2}(g)
\end{array}
$$

Oxygen gas reacts with the carbon anodes (at elevated temperatures) to form carbon monoxide, which escapes as a gas. The liquid aluminum metal (m.p. $660.2^{\circ} \mathrm{C}$ ) sinks to the bottom of the vessel, from which it can be drained from time to time during the procedure.

Aluminum is one of the most versatile metals known. It has a low density $\left(2.7 \mathrm{~g} / \mathrm{cm}^{3}\right)$ and high tensile strength (i.e., it can be stretched or drawn out). Aluminum is malleable, it can be rolled into thin foils, and it is an excellent electrical conductor. Its conductivity is about 65 percent that of copper. However, because aluminum is cheaper and lighter than copper, it is widely used in highvoltage transmission lines. Although aluminum's chief use is in aircraft construction, the pure metal itself is too soft and weak to withstand much strain. Its mechanical properties are greatly improved by alloying it with small amounts of metals such as copper, magnesium, and manganese, as well as silicon. Aluminum is not used by living systems and is generally considered to be nontoxic.

As we read across the periodic table from left to right in a given period, metallic properties gradually decrease. Thus, although aluminum is considered an active metal, it does not react with water as do sodium and calcium. Aluminum reacts with hydrochloric acid and with strong bases as follows:

$$
\begin{aligned}
2 \mathrm{Al}(s)+6 \mathrm{HCl}(a q) & \longrightarrow 2 \mathrm{AlCl}_{3}(a q)+3 \mathrm{H}_{2}(g) \\
2 \mathrm{Al}(s)+2 \mathrm{NaOH}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l) & \longrightarrow 2 \mathrm{NaAlO}_{2}(a q)+3 \mathrm{H}_{2}(g)
\end{aligned}
$$

Aluminum readily forms the oxide $\mathrm{Al}_{2} \mathrm{O}_{3}$ when exposed to air:

$$
4 \mathrm{Al}(s)+3 \mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{Al}_{2} \mathrm{O}_{3}(s)
$$

A tenacious film of this oxide protects metallic aluminum from further corrosion and accounts for some of the unexpected inertness of aluminum. Aluminum oxide has a very large exothermic enthalpy of formation ( $\Delta H_{\mathrm{f}}^{\circ}=-1670 \mathrm{~kJ} / \mathrm{mol}$ ). This property makes aluminum suitable for use in solid propellants for rockets such as those used for some space shuttles. When a mixture of aluminum and ammonium perchlorate $\left(\mathrm{NH}_{4} \mathrm{ClO}_{4}\right)$ is ignited, aluminum is oxidized to $\mathrm{Al}_{2} \mathrm{O}_{3}$, and the heat liberated in the reaction causes the gases that are formed to expand with great force. This action lifts the rocket.

The great affinity of aluminum for oxygen is illustrated nicely by the reaction of aluminum powder with a variety of metal oxides, particularly the transition metal oxides, to produce the corresponding metals. A typical reaction is

$$
2 \mathrm{Al}(s)+\mathrm{Fe}_{2} \mathrm{O}_{3}(s) \longrightarrow \mathrm{Al}_{2} \mathrm{O}_{3}(l)+2 \mathrm{Fe}(l) \quad \Delta H^{\circ}=-852 \mathrm{~kJ} / \mathrm{mol}
$$

which can result in temperatures approaching $3000^{\circ} \mathrm{C}$. This transformation, which is used in the welding of steel and iron, is called the thermite reaction (Figure 23.19).

Aluminum chloride exists as a dimer:

Each of the bridging chlorine atoms forms a normal covalent bond and a coordinate covalent bond (each indicated by an arrow) with two aluminum atoms. Each aluminum atom is assumed to be $s p^{3}$-hybridized, so the vacant $s p^{3}$ hybrid orbital can accept a lone pair from the chlorine atom (Figure 23.20). Aluminum chloride undergoes hydrolysis as follows:

$$
\mathrm{AlCl}_{3}(s)+3 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{Al}(\mathrm{OH})_{3}(s)+3 \mathrm{HCl}(a q)
$$

Aluminum hydroxide, like $\mathrm{Be}(\mathrm{OH})_{2}$, is amphoteric:

$$
\begin{aligned}
& \mathrm{Al}(\mathrm{OH})_{3}(s)+3 \mathrm{H}^{+}(a q) \longrightarrow \mathrm{Al}^{3+}(a q)+3 \mathrm{H}_{2} \mathrm{O}(l) \\
& \mathrm{Al}(\mathrm{OH})_{3}(s)+\mathrm{OH}^{-}(a q) \longrightarrow \mathrm{Al}(\mathrm{OH})_{4}^{-}(a q)
\end{aligned}
$$

In contrast to the boron hydrides, which are a well-defined series of compounds, aluminum hydride is a polymer in which each aluminum atom is surrounded octahedrally by bridging hydrogen atoms (Figure 23.21).

When an aqueous mixture of aluminum sulfate and potassium sulfate is evaporated slowly, crystals of $\mathrm{KAl}\left(\mathrm{SO}_{4}\right)_{2} \cdot 12 \mathrm{H}_{2} \mathrm{O}$ are formed. Similar crystals can be formed by substituting $\mathrm{Na}^{+}$or $\mathrm{NH}_{4}^{+}$for $\mathrm{K}^{+}$, and $\mathrm{Cr}^{3+}$ or $\mathrm{Fe}^{3+}$ for $\mathrm{Al}^{3+}$. These compounds are called alums, and they have the general formula

$$
\begin{array}{ll}
\mathrm{M}^{+} \mathrm{M}^{3+}\left(\mathrm{SO}_{4}\right)_{2} \cdot 12 \mathrm{H}_{2} \mathrm{O} & \mathrm{M}^{+}: \mathrm{K}^{+}, \mathrm{Na}^{+}, \mathrm{NH}_{4}^{+} \\
& \mathrm{M}^{3+}: \mathrm{Al}^{3+}, \mathrm{Cr}^{3+}, \mathrm{Fe}^{3+}
\end{array}
$$

Alums are examples of double salts-that is, salts that contain two different cations.

Figure 23.19 The temperature of a thermite reaction can reach $3000^{\circ} \mathrm{C}$.

Figure 23.20 The $s p^{3}$
hybridization of an Al atom in $\mathrm{Al}_{2} \mathrm{Cl}_{6}$. Each Al atom has one vacant $s p^{3}$ hybrid orbital that can accept a lone pair from the bridging Cl atom.

Figure 23.21 Structure of aluminum hydride. Note that this compound is a polymer. Each Al atom is surrounded in an octahedral arrangement by six bridging H atoms.

## Applying What You've Learned

Most health problems related to copper are the result of errors in copper metabolism. However, although it is rare, copper deficiency can result from a diet that is poor in copper. Symptoms of dietary copper deficiency include anemia (a deficiency of red blood cells) and neutropenia (a deficiency of a particular type of white blood cell).

The fact that copper is essential to human health was first demonstrated with a group of children in Peru. One patient's ordeal was detailed by Cordano and Graham in the journal Pediatrics in 1966. During her first few years of life, the patient was hospitalized several times with anemia, neutropenia, osteoporosis, and multiple fractures. At age 6 , over a period of 3 months, she received 20 blood transfusions for her severe anemia, which had not responded to treatment. When Dr. Cordano became aware of the patient's history, he initiated treatment with copper supplementation. The patient never required another transfusion and after 6 months on copper supplements, at age 7, she walked for the first time in her life.

## Writing Prompt:

Research the subject on the Web, and write a 500 -word essay on the causes, diagnosis, and treatment of dietary copper deficiency. Include a specific case study.

## Chapter Summary

## Section 23.1

- Depending on their reactivities, metals exist in nature in either the free or combined state. (More reactive metals are found combined with other elements.) Most metals are found in minerals. Minerals with high metal content are called ores.

## Section 23.2

- Metallurgy involves recovering metal from ores. The three stages of metal recovery are preparation, separation, and purification. An alloy is a solid mixture of one or more metals, sometimes also containing one or more nonmetals. An amalgam is a mixture of mercury and one or more other metals.
- The methods commonly used for purifying metals are distillation, electrolysis, and zone refining. Pyrometallurgy refers to metallurgical processes carried out at high temperatures.

## Section 23.3

- Metallic bonds can be thought of as the force between positive ions immersed in a sea of electrons. In terms of band theory, the atomic orbitals merge to form energy bands.
- A substance is a conductor when electrons can be readily promoted to the conduction band, where they are free to move through the substance. In an insulator, the energy gap between the valence band and the conduction band is so large that electrons cannot be promoted into the conduction band.
- Semiconductors are substances that normally are not conductors but will conduct electricity at elevated temperatures or when combined with a small amount of certain other elements. Semiconductors in which an electron-rich impurity is added to enhance conduction are known as n-type semiconductors. Semiconductors in which an electron-poor impurity is added to enhance conduction are known as p-type semiconductors.

## Section 23.4

- Metals typically are good conductors and are malleable and ductile. Metallic character increases from top to bottom in a group and decreases from left to right across a period.

## Section 23.5

- The alkali metals are the most reactive of all the metallic elements. They have an oxidation state of +1 in their compounds. Under special conditions, some of them can form anions with an oxidation state of -1 .

## Section 23.6

- The alkaline earth metals are somewhat less reactive than the alkali metals. They almost always have an oxidation number of +2 in their compounds. The properties of the alkaline earth elements become increasingly metallic from top to bottom in their group.

## Section 23.7

- Aluminum ordinarily does not react with water due to a protective coating of aluminum oxide; its hydroxide is amphoteric. The Hall process is used to reduce aluminum oxide to aluminum.

## Questions and Problems

## Section 23.1: Occurrence of Metals

## Review Questions

23.1 Define the terms mineral and ore.
23.2 List three metals that are usually found in an uncombined state in nature and three metals that are always found in a combined state in nature.

## Problems

H23.3 Write chemical formulas for the following minerals: (a) calcite, (b) dolomite, (c) fluorite, (d) halite, (e) corundum, (f) magnetite,
(g) beryl, (h) galena, (i) epsomite, (j) anhydrite.
23.4 Name the following minerals: (a) $\mathrm{MgCO}_{3}$, (b) $\mathrm{Na}_{3} \mathrm{AlF}_{6}$, (c) $\mathrm{Al}_{2} \mathrm{O}_{3}$, (d) $\mathrm{Ag}_{2} \mathrm{~S}$, (e) HgS , (f) ZnS , (g) $\mathrm{SrSO}_{4}$, (h) $\mathrm{PbCO}_{3}$, (i) $\mathrm{MnO}_{2}$, (j) $\mathrm{TiO}_{2}$.

## Section 23.2: Metallurgical Processes

## Review Questions

23.5 Define the terms metallurgy, alloy, and amalgam.
23.6 Describe the main steps involved in the preparation of an ore.
23.7 What does roasting mean in metallurgy? Why is roasting a major source of air pollution and acid rain?
23.8 Describe with examples the chemical and electrolytic reduction processes used in the production of metals.
23.9 Describe the main steps used to purify metals.
23.10 Describe the extraction of iron in a blast furnace.
23.11 Briefly discuss the steelmaking process.
23.12 Briefly describe the zone refining process.

## Problems

E1 23.13 In the Mond process for the purification of nickel, CO is passed over metallic nickel to give $\mathrm{Ni}(\mathrm{CO})_{4}$ :

$$
\mathrm{Ni}(s)+4 \mathrm{CO}(g) \rightleftarrows \mathrm{Ni}(\mathrm{CO})_{4}(g)
$$

Given that the standard free energies of formation of $\mathrm{CO}(g)$ and $\mathrm{Ni}(\mathrm{CO})_{4}(g)$ are -137.3 and $-587.4 \mathrm{~kJ} / \mathrm{mol}$, respectively, calculate the equilibrium constant of the reaction at $80^{\circ} \mathrm{C}$. (Assume $\Delta G_{\mathrm{f}}^{\circ}$ to be independent of temperature.)
$\$ 23.14$ Copper is purified by electrolysis (see Figure 23.6). A $5.00-\mathrm{kg}$ anode is used in a cell where the current is 37.8 A . How long (in hours) must the current run to dissolve this anode and electroplate it onto the cathode?

H23.15 Consider the electrolytic procedure for purifying copper described in Figure 23.6. Suppose that a sample of copper contains the following impurities: $\mathrm{Fe}, \mathrm{Ag}, \mathrm{Zn}, \mathrm{Au}, \mathrm{Co}, \mathrm{Pt}$, and Pb . Which of the metals will be oxidized and dissolved in solution and which will be unaffected and simply form the sludge that accumulates at the bottom of the cell?
23.16 How would you obtain zinc from sphalerite $(\mathrm{ZnS})$ ?

GI23.17 A certain mine produces $2.0 \times 10^{8} \mathrm{~kg}$ of copper from chalcopyrite $\left(\mathrm{CuFeS}_{2}\right)$ each year. The ore contains only 0.80 percent Cu by mass. (a) If the density of the ore is $2.8 \mathrm{~g} / \mathrm{cm}^{3}$, calculate the volume (in $\mathrm{cm}^{3}$ ) of ore removed each year. (b) Calculate the mass (in kg ) of $\mathrm{SO}_{2}$ produced by roasting (assume chalcopyrite to be the only source of sulfur).

E 23.18 Starting with rutile $\left(\mathrm{TiO}_{2}\right)$, explain how you would obtain pure titanium metal. (Hint: First convert $\mathrm{TiO}_{2}$ to $\mathrm{TiCl}_{4}$. Next, reduce $\mathrm{TiCl}_{4}$ with Mg . Look up physical properties of $\mathrm{TiCl}_{4}, \mathrm{Mg}$, and $\mathrm{MgCl}_{2}$ in a chemistry handbook.)
23.19 Which of the following compounds would require electrolysis to yield the free metals: $\mathrm{Ag}_{2} \mathrm{~S}, \mathrm{CaCl}_{2}, \mathrm{NaCl}, \mathrm{Fe}_{2} \mathrm{O}_{3}, \mathrm{Al}_{2} \mathrm{O}_{3}, \mathrm{TiCl}_{4}$ ?
23.20 Although iron is only about two-thirds as abundant as aluminum in Earth's crust, mass for mass it costs only about one-quarter as much to produce. Why?

## Section 23.3: Band Theory of Conductivity

## Review Questions

23.21 Define the following terms: conductor, insulator, semiconducting elements, donor impurities, acceptor impurities, n-type semiconductors, p-type semiconductors.
23.22 Briefly discuss the nature of bonding in metals, insulators, and semiconducting elements.
23.23 Describe the general characteristics of $n$-type and $p$-type semiconductors.

## Problems

E 23.24 State whether silicon would form $n$-type or $p$-type semiconductors with the following elements: $\mathrm{Ga}, \mathrm{Sb}, \mathrm{Al}, \mathrm{As}$.

## Section 23.4: Periodic Trends in Metallic Properties

## Review Questions

23.25 Discuss the general properties of metals.
23.26 Use periodic trends in ionization energy and electronegativity to show how the metallic character changes within a group.
23.27 Use periodic trends in ionization energy and electronegativity to show how the metallic character changes across a period.

## Section 23.5: The Alkali Metals

## Review Questions

23.28 How is sodium prepared commercially?
23.29 Why is potassium usually not prepared electrolytically from one of its salts?
23.30 Describe the uses of the following compounds: $\mathrm{NaCl}, \mathrm{Na}_{2} \mathrm{CO}_{3}$, $\mathrm{NaOH}, \mathrm{KOH}, \mathrm{KO}_{2}$.
23.31 Under what conditions do sodium and potassium form $\mathrm{Na}^{-}$and $\mathrm{K}^{-}$ions?

## Problems

EI23.32 Complete and balance the following equations:
(a) $\mathrm{K}(s)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow$
(b) $\mathrm{NaH}(s)+\mathrm{H}_{2} \mathrm{O}(l)$
(c) $\mathrm{Na}(s)+\mathrm{O}_{2}(g) \longrightarrow$
(d) $\mathrm{K}(s)+\mathrm{O}_{2}(g) \longrightarrow$

G23.33 Write a balanced equation for each of the following reactions: (a) sodium reacts with water, (b) an aqueous solution of NaOH reacts with $\mathrm{CO}_{2}$, (c) solid $\mathrm{Na}_{2} \mathrm{CO}_{3}$ reacts with an HCl solution, (d) solid $\mathrm{NaHCO}_{3}$ reacts with an HCl solution, (e) solid $\mathrm{NaHCO}_{3}$ is heated, (f) solid $\mathrm{Na}_{2} \mathrm{CO}_{3}$ is heated.
23.34 Sodium hydride ( NaH ) can be used as a drying agent for many organic solvents. Explain how it works.

G 23.35 Calculate the volume of $\mathrm{CO}_{2}$ at $10.0^{\circ} \mathrm{C}$ and 746 mmHg pressure obtained by treating 25.0 g of $\mathrm{Na}_{2} \mathrm{CO}_{3}$ with an excess of hydrochloric acid.

## Section 23.6: The Alkaline Earth Metals

## Review Questions

23.36 List the common ores of magnesium and calcium.
23.37 How are magnesium and calcium obtained commercially?

## Problems

E 23.38 From the thermodynamic data in Appendix 2, calculate the $\Delta H^{\circ}$ values for the following decompositions:
(a) $\mathrm{MgCO}_{3}(s) \longrightarrow \mathrm{MgO}(s)+\mathrm{CO}_{2}(g)$
(b) $\mathrm{CaCO}_{3}(s) \longrightarrow \mathrm{CaO}(s)+\mathrm{CO}_{2}(g)$

Which of the two compounds is more easily decomposed by heat?

E 23.39 Starting with magnesium and concentrated nitric acid, describe how you would prepare magnesium oxide. [Hint: First convert Mg to $\mathrm{Mg}\left(\mathrm{NO}_{3}\right)_{2}$. Next, MgO can be obtained by heating $\mathrm{Mg}\left(\mathrm{NO}_{3}\right)_{2}$.]
23.40 Describe two ways of preparing magnesium chloride.
$\$$ 23.41 The second ionization energy of magnesium is only about twice as great as the first, but the third ionization energy is 10 times as great. Why does it take so much more energy to remove the third electron?

EI 23.42 List the sulfates of the Group 2A metals in order of increasing solubility in water. Explain the trend. (Hint: You need to consult a chemistry handbook.)
23.43 Helium contains the same number of electrons in its outer shell as do the alkaline earth metals. Explain why helium is inert whereas the Group 2A metals are not.

E 23.44 When exposed to air, calcium first forms calcium oxide, which is then converted to calcium hydroxide, and finally to calcium carbonate. Write a balanced equation for each step.
23.45 Write chemical formulas for (a) quicklime and (b) slaked lime.

## Section 23.7: Aluminum

## Review Questions

23.46 Describe the Hall process for preparing aluminum.
23.47 What action renders aluminum inert?

## Problems

23.48 Before Hall invented his electrolytic process, aluminum was produced by the reduction of its chloride with an active metal. Which metals would you use for the production of aluminum in that way?

E 23.49 With the Hall process, how many hours will it take to deposit 664 g of Al at a current of 32.6 A ?

G23.50 Aluminum forms the complex ions $\mathrm{AlCl}_{4}^{-}$and $\mathrm{AlF}_{6}^{3-}$. Describe the shapes of these ions. $\mathrm{AlCl}_{6}^{3-}$ does not form. Why? (Hint: Consider the relative sizes of $\mathrm{Al}^{3+}, \mathrm{F}^{-}$, and $\mathrm{Cl}^{-}$ions.)
$\boldsymbol{\Psi} \boldsymbol{2 3 . 5 1}$ The overall reaction for the electrolytic production of aluminum by means of the Hall process may be represented as

$$
\mathrm{Al}_{2} \mathrm{O}_{3}(s)+3 \mathrm{C}(s) \longrightarrow 2 \mathrm{Al}(l)+3 \mathrm{CO}(g)
$$

At $1000^{\circ} \mathrm{C}$, the standard free-energy change for this process is $594 \mathrm{~kJ} / \mathrm{mol}$. (a) Calculate the minimum voltage required to produce 1 mole of aluminum at this temperature. (b) If the actual voltage applied is exactly three times the ideal value, calculate the energy required to produce 1.00 kg of the metal.

G23.52 In basic solution, aluminum metal is a strong reducing agent and is oxidized to $\mathrm{AlO}_{2}^{-}$. Give balanced equations for the reaction of Al in basic solution with the following: (a) $\mathrm{NaNO}_{3}$, to give ammonia; (b) water, to give hydrogen; (c) $\mathrm{Na}_{2} \mathrm{SnO}_{3}$, to give metallic tin.

E 23.53 Write a balanced equation for the thermal decomposition of aluminum nitrate to form aluminum oxide, nitrogen dioxide, and oxygen gas.
23.54 Describe some of the properties of aluminum that make it one of the most versatile metals known.
23.55 The pressure of gaseous $\mathrm{Al}_{2} \mathrm{Cl}_{6}$ increases more rapidly with temperature than predicted by the ideal gas equation even though $\mathrm{Al}_{2} \mathrm{Cl}_{6}$ behaves like an ideal gas. Explain.
23.56 Starting with aluminum, describe with balanced equations how you would prepare (a) $\mathrm{Al}_{2} \mathrm{Cl}_{6}$, (b) $\mathrm{Al}_{2} \mathrm{O}_{3}$, (c) $\mathrm{Al}_{2}\left(\mathrm{SO}_{4}\right)_{3}$, (d) $\mathrm{NH}_{4} \mathrm{Al}\left(\mathrm{SO}_{4}\right)_{2} \cdot 12 \mathrm{H}_{2} \mathrm{O}$.
23.57 Explain the change in bonding when $\mathrm{Al}_{2} \mathrm{Cl}_{6}$ dissociates to form $\mathrm{AlCl}_{3}$ in the gas phase.

## Additional Problems

23.58 In steelmaking, nonmetallic impurities such as $\mathrm{P}, \mathrm{S}$, and Si are removed as the corresponding oxides. The inside of the furnace is usually lined with $\mathrm{CaCO}_{3}$ and $\mathrm{MgCO}_{3}$, which decompose at high temperatures to yield CaO and MgO . How do CaO and MgO help in the removal of the nonmetallic oxides?

E23.59 When 1.164 g of a certain metal sulfide was roasted in air, 0.972 g of the metal oxide was formed. If the oxidation number of the metal is +2 , calculate the molar mass of the metal.
23.60 An early view of metallic bonding assumed that bonding in metals consisted of localized, shared electron-pair bonds between metal atoms. What evidence would help you to argue against this viewpoint?
23.61 Referring to Figure 23.6, would you expect $\mathrm{H}_{2} \mathrm{O}$ and H to be reduced at the cathode and $\mathrm{H}_{2} \mathrm{O}$ oxidized at the anode?
$\boldsymbol{H}$ 23.62 A $0.450-\mathrm{g}$ sample of steel contains manganese as an impurity. The sample is dissolved in acidic solution and the manganese is oxidized to the permanganate ion $\mathrm{MnO}_{4}^{-}$. The $\mathrm{MnO}_{4}^{-}$ion is reduced to $\mathrm{Mn}^{2+}$ by reacting with 50.0 mL of $0.0800 M \mathrm{FeSO}_{4}$ solution. The excess $\mathrm{Fe}^{2+}$ ions are then oxidized to $\mathrm{Fe}^{3+}$ by 22.4 mL of $0.0100 M \mathrm{~K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$. Calculate the percent by mass of manganese in the sample.
§23.63 Given that $\Delta G_{\mathrm{f}}^{\circ}\left(\mathrm{Fe}_{2} \mathrm{O}_{3}\right)=-741.0 \mathrm{~kJ} / \mathrm{mol}$ and that $\Delta G_{\mathrm{f}}^{\circ}\left(\mathrm{Al}_{2} \mathrm{O}_{3}\right)=-1576.4 \mathrm{~kJ} / \mathrm{mol}$, calculate $\Delta G^{\circ}$ for the following reactions at $25^{\circ} \mathrm{C}$ :
(a) $2 \mathrm{Fe}_{2} \mathrm{O}_{3}(s) \longrightarrow 4 \mathrm{Fe}(s)+3 \mathrm{O}_{2}(g)$
(b) $2 \mathrm{Al}_{2} \mathrm{O}_{3}(s) \longrightarrow 4 \mathrm{Al}(s)+3 \mathrm{O}_{2}(g)$
23.64 Use compounds of aluminum as examples to explain what is meant by amphoterism.
23.65 When an inert atmosphere is needed for a metallurgical process, nitrogen is frequently used. However, in the reduction of $\mathrm{TiCl}_{4}$ by magnesium, helium is used. Explain why nitrogen is not suitable for this process.
23.66 It has been shown that $\mathrm{Na}_{2}$ species form in the vapor phase. Describe the formation of the "disodium molecule" in terms of a molecular orbital energy level diagram. Would you expect the alkaline earth metals to exhibit a similar property?
23.67 Explain each of the following statements: (a) An aqueous solution of $\mathrm{AlCl}_{3}$ is acidic. (b) $\mathrm{Al}(\mathrm{OH})_{3}$ is soluble in NaOH solution but not in $\mathrm{NH}_{3}$ solution.

EI 23.68 Write balanced equations for the following reactions: (a) the heating of aluminum carbonate, (b) the reaction between $\mathrm{AlCl}_{3}$ and K , (c) the reaction between solutions of $\mathrm{Na}_{2} \mathrm{CO}_{3}$ and $\mathrm{Ca}(\mathrm{OH})_{2}$.
23.69 Write a balanced equation for the reaction between calcium oxide and dilute HCl solution.

E 23.70 What is wrong with the following procedure for obtaining magnesium?

$$
\begin{aligned}
\mathrm{MgCO}_{3}(s) & \longrightarrow \mathrm{MgO}(s)+\mathrm{CO}_{2}(g) \\
\mathrm{MgO}(s)+\mathrm{CO}(g) & \longrightarrow \mathrm{Mg}(s)+\mathrm{CO}_{2}(g)
\end{aligned}
$$

$\boldsymbol{H}$ 23.71 Explain why most metals have a flickering appearance.
23.72 Predict the chemical properties of francium, the last member of Group 1A.

H23.73 Describe a medicinal or health-related application for each of the following compounds: $\mathrm{NaF}, \mathrm{Li}_{2} \mathrm{CO}_{3}, \mathrm{Mg}(\mathrm{OH})_{2}, \mathrm{CaCO}_{3}, \mathrm{BaSO}_{4}$.

Ef 23.74 The following are two reaction schemes involving magnesium. Scheme I: When magnesium burns in oxygen, a white solid (A) is formed. A dissolves in 1 MHCl to give a colorless solution (B). Upon addition of $\mathrm{Na}_{2} \mathrm{CO}_{3}$ to B , a white precipitate is formed (C). On heating, C decomposes to D and a colorless gas is generated ( E ). When E is passed through limewater [an aqueous suspension of $\mathrm{Ca}(\mathrm{OH})_{2}$ ], a white precipitate appears (F). Scheme II: Magnesium reacts with $1 M \mathrm{H}_{2} \mathrm{SO}_{4}$ to produce a colorless solution (G). Treating G with an excess of NaOH produces a white precipitate $(\mathrm{H})$. H dissolves in $1 \mathrm{M} \mathrm{HNO}_{3}$ to form a colorless solution. When the solution is slowly evaporated, a white solid (I) appears. On heating I, a brown gas is given off. Identify A-I, and write equations representing the reactions involved.
23.75 Lithium and magnesium exhibit a diagonal relationship in some chemical properties. How does lithium resemble magnesium in its reaction with oxygen and nitrogen? Consult a handbook of chemistry and compare the solubilities of carbonates, fluorides, and phosphates of these metals.

E 23.76 To prevent the formation of oxides, peroxides, and superoxides, alkali metals are sometimes stored in an inert atmosphere. Which of the following gases should not be used for lithium: $\mathrm{Ne}, \mathrm{Ar}, \mathrm{N}_{2}$, Kr ? Why?

EI 23.77 Which of the following metals is not found in the free state in nature: $\mathrm{Ag}, \mathrm{Cu}, \mathrm{Zn}, \mathrm{Au}, \mathrm{Pt}$ ?
23.78 After heating, a metal surface (such as that of a cooking pan or skillet) develops a color pattern like an oil slick on water. Explain.
$\boldsymbol{\Psi} \boldsymbol{2 3 . 7 9}$ A sample of 10.00 g of sodium reacts with oxygen to form 13.83 g of sodium oxide $\left(\mathrm{Na}_{2} \mathrm{O}\right)$ and sodium peroxide $\left(\mathrm{Na}_{2} \mathrm{O}_{2}\right)$. Calculate the percent composition of the mixture.
23.80 The electrical conductance of copper metal decreases with temperature, but that of a $\mathrm{CuSO}_{4}$ solution increases with temperature. Explain.

E 23.81 As stated in the chapter, potassium superoxide $\left(\mathrm{KO}_{2}\right)$ is a useful source of oxygen employed in breathing equipment. Calculate the pressure at which oxygen gas stored at $20^{\circ} \mathrm{C}$ would have the same density as the oxygen gas provided by $\mathrm{KO}_{2}$. The density of $\mathrm{KO}_{2}$ at $20^{\circ} \mathrm{C}$ is $2.15 \mathrm{~g} / \mathrm{cm}^{3}$.

E 23.82 Chemical tests of four metals $\mathrm{A}, \mathrm{B}, \mathrm{C}$, and D show the following results: (a) Only B and C react with 0.5 M HCl to give $\mathrm{H}_{2}$ gas. (b) When B is added to a solution containing the ions of the other metals, metallic A, C, and D are formed. (c) A reacts with $6 M$ $\mathrm{HNO}_{3}$, but D does not. Arrange the metals in the increasing order as reducing agents. Suggest four metals that fit these descriptions.

## Pre-Professional Practice Exam Problems: Verbal Reasoning

Copper is essential for a wide range of biochemical processes, which are vital for human health. However, copper is also potentially toxic. Under physiological conditions, copper exists in two different oxidation states: $\mathrm{Cu}^{+}$(cuprous) and $\mathrm{Cu}^{2+}$ (cupric). It is the one-electron shift back and forth between these two oxidation states that makes copper essential to the function of cuproenzymes. However, this electron transfer also contributes to the potential toxicity of copper in the body. Cycling between $\mathrm{Cu}^{+}$and $\mathrm{Cu}^{2+}$ can generate hydroxyl radicals ( $\cdot \mathrm{OH}$ ), highly reactive oxygen species that can damage biological molecules such as DNA and proteins. Recently, intracellular proteins have been discovered that appear to prevent the toxic effects of copper ions. These so-called copper chaperones escort copper ions directly to the cuproenzymes that need them, keeping the cells free of "unchaperoned" copper ions, which would otherwise be involved in the formation of hydroxyl radicals.

Menkes disease results from an inability to absorb copper in the intestine. Lack of availability of copper results in reduced activity of cuproenzymes. Symptoms of Menkes disease include mental retardation and abnormalities in connective tissue. Victims of Menkes disease are almost always male, and they typically do not survive beyond the age of 3 . In recent years, an experimental treatment for Menkes disease has been reported. The treatment involves injection of a copper compound (copper histadine) to supply copper to the body's cells. One report details the effects of this treatment on four patients who exceeded the life expectancy of Menkes disease sufferers by as much as 20 years with regular injections of copper histadine. Although the mental retardation was largely mitigated by the treatment, abnormalities in connective tissue were not and so although the patients survived, they were severely disabled by their symptoms.

1. According to the passage, the potential toxicity of copper in the human body results from
a) copper ions damaging DNA and proteins.
b) increased activity of cuproenzymes.
c) the formation of hydroxyl radicals.
d) excess copper accumulating in the brain.
2. What is the function of a copper chaperone?
a) To convert copper atoms into copper ions.
b) To convert $\mathrm{Cu}^{+}$ions to $\mathrm{Cu}^{2+}$ ions.
c) To convert $\mathrm{Cu}^{2+}$ ions to $\mathrm{Cu}^{+}$ions.
d) To escort copper ions to the cuproenzymes that require them.
3. According to the passage, what is the cause of Menkes disease?
a) Abnormalities in connective tissue
b) Failure to absorb copper in the intestine
c) Excess copper in the cells
d) Faulty cuproenzymes
4. According to the passage, victims of Menkes disease
a) are typically male.
b) typically live up to 20 years.
c) can be cured with copper histidine injections.
d) all of the above.

## Toxicity of Arsenic(III) Compounds

Arsenic has always been the poison of choice for murder mysteries. In the 1960s, samples of Napoleon's hair were analyzed and found to contain a high level of arsenic. It was naturally concluded that he was intentionally poisoned. Studies in recent years, however, have shown that Napoleon's exposure to arsenic may have been environmental. The wallpaper in his drawing room was found to contain the green pigment copper arsenite $\left(\mathrm{CuHAsO}_{4}\right)$. The mold growing on the papers could have converted the compound to the volatile, toxic trimethyl arsine $\left[\left(\mathrm{CH}_{3}\right)_{3} \mathrm{As}\right]$, which Napoleon then ingested.

Unlike the first two elements in Group 5A, nitrogen and phosphorus, arsenic is not an essential element in the human body. Moreover, elemental arsenic itself is not all that harmful. The commonly used poison is actually arsenic(III) oxide $\left(\mathrm{As}_{2} \mathrm{O}_{3}\right)$, a white compound that dissolves in water, has no taste, and if administered over a period of time, is hard to detect. The toxicity of As(III) inorganic compounds lies in their ability to bind to the sulfhydryl group ( -SH ) of proteins and enzymes, thus impairing their normal functions. Arsenite also inhibits enzyme activities in the mitochondria and uncouples oxidative phosphorylation. This results in a decrease in ATP production and an increase in harmful reactive oxygen species (ROS) such as hydrogen peroxide and superoxide ion. The accumulation of ROS can lead to DNA damage and initiate carcinogenic processes.

Arsenic is a metalloid. The metalloids and the nonmetallic elements and their compounds exhibit chemistry that varies considerably.

At the end of this chapter, you will have an appreciation for the widely varied properties of nonmetals and the important chemistry they exhibit [ $N$ Page 992].

## In This Chapter, You Will Learn:

Some of the properties of metalloids and nonmetals and which compounds they form.

## Before you begin, you should review

- General trends in chemical properties [ 14 Section 7.7]

### 24.1 General Properties of Nonmetals

Properties of nonmetals are more varied than those of metals. Hydrogen, oxygen, nitrogen, fluorine, chlorine, and the noble gases are all gases in the elemental state, whereas only bromine is a liquid. All the remaining nonmetals are solids at room temperature. Unlike metals, nonmetals are poor conductors of heat and electricity, and when they form compounds, nonmetals can exhibit either positive or negative oxidation numbers.

A small group of elements, called metalloids, have properties characteristic of both metals and nonmetals. The metalloids boron, silicon, germanium, and arsenic are semiconducting elements (see Section 20.3).

Nonmetals are more electronegative than metals [144 Section 8.4]. The electronegativity of elements increases from left to right across any period and from bottom to top in any group in the periodic table (see Figure 8.6). With the exception of hydrogen, the nonmetals are concentrated in the upper right-hand corner of the periodic table (Figure 24.1). Compounds formed by a combination of metals with nonmetals tend to be ionic, having a metallic cation and a nonmetallic anion.

In this chapter we will discuss the chemistry of a number of common and important nonmetallic elements-namely, hydrogen; carbon (Group 4A); nitrogen and phosphorus (Group 5A); oxygen and sulfur (Group 6A); and the halogens: fluorine, chlorine, bromine, and iodine (Group 7A).

### 24.2 Hydrogen

Hydrogen is the simplest element known-its most common atomic form contains only one proton and one electron. The atomic form of hydrogen exists only at very high temperatures, however. Normally, elemental hydrogen is a diatomic molecule, the product of an exothermic reaction between H atoms:

$$
\mathrm{H}(g)+\mathrm{H}(g) \longrightarrow \mathrm{H}_{2}(g) \quad \Delta H^{\circ}=-436.4 \mathrm{~kJ} / \mathrm{mol}
$$

Molecular hydrogen is a colorless, odorless, and nonpoisonous gas. At 1 atm, liquid hydrogen has a boiling point of $-252.9^{\circ} \mathrm{C}(20.3 \mathrm{~K})$.

Hydrogen is the most abundant element in the universe, accounting for about 70 percent of the universe's total mass. It is the tenth most abundant element in Earth's crust, where it is found in combination with other elements. Unlike Jupiter and Saturn, Earth does not have a strong enough gravitational pull to retain the lightweight $\mathrm{H}_{2}$ molecules, so hydrogen is not found in our atmosphere.

The ground-state electron configuration of H is $1 s^{1}$. It resembles the alkali metals (Group 1A) in that it can be oxidized to the $\mathrm{H}^{+}$ion, which exists in aqueous solutions in the hydrated form. On the other hand, hydrogen resembles the halogens (Group 7A) in that it forms the hydride ion $\left(\mathrm{H}^{-}\right)$, which is isoelectronic with helium $\left(1 s^{2}\right)$. Hydrogen is found in a large number of covalent compounds. It also has the unique capacity, when bonded to small, electronegative atoms, for hydrogen-

Figure 24.1 Main group nonmetallic elements (in blue) and metalloids (in orange).

Student Annotation: Remember that the halogens also form anions that are isoelectronic with the noble gases [ 144 Section 7.5].
bond formation [ 144 Section 12.1].

Hydrogen gas plays an important role in industrial processes. About 95 percent of the hydrogen produced is produced at or near the plant where it is used for industrial processes, such as the synthesis of ammonia. The large-scale industrial preparation is the reaction between propane (from natural gas and also as a product of oil refineries) and steam in the presence of a catalyst at $900^{\circ} \mathrm{C}$ :

$$
\mathrm{C}_{3} \mathrm{H}_{8}(g)+3 \mathrm{H}_{2} \mathrm{O}(g) \longrightarrow 3 \mathrm{CO}(g)+7 \mathrm{H}_{2}(g)
$$

In another process, steam is passed over a bed of red-hot coke:

$$
\mathrm{C}(s)+\mathrm{H}_{2} \mathrm{O}(\mathrm{~g}) \longrightarrow \mathrm{CO}(\mathrm{~g})+\mathrm{H}_{2}(g)
$$

The mixture of carbon monoxide and hydrogen gas produced in this reaction is commonly known as water gas. Because both CO and $\mathrm{H}_{2}$ burn in air, water gas was used as a fuel for many years. But because CO is poisonous, water gas has been replaced by natural gases, such as methane and propane.

Small quantities of hydrogen gas can be prepared conveniently in the laboratory by combining zinc with dilute hydrochloric acid (Figure 24.2):

$$
\mathrm{Zn}(s)+2 \mathrm{HCl}(a q) \longrightarrow \mathrm{ZnCl}_{2}(a q)+\mathrm{H}_{2}(g)
$$

Hydrogen gas can also be produced by the reaction between an alkali metal or an alkaline earth metal ( Ca or Ba ) and water (see Section 7.7), but these reactions are too violent to be suitable for the laboratory preparation of hydrogen gas. Very pure hydrogen gas can be obtained by the electrolysis of water, but this method consumes too much energy to be practical on a large scale.

## Binary Hydrides

Binary hydrides are compounds containing hydrogen and another element, either a metal or a nonmetal. Depending on the structure and properties, these hydrides are broadly divided into three types: (1) ionic hydrides, (2) covalent hydrides, and (3) interstitial hydrides.

Ionic hydrides are formed when molecular hydrogen combines directly with any alkali metal or with the alkaline earth metals $\mathrm{Ca}, \mathrm{Sr}$, or Ba :

$$
\begin{aligned}
& 2 \mathrm{Li}(s)+\mathrm{H}_{2}(g) \longrightarrow 2 \mathrm{LiH}(s) \\
& \mathrm{Ca}(s)+\mathrm{H}_{2}(g) \longrightarrow \mathrm{CaH}_{2}(s)
\end{aligned}
$$

All ionic hydrides are solids that have the high melting points characteristic of ionic compounds. The anion in these compounds is the hydride ion $\left(\mathrm{H}^{-}\right)$, which is a very strong Brønsted base. It readily accepts a proton from a proton donor such as water:

$$
\mathrm{H}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{OH}^{-}(a q)+\mathrm{H}_{2}(g)
$$

Figure 24.2 Apparatus for the laboratory preparation of hydrogen gas. The gas is collected over water.

Figure 24.3 Binary hydrides of the representative elements. In cases in which hydrogen forms more than one compound with the same element, only the formula of the simplest hydride is shown. The properties of many of the transition metal hydrides are not well characterized.

Because of their high reactivity with water, ionic hydrides are frequently used to remove traces of water from organic solvents.

In covalent hydrides, the hydrogen atom is covalently bonded to the atom of another element. There are two types of covalent hydrides-those containing discrete molecular units, such as $\mathrm{CH}_{4}$ and $\mathrm{NH}_{3}$, and those having complex polymeric structures, such as $\left(\mathrm{BeH}_{2}\right)_{x}$ and $\left(\mathrm{AlH}_{3}\right)_{x}$, where $x$ is a very large number.

Figure 24.3 shows the binary ionic and covalent hydrides of the main group elements. The physical and chemical properties of these compounds change from ionic to covalent across a given period. Consider, for example, the hydrides of the second-period elements: $\mathrm{LiH}, \mathrm{BeH}_{2}, \mathrm{~B}_{2} \mathrm{H}_{6}, \mathrm{CH}_{4}$, $\mathrm{NH}_{3}, \mathrm{H}_{2} \mathrm{O}$, and HF . LiH is an ionic compound with a high melting point $\left(680^{\circ} \mathrm{C}\right)$. The structure of $\mathrm{BeH}_{2}$ (in the solid state) is polymeric; it is a covalent compound. The molecules $\mathrm{B}_{2} \mathrm{H}_{6}$ and $\mathrm{CH}_{4}$ are nonpolar. In contrast, $\mathrm{NH}_{3}, \mathrm{H}_{2} \mathrm{O}$, and HF are all polar molecules in which the hydrogen atom is the positive end of the polar bond. Of this group of hydrides $\left(\mathrm{NH}_{3}, \mathrm{H}_{2} \mathrm{O}\right.$, and HF$)$, only HF is acidic in water.

As we move down any group in Figure 24.3, the compounds change from covalent to ionic. In Group 2A, for example, $\mathrm{BeH}_{2}$ and $\mathrm{MgH}_{2}$ are covalent, but $\mathrm{CaH}_{2}, \mathrm{SrH}_{2}$, and $\mathrm{BaH}_{2}$ are ionic.

Molecular hydrogen forms a number of hydrides with transition metals. In some of these compounds, the ratio of hydrogen atoms to metal atoms is not a constant. Such compounds are called interstitial hydrides. Depending on conditions, for example, the formula for titanium hydride can vary between $\mathrm{TiH}_{1.8}$ and $\mathrm{TiH}_{2}$.

Many of the interstitial hydrides have metallic properties such as electrical conductivity. It is known, however, that hydrogen is definitely bonded to the metal in these compounds, although the exact nature of the bonding is often unclear.

Molecular hydrogen interacts in a unique way with palladium (Pd). Hydrogen gas is readily adsorbed onto the surface of the palladium metal, where it dissociates into atomic hydrogen. The H atoms then "dissolve" into the metal. On heating and under the pressure of $\mathrm{H}_{2}$ gas on one side of the metal, these atoms diffuse through the metal and recombine to form molecular hydrogen, which emerges as the gas from the other side. Because no other gas behaves in this way with palladium, this process has been used to separate hydrogen gas from other gases on a small scale.

## Isotopes of Hydrogen

Hydrogen has three isotopes: ${ }_{1}^{1} \mathrm{H}$ (hydrogen), ${ }_{1}^{2} \mathrm{H}$ (deuterium, symbol D), and ${ }_{1}^{3} \mathrm{H}$ (tritium, symbol T). The natural abundances of the stable hydrogen isotopes are hydrogen, 99.985 percent; and deuterium, 0.015 percent. Tritium is a radioactive isotope with a half-life of about 12.5 years.

Table 24.1 compares some of the common properties of $\mathrm{H}_{2} \mathrm{O}$ with those of $\mathrm{D}_{2} \mathrm{O}$. Deuterium oxide, or heavy water as it is commonly called, is used in some nuclear reactors as a coolant and a moderator of nuclear reactions [ 14 Section 20.5]. $\mathrm{D}_{2} \mathrm{O}$ can be separated from $\mathrm{H}_{2} \mathrm{O}$ by fractional distillation because $\mathrm{H}_{2} \mathrm{O}$ boils at a lower temperature, as Table 24.1 shows. Another technique

TABLE 24.1 $\quad$ Properties of $\mathrm{H}_{2} \mathrm{O}$ and $\mathrm{D}_{2} \mathrm{O}$

| Property | $\mathbf{H}_{2} \mathbf{O}$ | $\mathbf{D}_{2} \mathbf{O}$ |
| :--- | :---: | :---: |
| Molar mass $(\mathrm{g} / \mathrm{mol})$ | 18.02 | 20.03 |
| Melting point $\left({ }^{\circ} \mathrm{C}\right)$ | 0 | 3.8 |
| Boiling point $\left({ }^{\circ} \mathrm{C}\right)$ | 100 | 101.4 |
| Density at $4{ }^{\circ} \mathrm{C}\left(\mathrm{g} / \mathrm{cm}^{3}\right)$ | 1.000 | 1.108 |

for separating $\mathrm{D}_{2} \mathrm{O}$ is the electrolysis of water. Because $\mathrm{H}_{2}$ gas is formed about eight times as fast as $D_{2}$ during electrolysis, the water remaining in the electrolytic cell becomes progressively enriched with $\mathrm{D}_{2} \mathrm{O}$. Interestingly, the Dead Sea, which for thousands of years has entrapped water that has no outlet other than through evaporation, has a higher $\left[\mathrm{D}_{2} \mathrm{O}\right] /\left[\mathrm{H}_{2} \mathrm{O}\right]$ ratio than water found elsewhere.

Although $\mathrm{D}_{2} \mathrm{O}$ resembles $\mathrm{H}_{2} \mathrm{O}$ chemically in most respects, it is still a toxic substance. The reason is that deuterium is heavier than hydrogen, so its compounds often react more slowly than those of the lighter isotope. Drinking $\mathrm{D}_{2} \mathrm{O}$ instead of $\mathrm{H}_{2} \mathrm{O}$ on a regular basis could prove fatal because of the slower rate of transfer of D compared with that of H in the acid-base reactions involved in enzyme catalysis. This kinetic isotope effect is also manifest in acid ionization constants. For example, the ionization constant of acetic acid

$$
\mathrm{CH}_{3} \mathrm{COOH}(a q) \rightleftarrows \mathrm{CH}_{3} \mathrm{COO}(a q)+\mathrm{H}^{+}(a q) \quad K_{\mathrm{a}}=1.8 \times 10^{-5}
$$

is about three times as large as that of deuterated acetic acid, in which the ionizable hydrogen atom is replaced by a deuterium atom:

$$
\mathrm{CH}_{3} \mathrm{COOD}(a q) \rightleftarrows \mathrm{CH}_{3} \mathrm{COO}(a q)+\mathrm{D}^{+}(a q) \quad K_{\mathrm{a}}=6 \times 10^{-6}
$$

## Hydrogenation

Hydrogenation is the addition of hydrogen to compounds containing multiple bonds, usually $\mathrm{C}=\mathrm{C}$ and $\mathrm{C} \equiv \mathrm{C}$ bonds. A simple example of hydrogenation is the conversion of ethylene to ethane:

This reaction is quite slow under normal conditions, but the rate can be greatly increased by the presence of a catalyst such as nickel or platinum.

Hydrogenation is an extremely important process in the food industry. Vegetable oils have considerable nutritional value, but some oils must be hydrogenated before we can use them because of their unsavory flavor and their inappropriate molecular structures (i.e., there are too many $\mathrm{C}=\mathrm{C}$ bonds present). Upon exposure to air, these polyunsaturated molecules (i.e., molecules with many $\mathrm{C}=\mathrm{C}$ bonds) undergo oxidation to yield unpleasant-tasting products (oil that has oxidized is said to be rancid). In the hydrogenation process, a small amount of nickel (about 0.1 percent by mass) is added to the oil and the mixture is exposed to hydrogen gas at high temperature and pressure. Afterward, the nickel is removed by filtration. Hydrogenation reduces the number of double bonds in the molecule but does not completely eliminate them. If all the double bonds are eliminated, the oil becomes hard and brittle. Under controlled conditions, suitable cooking oils and margarine may be prepared by the hydrogenation of vegetable oils extracted from cottonseed, corn, and soybeans.

## The Hydrogen Economy

The world's fossil fuel reserves are being depleted at an alarmingly fast rate. Faced with this dilemma, scientists have made intensive efforts in recent years to develop a method of obtaining hydrogen gas as an alternative energy source. Hydrogen gas could replace gasoline to power automobiles (after considerable modification of the engine) or be used with oxygen gas in fuel cells to

Figure 24.4 Phase diagram of carbon. Note that under atmospheric conditions, graphite is the stable form of carbon.

Figure 24.5 A synthetic diamond and the starting material—graphite.
generate electricity (see page 840). One major advantage of using hydrogen gas in these ways is that the reactions are essentially free of pollutants; the end product formed in a hydrogen-powered engine or in a fuel cell would be water, just as in the burning of hydrogen gas in air:

$$
2 \mathrm{H}_{2}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l)
$$

Despite these attractive features, though, the success of a hydrogen economy would depend on how cheaply we could produce hydrogen gas and how easily we could store it.

Although electrolysis of water consumes too much energy for large-scale application, if scientists can devise a more practical method of "splitting" water molecules, we could obtain vast amounts of hydrogen from seawater. One approach that is currently in the early stages of development would use solar energy. In this scheme, a catalyst (a complex molecule containing one or more transition metal atoms, such as ruthenium) absorbs a photon from solar radiation and becomes energetically excited. In its excited state, the catalyst is capable of reducing water to molecular hydrogen.

Some of the interstitial hydrides we have discussed would make suitable storage compounds for hydrogen. The reactions that form these hydrides are usually reversible, so hydrogen gas can be obtained simply by reducing the pressure of the hydrogen gas above the metal. The advantages of using interstitial hydrides are as follows: (1) many metals have a high capacity to take up hydrogen gas-sometimes up to three times as many hydrogen atoms as there are metal atoms; and (2) because these hydrides are solids, they can be stored and transported more easily than gases or liquids.

### 24.3 Carbon

Although it constitutes only about 0.09 percent by mass of Earth's crust, carbon is an essential element of living matter. It is found free in the form of diamond and graphite, and it is also a component of natural gas, petroleum, and coal. (Coal is a natural dark-brown to black solid used as a fuel; it is formed from fossilized plants and consists of amorphous carbon with various organic and some inorganic compounds.) Carbon combines with oxygen to form carbon dioxide in the atmosphere and occurs as carbonate in limestone and chalk.

Diamond and graphite are allotropes of carbon. Figure 24.4 shows the phase diagram of carbon. Although graphite is the stable form of carbon at 1 atm and $25^{\circ} \mathrm{C}$, owners of diamond jewelry need not be alarmed, because the rate of the spontaneous process

$$
\mathrm{C}(\text { diamond }) \longrightarrow \mathrm{C}(\text { graphite }) \quad \Delta G^{\circ}=-2.87 \mathrm{~kJ} / \mathrm{mol}
$$

is extremely slow. In fact, millions of years may pass before a diamond turns to graphite.
Synthetic diamond can be prepared from graphite by applying very high pressures and temperatures. Figure 24.5 shows a synthetic diamond and its starting material, graphite. Synthetic diamonds generally lack the optical properties of natural diamonds. They are useful, however, as abrasives and in cutting concrete and many other hard substances, including metals and alloys. Graphite is used as a lubricant and as the "lead" in pencils.

Carbon has the unique ability to form long chains (consisting of more than 50 C atoms) and stable rings with five or six members. This phenomenon is called catenation, the linking of like atoms. Carbon's versatility is responsible for the millions of organic compounds (made up of carbon and hydrogen and other elements such as oxygen, nitrogen, and the halogens) found on Earth [ 14 Chapter 10].

Carbon combines with metals to form ionic compounds called carbides, such as $\mathrm{CaC}_{2}$ and $\mathrm{Be}_{2} \mathrm{C}$, in which carbon is in the form of $\mathrm{C}_{2}^{2-}$ or $\mathrm{C}^{4-}$ ions. These ions are strong Brønsted bases and react with water as follows:

$$
\begin{aligned}
& \mathrm{C}_{2}^{2-}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{OH}^{-}(a q)+\mathrm{C}_{2} \mathrm{H}_{2}(g) \\
& \mathrm{C}^{4-}(a q)+4 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 4 \mathrm{OH}^{-}(a q)+\mathrm{CH}_{4}(g)
\end{aligned}
$$

Carbon also forms a covalent compound with silicon. Silicon carbide ( SiC ) is called carborundum and is prepared as follows:

$$
\mathrm{SiO}_{2}(s)+3 \mathrm{C}(s) \longrightarrow \mathrm{SiC}(s)+2 \mathrm{CO}(g)
$$

Carborundum is also formed by heating silicon with carbon at $1500^{\circ} \mathrm{C}$. Carborundum is almost as hard as diamond, and it has the diamond structure; that is, each carbon atom is bonded tetrahedrally to four Si atoms, and vice versa. It is used mainly for cutting, grinding, and polishing metals and glasses.

Another important class of carbon compounds, the cyanides, contain the anion group : $\mathrm{C} \equiv \mathrm{N}:^{-}$. Cyanide ions are extremely toxic because they bind almost irreversibly to the Fe (III) ion in cytochrome oxidase, a key enzyme in metabolic processes. Hydrogen cyanide, which has the aroma of bitter almonds, is even more dangerous because of its volatility (b.p. $26^{\circ} \mathrm{C}$ ). A few tenths of 1 percent by volume of HCN in air can cause death within minutes. Hydrogen cyanide can be prepared by treating sodium cyanide or potassium cyanide with acid:

$$
\mathrm{NaCN}(s)+\mathrm{HCl}(a q) \longrightarrow \mathrm{NaCl}(a q)+\mathrm{HCN}(a q)
$$

Because HCN (in solution it is called hydrocyanic acid) is a very weak acid ( $K_{\mathrm{a}}=4.9 \times 10^{-10}$ ), most of the HCN produced in this reaction is in the nonionized form and leaves the solution as hydrogen cyanide gas. For this reason, acids should never be mixed with metal cyanides in the laboratory without proper ventilation.

Cyanide ions are used to extract gold and silver. Although these metals are usually found in the uncombined state in nature, in other metal ores they may be present in relatively small concentrations and are more difficult to extract. In a typical process, the crushed ore is treated with an aqueous cyanide solution in the presence of air to dissolve the gold by forming the soluble complex ion $\left[\mathrm{Au}(\mathrm{CN})_{2}\right]^{-}$:

$$
4 \mathrm{Au}(s)+8 \mathrm{CN}^{-}(a q)+\mathrm{O}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 4\left[\mathrm{Au}(\mathrm{CN})_{2}\right]^{-}(a q)+4 \mathrm{OH}^{-}(a q)
$$

The complex ion $\left[\mathrm{Au}(\mathrm{CN})_{2}\right]^{-}$(along with some cation, such as $\mathrm{Na}^{+}$) is separated from other insoluble materials by filtration and treated with an electropositive metal such as zinc to recover the gold:

$$
\mathrm{Zn}(s)+2\left[\mathrm{Au}(\mathrm{CN})_{2}\right]^{-}(a q) \longrightarrow\left[\mathrm{Zn}(\mathrm{CN})_{4}\right]^{2-}(a q)+2 \mathrm{Au}(s)
$$

Figure 24.6 shows an aerial view of a "cyanide pond" used for the extraction of gold.
Of the several oxides of carbon, the most important are carbon monoxide (CO) and carbon dioxide $\left(\mathrm{CO}_{2}\right)$. Carbon monoxide is a colorless, odorless gas formed by the incomplete combustion of carbon or carbon-containing compounds:

$$
2 \mathrm{C}(s)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{CO}(g)
$$

Carbon monoxide is used in metallurgical processes for extracting nickel in organic synthesis and in the production of hydrocarbon fuels with hydrogen. Industrially, it is prepared by passing steam over heated coke. Carbon monoxide burns readily in oxygen to form carbon dioxide:

$$
2 \mathrm{CO}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{CO}_{2}(g) \quad \Delta H^{\circ}=-566 \mathrm{~kJ} / \mathrm{mol}
$$

Carbon monoxide is not an acidic oxide (it differs from carbon dioxide in that regard), and it is only slightly soluble in water.

Carbon dioxide is a colorless and odorless gas. Unlike carbon monoxide, $\mathrm{CO}_{2}$ is nontoxicalthough it is a simple asphyxiant. It is an acidic oxide. Carbon dioxide is used in beverages, in fire extinguishers, and in the manufacture of baking soda $\left(\mathrm{NaHCO}_{3}\right)$ and soda ash $\left(\mathrm{Na}_{2} \mathrm{CO}_{3}\right)$. Solid carbon dioxide, called dry ice, is used as a refrigerant.

### 24.4 Nitrogen and Phosphorus

## Nitrogen

About 78 percent of air by volume is nitrogen. The most important mineral sources of nitrogen are saltpeter $\left(\mathrm{KNO}_{3}\right)$ and Chile saltpeter $\left(\mathrm{NaNO}_{3}\right)$. Nitrogen is an essential element of life because it is a component of proteins and nucleic acids.

Molecular nitrogen is obtained by the fractional distillation of air (the boiling points of liquid nitrogen and liquid oxygen are $-196^{\circ} \mathrm{C}$ and $-183^{\circ} \mathrm{C}$, respectively). In the laboratory, very pure nitrogen gas can be prepared by the thermal decomposition of ammonium nitrite:

$$
\mathrm{NH}_{4} \mathrm{NO}_{2}(s) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(g)+\mathrm{N}_{2}(g)
$$

The $\mathrm{N}_{2}$ molecule contains a triple bond and is very stable with respect to dissociation into atomic species. However, nitrogen forms a large number of compounds with hydrogen and oxygen in which the oxidation number of nitrogen varies from -3 to +5 (Table 24.2). Most nitrogen compounds are covalent; when heated with certain metals, however, nitrogen forms ionic nitrides containing the $\mathrm{N}^{3-}$ ion:

$$
6 \mathrm{Li}(s)+\mathrm{N}_{2}(g) \longrightarrow 2 \mathrm{Li}_{3} \mathrm{~N}(s)
$$

Student Annotation: Hydrogen cyanide (HCN) is the gas used in gas-chamber executions.

Figure 24.6 A cyanide pond for extracting gold from metal ore.

TABLE 24.2 Common Compounds of Nitrogen

| Oxidation Number | Compound | Formula | Structure |
| :---: | :---: | :---: | :---: |
| -3 | Ammonia | $\mathrm{NH}_{3}$ |  |
| -2 | Hydrazine | $\mathrm{N}_{2} \mathrm{H}_{4}$ |  |
| -1 | Hydroxylamine | $\mathrm{NH}_{2} \mathrm{OH}$ |  |
| 0 | Nitrogen (for reference) | $\mathrm{N}_{2}$ | $: N \equiv N$ : |
| +1 | Nitrous oxide | $\mathrm{N}_{2} \mathrm{O}$ | : $\mathrm{N} \equiv \mathrm{N}-\mathrm{O} \mathrm{O}$ : |

| +5 | Nitric acid | $\mathrm{HNO}_{3}$ |  |

The nitride ion is a very strong Brønsted base and reacts with water to produce ammonia and hydroxide ions:

$$
\mathrm{N}^{3-}(a q)+3 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{NH}_{3}(g)+3 \mathrm{OH}^{-}(a q)
$$

Ammonia is one of the best-known nitrogen compounds. It is prepared industrially from nitrogen and hydrogen by the Haber process. It can be prepared in the laboratory by treating ammonium chloride with sodium hydroxide:

$$
\mathrm{NH}_{4} \mathrm{Cl}(a q)+\mathrm{NaOH}(a q) \longrightarrow \mathrm{NaCl}(a q)+\mathrm{H}_{2} \mathrm{O}(l)+\mathrm{NH}_{3}(g)
$$

Ammonia is a colorless gas (b.p. $-33.4^{\circ} \mathrm{C}$ ) with an irritating odor. Most of the ammonia produced annually in the United States is used in fertilizers.

Liquid ammonia, like water, undergoes autoionization:

$$
2 \mathrm{NH}_{3}(l) \rightleftarrows \mathrm{NH}_{4}^{+}+\mathrm{NH}_{2}^{-}
$$

or simply

$$
\mathrm{NH}_{3}(l) \rightleftarrows \mathrm{H}^{+}+\mathrm{NH}_{2}^{-}
$$

where $\mathrm{NH}_{2}^{-}$is called the amide ion. Both the $\mathrm{H}^{+}$and $\mathrm{NH}_{2}^{-}$ions are solvated with $\mathrm{NH}_{3}$ mol-ecules-an example of an ion-dipole interaction [ 144 Section 12.1]. At $50^{\circ} \mathrm{C}$, the ion product $\left[\mathrm{H}^{+}\right]\left[\mathrm{NH}_{2}^{-}\right]$is about $1 \times 10^{-33}$, considerably smaller than the $1 \times 10^{-14}$ for water at $25^{\circ} \mathrm{C}$. Nevertheless, liquid ammonia is a suitable solvent for many electrolytes, especially when a more basic medium is required or if the solutes react with water.

Another important hydride of nitrogen is hydrazine:

Each N atom is $s p^{3}$-hybridized. Hydrazine is a colorless liquid that smells like ammonia. It melts at $2^{\circ} \mathrm{C}$ and boils at $114^{\circ} \mathrm{C}$.

Hydrazine is a base that can be protonated to give the $\mathrm{N}_{2} \mathrm{H}_{5}^{+}$and $\mathrm{N}_{2} \mathrm{H}_{6}^{2+}$ ions. A reducing agent, it can reduce $\mathrm{Fe}^{3+}$ to $\mathrm{Fe}^{2+}, \mathrm{MnO}_{4}^{-}$to $\mathrm{Mn}^{2+}$, and $\mathrm{I}_{2}$ to $\mathrm{I}^{-}$. Its reaction with oxygen is highly exothermic:

$$
\mathrm{N}_{2} \mathrm{H}_{4}(l)+\mathrm{O}_{2}(g) \longrightarrow \mathrm{N}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(l) \quad \Delta H^{\circ}=-666.6 \mathrm{~kJ} / \mathrm{mol}
$$

Hydrazine and its derivative methylhydrazine $\left[\mathrm{N}_{2} \mathrm{H}_{3}\left(\mathrm{CH}_{3}\right)\right]$, together with the oxidizer dinitrogen tetroxide $\left(\mathrm{N}_{2} \mathrm{O}_{4}\right)$, are used as rocket fuels. Hydrazine also plays a role in polymer synthesis and in the manufacture of pesticides.

There are many nitrogen oxides, but the three particularly important ones are nitrous oxide, nitric oxide, and nitrogen dioxide. Nitrous oxide $\left(\mathrm{N}_{2} \mathrm{O}\right)$ is a colorless gas with a pleasing odor and sweet taste. It is prepared by heating ammonium nitrate to about $270^{\circ} \mathrm{C}$ :

$$
\mathrm{NH}_{4} \mathrm{NO}_{3}(s) \longrightarrow \mathrm{N}_{2} \mathrm{O}(g)+2 \mathrm{H}_{2} \mathrm{O}(g)
$$

Nitrous oxide resembles molecular oxygen in that it supports combustion. It does so because it decomposes when heated to form molecular nitrogen and molecular oxygen:

$$
2 \mathrm{~N}_{2} \mathrm{O}(g) \longrightarrow 2 \mathrm{~N}_{2}(g)+\mathrm{O}_{2}(g)
$$

It is chiefly used as an anesthetic in dental procedures and other minor surgery. Nitrous oxide is also called "laughing gas" because a person inhaling the gas becomes somewhat giddy. No satisfactory explanation has yet been proposed for this unusual physiological response.

Nitric oxide (NO) is a colorless gas. The reaction of $\mathrm{N}_{2}$ and $\mathrm{O}_{2}$ in the atmosphere,

$$
\mathrm{N}_{2}(g)+\mathrm{O}_{2}(g) \rightleftarrows 2 \mathrm{NO}(g) \quad \Delta G^{\circ}=173.4 \mathrm{~kJ} / \mathrm{mol}
$$

is a form of nitrogen fixation. The equilibrium constant for the preceding reaction is very small at room temperature: $K_{P}$ is only $4.0 \times 10^{-31}$ at $25^{\circ} \mathrm{C}$, so very little NO will form at that temperature. However, the equilibrium constant increases rapidly with temperature, such as in a running auto engine. An appreciable amount of nitric oxide is formed in the atmosphere by the action of lightning. In the laboratory, the gas can be prepared by the reduction of dilute nitric acid with copper:

$$
3 \mathrm{Cu}(s)+8 \mathrm{HNO}_{3}(a q) \longrightarrow 3 \mathrm{Cu}\left(\mathrm{NO}_{3}\right)_{2}(a q)+4 \mathrm{H}_{2} \mathrm{O}(l)+2 \mathrm{NO}(g)
$$

The nitric oxide molecule is paramagnetic, containing one unpaired electron. It can be represented by the following resonance structures:

$$
\dot{\mathrm{N}}=\mathrm{O} \dot{\cdot} \quad \longleftrightarrow \quad-\dot{\mathrm{N}}=\mathrm{O}^{+}
$$

Unlike nitrous oxide and nitric oxide, nitrogen dioxide is a highly toxic, yellow-brown gas with a choking odor. In the laboratory, nitrogen dioxide is prepared by the action of concentrated nitric acid on copper (Figure 24.7):

$$
\mathrm{Cu}(s)+4 \mathrm{HNO}_{3}(a q) \longrightarrow \mathrm{Cu}\left(\mathrm{NO}_{3}\right)_{2}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l)+2 \mathrm{NO}_{2}(g)
$$

Nitrogen dioxide is paramagnetic, and it has a strong tendency to dimerize to dinitrogen tetroxide, which is diamagnetic:

$$
2 \mathrm{NO}_{2} \rightleftarrows \mathrm{~N}_{2} \mathrm{O}_{4}
$$

This reaction occurs in both the gas phase and the liquid phase.
Nitrogen dioxide is an acidic oxide; it reacts rapidly with cold water to form both nitrous acid $\left(\mathrm{HNO}_{2}\right)$ and nitric acid $\left(\mathrm{HNO}_{3}\right)$ :

$$
2 \mathrm{NO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{HNO}_{2}(a q)+\mathrm{HNO}_{3}(a q)
$$

This is a disproportionation reaction in which the oxidation number of nitrogen changes from +4 (in $\mathrm{NO}_{2}$ ) to +3 (in $\mathrm{HNO}_{2}$ ) and +5 (in $\mathrm{HNO}_{3}$ ). This reaction is quite different from that between $\mathrm{CO}_{2}$ and $\mathrm{H}_{2} \mathrm{O}$, in which only one acid (carbonic acid) is formed.

Nitric acid is one of the most important inorganic acids. It is a liquid (b.p. $82.6^{\circ} \mathrm{C}$ ), but it does not exist as a pure liquid because it decomposes spontaneously to some extent as follows:

$$
4 \mathrm{HNO}_{3}(l) \longrightarrow 4 \mathrm{NO}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{O}_{2}(g)
$$

The concentrated nitric acid used in the laboratory is 68 percent $\mathrm{HNO}_{3}$ by mass (density $1.42 \mathrm{~g} / \mathrm{cm}^{3}$ ), which corresponds to 15.7 M .

Nitric acid is a powerful oxidizing agent. The oxidation number of N in $\mathrm{HNO}_{3}$ is +5 . The most common reduction products of nitric acid are $\mathrm{NO}_{2}$ (oxidation number of $\mathrm{N}=+4$ ), NO (oxidation number of $\mathrm{N}=+2$ ), and $\mathrm{NH}_{4}^{+}$(oxidation number of $\mathrm{N}=-3$ ). Nitric acid can oxidize metals both above and below hydrogen in the activity series. Copper, for example, is oxidized by concentrated nitric acid.

In the presence of a strong reducing agent, such as zinc metal, nitric acid can be reduced all the way to the ammonium ion:

$$
4 \mathrm{Zn}(s)+10 \mathrm{H}^{+}(a q)+\mathrm{NO}_{3}^{-}(a q) \longrightarrow 4 \mathrm{Zn}^{2+}(a q)+\mathrm{NH}_{4}^{+}(a q)+3 \mathrm{H}_{2} \mathrm{O}(l)
$$

Student Annotation: The NO molecule does not obey the octet rule [144 Section 8.8].

Figure 24.7 The production of $\mathrm{NO}_{2}$ gas when copper reacts with concentrated nitric acid.

Figure 24.8 Fluoroapatite $\left[\mathrm{Ca}_{5}\left(\mathrm{PO}_{4}\right)_{3} \mathrm{~F}\right]$.

Concentrated nitric acid does not oxidize gold. However, when the acid is added to concentrated hydrochloric acid in a 1:3 ratio by volume (one part $\mathrm{HNO}_{3}$ to three parts HCl ), the resulting solution, called aqua regia, can oxidize gold as follows:

$$
\mathrm{Au}(s)+3 \mathrm{HNO}_{3}(a q)+4 \mathrm{HCl}(a q) \longrightarrow \mathrm{HAuCl}_{4}(a q)+3 \mathrm{H}_{2} \mathrm{O}(l)+3 \mathrm{NO}_{2}(g)
$$

The oxidation of Au is promoted by the complexing ability of the $\mathrm{Cl}^{-}$ion (to form the $\mathrm{AuCl}_{4}^{-}$ ion).

Concentrated nitric acid also oxidizes a number of nonmetals to their corresponding oxoacids:

$$
\begin{gathered}
\mathrm{P}_{4}(s)+20 \mathrm{HNO}_{3}(a q) \longrightarrow 4 \mathrm{H}_{3} \mathrm{PO}_{4}(a q)+20 \mathrm{NO}_{2}(g)+4 \mathrm{H}_{2} \mathrm{O}(l) \\
\mathrm{S}(s)+6 \mathrm{HNO}_{3}(a q) \longrightarrow \mathrm{H}_{2} \mathrm{SO}_{4}(a q)+6 \mathrm{NO}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(l)
\end{gathered}
$$

Nitric acid is used in the manufacture of fertilizers, dyes, drugs, and explosives.

## Phosphorus

Like nitrogen, phosphorus is a member of the Group 5A family, and in some respects the chemistry of phosphorus resembles that of nitrogen. Phosphorus occurs most commonly in nature as phosphate rocks, which are mostly calcium phosphate $\left[\mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}\right]$ and fluoroapatite $\left[\mathrm{Ca}_{5}\left(\mathrm{PO}_{4}\right)_{3} \mathrm{~F}\right]$ (Figure 24.8). Elemental phosphorus can be obtained by heating calcium phosphate with coke and silica sand:

$$
2 \mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}(s)+10 \mathrm{C}(s)+6 \mathrm{SiO}_{2}(s) \longrightarrow 6 \mathrm{CaSiO}_{3}(s)+10 \mathrm{CO}(g)+\mathrm{P}_{4}(s)
$$

There are several allotropic forms of phosphorus, but only white phosphorus and red phosphorus are of importance. White phosphorus consists of discrete tetrahedral $\mathrm{P}_{4}$ molecules (Figure 24.9). A solid (m.p. $44.2^{\circ} \mathrm{C}$ ), white phosphorus is insoluble in water but quite soluble in carbon disulfide $\left(\mathrm{CS}_{2}\right)$ and organic solvents such as chloroform $\left(\mathrm{CHCl}_{3}\right)$. White phosphorus is a highly toxic substance. It bursts into flames spontaneously when exposed to air; hence, it is used in incendiary bombs and grenades:

$$
\mathrm{P}_{4}(s)+5 \mathrm{O}_{2}(g) \longrightarrow \mathrm{P}_{4} \mathrm{O}_{10}(s)
$$

The high reactivity of white phosphorus is attributed to structural strain: the $\mathrm{P}-\mathrm{P}$ bonds are compressed in the tetrahedral $\mathrm{P}_{4}$ molecule. White phosphorus was once used in matches, but because of its toxicity it has been replaced by tetraphosphorus trisulfide $\left(\mathrm{P}_{4} \mathrm{~S}_{3}\right)$.

When heated in the absence of air, white phosphorus is slowly converted to red phosphorus at about $300^{\circ} \mathrm{C}$ :

$$
n \mathrm{P}_{4}(\text { white phosphorus }) \longrightarrow\left(\mathrm{P}_{4}\right)_{n}(\text { red phosphorus })
$$

Red phosphorus has a polymeric structure (see Figure 24.9) and is more stable and less volatile than white phosphorus.

The most important hydride of phosphorus is phosphine $\left(\mathrm{PH}_{3}\right)$, a colorless, very poisonous gas formed by heating white phosphorus in concentrated sodium hydroxide:

$$
\mathrm{P}_{4}(s)+3 \mathrm{NaOH}(a q)+3 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 3 \mathrm{NaH}_{2} \mathrm{PO}_{2}(a q)+\mathrm{PH}_{3}(g)
$$

White phosphorus

Red phosphorus

Phosphine is moderately soluble in water and more soluble in carbon disulfide and organic solvents. Its aqueous solution is neutral, unlike that of ammonia. In liquid ammonia, phosphine dissolves to give $\mathrm{NH}_{4}^{+} \mathrm{PH}_{2}^{-}$. Phosphine is a strong reducing agent; it reduces many metal salts to the corresponding metals. The gas burns in air:

$$
\mathrm{PH}_{3}(\mathrm{~g})+2 \mathrm{O}_{2}(\mathrm{~g}) \longrightarrow \mathrm{H}_{3} \mathrm{PO}_{4}(\mathrm{~s})
$$

Phosphorus forms binary compounds with halogens-namely, the trihalides $\left(\mathrm{PX}_{3}\right)$ and the pentahalides $\left(\mathrm{PX}_{5}\right)$, where X denotes a halogen atom. In contrast, nitrogen can form only trihalides $\left(\mathrm{NX}_{3}\right)$. Unlike nitrogen, phosphorus has a $3 d$ subshell, which can be used for valence-shell expansion. We can explain the bonding in $\mathrm{PCl}_{5}$ by assuming that phosphorus undergoes $s p^{3} d$ hybridization of its $3 s, 3 p$, and $3 d$ orbitals [ $1 / 4$ Section 9.4]. The five $s p^{3} d$ hybrid orbitals also account for the trigonal bipyramidal geometry of the $\mathrm{PCl}_{5}$ molecule (see Table 9.4).

Phosphorus trichloride is prepared by heating white phosphorus in chlorine:

$$
\mathrm{P}_{4}(l)+6 \mathrm{Cl}_{2}(g) \longrightarrow 4 \mathrm{PCl}_{3}(g)
$$

A colorless liquid (b.p. $76^{\circ} \mathrm{C}$ ), $\mathrm{PCl}_{3}$ is hydrolyzed according to the following equation:

$$
\mathrm{PCl}_{3}(l)+3 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}_{3} \mathrm{PO}_{3}(a q)+3 \mathrm{HCl}(g)
$$

In the presence of an excess of chlorine gas, $\mathrm{PCl}_{3}$ is converted to phosphorus pentachloride, which is a light-yellow solid:

$$
\mathrm{PCl}_{3}(l)+\mathrm{Cl}_{2}(g) \longrightarrow \mathrm{PCl}_{5}(s)
$$

X-ray studies indicate that solid phosphorus pentachloride exists as $\left[\mathrm{PCl}_{4}^{+}\right]\left[\mathrm{PCl}_{6}^{-}\right]$, in which the $\mathrm{PCl}_{4}^{+}$ion has a tetrahedral geometry and the $\mathrm{PCl}_{6}^{-}$ion has an octahedral geometry. In the gas phase, $\mathrm{PCl}_{5}$ (which has trigonal bipyramidal geometry) is in equilibrium with $\mathrm{PCl}_{3}$ and $\mathrm{Cl}_{2}$ :

$$
\mathrm{PCl}_{5}(\mathrm{~g}) \rightleftarrows \mathrm{PCl}_{3}(\mathrm{~g})+\mathrm{Cl}_{2}(\mathrm{~g})
$$

Phosphorus pentachloride reacts with water as follows:

$$
\mathrm{PCl}_{5}(s)+4 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}_{3} \mathrm{PO}_{4}(a q)+5 \mathrm{HCl}(a q)
$$

The two important oxides of phosphorus are tetraphosphorus hexaoxide $\left(\mathrm{P}_{4} \mathrm{O}_{6}\right)$ and tetraphosphorus decaoxide $\left(\mathrm{P}_{4} \mathrm{O}_{10}\right)$, shown in Figure 24.10 . The oxides are obtained by burning white phosphorus in limited and excess amounts of oxygen gas, respectively:

$$
\begin{gathered}
\mathrm{P}_{4}(s)+3 \mathrm{O}_{2}(\mathrm{~g}) \longrightarrow \mathrm{P}_{4} \mathrm{O}_{6}(s) \\
\mathrm{P}_{4}(s)+5 \mathrm{O}_{2}(\mathrm{~g}) \longrightarrow \mathrm{P}_{4} \mathrm{O}_{10}(s)
\end{gathered}
$$

Both oxides are acidic; that is, they are converted to acids in water. The compound $\mathrm{P}_{4} \mathrm{O}_{10}$ is a white flocculent powder (m.p. $420^{\circ} \mathrm{C}$ ) that has a great affinity for water:

$$
\mathrm{P}_{4} \mathrm{O}_{10}(s)+6 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 4 \mathrm{H}_{3} \mathrm{PO}_{4}(a q)
$$

For this reason, it is often used for drying gases and for removing water from solvents.
There are many oxoacids containing phosphorus. Some examples are phosphorous acid $\left(\mathrm{H}_{3} \mathrm{PO}_{3}\right)$, phosphoric acid $\left(\mathrm{H}_{3} \mathrm{PO}_{4}\right)$, hypophosphorous acid $\left(\mathrm{H}_{3} \mathrm{PO}_{2}\right)$, and triphosphoric acid $\left(\mathrm{H}_{5} \mathrm{P}_{3} \mathrm{O}_{10}\right)$ (the structures of which are shown in Figure 24.11). Phosphoric acid, also called orthophosphoric acid, is a weak triprotic acid. It is prepared industrially by the reaction of calcium phosphate with sulfuric acid:

$$
\mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}(s)+3 \mathrm{H}_{2} \mathrm{SO}_{4}(a q) \longrightarrow 2 \mathrm{H}_{3} \mathrm{PO}_{4}(a q)+3 \mathrm{CaSO}_{4}(s)
$$

Figure 24.10 The structures of $\mathrm{P}_{4} \mathrm{O}_{6}$ and $\mathrm{P}_{4} \mathrm{O}_{10}$. Note the tetrahedral arrangement of the P atoms in $\mathrm{P}_{4} \mathrm{O}_{10}$.

Figure 24.11 Structures of some common phosphorus-containing oxoacids.

Student Annotation: Pregnant women are advised not to consume large quantities of soda because of the phosphate content.

Phosphorous acid $\left(\mathrm{H}_{3} \mathrm{PO}_{3}\right)$

Phosphoric acid $\left(\mathrm{H}_{3} \mathrm{PO}_{4}\right)$

Hypophosphorous acid $\left(\mathrm{H}_{3} \mathrm{PO}_{2}\right)$

Triphosphoric acid $\left(\mathrm{H}_{5} \mathrm{P}_{3} \mathrm{O}_{10}\right)$

In the pure form, phosphoric acid is a colorless solid (m.p. $42.2^{\circ} \mathrm{C}$ ). The phosphoric acid we use in the laboratory is usually an $82 \% \mathrm{H}_{3} \mathrm{PO}_{4}$ solution (by mass). Phosphoric acid and phosphates have many commercial applications in detergents, fertilizers, flame retardants, and toothpastes, and as buffers in carbonated beverages.

Like nitrogen, phosphorus is an element that is essential to life. It constitutes only about 1 percent by mass of the human body, but it is a very important 1 percent. About 23 percent of the human skeleton is mineral matter. The phosphorus content of this mineral matter, calcium phosphate $\left[\mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}\right]$, is 20 percent. Our teeth are basically $\mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}$ and $\mathrm{Ca}_{5}\left(\mathrm{PO}_{4}\right)_{3} \mathrm{OH}$. Phosphates are also important components of the genetic materials deoxyribonucleic acid (DNA) and ribonucleic acid (RNA).

### 24.5 Oxygen and Sulfur

## Oxygen

Oxygen is by far the most abundant element in Earth's crust, constituting about 46 percent of its mass. In addition, the atmosphere contains about 21 percent molecular oxygen by volume ( 23 percent by mass). Like nitrogen, oxygen in the free state is a diatomic molecule $\left(\mathrm{O}_{2}\right)$. In the laboratory, oxygen gas can be obtained by heating potassium chlorate:

$$
2 \mathrm{KClO}_{3}(s) \longrightarrow 2 \mathrm{KCl}(s)+3 \mathrm{O}_{2}(g)
$$

The reaction is usually catalyzed by manganese(IV) dioxide $\left(\mathrm{MnO}_{2}\right)$. Pure oxygen gas can be prepared by electrolyzing water (page 843). Industrially, oxygen gas is prepared by the fractional distillation of liquefied air. Oxygen gas is colorless and odorless.

Oxygen is a building block of practically all biomolecules, accounting for about a fourth of the atoms in living matter. Molecular oxygen is the essential oxidant in the metabolic breakdown of food molecules. Without it, a human being cannot survive for more than a few minutes.

Although oxygen has two allotropes, $\mathrm{O}_{2}$ and $\mathrm{O}_{3}$, when we speak of molecular oxygen, we normally mean $\mathrm{O}_{2}$. Ozone $\left(\mathrm{O}_{3}\right)$ is less stable than $\mathrm{O}_{2}$. The $\mathrm{O}_{2}$ molecule is paramagnetic because it contains two unpaired electrons (see Section 10.7).

A strong oxidizing agent, molecular oxygen is one of the most widely used industrial chemicals. Its main uses are in the steel industry and in sewage treatment. Oxygen is also used as a bleaching agent for pulp and paper, in medicine to ease breathing difficulties, in oxyacetylene torches, and as an oxidizing agent in many inorganic and organic reactions.

Oxygen forms three types of oxides: the normal oxide (or simply the oxide), which contains the $\mathrm{O}^{2-}$ ion; the peroxide, which contains the $\mathrm{O}_{2}^{2-}$ ion; and the superoxide, which contains the $\mathrm{O}_{2}^{-}$ion:

$$
\begin{array}{lcc}
: O ̣ ̈::^{-} & : O ̣: O ̣ ̈: & \text { :Ọ̈:Ọ: } \\
\text { Oxide } & \text { Peroxide } & \text { Superoxide }
\end{array}
$$

The ions are all strong Brønsted bases and react with water as follows:

| Oxide: | $\mathrm{O}^{2-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{OH}^{-}(a q)$ |
| :--- | ---: | :--- |
| Peroxide: | $2 \mathrm{O}_{2}^{2-}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{O}_{2}(g)+4 \mathrm{OH}^{-}(a q)$ |
| Superoxide: | $4 \mathrm{O}_{2}^{-}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 3 \mathrm{O}_{2}(g)+4 \mathrm{OH}^{-}(a q)$ |

The reaction of $\mathrm{O}^{2-}$ with water is a hydrolysis reaction, but those involving $\mathrm{O}_{2}^{2-}$ and $\mathrm{O}_{2}^{-}$are redox processes.

The nature of bonding in oxides changes across any period in the periodic table. Oxides of elements on the left side of the periodic table, such as those of the alkali metals and alkaline earth metals, are generally ionic solids with high melting points. Oxides of the metalloids and of the metallic elements toward the middle of the periodic table are also solids, but they have much less ionic character. Oxides of nonmetals are covalent compounds that generally exist as liquids or gases at room temperature. The acidic character of the oxides increases from left to right. Consider the oxides of the third-period elements:

$$
\underbrace{\mathrm{Na}_{2} \mathrm{O} \quad \mathrm{MgO}}_{\text {Basic }} \quad \underbrace{\mathrm{Al}_{2} \mathrm{O}_{3}}_{\text {Amphoteric }} \quad \underbrace{\mathrm{SiO}_{2}}_{\text {Acidic }} \quad \mathrm{P}_{4} \mathrm{O}_{10} \quad \mathrm{SO}_{3} \quad \mathrm{Cl}_{2} \mathrm{O}_{7} 7
$$

The basicity of the oxides increases as we move down a particular group. MgO does not react with water, for example, but reacts with acid as follows:

$$
\mathrm{MgO}(s)+2 \mathrm{H}^{+}(a q) \longrightarrow \mathrm{Mg}^{2+}(a q)+\mathrm{H}_{2} \mathrm{O}(l)
$$

On the other hand, BaO , which is more basic, undergoes hydrolysis to yield the corresponding hydroxide:

$$
\mathrm{BaO}(s)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{Ba}(\mathrm{OH})_{2}(a q)
$$

The best-known peroxide is hydrogen peroxide $\left(\mathrm{H}_{2} \mathrm{O}_{2}\right)$. It is a colorless, syrupy liquid (m.p. $-0.9^{\circ} \mathrm{C}$ ), prepared in the laboratory by the action of cold dilute sulfuric acid on barium peroxide octahydrate:

$$
\mathrm{BaO}_{2}(s)+8 \mathrm{H}_{2} \mathrm{O}(s)+\mathrm{H}_{2} \mathrm{SO}_{4}(a q) \longrightarrow \mathrm{BaSO}_{4}(s)+\mathrm{H}_{2} \mathrm{O}_{2}(a q)+8 \mathrm{H}_{2} \mathrm{O}(l)
$$

The structure of hydrogen peroxide is shown in Figure 24.12. Using the VSEPR method, we see that the $\mathrm{H}-\mathrm{O}$ and $\mathrm{O}-\mathrm{O}$ bonds are bent about each oxygen atom in a configuration similar to the structure of water. The lone-pair-bonding-pair repulsion is greater in $\mathrm{H}_{2} \mathrm{O}_{2}$ than in $\mathrm{H}_{2} \mathrm{O}$, so the $\mathrm{H}-\mathrm{O}-\mathrm{O}$ angle is only $97^{\circ}$ (compared with $104.5^{\circ}$ for $\mathrm{H}-\mathrm{O}-\mathrm{H}$ in $\mathrm{H}_{2} \mathrm{O}$ ). Hydrogen peroxide is a polar molecule ( $\mu=2.16 \mathrm{D}$ ). Hydrogen peroxide readily decomposes when heated or exposed to sunlight or even in the presence of dust particles or certain metals, including iron and copper:

$$
2 \mathrm{H}_{2} \mathrm{O}_{2}(l) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{O}_{2}(g) \quad \Delta H^{\circ}=-196.4 \mathrm{~kJ} / \mathrm{mol}
$$

This is a disproportionation reaction. The oxidation number of oxygen changes from -1 to -2 and 0 .

Hydrogen peroxide is miscible with water in all proportions due to its ability to hydrogenbond with water. Dilute hydrogen peroxide solutions ( 3 percent by mass), available in drugstores, are used as mild antiseptics; more concentrated $\mathrm{H}_{2} \mathrm{O}_{2}$ solutions are employed as bleaching agents for textiles, fur, and hair. The high heat of decomposition of hydrogen peroxide also makes it a suitable component in rocket fuel.

Hydrogen peroxide is a strong oxidizing agent; it can oxidize $\mathrm{Fe}^{2+}$ ions to $\mathrm{Fe}^{3+}$ ions in an acidic solution:

$$
\mathrm{H}_{2} \mathrm{O}_{2}(a q)+2 \mathrm{Fe}^{2+}(a q)+2 \mathrm{H}^{+}(a q) \longrightarrow 2 \mathrm{Fe}^{3+}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l)
$$

It also oxidizes $\mathrm{SO}_{3}^{2-}$ ions to $\mathrm{SO}_{4}^{2-}$ ions:

$$
\mathrm{H}_{2} \mathrm{O}_{2}(a q)+\mathrm{SO}_{3}^{2-}(a q) \longrightarrow \mathrm{SO}_{4}^{2-}(a q)+\mathrm{H}_{2} \mathrm{O}(l)
$$

In addition, hydrogen peroxide can act as a reducing agent toward substances that are stronger oxidizing agents than itself. For example, hydrogen peroxide reduces silver oxide to metallic silver,

$$
\mathrm{H}_{2} \mathrm{O}_{2}(a q)+\mathrm{Ag}_{2} \mathrm{O}(s) \longrightarrow 2 \mathrm{Ag}(s)+\mathrm{H}_{2} \mathrm{O}(l)+\mathrm{O}_{2}(g)
$$

Figure 24.12 The structure of $\mathrm{H}_{2} \mathrm{O}_{2}$.

Figure 24.13 The preparation of $\mathrm{O}_{3}$ from $\mathrm{O}_{2}$ by electrical discharge. The outside of the outer tube and the inside of the inner tube are coated with metal foils that are connected to a highvoltage source. (The metal foil on the inside of the inner tube is not shown.) During the electrical discharge, $\mathrm{O}_{2}$ gas is passed through the tube. The $\mathrm{O}_{3}$ gas formed exits from the upper right-hand tube, along with some unreacted $\mathrm{O}_{2}$ gas.

and permanganate $\left(\mathrm{MnO}_{4}^{-}\right)$to manganese(II) in an acidic solution,

$$
5 \mathrm{H}_{2} \mathrm{O}_{2}(a q)+2 \mathrm{MnO}_{4}^{-}(a q)+6 \mathrm{H}^{+}(a q) \longrightarrow 2 \mathrm{Mn}^{2+}(a q)+5 \mathrm{O}_{2}(g)+8 \mathrm{H}_{2} \mathrm{O}(l)
$$

If we want to determine hydrogen peroxide concentration, this reaction can be carried out as a redox titration, using a standard permanganate solution.

There are relatively few known superoxides (i.e., compounds containing the $\mathrm{O}_{2}^{-}$ion). In general, only the most reactive alkali metals ( $\mathrm{K}, \mathrm{Rb}$, and Cs ) form superoxides.

Both the peroxide ion and the superoxide ion are by-products of metabolism. Because these ions are highly reactive, they can inflict great damage on living cells. Fortunately, our bodies are equipped with the enzymes catalase, peroxidase, and superoxide dismutase, which convert these toxic substances to water and molecular oxygen.

Ozone is a rather toxic, light-blue gas (b.p. $-111.3^{\circ} \mathrm{C}$ ). Its pungent odor is noticeable around sources of significant electrical discharges (such as a subway train). Ozone can be prepared from molecular oxygen, either photochemically or by subjecting $\mathrm{O}_{2}$ to an electrical discharge (Figure 24.13):

$$
3 \mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{O}_{3}(g) \quad \Delta G^{\circ}=326.8 \mathrm{~kJ} / \mathrm{mol}
$$

Because the standard free energy of formation of ozone is a large positive quantity ( $\Delta G_{\mathrm{f}}^{\mathrm{o}}=$ $163.4 \mathrm{~kJ} / \mathrm{mol}$ ), ozone is less stable than molecular oxygen. The ozone molecule has a bent structure in which the bond angle is $116.5^{\circ}$ :

Ozone is mainly used to purify drinking water; to deodorize air and sewage gases; and to bleach waxes, oils, and textiles.

Ozone is a very powerful oxidizing agent-its oxidizing power is exceeded only by that of molecular fluorine (see Table 19.1). For example, ozone can oxidize sulfides of many metals to the corresponding sulfates:

$$
4 \mathrm{O}_{3}(\mathrm{~g})+\mathrm{PbS}(s) \longrightarrow \mathrm{PbSO}_{4}(s)+4 \mathrm{O}_{2}(g)
$$

Ozone oxidizes all the common metals except gold and platinum. In fact, a convenient test for ozone is based on its action on mercury. When exposed to ozone, mercury loses its metallic luster and sticks to glass tubing (instead of flowing freely through it). This behavior is attributed to the change in surface tension caused by the formation of mercury(II) oxide:

$$
\mathrm{O}_{3}(g)+3 \mathrm{Hg}(l) \longrightarrow 3 \mathrm{HgO}(s)
$$

The beneficial effect of ozone in the stratosphere and its undesirable action in smog formation were discussed in Chapter 21.

## Sulfur

Although sulfur is not a very abundant element (it constitutes only about 0.06 percent of Earth's crust by mass), it is readily available because it occurs commonly in nature in the elemental form.

The largest known reserves of sulfur are found in sedimentary deposits. In addition, sulfur occurs widely in gypsum $\left(\mathrm{CaSO}_{4} \cdot 2 \mathrm{H}_{2} \mathrm{O}\right)$ and various sulfide minerals such as pyrite $\left(\mathrm{FeS}_{2}\right)$ (Figure 24.14). Sulfur is also present in natural gas as $\mathrm{H}_{2} \mathrm{~S}, \mathrm{SO}_{2}$, and other sulfur-containing compounds.

Sulfur is extracted from underground deposits by the Frasch ${ }^{1}$ process, shown in Figure 24.15. In this process, superheated water (liquid water heated to about $160^{\circ} \mathrm{C}$ under high pressure to prevent it from boiling) is pumped down the outermost pipe to melt the sulfur. Next, compressed air is forced down the innermost pipe. Liquid sulfur mixed with air forms an emulsion that is less dense than water and therefore rises to the surface as it is forced up the middle pipe. Sulfur produced in this manner, which amounts to about 10 million tons per year, has a purity of about 99.5 percent.

There are several allotropic forms of sulfur, the most important being the rhombic and monoclinic forms. Rhombic sulfur is thermodynamically the most stable form; it has a puckered $\mathrm{S}_{8}$ ring structure:

$\mathrm{S}_{8}$
It is a yellow, tasteless, and odorless solid (m.p. $112^{\circ} \mathrm{C}$ ) that is insoluble in water but soluble in carbon disulfide. When heated, it is slowly converted to monoclinic sulfur (m.p. $119^{\circ} \mathrm{C}$ ), which also consists of the $\mathrm{S}_{8}$ units. When liquid sulfur is heated above $150^{\circ} \mathrm{C}$, the rings begin to break up, and the entangling of the sulfur chains results in a sharp increase in the liquid's viscosity. Further heating tends to rupture the chains, so the viscosity decreases.

Like nitrogen, sulfur shows a wide variety of oxidation numbers in its compounds (Table 24.3). The best-known hydrogen compound of sulfur is hydrogen sulfide, which is prepared by the action of an acid on a sulfide; for example,

$$
\mathrm{FeS}(s)+\mathrm{H}_{2} \mathrm{SO}_{4}(a q) \longrightarrow \mathrm{FeSO}_{4}(a q)+\mathrm{H}_{2} \mathrm{~S}(g)
$$

[^51]

Figure 24.14 Pyrite $\left(\mathrm{FeS}_{2}\right)$.

Nonmetallic elements-the extraction of sulfur.

Figure 24.15 The Frasch process. Three concentric pipes are inserted into a hole drilled down to the sulfur deposit. Superheated water is forced down the outer pipe into the sulfur, causing it to melt. Molten sulfur is then forced up the middle pipe by compressed air.

## TABLE 24.3 Common Compounds of Sulfur

| Oxidation Number | Compound | Formula | Structure |
| :---: | :---: | :---: | :---: |
| -2 | Hydrogen sulfide | $\mathrm{H}_{2} \mathrm{~S}$ |  |
| 0 | Sulfur (for reference) | $\mathrm{S}_{8}$ |  |
| +1 | Disulfur dichloride | $\mathrm{S}_{2} \mathrm{Cl}_{2}$ | $\ddot{\mathrm{C} \mid}-\ddot{\mathrm{S}}-\ddot{\mathrm{S}}-\ddot{\mathrm{C}} \mathrm{l}:$ |
| +2 | Sulfur dichloride | $\mathrm{SCl}_{2}$ |  |
| +4 | Sulfur dioxide | $\mathrm{SO}_{2}$ |  |
| +6 | Sulfur trioxide | $\mathrm{SO}_{3}$ |  |

Nowadays, hydrogen sulfide used in qualitative analysis is prepared by the hydrolysis of thioacetamide:

$$
\mathrm{CH}_{3} \mathrm{CSNH}_{2}+2 \mathrm{H}_{2} \mathrm{O}+\mathrm{H}^{+} \longrightarrow \mathrm{CH}_{3} \mathrm{COOH}+\mathrm{H}_{2} \mathrm{~S}+\mathrm{NH}_{4}^{+}
$$

Thioacetamide
Acetic acid
Hydrogen sulfide is a colorless gas (b.p. $-60.2^{\circ} \mathrm{C}$ ) that smells like rotten eggs. (The odor of rotten eggs actually does come from hydrogen sulfide, which is formed by the bacterial decomposition of sulfur-containing proteins.) Hydrogen sulfide is a highly toxic substance that, like hydrogen cyanide, attacks respiratory enzymes. It is a very weak diprotic acid (see Table 16.8). In basic solution, $\mathrm{H}_{2} \mathrm{~S}$ is a reducing agent. For example, it is oxidized by permanganate to elemental sulfur:

$$
3 \mathrm{H}_{2} \mathrm{~S}(a q)+2 \mathrm{MnO}_{4}^{-}(a q) \longrightarrow 3 \mathrm{~S}(s)+2 \mathrm{MnO}_{2}(s)+2 \mathrm{H}_{2} \mathrm{O}(l)+2 \mathrm{OH}^{-}(a q)
$$

Sulfur has two important oxides: sulfur dioxide $\left(\mathrm{SO}_{2}\right)$ and sulfur trioxide $\left(\mathrm{SO}_{3}\right)$. Sulfur dioxide is formed when sulfur burns in air:

$$
\mathrm{S}(s)+\mathrm{O}_{2}(g) \longrightarrow \mathrm{SO}_{2}(g)
$$

In the laboratory, it can be prepared by the action of an acid on a sulfite; for example,

$$
2 \mathrm{HCl}(a q)+\mathrm{Na}_{2} \mathrm{SO}_{3}(a q) \longrightarrow 2 \mathrm{NaCl}(a q)+\mathrm{H}_{2} \mathrm{O}(l)+\mathrm{SO}_{2}(g)
$$

or by the action of concentrated sulfuric acid on copper:

$$
\mathrm{Cu}(s)+2 \mathrm{H}_{2} \mathrm{SO}_{4}(a q) \longrightarrow \mathrm{CuSO}_{4}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{SO}_{2}(g)
$$

Sulfur dioxide (b.p. $-10^{\circ} \mathrm{C}$ ) is a pungent, colorless gas that is quite toxic. An acidic oxide, it reacts with water as follows:

$$
\mathrm{SO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{H}^{+}(a q)+\mathrm{HSO}_{3}^{-}(a q)
$$

Sulfur dioxide is slowly oxidized to sulfur trioxide, but the reaction rate can be greatly enhanced by a platinum or vanadium oxide catalyst:

$$
2 \mathrm{SO}_{2}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{SO}_{3}(g)
$$

Sulfur trioxide dissolves in water to form sulfuric acid:

$$
\mathrm{SO}_{3}(g)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}_{2} \mathrm{SO}_{4}(a q)
$$

The contributing role of sulfur dioxide to acid rain is discussed on page 908.
Sulfuric acid is the world's most important industrial chemical. It is prepared industrially by first burning sulfur in air:

$$
\mathrm{S}(s)+\mathrm{O}_{2}(g) \longrightarrow \mathrm{SO}_{2}(g)
$$

Next is the key step of converting sulfur dioxide to sulfur trioxide:

$$
2 \mathrm{SO}_{2}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{SO}_{3}(g)
$$

$\operatorname{Vanadium}(\mathrm{V})$ oxide $\left(\mathrm{V}_{2} \mathrm{O}_{5}\right)$ is the catalyst used for the second step. Because the sulfur dioxide and oxygen molecules react in contact with the surface of solid $\mathrm{V}_{2} \mathrm{O}_{5}$, the process is referred to as the contact process.

Sulfuric acid is a diprotic acid. It is a colorless, viscous liquid (m.p. $10.4^{\circ} \mathrm{C}$ ). The concentrated sulfuric acid we use in the laboratory is 98 percent $\mathrm{H}_{2} \mathrm{SO}_{4}$ by mass (density $=1.84 \mathrm{~g} / \mathrm{cm}^{3}$ ), which corresponds to a concentration of 18 M . The oxidizing strength of sulfuric acid depends on its temperature and concentration. A cold, dilute sulfuric acid solution reacts with metals above hydrogen in the activity series, thereby liberating molecular hydrogen in a displacement reaction:

$$
\mathrm{Mg}(s)+\mathrm{H}_{2} \mathrm{SO}_{4}(a q) \longrightarrow \mathrm{MgSO}_{4}(a q)+\mathrm{H}_{2}(g)
$$

This is a typical reaction of an active metal with an acid. The strength of sulfuric acid as an oxidizing agent is greatly enhanced when it is both hot and concentrated. In such a solution, the oxidizing agent is actually the sulfate ion rather than the hydrated proton, $\mathrm{H}^{+}(a q)$. Thus, copper reacts with concentrated sulfuric acid as follows:

$$
\mathrm{Cu}(s)+2 \mathrm{H}_{2} \mathrm{SO}_{4}(a q) \longrightarrow \mathrm{CuSO}_{4}(a q)+\mathrm{SO}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(l)
$$

Depending on the nature of the reducing agents, the sulfate ion may be further reduced to elemental sulfur or the sulfide ion. For example, the reduction of $\mathrm{H}_{2} \mathrm{SO}_{4}$ by HI yields $\mathrm{H}_{2} \mathrm{~S}$ and $\mathrm{I}_{2}$ :

$$
8 \mathrm{HI}(a q)+\mathrm{H}_{2} \mathrm{SO}_{4}(a q) \longrightarrow \mathrm{H}_{2} \mathrm{~S}(a q)+4 \mathrm{I}_{2}(s)+4 \mathrm{H}_{2} \mathrm{O}(l)
$$

Concentrated sulfuric acid oxidizes nonmetals. For example, it oxidizes carbon to carbon dioxide and sulfur to sulfur dioxide:

$$
\begin{aligned}
& \mathrm{C}(s)+2 \mathrm{H}_{2} \mathrm{SO}_{4}(a q) \longrightarrow \mathrm{CO}_{2}(g)+2 \mathrm{SO}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(l) \\
& \mathrm{S}(s)+2 \mathrm{H}_{2} \mathrm{SO}_{4}(\mathrm{aq}) \longrightarrow 3 \mathrm{SO}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(l)
\end{aligned}
$$

Carbon disulfide, a colorless, flammable liquid (b.p. $46^{\circ} \mathrm{C}$ ), is formed by heating carbon and sulfur to a high temperature:

$$
\mathrm{C}(s)+2 \mathrm{~S}(l) \longrightarrow \mathrm{CS}_{2}(l)
$$

It is only slightly soluble in water. Carbon disulfide is a good solvent for sulfur, phosphorus, iodine, and nonpolar substances such as waxes and rubber.

Another interesting compound of sulfur is sulfur hexafluoride $\left(\mathrm{SF}_{6}\right)$, which is prepared by heating sulfur in an atmosphere of fluorine:

$$
\mathrm{S}(l)+3 \mathrm{~F}_{2}(g) \longrightarrow \mathrm{SF}_{6}(g)
$$

Sulfur hexafluoride is a nontoxic, colorless gas (b.p. $63.8^{\circ} \mathrm{C}$ ). It is the most inert of all sulfur compounds; it resists attack even by molten KOH . The structure and bonding of $\mathrm{SF}_{6}$ were discussed in Chapters 8 and 9.

### 24.6 The Halogens

The halogens-fluorine, chlorine, bromine, and iodine-are reactive nonmetals. Table 24.4 lists some of the properties of these elements. Although all halogens are highly reactive and toxic, the magnitude of reactivity and toxicity generally decreases from fluorine to iodine. The chemistry of fluorine differs from that of the rest of the halogens in the following ways:

1. Fluorine is the most reactive of all the halogens. The difference in reactivity between fluorine and chlorine is greater than that between chlorine and bromine. Table 24.4 shows that

## TABLE 24.4 Properties of the Halogens

| Property | $\mathbf{F}$ | $\mathbf{C l}$ | $\mathbf{B r}$ | $\mathbf{I}$ |
| :--- | :--- | :--- | :--- | :--- |

| Ionic radius (pm) $\dagger$ | 136 | 181 | 195 | 216 |
| Ionization energy <br> (kJ/mol) | 1680 | 1251 | 1139 | 1003 |
| Electronegativity | 4.0 | 3.0 | 2.8 | 2.5 |
| Standard reduction <br> potential (V)* | 2.87 | 1.36 | 1.07 | 0.53 |
| Bond enthalpy <br> (kJ/mol)* | 150.6 | 242.7 | 192.5 | 151.0 |

* These values and descriptions apply to the diatomic species $X_{2}$, where $X$ represents a halogen atom. The half-reaction is
$\mathrm{X}_{2}(g)+2 e^{-} \longrightarrow 2 \mathrm{X}^{-}(a q)$.
$\dagger$ Refers to the anion $\mathrm{X}^{-}$.
the $\mathrm{F}-\mathrm{F}$ bond is considerably weaker than the $\mathrm{Cl}-\mathrm{Cl}$ bond. The weak bond in $\mathrm{F}_{2}$ can be explained in terms of the lone pairs on the F atoms:

$$
\text { : } \mathrm{F} \text { ت}-\ddot{\mathrm{F}}:
$$

The small size of the F atoms (see Table 24.4) allows a close approach of the three lone pairs on each of the F atoms, resulting in a greater repulsion than that found in $\mathrm{Cl}_{2}$, which consists of larger atoms.
2. Hydrogen fluoride (HF) has a relatively high boiling point $\left(19.5^{\circ} \mathrm{C}\right)$ as a result of strong intermolecular hydrogen bonding, whereas all other hydrogen halides have much lower boiling points.
3. Hydrofluoric acid is a weak acid, whereas all other hydrohalic acids $(\mathrm{HCl}, \mathrm{HBr}$, and HI$)$ are strong acids.
4. Fluorine reacts with cold sodium hydroxide solution to produce oxygen difluoride as follows:

$$
2 \mathrm{~F}_{2}(g)+2 \mathrm{NaOH}(a q) \longrightarrow 2 \mathrm{NaF}(a q)+\mathrm{H}_{2} \mathrm{O}(l)+\mathrm{OF}_{2}(g)
$$

The same reaction with chlorine or bromine, on the other hand, produces a halide and a hypohalite:

$$
\mathrm{X}_{2}(g)+2 \mathrm{NaOH}(a q) \longrightarrow \mathrm{NaX}(a q)+\mathrm{NaXO}(a q)+\mathrm{H}_{2} \mathrm{O}(l)
$$

where X stands for Cl or Br . Iodine does not react under the same conditions.
5. Silver fluoride $(\mathrm{AgF})$ is soluble. All other silver halides $(\mathrm{AgCl}, \mathrm{AgBr}$, and AgI$)$ are insoluble.

The element astatine also belongs to the Group 7A family. However, all isotopes of astatine are radioactive; its longest-lived isotope is astatine-210, which has a half-life of 8.3 h . As a result, it is both difficult and expensive to study astatine in the laboratory.

The halogens form a very large number of compounds. In the elemental state, they form diatomic molecules ( $\mathrm{X}_{2}$ ). In nature, however, because of their high reactivity, halogens are always found combined with other elements. Chlorine, bromine, and iodine occur as halides in seawater, and fluorine occurs in the minerals fluorite $\left(\mathrm{CaF}_{2}\right)$ and cryolite $\left(\mathrm{Na}_{3} \mathrm{AlF}_{6}\right)$.

## Preparation and General Properties of the Halogens

Because fluorine and chlorine are strong oxidizing agents, they must be prepared by electrolysis rather than by chemical oxidation of the fluoride and chloride ions. Electrolysis does not work for aqueous solutions of fluorides, however, because fluorine is a stronger oxidizing agent than oxygen. From Table 19.1 (page 827), we find that

$$
\begin{aligned}
\mathrm{F}_{2}(g)+2 e^{-} \longrightarrow 2 \mathrm{~F}^{-}(a q) & E^{\circ}=2.87 \mathrm{~V} \\
\mathrm{O}_{2}(g)+4 \mathrm{H}^{+}(a q)+4 e^{-} \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l) & E^{\circ}=1.23 \mathrm{~V}
\end{aligned}
$$

If $\mathrm{F}_{2}$ were formed by the electrolysis of an aqueous fluoride solution, it would immediately oxidize water to oxygen. For this reason, fluorine is prepared by electrolyzing liquid hydrogen fluoride containing potassium fluoride to increase its conductivity, at about $70^{\circ} \mathrm{C}$ (Figure 24.16):

$$
\begin{array}{lr}
\text { Anode (oxidation): } & 2 \mathrm{~F}^{-} \longrightarrow \mathrm{F}_{2}(g)+2 e^{-} \\
\text {Cathode (reduction): } & \frac{2 \mathrm{H}^{+}+2 e^{-} \longrightarrow \mathrm{H}_{2}(g)}{} \begin{array}{lrl}
\text { Overall reaction: } & 2 \mathrm{HF}(l) \longrightarrow \mathrm{H}_{2}(g)+\mathrm{F}_{2}(g)
\end{array}
\end{array}
$$

Chlorine gas $\left(\mathrm{Cl}_{2}\right)$ is prepared industrially by the electrolysis of molten NaCl or by the chloralkali process, the electrolysis of a concentrated aqueous NaCl solution (called brine). (Chlor denotes chlorine, and alkali denotes an alkali metal, such as sodium.) Two of the common cells used in the chlor-alkali process are the mercury cell and the diaphragm cell. In both cells, the overall reaction is

$$
2 \mathrm{NaCl}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l) \xrightarrow{\text { electrolysis }} 2 \mathrm{NaOH}(a q)+\mathrm{H}_{2}(g)+\mathrm{Cl}_{2}(g)
$$

As you can see, this reaction yields two useful by-products, NaOH and $\mathrm{H}_{2}$. The cells are designed to separate the molecular chlorine from the sodium hydroxide solution and the molecular hydrogen to prevent side reactions such as

$$
2 \mathrm{NaOH}(a q)+\mathrm{Cl}_{2}(g) \longrightarrow \mathrm{NaOCl}(a q)+\mathrm{NaCl}(a q)+\mathrm{H}_{2} \mathrm{O}(l)
$$

and

$$
\mathrm{H}_{2}(g)+\mathrm{Cl}_{2}(g) \longrightarrow 2 \mathrm{HCl}(g)
$$

These reactions must be prevented because they consume the desired products and can be dangerous because a mixture of $\mathrm{H}_{2}$ and $\mathrm{Cl}_{2}$ is explosive.

Figure 24.17 shows the mercury cell used in the chlor-alkali process. The cathode is a liquid mercury pool at the bottom of the cell, and the anode is made of either graphite or titanium coated

Figure 24.16 Electrolytic cell for the preparation of fluorine gas. Note that because $\mathrm{H}_{2}$ and $\mathrm{F}_{2}$ form an explosive mixture, these gases must be separated from each other.

Figure 24.17 Mercury cell used in the chlor-alkali process. The cathode contains mercury. The sodium-mercury amalgam is treated with water outside the cell to produce sodium hydroxide and hydrogen gas.

Figure 24.18 The industrial manufacture of chlorine gas.

Figure 24.19 Diaphragm cell used in the chlor-alkali process.

with platinum. Brine is continuously passed through the cell as shown in the diagram. The electrode reactions are

where $\mathrm{Na} / \mathrm{Hg}$ denotes the formation of sodium amalgam. The chlorine gas generated this way is very pure. The sodium amalgam does not react with the brine solution but decomposes as follows when treated with pure water outside the cell:

$$
2 \mathrm{Na} / \mathrm{Hg}+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{NaOH}(a q)+\mathrm{H}_{2}(g)+2 \mathrm{Hg}(l)
$$

The by-products are sodium hydroxide and hydrogen gas. Although the mercury is cycled back into the cell for reuse, some of it is always discharged with waste solutions into the environment, resulting in mercury pollution. This is a major drawback of the mercury cell. Figure 24.18 shows the industrial manufacture of chlorine gas.

The half-cell reactions in a diaphragm cell are shown in Figure 24.19. The asbestos diaphragm is permeable to the ions but not to the hydrogen and chlorine gases and so prevents the gases from mixing. During electrolysis, a positive pressure is applied on the anode side of the compartment to prevent the migration of the $\mathrm{OH}^{-}$ions from the cathode compartment. Periodically, fresh brine solution is added to the cell and the sodium hydroxide solution is run off as shown. The diaphragm cell presents no pollution problems. Its main disadvantage is that the sodium hydroxide solution is contaminated with unreacted sodium chloride.

In the laboratory, chlorine, bromine, and iodine can be prepared by heating the alkali halides $(\mathrm{NaCl}, \mathrm{KBr}$, or KI$)$ in concentrated sulfuric acid in the presence of manganese(IV) oxide. A representative reaction is

$$
\mathrm{MnO}_{2}(s)+2 \mathrm{H}_{2} \mathrm{SO}_{4}(a q)+2 \mathrm{NaCl}(a q) \longrightarrow \mathrm{MnSO}_{4}(a q)+\mathrm{Na}_{2} \mathrm{SO}_{4}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{Cl}_{2}(g)
$$

## Compounds of the Halogens

Most of the halides can be categorized as either ionic or covalent. The fluorides and chlorides of many metallic elements, especially those belonging to the alkali metal and alkaline earth metal (except beryllium) families, are ionic compounds. Most of the halides of nonmetals such as sulfur and phosphorus are covalent compounds. The oxidation numbers of the halogens can vary from -1 to +7 . The only exception is fluorine. Because it is the most electronegative element, fluorine can have only two oxidation numbers, 0 (as in $\mathrm{F}_{2}$ ) and -1 , in all its compounds.

The hydrogen halides, an important class of halogen compounds, can be formed by the direct combination of the elements:

$$
\mathrm{H}_{2}(g)+\mathrm{X}_{2}(g) \rightleftarrows 2 \mathrm{HX}(g)
$$

where X denotes a halogen atom. These reactions (especially the ones involving $\mathrm{F}_{2}$ and $\mathrm{Cl}_{2}$ ) can occur with explosive violence. Industrially, hydrogen chloride is produced as a by-product in the manufacture of chlorinated hydrocarbons:

$$
\mathrm{C}_{2} \mathrm{H}_{6}(g)+\mathrm{Cl}_{2}(g) \longrightarrow \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{Cl}(g)+\mathrm{HCl}(g)
$$

In the laboratory, hydrogen fluoride and hydrogen chloride can be prepared by combining the metal halides with concentrated sulfuric acid:

$$
\begin{gathered}
\mathrm{CaF}_{2}(s)+\mathrm{H}_{2} \mathrm{SO}_{4}(a q) \longrightarrow 2 \mathrm{HF}(g)+\mathrm{CaSO}_{4}(s) \\
2 \mathrm{NaCl}(s)+\mathrm{H}_{2} \mathrm{SO}_{4}(a q) \longrightarrow 2 \mathrm{HCl}(g)+\mathrm{Na}_{2} \mathrm{SO}_{4}(a q)
\end{gathered}
$$

Hydrogen bromide and hydrogen iodide cannot be prepared this way because they are oxidized to elemental bromine and iodine. For example, the reaction between NaBr and $\mathrm{H}_{2} \mathrm{SO}_{4}$ is

$$
2 \mathrm{NaBr}(s)+2 \mathrm{H}_{2} \mathrm{SO}_{4}(a q) \longrightarrow \mathrm{Br}_{2}(l)+\mathrm{SO}_{2}(g)+\mathrm{Na}_{2} \mathrm{SO}_{4}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l)
$$

Instead, hydrogen bromide is prepared by first reacting bromine with phosphorus to form phosphorus tribromide:

$$
\mathrm{P}_{4}(s)+6 \mathrm{Br}_{2}(l) \longrightarrow 4 \mathrm{PBr}_{3}(l)
$$

Next, $\mathrm{PBr}_{3}$ is treated with water to yield HBr :

$$
\operatorname{PBr}_{3}(l)+3 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 3 \mathrm{HBr}(g)+\mathrm{H}_{3} \mathrm{PO}_{3}(a q)
$$

Hydrogen iodide can be prepared in a similar manner.
HF is so highly reactive that it attacks silica and silicates:

$$
6 \mathrm{HF}(a q)+\mathrm{SiO}_{2}(g) \longrightarrow \mathrm{H}_{2} \mathrm{SiF}_{6}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l)
$$

This property makes HF suitable for etching glass and is the reason that hydrogen fluoride must be kept in plastic or inert metal (e.g., Pt) containers. Hydrogen fluoride is used in the manufacture of Freons (see Chapter 17); for example,

$$
\begin{aligned}
\mathrm{CCl}_{4}(l)+\mathrm{HF}(g) & \longrightarrow \mathrm{CFCl}_{3}(g)+\mathrm{HCl}(g) \\
\mathrm{CFCl}_{3}(g)+\mathrm{HF}(g) & \longrightarrow \mathrm{CF}_{2} \mathrm{Cl}_{2}(g)+\mathrm{HCl}(g)
\end{aligned}
$$

It is also important in the production of aluminum. Hydrogen chloride is used in the preparation of hydrochloric acid, inorganic chlorides, and in various metallurgical processes. Hydrogen bromide and hydrogen iodide do not have any major industrial uses.

Aqueous solutions of hydrogen halides are acidic. The strength of the acids increases as follows:

$$
\mathrm{HF} \ll \mathrm{HCl}<\mathrm{HBr}<\mathrm{HI}
$$

The halogens also form a series of oxoacids with the following general formulas:

| HXO | $\mathrm{HXO}_{2}$ | $\mathrm{HXO}_{3}$ | $\mathrm{HXO}_{4}$ <br> Hypohalous acid |
| :---: | :---: | :---: | :---: |
| Halous acid |  |  |  |

(for example, HClO , hypochlorous acid; $\mathrm{HClO}_{2}$, chlorous acid; $\mathrm{HClO}_{3}$, chloric acid; and $\mathrm{HClO}_{4}$, perchloric acid).

Chlorous acid $\left(\mathrm{HClO}_{2}\right)$ is the only known halous acid. All the halogens except fluorine form halic and perhalic acids. The Lewis structures of the chlorine oxoacids are

|  |  | $\begin{gathered} \mathrm{H}: O ̣: \ddot{\mathrm{C}}: \ddot{\mathrm{C}}: \ddot{\mathrm{O}}: \\ \quad: \mathrm{Ọ}: \end{gathered}$ |  |
| :---: | :---: | :---: | :---: |
| Hypochlorous acid | Chlorous acid | Chloric acid | Perchloric acid |

For a given halogen, the acid strength decreases from perhalic acid to hypohalous acid [ 14 Section 16.9].

Table 24.5 lists some of the halogen compounds. Periodic acid $\left(\mathrm{HIO}_{4}\right)$ does not appear because this compound cannot be isolated in the pure form. Instead the formula $\mathrm{H}_{5} \mathrm{IO}_{6}$ is often used to represent periodic acid.

## Uses of the Halogens

Applications of the halogens and their compounds are widespread in industry, health care, and other areas. One such application is fluoridation, the practice of adding small quantities of fluorides (about 1 ppm by mass) such as NaF to drinking water to reduce dental caries.

One of the most important inorganic fluorides is uranium hexafluoride $\left(\mathrm{UF}_{6}\right)$, which is essential to the gaseous diffusion process for separating isotopes of uranium (U-235 and U-238). Industrially, fluorine is used to produce polytetrafluoroethylene, a polymer better known as Teflon:

$$
\left.+\mathrm{CF}_{2}-\mathrm{CF}_{2}\right)_{n}
$$

where $n$ is a large number. Teflon is used in electrical insulators, high-temperature plastics, cooking utensils, and so on.

Chlorine plays an important biological role in the human body, where the chloride ion is the principal anion in intracellular and extracellular fluids. Chlorine is widely used as an industrial bleaching agent for paper and textiles. Ordinary household laundry bleach contains the active ingredient sodium hypochlorite (about 5 percent by mass), which is prepared by combining chlorine gas with a cold solution of sodium hydroxide:

$$
\mathrm{Cl}_{2}(g)+2 \mathrm{NaOH}(a q) \longrightarrow \mathrm{NaCl}(a q)+\mathrm{NaClO}(a q)+\mathrm{H}_{2} \mathrm{O}(l)
$$

Chlorine is also used to purify water and disinfect swimming pools. When chlorine dissolves in water, it undergoes the following reaction:

$$
\mathrm{Cl}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{HCl}(a q)+\mathrm{HClO}(a q)
$$

It is thought that the $\mathrm{ClO}^{-}$ions destroy bacteria by oxidizing life-sustaining compound within them.

Chlorinated methanes, such as carbon tetrachloride and chloroform, are useful organic solvents. Large quantities of chlorine are used to produce insecticides, such as DDT. However, in

## TABLE 24.5 Common Compounds of Halogens*

| Compound | F | Cl | Br | l |
| :--- | :--- | :--- | :--- | :--- |

| Oxides | $\mathrm{OF}_{2}(-1)$ | $\mathrm{Cl}_{2} \mathrm{O}(+1)$ | $\mathrm{Br}_{2} \mathrm{O}(+1)$ | $\mathrm{I}_{2} \mathrm{O}_{5}(+5)$ |
|  |  | $\mathrm{ClO}_{2}(+4)$ | $\mathrm{BrO}_{2}(+4)$ |  |
|  | $\mathrm{Cl}_{2} \mathrm{O}_{7}(+7)$ |  |  |  |
| Oxoacids | $\mathrm{HFO}(-1)$ | $\mathrm{HClO}(+1)$ | $\mathrm{HBrO}(+1)$ | $\mathrm{HIO}(+1)$ |
|  |  | $\mathrm{HClO}_{2}(+3)$ |  |  |
|  |  | $\mathrm{HCO}_{3}(+5)$ | $\mathrm{HBrO}_{3}(+5)$ | $\mathrm{HIO}_{3}(+5)$ |
|  |  | $\mathrm{HCO}_{4}(+7)$ | $\mathrm{HBrO}_{4}(+7)$ | $\mathrm{H}_{5} \mathrm{IO}_{6}(+7)$ |

[^52]view of the damage they inflict on the environment, the use of many of these compounds is either totally banned or greatly restricted in the United States. Chlorine is also used to produce polymers such as poly(vinyl chloride).

So far as we know, bromine compounds occur naturally only in some marine organisms. Seawater is about $1 \times 10^{-3} M \mathrm{Br}^{-}$, so it is the main source of bromine. Bromine is used to prepare ethylene dibromide $\left(\mathrm{BrCH}_{2} \mathrm{CH}_{2} \mathrm{Br}\right)$, which is used as an insecticide and as a scavenger for lead (i.e., to combine with lead) in gasoline to keep lead deposits from clogging engines. Studies have shown that ethylene dibromide is a very potent carcinogen.

Bromine combines directly with silver to form silver bromide ( AgBr ), which is used in photographic films.

Iodine is not used as widely as the other halogens. A 50 percent (by mass) alcohol solution of iodine, known as tincture of iodine, is used medicinally as an antiseptic. Iodine is an essential constituent of the thyroid hormone thyroxine:

Iodine deficiency in the diet may result in enlargement of the thyroid gland (known as goiter). Iodized table salt sold in the United States usually contains 0.01 percent KI or NaI, which is more than sufficient to satisfy the 1 mg of iodine per week required for the formation of thyroxine in the human body.

Silver iodide (AgI) is a pale-yellow solid that darkens when exposed to light. In this respect, it is similar to silver bromide. Silver iodide is sometimes used in cloud seeding, a process for inducing rainfall on a small scale (Figure 24.20). The advantage of using silver iodide is that enormous numbers of nuclei (i.e., small particles of silver iodide on which ice crystals can form) become available. About $10^{15}$ nuclei are produced from 1 g of AgI by vaporizing an acetone solution of silver iodide in a hot flame. The nuclei are then dispersed into the clouds from an airplane.

Figure 24.20 Cloud seeding using AgI particles.

## Applying What You've Learned

King George III of Britain (1738-1820) suffered from periodic physical and mental illness throughout his adult life. Several of the episodes were severe enough to render the king temporarily unable to rule. Although most of the king's symptoms are now attributed to porphyria, a hereditary metabolic disorder, a 2004 analysis of samples of the king's hair revealed high levels of arsenic. One possibility that has been raised regarding the source of the arsenic is the antimony used in the king's treatment for chronic illness. Antimony is an element known since ancient times and used in cosmetics (stibnite, the most common antimony ore was used as eye liner during biblical times) and in medicine.

## Writing Prompt:

Research arsenic and antimony, and write a 500-word essay describing their history and explaining how medicinal antimony might have been the source of the arsenic found in the hair samples from Britain's King George III.

## Chapter Summary

## Section 24.1

- Properties of nonmetals vary more than properties of metals.
- Nonmetal elements may be solid, liquid, or gaseous and may exhibit both positive and negative oxidation numbers in their compounds.

## Section 24.2

- Hydrogen atoms contain one proton and one electron. They are the simplest atoms.
- Hydrogen combines with many metals and nonmetals to form hydrides; some hydrides are ionic and some are covalent.
- There are three isotopes of hydrogen: ${ }_{1}^{1} \mathrm{H},{ }_{1}^{2} \mathrm{H}$ (deuterium), and ${ }_{1}^{3} \mathrm{H}$ (tritium).
- "Heavy water" $\left(\mathrm{D}_{2} \mathrm{O}\right)$ contains deuterium.

## Section 24.3

- The important inorganic compounds of carbon are the carbides; the cyanides, most of which are extremely toxic; carbon monoxide, also toxic and a major air pollutant; the carbonates and bicarbonates; and carbon dioxide, an end product of metabolism and a component of the global carbon cycle.

## Section 24.4

- Elemental nitrogen $\left(\mathrm{N}_{2}\right)$ contains a triple bond and is very stable.
- Compounds in which nitrogen has oxidation numbers from -3 to +5 are formed between nitrogen and hydrogen and/or oxygen atoms.
- Ammonia $\left(\mathrm{NH}_{3}\right)$ is widely used in fertilizers.
- White phosphorus $\left(\mathrm{P}_{4}\right)$ is highly toxic, very reactive, and flammable; the polymeric red phosphorus $\left[\left(\mathrm{P}_{4}\right)_{n}\right]$ is more stable.
- Phosphorus forms oxides and halides with oxidation numbers of +3 and +5 and several oxoacids. The phosphates are the most important phosphorus compounds.

## Section 24.5

- Elemental oxygen $\left(\mathrm{O}_{2}\right)$ is paramagnetic and contains two unpaired electrons.
- Oxygen forms ozone $\left(\mathrm{O}_{3}\right)$, oxides $\left(\mathrm{O}^{2-}\right)$, peroxides $\left(\mathrm{O}_{2}^{2-}\right)$, and superoxides $\left(\mathrm{O}_{2}^{-}\right)$.
- The most abundant element in Earth's crust, oxygen is essential for life on Earth.
- Sulfur is obtained from Earth's crust as a molten liquid via the Frasch process.
- Sulfur exists in a number of allotropic forms and has a variety of oxidation numbers in its compounds.
- Sulfuric acid is the cornerstone of the chemical industry. It is produced from sulfur via sulfur dioxide and sulfur trioxide by means of the contact process.

## Section 24.6

- The halogens are toxic and reactive elements that are found only in compounds with other elements.
- Fluorine and chlorine are strong oxidizing agents and are prepared by electrolysis.
- With the exception of fluorine, the halogens may have both negative and positive oxidation states.
- Fluorine's oxidation state in its compounds is always -1 .

## Questions and Problems

## Section 24.1: General Properties of Nonmetals

## Review Questions

Ef24.1 Without referring to Figure 24.1, state whether each of the following elements are metals, metalloids, or nonmetals: (a) Cs , (b) Ge , (c) I , (d) Kr , (e) W , (f) Ga , (g) Te , (h) Bi .
24.2 List two chemical and two physical properties that distinguish a metal from a nonmetal.
24.3 Make a list of physical and chemical properties of chlorine $\left(\mathrm{Cl}_{2}\right)$ and magnesium. Comment on their differences with reference to the fact that one is a metal and the other is a nonmetal.
24.4 Carbon is usually classified as a nonmetal. However, the graphite used in "lead" pencils conducts electricity. Look at a pencil, and list two nonmetallic properties of graphite.

## Section 24.2: Hydrogen

## Review Questions

24.5 Explain why hydrogen has a unique position in the periodic table.
24.6 Describe two laboratory and two industrial preparations for hydrogen.
24.7 Hydrogen exhibits three types of bonding in its compounds. Describe each type of bonding with an example.
24.8 What are interstitial hydrides?

E 24.9 Give the name of (a) an ionic hydride and (b) a covalent hydride. In each case describe the preparation and give the structure of the compound.
24.10 Describe what is meant by the "hydrogen economy."

## Problems

\&24.11 Elements number 17 and 20 form compounds with hydrogen. Write the formulas for these two compounds, and compare their chemical behavior in water.
24.12 Give an example of hydrogen as (a) an oxidizing agent and (b) a reducing agent.

E 24.13 Compare the physical and chemical properties of the hydrides of each of the following elements: $\mathrm{Na}, \mathrm{Ca}, \mathrm{C}, \mathrm{N}, \mathrm{O}, \mathrm{Cl}$.
24.14 Suggest a physical method that would enable you to separate hydrogen gas from neon gas.
$\leftrightarrows$ 24.15 Write a balanced equation to show the reaction between $\mathrm{CaH}_{2}$ and $\mathrm{H}_{2} \mathrm{O}$. How many grams of $\mathrm{CaH}_{2}$ are needed to produce 26.4 L of $\mathrm{H}_{2}$ gas at $20^{\circ} \mathrm{C}$ and 746 mmHg ?

E24.16 How many kilograms of water must be processed to obtain 2.0 L of $\mathrm{D}_{2}$ at $25^{\circ} \mathrm{C}$ and 0.90 atm pressure? Assume that deuterium abundance is 0.015 percent and that recovery is 80 percent.

E 24.17 Predict the outcome of the following reactions:
(a) $\mathrm{CuO}(s)+\mathrm{H}_{2}(g)$
(b) $\mathrm{Na}_{2} \mathrm{O}(s)+\mathrm{H}_{2}(g) \longrightarrow$
24.18 Starting with $\mathrm{H}_{2}$, describe how you would prepare (a) HCl , (b) $\mathrm{NH}_{3}$, and (c) LiOH .

## Section 24.3: Carbon

## Review Questions

24.19 Give an example of a carbide and a cyanide.
24.20 How are cyanide ions used in metallurgy?
24.21 Briefly discuss the preparation and properties of carbon monoxide and carbon dioxide.
24.22 What is coal?
24.23 Describe two chemical differences between CO and $\mathrm{CO}_{2}$.
24.24 Describe the reaction between $\mathrm{CO}_{2}$ and $\mathrm{OH}^{-}$in terms of a Lewis acid-base reaction.

## Problems

© 24.25 Draw a Lewis structure for the $\mathrm{C}_{2}^{2-}$ ion.
E24.26 Balance the following equations:
(a) $\mathrm{Be}_{2} \mathrm{C}(s)+\mathrm{H}_{2} \mathrm{O}(l)$
(b) $\mathrm{CaC}_{2}(s)+\mathrm{H}_{2} \mathrm{O}(l)$
§24.27 Unlike $\mathrm{CaCO}_{3}, \mathrm{Na}_{2} \mathrm{CO}_{3}$ does not readily yield $\mathrm{CO}_{2}$ when heated. On the other hand, $\mathrm{NaHCO}_{3}$ undergoes thermal decomposition to produce $\mathrm{CO}_{2}$ and $\mathrm{Na}_{2} \mathrm{CO}_{3}$. (a) Write a balanced equation for the reaction. (b) How would you test for the $\mathrm{CO}_{2}$ evolved? [Hint: Treat the gas with limewater, an aqueous solution of $\mathrm{Ca}(\mathrm{OH})_{2}$.]
24.28 Two solutions are labeled A and B . Solution A contains $\mathrm{Na}_{2} \mathrm{CO}_{3}$, and solution B contains $\mathrm{NaHCO}_{3}$. Describe how you would distinguish between the two solutions if you were provided with an $\mathrm{MgCl}_{2}$ solution. (Hint: You need to know the solubilities of $\mathrm{MgCO}_{3}$ and $\mathrm{MgHCO}_{3}$.)
24.29 Magnesium chloride is dissolved in a solution containing sodium bicarbonate. On heating, a white precipitate is formed. Explain what causes the precipitation.

E 24.30 A few drops of concentrated ammonia solution added to a calcium bicarbonate solution cause a white precipitate to form. Write a balanced equation for the reaction.
\$ 24.31 Sodium hydroxide is hygroscopic-that is, it absorbs moisture when exposed to the atmosphere. A student placed a pellet of NaOH on a watch glass. A few days later, she noticed that the pellet was covered with a white solid. What is the identity of this solid? (Hint: Air contains $\mathrm{CO}_{2}$.)
24.32 A piece of red-hot magnesium ribbon will continue to burn in an atmosphere of $\mathrm{CO}_{2}$ even though $\mathrm{CO}_{2}$ does not support combustion. Explain.
24.33 Is carbon monoxide isoelectronic with nitrogen $\left(\mathrm{N}_{2}\right)$ ?

## Section 24.4: Nitrogen and Phosphorus

## Review Questions

24.34 Describe a laboratory and an industrial preparation of nitrogen gas.
24.35 What is meant by nitrogen fixation? Describe a process for fixation of nitrogen on an industrial scale.
24.36 Describe an industrial preparation of phosphorus.
24.37 Why is the $\mathrm{P}_{4}$ molecule unstable?

## Problems

E 24.38 Nitrogen can be obtained by (a) passing ammonia over red-hot copper(II) oxide and (b) heating ammonium dichromate [one of the products is $\mathrm{Cr}(\mathrm{III})$ oxide]. Write a balanced equation for each preparation.

EI 24.39 Write balanced equations for the preparation of sodium nitrite by (a) heating sodium nitrate and (b) heating sodium nitrate with carbon.
$\boldsymbol{G}$ 24.40 Sodium amide $\left(\mathrm{NaNH}_{2}\right)$ reacts with water to produce sodium hydroxide and ammonia. Describe this reaction as a Brønsted acid-base reaction.
§ 24.41 Write a balanced equation for the formation of urea, $\left[\left(\mathrm{NH}_{2}\right)_{2} \mathrm{CO}\right]$, from carbon dioxide and ammonia. Should the reaction be run at a high or low pressure to maximize the yield?
24.42 Some farmers feel that lightning helps produce a better crop. What is the scientific basis for this belief?
24.43 Explain why nitric acid can be reduced but not oxidized.
24.44 At 620 K , the vapor density of ammonium chloride relative to hydrogen $\left(\mathrm{H}_{2}\right)$ under the same conditions of temperature and pressure is 14.5 , although, according to its formula mass, it should have a vapor density of 26.8. How would you account for this discrepancy?
$\leftrightarrows$ 24.45 Write a balanced equation for each of the following processes: (a) On heating, ammonium nitrate produces nitrous oxide. (b) On heating, potassium nitrate produces potassium nitrite and oxygen gas. (c) On heating, lead nitrate produces lead(II) oxide, nitrogen dioxide $\left(\mathrm{NO}_{2}\right)$, and oxygen gas.
24.46 Explain why, under normal conditions, the reaction of zinc with nitric acid does not produce hydrogen.
$\boldsymbol{Y}$ 24.47 Potassium nitrite can be produced by heating a mixture of potassium nitrate and carbon. Write a balanced equation for this reaction. Calculate the theoretical yield of $\mathrm{KNO}_{2}$ produced by heating 57.0 g of $\mathrm{KNO}_{3}$ with an excess of carbon.

G24.48 Predict the geometry of nitrous oxide $\left(\mathrm{N}_{2} \mathrm{O}\right)$, by the VSEPR method, and draw resonance structures for the molecule. (Hint: The atoms are arranged as NNO.)
© 24.49 Consider the reaction

$$
\mathrm{N}_{2}(g)+\mathrm{O}_{2}(g) \rightleftarrows 2 \mathrm{NO}(g)
$$

Given that the $\Delta G^{\circ}$ for the reaction at 298 K is $173.4 \mathrm{~kJ} / \mathrm{mol}$, calculate (a) the standard free energy of formation of NO , (b) $K_{P}$ for the reaction, and (c) $K_{\mathrm{c}}$ for the reaction.
$\leftrightarrows$ 24.50 From the data in Appendix 2, calculate $\Delta H^{\circ}$ for the synthesis of NO (which is the first step in the manufacture of nitric acid) at $25^{\circ} \mathrm{C}$ :

$$
4 \mathrm{NH}_{3}(g)+5 \mathrm{O}_{2}(g) \longrightarrow 4 \mathrm{NO}(g)+6 \mathrm{H}_{2} \mathrm{O}(l)
$$

E24.51 When 1.645 g of white phosphorus is dissolved in 75.5 g of $\mathrm{CS}_{2}$, the solution boils at $46.709^{\circ} \mathrm{C}$, whereas pure $\mathrm{CS}_{2}$ boils at $46.300^{\circ} \mathrm{C}$. The molal boiling-point elevation constant for $\mathrm{CS}_{2}$ is $2.34^{\circ} \mathrm{C} / \mathrm{m}$. Calculate the molar mass of white phosphorus, and give the molecular formula.
24.52 Explain why two N atoms can form a double bond or a triple bond, whereas two P atoms normally can form only a single bond.
$\boldsymbol{Y}$ 24.53 Dinitrogen pentoxide is a product of the reaction between $\mathrm{P}_{4} \mathrm{O}_{10}$ and $\mathrm{HNO}_{3}$. Write a balanced equation for this reaction. Calculate the theoretical yield of $\mathrm{N}_{2} \mathrm{O}_{5}$ if 79.4 g of $\mathrm{P}_{4} \mathrm{O}_{10}$ is combined with an excess of $\mathrm{HNO}_{3}$. (Hint: One of the products is $\mathrm{HPO}_{3}$.)
24.54 Starting with elemental phosphorus $\left(\mathrm{P}_{4}\right)$, show how you would prepare phosphoric acid.
24.55 What is the hybridization of phosphorus in the phosphonium ion $\left(\mathrm{PH}_{4}^{+}\right)$?
24.56 Explain why (a) $\mathrm{NH}_{3}$ is more basic than $\mathrm{PH}_{3}$, (b) $\mathrm{NH}_{3}$ has a higher boiling point than $\mathrm{PH}_{3}$, (c) $\mathrm{PCl}_{5}$ exists but $\mathrm{NCl}_{5}$ does not, and (d) $\mathrm{N}_{2}$ is more inert than $\mathrm{P}_{4}$.

## Section 24.5: Oxygen and Sulfur

## Review Questions

24.57 Describe one industrial and one laboratory preparation of $\mathrm{O}_{2}$.
24.58 Give an account of the various kinds of oxides that exist, and illustrate each type by two examples.
24.59 Hydrogen peroxide can be prepared by treating barium peroxide with sulfuric acid. Write a balanced equation for this reaction.
24.60 Describe the Frasch process for obtaining sulfur.
24.61 Describe the contact process for the production of sulfuric acid.
24.62 How is hydrogen sulfide generated in the laboratory?

## Problems

24.63 One of the steps involved in the depletion of ozone in the stratosphere by nitric oxide may be represented as

$$
\mathrm{NO}(g)+\mathrm{O}_{3}(g) \longrightarrow \mathrm{NO}_{2}(g)+\mathrm{O}_{2}(g)
$$

From the data in Appendix 2, calculate $\Delta G^{\circ}, K_{P}$, and $K_{\mathrm{c}}$ for the reaction at $25^{\circ} \mathrm{C}$.
24.64 Draw molecular orbital energy level diagrams for $\mathrm{O}_{2}, \mathrm{O}_{2}^{-}$, and $\mathrm{O}_{2}^{2-}$.

H24.65 Hydrogen peroxide is unstable and decomposes readily:

$$
2 \mathrm{H}_{2} \mathrm{O}_{2}(a q) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{O}_{2}(g)
$$

This reaction is accelerated by light, heat, or a catalyst. (a) Explain why hydrogen peroxide sold in drugstores comes in dark bottles. (b) The concentrations of aqueous hydrogen peroxide solutions are normally expressed as percent by mass. In the decomposition of hydrogen peroxide, how many liters of oxygen gas can be produced at STP from 15.0 g of a $7.50 \%$ hydrogen peroxide solution?
24.66 Oxygen forms double bonds in $\mathrm{O}_{2}$, but sulfur forms single bonds in $\mathrm{S}_{8}$. Explain.

Ef 24.67 What are the oxidation numbers of O and F in HFO?

- 24.68 In 2004 about 48 million tons of sulfuric acid was produced in the United States. Calculate the amount of sulfur (in grams and moles) used to produce that amount of sulfuric acid.
24.69 Sulfuric acid is a dehydrating agent. Write balanced equations for the reactions between sulfuric acid and the following substances: (a) HCOOH , (b) $\mathrm{H}_{3} \mathrm{PO}_{4}$, (c) $\mathrm{HNO}_{3}$, (d) $\mathrm{HClO}_{3}$. (Hint: Sulfuric acid is not decomposed by the dehydrating action.)

E 24.70 Calculate the amount of $\mathrm{CaCO}_{3}$ (in grams) that would be required to react with 50.6 g of $\mathrm{SO}_{2}$ emitted by a power plant.
24.71 $\mathrm{SF}_{6}$ exists, but $\mathrm{OF}_{6}$ does not. Explain.
24.72 Explain why $\mathrm{SCl}_{6}, \mathrm{SBr}_{6}$, and $\mathrm{SI}_{6}$ cannot be prepared.
$\boldsymbol{\leftrightarrows}$ 24.73 The bad smell of water containing hydrogen sulfide can be removed by the action of chlorine. The reaction is

$$
\mathrm{H}_{2} \mathrm{~S}(a q)+\mathrm{Cl}_{2}(a q) \longrightarrow 2 \mathrm{HCl}(a q)+\mathrm{S}(s)
$$

If the hydrogen sulfide content of contaminated water is 22 ppm by mass, calculate the amount of $\mathrm{Cl}_{2}$ (in grams) required to remove all the $\mathrm{H}_{2} \mathrm{~S}$ from $2.0 \times 10^{2}$ gal of water. ( 1 gallon $=$ 3.785 L.)
24.74 Compare the physical and chemical properties of $\mathrm{H}_{2} \mathrm{O}$ and $\mathrm{H}_{2} \mathrm{~S}$.
$\boldsymbol{H} 24.75$ Concentrated sulfuric acid reacts with sodium iodide to produce molecular iodine, hydrogen sulfide, and sodium hydrogen sulfate. Write a balanced equation for the reaction.
24.76 Describe two reactions in which sulfuric acid acts as an oxidizing agent.

## Section 24.6: The Halogens

## Review Questions

24.77 Describe an industrial method for preparing each of the halogens.
24.78 Name the major uses of the halogens.

## Problems

-1 24.79 Draw structures for (a) $(\mathrm{HF})_{2}$ and (b) $\mathrm{HF}_{2}^{-}$.
24.80 Sulfuric acid is a weaker acid than hydrochloric acid. Yet hydrogen chloride is evolved when concentrated sulfuric acid is added to sodium chloride. Explain.
124.81 Use the VSEPR method to predict the geometries of the following species: (a) $\mathrm{I}_{3}^{-}$, (b) $\mathrm{SiCl}_{4}$, (c) $\mathrm{PF}_{5}$, (d) $\mathrm{SF}_{4}$.
24.82 Metal chlorides can be prepared in a number of ways:
(a) direct combination of metal and molecular chlorine,
(b) reaction between metal and hydrochloric acid, (c) acid-base neutralization, (d) metal carbonate treated with hydrochloric acid, (e) precipitation reaction. Give an example for each type of preparation.

- 24.83 A $375-\mathrm{gal}$ tank is filled with water containing 167 g of bromine in the form of $\mathrm{Br}^{-}$ions. How many liters of $\mathrm{Cl}_{2}$ gas at 1.00 atm and $20^{\circ} \mathrm{C}$ will be required to oxidize all the bromide to molecular bromine?
24.84 Hydrogen fluoride can be prepared by the action of sulfuric acid on sodium fluoride. Explain why hydrogen bromide cannot be prepared by the action of the same acid on sodium bromide.
\& 24.85 What volume of bromine $\left(\mathrm{Br}_{2}\right)$ vapor measured at $100^{\circ} \mathrm{C}$ and 700 mmHg pressure would be obtained if 2.00 L of dry chlorine $\left(\mathrm{Cl}_{2}\right)$, measured at $15^{\circ} \mathrm{C}$ and 760 mmHg , was absorbed by a potassium bromide solution?
24.86 Aqueous copper(II) sulfate solution is blue. When aqueous potassium fluoride is added to the $\mathrm{CuSO}_{4}$ solution, a green precipitate is formed. If aqueous potassium chloride is added instead, a bright-green solution is formed. Explain what happens in each case.
$\boldsymbol{\xi} \mathbf{2 4 . 8 7}$ Iodine pentoxide $\left(\mathrm{I}_{2} \mathrm{O}_{5}\right)$ is sometimes used to remove carbon monoxide from the air by forming carbon dioxide and iodine. Write a balanced equation for this reaction, and identify species that are oxidized and reduced.
24.88 Show that chlorine, bromine, and iodine are very much alike by giving an account of their behavior (a) with hydrogen, (b) in producing silver salts, (c) as oxidizing agents, and (d) with sodium hydroxide. (e) In what respects is fluorine not a typical halogen element?

## Additional Problems

$\boldsymbol{\Psi}$ 24.89 Write a balanced equation for each of the following reactions: (a) Heating phosphorous acid yields phosphoric acid and phosphine $\left(\mathrm{PH}_{3}\right)$. (b) Lithium carbide reacts with hydrochloric acid to give lithium chloride and methane. (c) Bubbling HI gas through an aqueous solution of $\mathrm{HNO}_{2}$ yields molecular iodine and nitric oxide. (d) Hydrogen sulfide is oxidized by chlorine to give HCl and $\mathrm{SCl}_{2}$.
24.90 Both $\mathrm{N}_{2} \mathrm{O}$ and $\mathrm{O}_{2}$ support combustion. Suggest one physical and one chemical test to distinguish between the two gases.
\& 24.91 (a) Which of the following compounds has the greatest ionic character: $\mathrm{PCl}_{5}, \mathrm{SiCl}_{4}, \mathrm{CCl}_{4}, \mathrm{BCl}_{3}$ ? (b) Which of the following ions has the smallest ionic radius: $\mathrm{F}^{-}, \mathrm{C}^{4-}, \mathrm{N}^{3-}, \mathrm{O}^{2-}$ ? (c) Which of the following atoms has the highest ionization energy: $\mathrm{F}, \mathrm{Cl}$, $\mathrm{Br}, \mathrm{I}$ ? (d) Which of the following oxides is most acidic: $\mathrm{H}_{2} \mathrm{O}$, $\mathrm{SiO}_{2}, \mathrm{CO}_{2}$ ?
24.92 Describe the bonding in the $\mathrm{C}_{2}^{2-}$ ion in terms of the molecular orbital theory.
\&24.93 What is the change in oxidation number for the following reaction?

$$
3 \mathrm{O}_{2} \longrightarrow 2 \mathrm{O}_{3}
$$

24.94 Starting with deuterium oxide $\left(\mathrm{D}_{2} \mathrm{O}\right)$, describe how you would prepare (a) NaOD , (b) DCl , (c) $\mathrm{ND}_{3}$, (d) $\mathrm{C}_{2} \mathrm{D}_{2}$, (e) $\mathrm{CD}_{4}$, and (f) $\mathrm{D}_{2} \mathrm{SO}_{4}$.
\& 24.95 Solid $\mathrm{PCl}_{5}$ exists as $\left[\mathrm{PCl}_{4}^{+}\right]\left[\mathrm{PCl}_{6}^{-}\right]$. Draw Lewis structures for these ions. Describe the hybridization state of the P atoms.
24.96 Consider the Frasch process. (a) How is it possible to heat water well above $100^{\circ} \mathrm{C}$ without turning it into steam? (b) Why is water sent down the outermost pipe? (c) Why would excavating a mine and digging for sulfur be a dangerous procedure for obtaining the element?
$\leftrightarrows$ 24.97 As we saw in Section 23.2, the reduction of iron oxides is accomplished by using carbon monoxide as a reducing agent. Starting with coke in a blast furnace, the following equilibrium plays a key role in the extraction of iron:

$$
\mathrm{C}(\mathrm{~s})+\mathrm{CO}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{CO}(\mathrm{~g})
$$

Use the data in Appendix 2 to calculate the equilibrium constant at $25^{\circ} \mathrm{C}$ and $100^{\circ} \mathrm{C}$. Assume $\Delta H^{\circ}$ and $\Delta S^{\circ}$ to be independent of temperature.
24.98 Lubricants used in watches usually consist of long-chain hydrocarbons. Oxidation by air forms solid polymers that eventually destroy the effectiveness of the lubricants. It is believed that one of the initial steps in the oxidation is removal of a hydrogen atom (hydrogen abstraction). By replacing the hydrogen atoms at reactive sites with deuterium atoms, it is possible to substantially slow down the overall oxidation rate. Why? (Hint: Consider the kinetic isotope effect.)
24.99 How are lightbulbs frosted? (Hint: Consider the action of hydrofluoric acid on glass, which is made of silicon dioxide.)
24.100 Life evolves to adapt to its environment. In this respect, explain why life most frequently needs oxygen for survival, rather than the more abundant nitrogen.
$\boldsymbol{H}$ 24.101 A 10.0-g sample of white phosphorus was burned in an excess of oxygen. The product was dissolved in enough water to make 500 mL of solution. Calculate the pH of the solution at $25^{\circ} \mathrm{C}$.
24.102 Predict the physical and chemical properties of astatine, a radioactive element and the last member of Group 7A.
24.103 Assuming ideal behavior, calculate the density of gaseous HF at its normal boiling point $\left(19.5^{\circ} \mathrm{C}\right)$. The experimentally measured density under the same conditions is $3.10 \mathrm{~g} / \mathrm{L}$. Account for the discrepancy between your calculated value and the experimental result.
24.104 Ammonium nitrate is the most important nitrogen-containing fertilizer in the world. Given only air and water as starting materials and any equipment and catalyst at your disposal, describe how you would prepare ammonium nitrate. State conditions under which you can increase the yield in each step.

## Pre-Professional Practice Exam Problems: Verbal Reasoning

Iodine deficiency results in a condition known as goiter, which is characterized by an enlarged thyroid, often appearing as a large, bulbous protrusion on the neck. Although it is relatively rare today, goiter was once common in regions where the soil and food supply are iodine poor, including the northern half of the contiguous United States. In 1918, 30 percent of the men registering for the World War I draft in Michigan were found to have significant goiter symptoms. Many of the young men were so ill as to be disqualified from enlisting in the Army.

In 1922, concerned about the high incidence of goiter in his home state, David Murray Cowie, a professor of pediatrics at the University of Michigan, began a campaign for the addition of a small amount of sodium iodide or potassium iodide to the table salt used by all Americans. Dr. Cowie was actually modeling a successful public health program that had all but eliminated iodine deficiency disorders (IDD) in Switzerland. In 1924 the Morton Salt Company began distributing iodized salt nationwide.

1. The main point of the passage is that
a) goiter was once common but is now rare because of iodized salt.
b) goiter is caused by iodine deficiency.
c) David Murray Cowie was a pediatrician in Michigan.
d) men suffering from goiter were disqualified from serving in the Army.
2. The reason dietary iodine is added to table salt is most likely that
a) sodium iodide closely resembles sodium chloride.
b) citizens of all socioeconomic strata use table salt.
c) sodium iodide is not water soluble.
d) elemental iodine is toxic.
3. The most likely reason it took 2 years to have iodized salt made available nationwide is that
a) shipping took longer without interstate highways.
b) the Morton Salt Company didn't exist before 1924.
c) public health officials had to be convinced that iodization of salt was safe and effective.
d) Michigan was not yet part of the United States.
4. According to the passage, goiter
a) can be caused by a low-salt diet.
b) can be cured by the addition of iodide to the diet.
c) is potentially debilitating.
d) was a more serious public health problem in Switzerland than in the United States.

## Modern Materials Chemistry and the 2005 Nobel Prize

The 2005 Nobel Prize in Chemistry was awarded to Yves Chauvin, Robert H. Grubbs, and Richard R. Schrock for the development of the metathesis method in organic synthesis. In the metathesis method, double bonds in organic molecules are broken, and then new double bonds are formed. In olefin metathesis, a carbon-carbon double bond is broken in each of two olefins. The subsequent formation of two new carbon-carbon double bonds results in products in which the compounds have exchanged substituent groups with each other:

Note that each reactant molecule has one R group and one $\mathrm{R}^{\prime}$ group, whereas each product molecule has two identical groups (i.e., two R groups or two $\mathrm{R}^{\prime}$ groups). This process requires a metal catalyst and is believed to occur by the formation of a four-membered ring:

The metathesis method can be applied to many industrial chemical processes, including those that potentially can produce pharmaceuticals for the treatment of such conditions as bacterial and viral infections, cancer, and Alzheimer's disease.

Student Annotation: Metathesis is a word meaning "an exchange of position," and olefin is an old-fashioned word for an alkene, a molecule with a carbon-carbon double bond.

At the end of this chapter, you will be able to answer questions about modern polymeric materials [ $n$ Page 1022].

## In This Chapter, You Will Learn:

About some of the chemistry involved in the development of modern materials.
Before you begin, you should review

- Functional groups [ $\mathrm{K4}$ Section 10.2]
- Organic polymers [ 14 Section 10.6]

Bottles that can be recycled are made of thermoplastic polymers.

Student Annotation: The systematic name of $\mathrm{C}_{2} \mathrm{H}_{4}$ is ethene, but the common name ethylene is still widely used.

Student Annotation: Recall that species with an unpaired electron are called free radicals [14 Section 8.8].

## Multimedia

Organic and Biochemistry-natural and synthetic polymers.

### 25.1 Polymers

Many biological molecules, such as DNA, starch, and proteins, have very large molecular masses. These molecules are polymers because they are made up of many smaller parts linked together [ 144 Section 10.6]. The prefix poly comes from a Greek root meaning "many," and the small molecules that make up the individual building blocks of polymers are called monomers. Many natural polymers, such as silk and rubber, now have synthetic analogues that are manufactured by the chemical industry.

Polymers are used in many medical applications, such as flexible wound dressings, surgical implants, and prosthetics. Some of these polymers are thermoplastic, which means that they can be melted and reshaped, or heated and bent. Others are thermosetting, which means that their shape is determined as part of the chemical process that formed the polymer. Thermosetting polymers cannot be reshaped easily and are not easily recycled, whereas thermoplastic polymers can be melted down and cast into new shapes in different products.

## Addition Polymers

The simplest type of polymerization reaction involves the bonding of monomer molecules by movement of electrons from a multiple bond into new single bonds between molecules. This type of polymerization is called addition polymerization [ 14 Section 10.6]. A molecule with a carbon-carbon double bond is called an alkene, and a molecule with a carbon-carbon triple bond is called an alkyne. The synthesis of polyethylene from ethylene $\left(\mathrm{C}_{2} \mathrm{H}_{4}\right)$ illustrates an addition polymerization. The arrows with half-pointed heads show movement of a single electron. The process of "splitting open" the double bond is initiated by a molecule with a single $\mathrm{O}-\mathrm{O}$ bond that can be broken in half by heating. The free radical initiator molecule attaches to one of the ethylene carbon atoms and breaks the pi bond between the two carbon atoms in ethylene. Figure 25.1 shows the scheme of addition polymerization with respect to the double bonds opening up to form single bonds between monomer units to form polyethylene from ethylene.

The structure of polyethylene can be represented as $\left.+\mathrm{CH}_{2}-\mathrm{CH}_{2}\right)_{n}$, where $n$ is the number of ethylene monomer molecules that reacted (which could be hundreds, thousands, or more). The end of the chain contains a carbon atom with an unpaired electron (i.e., $-\mathrm{CH}_{2} \mathrm{CH}_{2} \cdot$ ), though, so it must be closed by bonding with another atom. This might be a hydrogen atom (e.g., $-\mathrm{CH}_{2} \mathrm{CH}_{2}-\mathrm{H}$ ), but it might also be part of the initiator molecule (e.g., $-\mathrm{CH}_{2} \mathrm{CH}_{2}-\mathrm{OR}$ ). Although the residue of the initiator molecule has very different chemical properties than the main polymer chain, it will not significantly affect the polymer's properties because the polyethylene chain is so long.

Although the structure of a polyethylene chain is drawn in Figure 25.1 as a straight line, the bond angles around a central carbon atom with four bonds are approximately $109.5^{\circ}$ each [If Section 9.1]. Thus, the "straight" chain really zigzags, instead. The polymer chain bends, too, because there is free rotation about carbon-carbon single bonds. These molecular-level features manifest themselves in such macroscopic properties as flexibility.

It is possible, depending on the reaction conditions, for branches to form off the main polyethylene chain during polymerization. Polymer chains with many branches cannot pack together as efficiently as "straight" or unbranched chains, so branched-chain polyethylene is more flexible and lower in density than straight-chain polyethylene. The difference between branched and unbranched polyethylene is shown schematically in Figure 25.2.

Polyethylene consisting primarily of unbranched chains is known as high-density polyethylene (HDPE), whereas polyethylene that consists primarily of branched chains is known as lowdensity polyethylene (LDPE). HDPE is used in plastic bottles and containers where it is important to maintain shape, whereas LDPE is used in plastic food bags and wraps.

Natural rubber formed from latex is an addition polymer. The monomer unit is isoprene, a molecule with two $\mathrm{C}=\mathrm{C}$ double bonds. In the reaction that forms polyisoprene, a pair of

Figure 25.1 Addition polymerization to form polyethylene from ethylene. Each curved, single-headed arrow represents the movement of one electron.

Molecules of linear polyethylene, or HDPE

A molecule of branched polyethylene, or LDPE
electrons moves from one double bond to form a new double bond between the middle two carbon atoms, and the other double bond opens up to form a carbon-carbon single bond to the next monomer unit.

Natural rubber is not very durable-it only retains its useful properties in a relatively narrow temperature range. To address this problem, Charles Goodyear ${ }^{1}$ developed industrial vulcanization in 1839 , a process in which sulfur is used to create linkages between individual polymer chains in the rubber. By heating the rubber with sulfur $\left(\mathrm{S}_{8}\right)$ under carefully controlled conditions, some of the carbon-hydrogen bonds are broken and replaced with carbon-sulfur bonds. The sulfur atoms are bonded to one or more additional sulfur atoms and then to another polymer chain through another sulfur-carbon bond (Figure 25.3). These linkages, called cross-links, make the rubber much stronger and more rigid than natural polyisoprene. Rubber is an elastomer, a material that can stretch or bend and then return to its original shape as long as the limits of its elasticity are not exceeded. The cross-linking of the polyisoprene chains plays an important role in maintaining rubber's elastomer properties.

Goodyear, the current supplier of tires to NASCAR teams, varies the composition of the rubber in its tires for each race depending on the expected tire wear and banking of the track. The left- and right-side tires can even be of different compositions depending on the track layout and

[^53]Figure 25.2 Linear polyethylene is used to make plastic milk bottles. Plastic bags and wrap like Glad Cling Wrap are made from branched polyethylene.

Student Annotation: Each tire used in the NASCAR race series costs approximately $\$ 400$. A single race car can go through as many as 32 tires in one 500 -mile race, depending on track conditions. There are dozens of races throughout the year, and even more tires are used up during practices and prerace qualifying. It takes a lot of tires to compete in NASCAR!

Figure 25.3 Vulcanization.

Student Annotation: This figure shows the structure of a general "vinyl" compound. Styrene and vinyl chloride are vinyl compounds in which $R$ is a phenyl group and a chlorine atom, respectively.

Student Annotation: Traditional record albums are made of PVC mixed with carbon.

conditions. Softer tire compounds offer more grip but wear out faster, whereas harder compounds last longer but grip less.

Many other molecules containing carbon-carbon double bonds can form addition polymers. Styrene [Figure 25.4(a)] is an analogue of ethylene in which a hydrogen atom has been replaced with a $\mathrm{C}_{6} \mathrm{H}_{5}$ (a phenyl) group. The polymerization of styrene forms polystyrene (Figure 25.5). As a foam (with air or some other gas blown into the solid), polystyrene is used in disposable cups and plates as well as Styrofoam insulation and craft materials. Vinyl chloride [Figure 25.4(b)], an analogue of ethylene in which one of the hydrogen atoms has been replaced by a chlorine atom, is another monomer that can be used to form a polymer with many common uses. Poly (vinyl chloride) (PVC) is used in pipes and fittings, some plastic wraps, and the classic "vinyl" records that were the predecessors to musical recordings on cassettes and CDs.

Figure 25.4 (a) Styrene, (b) vinyl chloride, and (c) tetrafluoroethylene (the monomer of Teflon).

Figure 25.5 Structure of polystyrene.

TABLE 25.1
Some Common Addition Polymers

Polytetrafluoroethylene, more commonly known as the trademarked brand name Teflon, is formed from the addition polymerization of tetrafluoroethylene. Tetrafluoroethylene, shown in Figure 25.4(c), is an analogue of ethylene in which fluorine atoms have replaced all four of the hydrogen atoms. Teflon is a very good electrical insulator, so it is commonly used to coat wires. It is probably best known, though, as a nonstick substance used to coat bakeware, frying pans, and pots. It is also used in films that can be inserted into threaded joints between metal pipes to make it easier to unscrew the connection when necessary. Because Teflon is chemically inert, it is not possible to cross-link the chains like an elastomer. The structures of some addition polymers, including the structures of their respective monomers and what they are typically used for, are summarized in Table 25.1.

The diversity of polymers increases greatly when different monomers are used in the same polymer chain. Copolymers are polymers made from two or more different monomers [ 14 Section 10.6]. Different combinations of the two or more monomers give rise to different types of copolymers. These different copolymers are summarized in Table 25.2.

[^54]Student Annotation: An Australian banknote issued in 1988 is printed on polypropylene for increased durability and security.

Think About It The general formula looks like the structure of the monomer, except that the carbon-carbon double bond has been opened up to form bonds to monomer units on each side. This means the answer is reasonable. In fact, the opposite process (i.e., restoring the carboncarbon double bond) can be used to determine the structure of the monomer used to create an addition polymer.

Sample Problem 25.1 lets you practice deducing the structure of an addition polymer based on the structure of its monomer.

## Sample Problem 25.1

Polypropylene is used in applications that range from indoor-outdoor carpeting to soda bottles to bank notes. It is produced by the addition polymerization of propylene, $\mathrm{H}_{2} \mathrm{C}=\mathrm{CH}-\mathrm{CH}_{3}$. Draw the structure of polypropylene, showing at least two repeating monomer units, and write its general formula.

Strategy Addition polymers form via a free-radical reaction in which the pi electrons in the carboncarbon double bond of a monomer molecule are used to form carbon-carbon single bonds to other monomer molecules. Draw the structural formula of propylene such that the double bond can be "opened up" to form single bonds between consecutive monomer units.

Setup The structural formula of propylene is

By drawing three adjacent propylene molecules, we can rearrange the bonds to show three repeating units.

Solution The structure of polypropylene showing three monomer units is

Thus, the general formula of polypropylene is

Practice Problem A Saran Wrap, the original plastic film, is polyvinylidene chloride, which is formed by the addition polymerization of vinylidene chloride, $\mathrm{H}_{2} \mathrm{C}=\mathrm{CCl}_{2}$. Draw the structure of polyvinylidene chloride, showing at least two repeating units, and write its general structure.

HPractice Problem B The general structure of polymethyl methacrylate, an addition polymer used in Plexiglas and Lucite, is as follows:

Draw the structure of the monomer used to make this polymer.

Butadiene $\left(\mathrm{CH}_{2}=\mathrm{CH}-\mathrm{CH}=\mathrm{CH}_{2}\right)$ and styrene, two monomers listed in Table 25.1, can form a block copolymer called poly(styrene-butadiene-styrene) or SBS rubber [Figure 25.6(a)], in which there are alternating blocks of polybutadiene and polystyrene. They also form a graft polymer known as high-impact polystyrene (HIPS) [Figure 25.6(b)], in which chains of polybutadiene branch off of the main polystyrene chain.

(a)

(b)

Polymers containing a vinyl group ( $-\mathrm{CH}_{2}-\mathrm{CHR}-$ ) can exist as optical isomers because the carbon atom bonded to the R group is tetrahedral and bonded to four different groups [ 144 Section 10.4]. Tacticity is the term that describes the relative arrangements of such chiral carbon atoms within a polymer. Polymers in which all the substituents (i.e., the R groups) are in the same relative orientation (i.e., on the same side of the polymer chain) are said to be isotactic. Polymers in which the substituents alternate positions along the polymer chain are said to be syndiotactic. Finally, polymers in which the substituents are oriented randomly along the polymer chain are said to be atactic. The tacticity of polystyrene is shown in Figure 25.7. Polymers that are formed by freeradical polymerization processes, such as polystyrene and PVC, are usually atactic. Special catalysts have been developed, though, that can be used to synthesize isotactic and syndiotactic polymers.

## Condensation Polymers

Condensation polymers form when monomers with two different functional groups combine, resulting in the elimination of a small molecule (usually water) [ 1 Fs Section 10.6]. Proteins are biological condensation polymers that can have molecular weights in the thousands or millions of grams per mole. Proteins form between amino acid monomers. Each amino acid contains an amino group $\left(-\mathrm{NH}_{2}\right)$ and a carboxy group $(-\mathrm{COOH})$, and the condensation reaction occurs between the amino group of one amino acid and the carboxy group of another. (See Figure 10.13.) One water molecule is produced as each new $\mathrm{C}-\mathrm{N}$ bond is formed.

Figure 25.6 Structures of (a) SBS rubber and (b) HIPS. SBS consists of alternating blocks of polybutadiene and polystyrene, whereas HIPS consists of a polystyrene backbone with polybutadiene branches.

Figure 25.7 Structures of
(a) isotactic, (b) syndiotactic, and
(c) atactic polymers.

Figure 25.8 Structure of DNA.

The $\mathrm{C}-\mathrm{N}$ bond formed between an amino group and a carboxy group is called an amide bond because RCONR ${ }^{\prime} \mathrm{R}^{\prime \prime}$ is the general form of an amide [ $\$ 4$ Section 10.2, Table 10.2]. Polymers in which the monomers are connected by amide linkages are called polyamides. The amide bond between amino acids is more specifically called a peptide bond, and proteins are routinely referred to as polypeptides. Although polypeptides can form from a single amino acid (e.g., polyvaline), most proteins in organisms consist of chains of different amino acids. As a result, most proteins are random copolymers (Table 25.2).

Nylon 6,6 is a synthetic condensation polymer formed from hexamethylenediamine, a molecule with two amino groups, and adipic acid, which has two carboxy groups. Water is the small molecule eliminated in this condensation reaction.

Both hexamethylenediamine and adipic acid contain six carbon atoms, which is why the resulting polymer is called nylon 6,6 . Like proteins, nylon 6,6 contains amide linkages between monomers, so nylon 6,6 is a polyamide, too. Also like proteins, nylon 6,6 is a copolymer, although nylon 6,6 is an alternating copolymer (Table 25.2), not a random copolymer.

Dacron is the trade name for the condensation copolymer formed from ethylene glycol (a diol—a molecule with two alcohol groups) and para-terephthalic acid (a diacid—a molecule with two carboxy groups). The condensation reaction removes the hydrogen atom from the alcohol on one monomer and the OH group from the carboxy group on a second monomer, producing water.

The bond that forms between each ethylene glycol monomer and each para-terephthalic acid monomer is called an ester linkage because RCOOR' is the general form of an ester [ 14 Section 10.2, Table 10.2]. Polymers in which the monomers are connected by ester linkages are called polyesters.

Deoxyribonucleic acid (DNA; see Figure 25.8), which stores the genetic information for every known organism and has a molecular weight as large as billions of grams per mole, is a biological condensation copolymer. If your body contained anything but a tiny fraction of a mole of DNA, you would be extremely heavy! DNA is a copolymer of a five-carbon sugar called deoxyribose, four different molecular bases (adenine, thymine, guanine, and cytosine), and phosphoric acid $\left(\mathrm{H}_{3} \mathrm{PO}_{4}\right)$. Ribonucleic acid (RNA) is a biological condensation copolymer analogous to DNA, except that RNA is made from a five-carbon sugar called ribose and the four different molecular bases are adenine, uracil, guanine, and cytosine. RNA molecules vary greatly in size. They are large molecules, but still much smaller than DNA molecules.

Sample Problem 25.2 shows how to determine the monomers in a copolymer.

## Sample Problem 25.2

Kevlar, a condensation polymer used in bulletproof vests, has the following general structure:

Write the structure of the two monomers that form Kevlar.
Strategy Identify the condensation linkages, split them apart, and then add H to one of the resulting exposed bonds and OH to the other.
Setup Kevlar contains an amide (linkage between $\stackrel{C}{\mathrm{C}}$ and N ). We split the $\mathrm{C}-\mathrm{N}$ bond, adding an H to the exposed N and an OH to the exposed C to produce an amine and a carboxylic acid, respectively.

Solution To determine what the monomers are, first remove the $\mathrm{C}-\mathrm{N}$ bond:

Next, add $\mathrm{H}_{2} \mathrm{O}$ as H to the N and OH to the C :

Finally, add the components of another water molecule to the open ends of the molecules- H to N and OH to C , as before:

Practice Problem A Nylon 6, like nylon 6,6, is a condensation polymer (a polyamide). Unlike nylon 6,6, however, nylon 6 is not a copolymer because it is synthesized from a single monomer called 6-aminohexanoic acid:

Draw the structure of at least three repeating units of nylon 6 .
HPractice Problem B Kodel is a polymer used to make stain-resistant carpets.

Draw the structure of the monomer. Is this an additional polymer or a condensation polymer?

## Bringing Chemistry to Life

## Electrically Conducting Polymers

You have seen so far that it is possible to polymerize organic compounds with carbon-carbon double bonds (alkenes). The resulting addition polymers (e.g., polyethylene) have carbon-carbon single bonds. It is also possible, though, to polymerize organic compounds with carbon-carbon triple bonds. The simplest of these compounds (known collectively as alkynes) is acetylene ( $\mathrm{C}_{2} \mathrm{H}_{2}$ ), which is commonly used in welding torches. The polymerization of acetylene is very similar to the addition polymerization of ethylene. That is, a free-radical initiator molecule attaches to one of the carbon atoms and breaks one of the pi bonds between the two carbon atoms in acetylene. The resulting polymer, polyacetylene, thus retains a carbon-carbon double bond:

The generalized form of the reaction can be represented as follows:

Student Annotation: The systematic name of acetylene is ethyne, but the common name acetylene is far more commonly used, which is somewhat unfortunate since the -ene ending makes it sound like it is an alkene with a double bond instead of an alkyne with a triple bond!

The structure of polyacetylene contains alternating carbon-carbon single and carboncarbon double bonds. Recall from Chapter 9 that the carbon atoms in a $\mathrm{C}=\mathrm{C}$ double bond are $s p^{2}$ hybridized and that it is the leftover $p$ orbital on each carbon atom that overlaps to form the pi bond. Each carbon atom in polyacetylene is identical (structurally and electronically), so there is extended overlap of the $p$ orbitals throughout the polymer chain. The $p$ electrons are delocalizedthat is, they can move throughout the network of overlapping orbitals that extend the length of the polymer chain. By being able to move electrons from one end of the polymer chain to the other, polyacetylene can conduct electricity much like a wire. That is, polyacetylene is a plastic that conducts electricity!

For comparison, consider polyethylene and Teflon. Both are polyalkenes in which the polymer chain contains only carbon-carbon single bonds. Since all the electrons are localized in sigma bonds between the carbon atoms, there are no delocalized electrons available to carry charge throughout the polymer chain. The presence of electrons in delocalized orbitals, such as those in polyacetylene, is the key to electrical conductivity.

Sample Problem 25.3 shows how to determine the structure of an electrically conducting polymer.

## Sample Problem 25.3

Propyne $\left(\mathrm{HC} \equiv \mathrm{CCH}_{3}\right)$ can be used to form an electrically conducting polymer. Draw the structure of polypropyne, showing at least three repeating units, and write the general formula for the polymer.

Strategy Addition polymers, whether they are synthesized from alkenes or alkynes, form via a free-radical reaction in which one pair of pi electrons in the carbon-carbon multiple bond of a monomer molecule is used to form carbon-carbon single bonds to other monomer molecules. Draw the structural formula of propyne such that the triple bond can be "opened up" to form single bonds between consecutive monomer units.

Setup The structural formula of propyne can be determined from the formula given and by analogy to acetylene. The only difference between propyne and acetylene is the $\mathrm{CH}_{3}$ group in place of one of the hydrogen atoms:

$$
\mathrm{H}-\mathrm{C} \equiv \mathrm{C}-\mathrm{CH}_{3}
$$

By drawing three adjacent propyne molecules, we can rearrange the bonds to show three repeating units:

Solution The structure of polypropylene showing three monomer units is

The repeating unit is $-\mathrm{CH}=\mathrm{C}\left(\mathrm{CH}_{3}\right)-$, so the general structure is

Practice Problem Draw the structures of poly(1-butyne) and poly(1-butene), showing three or more repeating units. How are they different? How are they similar? Which of them, if any, do you think will conduct electricity?

$\mathrm{H}_{2} \mathrm{C}=\mathrm{CH}-\mathrm{CH}_{2} \mathrm{CH}_{3}$
1-butene

### 25.2 Ceramics and Composite Materials

## Ceramics

The use of ceramics in the form of pottery dates back to antiquity. Along with common ceramic substances like brick and cement, modern advanced ceramics are found in electronic devices and on the exterior of spaceships. All these ceramics are polymeric inorganic compounds that share the properties of hardness, strength, and high melting points. Ceramics are usually formed by melting and then solidifying inorganic substances (including clays).

Most ceramic materials are electrical insulators, but some conduct electricity very well at very cold temperatures. Ceramics are also good heat insulators, which is why the outer layer of the space shuttle (shown in Figure 25.9) is made of ceramic tiles. These ceramic tiles can withstand the very hot temperatures of re-entry into the atmosphere (where temperatures can reach $1650^{\circ} \mathrm{C}$ ), while keeping the underlying metal structural body of the orbiter (and the astronauts within) relatively cool.

Ceramics can be prepared by heating a slurry of a powder of the inorganic substance in water to a very high temperature under high pressure. This process, called sintering, bonds the

Student Annotation: The larger the lattice energy of an ionic compound, the higher the melting point [ $\mathrm{K4}$ Section 8.2, Table 8.1]. Ceramics all have large lattice energies.

Multimedia
Chemical Reactions-thermite reaction.

Figure 25.9 Captain Wendy Lawrence inspects the ceramic tiles on the exterior of the space shuttle.

Student Annotation: The sintering of bronze in the manufacture of bearings takes advantage of the inherent imperfections produced by the process. Porous bearings are sometimes preferred because the porosity allows a lubricant to flow throughout the material.

Student Annotation: The "sol" in sol-gel refers to a colloidal suspension of individual particles. The "gel" refers to the suspension of the resulting polymer.
particles to each other, thus producing the finished ceramic. Sintering is a relatively easy process to perform, but the resulting particle size is irregular, so the solid may contain cracks, spaces, and imperfections. Imperfections in the interior of a solid ceramic can be impossible to detect, but they make weak spots in the substance that can cause the ceramic piece to fail. To avoid these problems, the sol-gel process is frequently employed for modern ceramics that are used in structural applications. The sol-gel process produces particles of nearly uniform size that are much more likely to produce a solid ceramic without gaps or cracks.

The first step in the sol-gel process is the preparation of an alkoxide of the metal or metalloid that is going to be made into the ceramic. This can be illustrated with the yttrium(III) ion, which is used to prepare a yttrium-oxygen ceramic:

$$
\mathrm{Y}+3 \mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH} \longrightarrow \underset{\text { yttrium alkoxide }}{\mathrm{Y}\left(\mathrm{OCH}_{3} \mathrm{CH}_{2}\right)_{3}}+3 \mathrm{H}^{+}
$$

The resulting metal alkoxide is dissolved in alcohol. Water is then added to generate the metal hydroxide and regenerate the alcohol:

$$
\underset{\text { yttrium alkoxide }}{\mathrm{Y}\left(\mathrm{OCH}_{3} \mathrm{CH}_{2}\right)_{3}}+3 \mathrm{H}_{2} \mathrm{O} \longrightarrow \underset{\text { yttrium hydroxide }}{\mathrm{Y}(\mathrm{OH})_{3}}+\underset{\text { ethanol }}{3 \mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}}
$$

The metal hydroxide, once formed, undergoes condensation polymerization to form a chain with bridging oxygen atoms between the metal atoms:

Just as in condensation polymerization between organic molecules, a small molecule (water, in this case) is produced by the combination of atoms from the two monomers. Repeated condensation produces an insoluble chain of metal atoms connected by oxygen atoms. The polymer chain may contain branches (i.e., it may be three dimensional) because all three of the hydroxide groups attached to the central metal ion are identical (and are thus equally likely to react). The suspension of the metal oxide-hydroxide polymer is called a gel. The gel is carefully heated to remove the liquid, and what remains is a collection of tiny, remarkably uniformly sized particles. Sintering of material produced by the sol-gel process produces a ceramic with relatively few imperfections.

## Composite Materials

A composite material is made from two or more substances with different properties that remain separate in the bulk material. Each contributes properties to the overall material, though, such that the composite exhibits the best properties of each of its components. One of the oldest examples of a human-made composite material is the formation of bricks from mud and straw, a process that dates back to biblical times.

Modern composite materials commonly include reinforcing fibers, analogous to the straw in mud bricks, in a polymer matrix called a resin. Fiberglass, Kevlar, or carbon fibers can be used to give strength to the composite, whereas polyester, polyamide, or epoxy forms the matrix that holds the fibers together. These types of composites are called polymer matrix composites. Composites made from a metal and a ceramic, organic polymer, or another metal are called metal matrix composites. Carbide drill tips are made with a combination of softer cobalt and tougher tungsten carbide. Toyota has used a metal matrix composite in the engine block of some of its cars, and some bicycles are made with aluminum metal matrix composites. Composites made of a ceramic as the primary reinforcing material accompanied by organic polymers are called ceramic matrix composites. A common biological ceramic matrix composite is bone. Bones consist of reinforcing fibers made of collagen (a protein) surrounded by a matrix of hydroxyapatite $\left[\mathrm{Ca}_{5}\left(\mathrm{PO}_{4}\right)_{3} \mathrm{OH}\right]$.

Another type of composite material that does not fit neatly into one of these categories is a reinforced carbon-carbon composite ( RCC ), which consists of carbon fibers in a graphite matrix. To prevent oxidation, a silicon carbide coating is applied. RCC is used on the nose cones of missiles, but it is most commonly known as the coating on the nose of the space shuttle. It is believed that the Space Shuttle Columbia disaster in 2003 occurred because the ceramic tiles and RCC panel material were both damaged on liftoff by the impact of falling foam insulation. The extreme heat of reentry into the atmosphere damaged the orbiter's structure through the breaches in the ceramic tiles and the RCC panel, and the orbiter and all seven astronauts on board were lost.

Carbon fibers can be woven into fabrics and threads to be used as the structural components of vehicles and for sporting equipment such as bicycles, tennis rackets, and skateboards.

### 25.3 Liquid Crystals

Liquid crystals are substances that exhibit properties of both liquids, such as the ability to flow and to take on the shape of a container, and those of crystals, such as a regular arrangement of particles in a lattice. Some substances exhibit liquid crystal behavior when they are melted from a solid. As the temperature increases, the solid liquefies but retains some order in one or two dimensions. At a higher temperature, the ordered liquid becomes a more conventional liquid in which there is no consistent orientation of the molecules.

Liquids are isotropic, because their properties are independent of the direction of testing. Because particles in a liquid are free to rotate, there are molecules present in every possible orientation, so the bulk sample gives the same measurements regardless of the direction in which the measurements are taken or observations are made. Liquid crystals are anisotropic because the properties they display depend on the direction (orientation) of the measurement. A box full of pencils, all neatly aligned, is an analogy for anisotropy, because the pencils are long and narrow. Looking at the pencils end on is different than looking at them from the side. What you see depends on the direction from which you view the pencils. Similarly, what you see when you look at anisotropic molecules depends on the direction from which you view them.

Frederick Reinitzer discovered the first compound to exhibit liquid crystal behavior in 1888. Cholesteryl benzoate was observed to form an ordered liquid crystalline phase when melted, and this liquid crystalline phase became an ordinary liquid at higher temperatures:

The structure of cholesteryl benzoate is fairly rigid due to the presence of the fused rings and $s p^{2}$-hybridized carbon atoms. The molecule is relatively long compared to its width, too. Rigidity and this particular shape makes it possible for the cholesteryl benzoate molecules to arrange themselves in an orderly manner, in much the way that pencils, chopsticks, or tongue depressors can be arranged.

There are three different types of ordering (called nematic, smectic, and cholesteric) that a liquid crystal can adopt (see Figure 25.10). A nematic liquid crystal contains molecules ordered in one dimension only. Nematic molecules are all aligned parallel to one another, but there is no organization into layers or rows. A smectic liquid crystal is ordered in two dimensions. Smectic molecules are aligned parallel to one other and are further arranged in layers that are parallel to one another. Cholesteric liquid crystal molecules are parallel to each other within each layer, but each layer is rotated with respect to the layers above and below it. The layers are rotated because there are repulsive intermolecular forces between layers.

Liquid crystalline substances were curiosities for many years but have found applications in many fields. Liquid crystal displays (LCDs) in calculators, watches, and laptop computers are possible, for example, because polarized light can be transmitted through liquid crystals in one phase but not transmitted through another (Figure 25.11). Polarized light is produced by passing ordinary

> Student Annotation: Recall from Chapter 9 that there is free rotation about carboncarbon single bonds (i.e., bonds between $s p^{3}$-hybridized carbon atoms), but not about carbon-carbon double bonds (i.e., bonds between $s p^{2}$-hybridized carbon atoms).

Figure 25.10 (a) Nematic, (b) cholesteric, and (c) smectic liquid crystals.

Figure 25.11 Liquid crystal display. When the current is on, the liquid crystal molecules are aligned and polarized light cannot pass through. When the current is off, the molecules are not aligned and light can pass through.

Figure 25.12 LCD thermometer.

Student Annotation: A material that changes color as the temperature changes is called thermochromic.

light (which oscillates in all directions perpendicular to the beam) through a filter that allows only the light waves oscillating in one particular plane to pass through. This plane-polarized light can be rotated by a twisted liquid crystal such that it is allowed to pass through another filter when a voltage is applied to the liquid. If the light passes through the liquid when the voltage is off, though, the light will not pass through. This principle can be used in calculator and watch displays because each digit is made up of no more than the seven segments shown in Figure 25.11, and the specific digit depends on which segments are bright and which are dark. LCDs in laptop computers and televisions are more sophisticated, but still operate on the same basic principle.

Liquid crystals can also be used in thermometers (Figure 25.12). The spacing between crystal layers depends on temperature, and the wavelength of light reflected by the crystal depends on this spacing. Thus, the color reflected by the liquid crystal will change with temperature, and this color can be used to indicate the temperature to which the liquid crystal is exposed.

Sample Problem 25.4 lets you practice determining whether or not a molecule might exhibit liquid crystal properties.

## Sample Problem 25.4

Would the following molecule make a good liquid crystal? Why or why not?

Strategy Cholesteryl benzoate exhibits liquid crystal properties because it has structurally rigid regions (fused rings and $s p^{2}$-hybridized carbon atoms) and because it is relatively long compared to
its width. Examine the structure in question to see if it has rigid regions and to see if it is longer in one dimension than in another.

Setup Carbon atoms that are $s p^{2}$-hybridized contribute to the rigidity of a molecule's shape.
Solution The left-hand portion of the molecule contains an $s p^{2}$ - hybridized carbon atom, a benzene ring, another $s p^{2}$-hybridized carbon atom, and another benzene ring. These features are relatively rigid and should allow the molecule to maintain its shape when heated. The chain of $\mathrm{CH}_{2}$ groups ending in a $\mathrm{CH}_{3}$ group is not rigid due to free rotation about the carbon-carbon single bonds (i.e., $s p^{3}$-hybridized carbon atoms). The overall shape of the molecule is longer than it is wide, though, which combined with a large portion that is rigid should make the molecule a good candidate for liquid crystal behavior.

Practice Problem A Which compound would you expect to exhibit liquid crystal behavior, and why?

Think About lt Double bonds in a molecular structure indicate the presence of pi bonds. Recall that it is the pi bonds that restrict rotation about bonds in a molecule [ 14 Section 9.5] and lend rigidity to the structure.

## Checkpoint 25.3 Liquid Crystals

25.3.1 Which of the following is a good analogy for anisotropy? (Select all that apply.)
a) Glass of water
b) Bucket of ice cubes
c) Box of spaghetti
d) Box of rice
e) Box of macaroni
25.3.2 What characteristics make a molecule likely to exhibit liquid crystal properties? (Select all that apply.)
a) Long narrow shape
b) Flexibility
c) Rigidity
d) Low molar mass
e) High molar mass

### 25.4 Biomedical Materials

Many modern materials are finding uses in medical applications. Replacement joints, dental implants, and artificial organs all contain modern polymers, composites, and ceramics. To function successfully in a biomedical application, though, a material must first be compatible with the living system. The human body very easily recognizes foreign substances and attacks them in an effort to rid them from the body. Thus, a biomaterial must be designed with enough similarity to the body's own systems that the body will accept the material as its own. Additionally, if the polymer, ceramic, or composite contains leftover chemicals from its manufacture, these contaminants may lead to adverse reactions with the body over the lifetime of the medical implant. It is important, therefore, that the substance be as pure as possible.

The physical properties of a biomedical material are important, too, because the longer the material lasts, the less often the medical device has to be replaced during the lifetime of the patient. Most biomedical materials must possess great strength and flexibility to perform in the body. For example, the materials in artificial joints and heart valves must be able to flex many times without breaking. Materials used in dental implants must show great hardness, moreover, so as not to crack during biting and chewing. It takes years of research to develop successful biomedical materials that meet these needs.

## Dental Implants

Dental implant materials have been used for many years. The oldest dental fillings were made of various materials including lead (which fell out of favor due to its softness-the danger of lead poisoning was as yet unknown), tin, platinum, gold, and aluminum. The remains of Confederate soldiers have been shown to include fillings made of a lead-tungsten mixture, probably from shotgun pellets; tin-iron; a mercury amalgam; gold; and even radioactive thorium. (The dentist probably thought he was using tin, which is similar in appearance.) Many modern fillings are made of dental amalgam [ 14 Chapter 19], a solution of several metals in mercury. Modern dental amalgam consists of 50 percent mercury and 50 percent of an alloy powder that usually contains (in order of abundance) silver, tin, copper, and zinc. These metals tend to expand slightly with age, causing fissures and cracks in the tooth that may require further intervention (e.g., crowns, root canals, or tooth replacement). Some people consider amalgam fillings to be unsightly, too.

Dental composite materials are now used that have several advantages over traditional amalgams. The composites can be made in a wide range of colors, for example, to match the color of the other teeth. The existing healthy portion of the tooth can be etched with acid, moreover, to create pores into which the composite material can bond. With traditional dental amalgam, the dentist must create indentations in the healthy tooth to hold the amalgam in place. Destroying a portion of the healthy tooth is undesirable and can be avoided with the use of the composite.

The dental composite consists of a matrix (made from a methacrylate resin) and a silica filler. The composite material is applied to the cavity in a putty-like consistency and then is dried and polymerized by a photochemical reaction initiated by light of a particular wavelength. Because the light does not penetrate very far into the composite, the thickness of the applied composite is critical. If the layer of composite is too thick, some of the composite will remain soft. A properly constructed dental composite filling will last more than 10 years. Over time, though, composite fillings tend to shrink, leaving breaches that can cause leakage, a situation that must be addressed to prevent further tooth decay.

Porcelain ceramic fillings and crowns are very common, but the ceramic has two disadvantages: it is very hard and can wear on the opposing teeth, and it is brittle and may crack if subjected to great force. Most dentists, therefore, do not recommend porcelain ceramic crowns and fillings for the molar teeth, which do the bulk of the grinding work during chewing.

A material used in dentistry must have properties that maximize both patient comfort and the lifetime of the implant. Dental fillings and tooth replacements must be resistant to acids, for example, because many foods (such as citrus fruits and soft drinks) contain acids directly. Any food containing carbohydrates can produce acids, though, if traces are left in the mouth because the bacteria that reside there consume carbohydrates, producing acids in the process. These acids eat away at the natural hydroxyapatite in teeth, creating caries (cavities). Materials like dental amalgam, gold, and dental composite resist attack by acids in the mouth.

A dental material should also have low thermal conductivity; that is, it should conduct heat poorly. This is especially important in applications where the implant material is in contact with the nerve inside the tooth. If the implant material conducts heat well, then whenever hot or cold foods come in contact with the implant, the hot or cold will be transmitted through the material to the nerve, causing pain. Metals are good thermal conductors, so dental amalgams must not touch nerves.

Finally, dental materials should resist wear (so they last a long time) and they should resist expansion and contraction as the temperature fluctuates. The close spacing and precision fits involved in dental fillings and implants would result in discomfort and possibly failure of the implant if the material expanded or contracted appreciably with changes in temperature.

## Soft Tissue Materials

Burn victims who have lost large amounts of skin do not have enough cells to grow new skin, so a synthetic substitute must be used. The most promising artificial skin material is based on a polymer of lactic acid and glycolic acid. Both of these compounds contain an alcohol group
$(-\mathrm{OH})$ and a carboxy group $(-\mathrm{COOH})$, so they can form a polyester copolymer in a condensation reaction that mirrors the formation of Dacron polyester (Section 25.1):

This copolymer forms the structural mesh that supports the growth of skin tissue cells from a source other than the patient. Once the skin cells grow on the structural mesh, the artificial skin is applied to the patient, and the copolymer mesh eventually disappears as the ester linkages are hydrolyzed. During this treatment, the patients must take drugs that will suppress their immune systems, which ordinarily would attack these substances as foreign to prevent their bodies from rejecting the new skin.

Sutures, commonly known as stitches, are now made of the same lactic acid-glycolic acid copolymer as the structural mesh of artificial skin. Before, sutures were made of materials that did not degrade so they eventually had to be removed again. This type of suture is still used in cases where the degrading suture is deemed a risk or there might be a need to reopen the incision at a later time. Biodegradable sutures are routinely used during operations on animals, too, which decreases the number of trips to the veterinarian, thereby reducing the stress on the pet and its owner.

When portions of blood vessels need to be replaced or circumvented in the body, it may or may not be possible to obtain a suitable vascular graft from another part of the patient's body. Dacron polyester (Section 25.1) can be woven into a tubular shape for this purpose, and pores can be worked into the material so that the graft can integrate itself into the tissue around it, as well as to allow capillaries to connect. Unfortunately, the body's immune system recognizes this as a foreign substance and blood platelets stick to the walls of the Dacron graft, causing clotting.

Artificial hearts and heart valves are potential solutions to the shortage of donor organs. Artificial hearts have not yet been perfected to the point that they can work on a permanent basis, but valve replacement is a common procedure that can successfully prolong a patient's life. The most common replacement heart valve is fixed in position by surrounding the valve with lactic acid-glycolic acid copolymer, the same polyester that is used in skin grafts and biodegradable sutures. The polymer is woven into a mesh ring that allows the body tissue to grow into the ring and hold it in place.

Researchers today are using electrospinning to place nanofibers directly onto wounds. (Nanofibers are products of nanotechnology; see Section 25.5.) Electrospinning uses a highvoltage electric field to create a jet of polymer solution that transforms into a spiraling dry fiber only nanometers in diameter. The wound dressings applied by direct electrospinning have high rates of moisture transmission and bacterial resistance. Enzymes can be added to the solution containing the nanofiber polymer, and these enzymes can be released into the skin after the dressing is applied. Proteins can also be cross-linked onto the nanofiber, making possible many applications of the nanofiber wound dressing.

## Artificial Joints

Joint replacements, such as artificial knees, elbows, and hips, require major surgery but have become relatively commonplace because suitable materials have become available for not only the bone replacement but also the contact surfaces. In knee replacement, for example, the goal is usually to replace worn-out cartilage surfaces (which may have resulted from arthritis or injury). It is possible to replace shattered bones that cannot heal back to their original state as well.

The materials originally used in joint replacements were ivory, metals, and glass, but they are fast being replaced by polymeric plastics and ceramics. Polymethyl methacrylate (PMMA), which was the subject of Practice Problem 25.1B in Section 25.1, and polyethylene have been used in many total joint replacements. However, these joints tend to fail over time when they are implanted in younger, more active patients, so efforts are under way to improve the wear quality of the PMMA and polyethylene parts.

Although metallurgical research provided new substances that were much stronger and less likely to break, including titanium-based alloys, total joint replacements were predicted to last no more than 20 years in a patient before needing to be replaced again. Ultrahigh-molecular-weight polyethylene, treated with radiation to initiate cross-linking of the polymer chains and stored under inert nitrogen gas to stop free-radical damage to the chain from the radiation, is now commonly

Student Annotation: Hydrolysis is essentially the opposite of a condensation reaction.

Student Annotation: Recall that allotropes are different forms of the same element [14 Section 2.6].
used in many replacement joints, with the expectation of improved wear. It remains to be seen whether ultrahigh-molecular-weight polyethylene will prolong the life of these devices, since many of the joints have been in service in patients for less than a decade.

Other surfaces have also been researched to reduce wear. Metal-on-metal bearing surfaces suffered early setbacks due to the manufacturing tolerances of the cobalt-based alloy used. As the bearing surfaces wore, they produced metal sludge, and high friction between components caused loosening of the joint. Modern metal-on-metal bearing surfaces have improved as the manufacturing has become more consistent and produced components lower in friction.

Ceramic-on-ceramic bearing surfaces have also been developed. Some ceramics have been prone to cracking, but many have shown great promise for long-lasting use. When a ceramic component in a replacement joint does crack, however, it can be disastrous because the entire joint may need to be replaced and further healthy bone may need to be sacrificed to install the new replacement joint.

Despite the progress made so far on developing safe, durable, and useful artificial joints, much work remains to be done. One long-term issue that has yet to be researched extensively, for example, is the effect of the release of metal cations from the joint into the body over the lifetime of the joint replacement. This may become a more urgent health issue as the lifetimes of the artificial joints increases and the ages at which patients get the replacements decreases.

### 25.5 Nanotechnology

Atoms and molecules have sizes on the order of a tenth of a nanometer (where $1 \mathrm{~nm}=10^{-9} \mathrm{~m}$ ) [14 Section 2.2]. Nanotechnology is the development and study of such small-scale materials and objects. An atomic force microscope [Figure $25.13(\mathrm{a})$ ] is one way to image the surface of a material at the atomic or molecular level.

A sharp-pointed stylus is moved over the surface of the substance under study, and the intermolecular forces between the material and the stylus force the stylus up and down. The stylus is mounted on a probe that reflects a laser beam into a detector. From the differences in deflection of the laser beam, the electronics attached to the probe can create an image of the surface of the object [Figure 25.13(b)].

The scanning tunneling microscope (STM) works on a similar principle but only for samples that conduct electricity. The STM measures the peak and valley heights of the sample from the flow of electric current. The tip of the STM must move up and down to keep the current constant, and the up-and-down movements are translated into an image of the atomic and molecular structure of the substance [Figure 25.13(c)].

## Graphite, Buckyballs, and Nanotubes

Carbon exists as several allotropes, one of which is graphite. Graphite consists of sheets of carbon atoms that are all $s p^{2}$-hybridized [ $1 \$ 4$ Section 9.4]:

Intermolecular forces [ 14 Chapter 11] hold the sheets together. Because of the delocalization of the electrons in the extended network of $p$ orbitals perpendicular to the graphite sheet, graphite is an electrical conductor within its sheets, but not between them. Electrical conductivity is much more common for metals than it is for nonmetals like graphite.

Graphite and diamond were long thought to be the only two allotropes of carbon. In 1985, though, a compound consisting of 60 carbon atoms was isolated from graphite rods that had been vaporized with an intense pulse of laser light. The structure of the compound $\left(\mathrm{C}_{60}\right)$ was identical to

Figure 25.13 (a) Atomic force microscope (AFM). (b) AFM image of a yeast cell. (c) STM image of iron atoms arranged to display the Chinese characters for atom on a copper surface.
that of a soccer ball, with 12 pentagonal and 20 hexagonal faces and carbon atoms at the corners of each face:

This pattern also resembles an architectural structure called a geodesic dome, so the $\mathrm{C}_{60}$ molecule was named buckminsterfullerene in honor of R. Buckminster Fuller, the designer of the geodesic dome. The nickname for $\mathrm{C}_{60}$ is the buckyball.

Since the discovery of $\mathrm{C}_{60}$, elongated and elliptical cages of 70 and 80 carbon atoms have also been discovered. These molecules, called fullerenes as a group, have been proposed to exist in such exotic places as stars and interstellar media and have been observed in such mundane places as deposits of chimney soot.

A single sheet of graphite is known as graphene. A graphene is essentially a two-dimensional carbon crystal consisting of an array of six-membered rings. Graphenes are extraordinarily strong (hundreds of times stronger than steel), they conduct electricity, and their shapes can be customized by the introduction of five-membered and seven-membered rings at specific locations. Because of their unique combination of properties, graphenes currently are the subject of a great deal of research. Proposed uses of graphenes include replacement of copper interconnects in integrated circuits, production of transparent conduction electrodes-useful for touchscreens and liquid crystal displays-and ultrahigh-sensitivity detection devices.

Unless otherwise constrained, graphene sheets will wrap around on themselves forming cylinders with diameters on the scale of nanometers. Such cylinders are called a carbon nanotubes. Two types of nanotube structures are known, as shown in Figure 25.14. The differences in arrangement of hexagons give the two kinds of nanotubes different electrical conductivities.

Carbon nanotubes of different diameters can nest inside each other, producing multiplewalled nanotubes. Most nanotubes are single-walled, though, and they can be as narrow as 1 nm in diameter. These nanotubes are remarkably strong-stronger, in fact, than a comparably sized piece of steel! Because nanotubes consist only of carbon atoms, they can come into close contact, thereby allowing intermolecular forces to hold large numbers of tubes together. This, in turn, makes it possible to align groups of tubes, potentially forming long strands and fibers. Lightweight fibers and strands with tremendous strength have many applications in such things as auto parts, medical implants, and sports equipment.

Besides carbon, other elements have been fashioned into nanotubes, too. Molybdenum sulfide nanotubes have been synthesized, for example, with openings between atoms that are just the right size to permit some gas molecules to pass through, but not others. This may have potential for the nanoscale storage of gases for fuel cells.

Student Annotation: An analogy is to take a piece of paper and roll it so that you have a tube.

Figure 25.14 Carbon nanotubes.

Figure 25.15 Energy bands in metals (conductors), semiconductors, and insulators.

Many universities have developed large-scale facilities for nanotechnology research in collaboration with industrial partners. Since the lower limits of size have been reached in the production of silicon chip-based electronic circuits, nanotechnology may provide the pathway to circuits that are much smaller than have ever been imagined.

### 25.6 Semiconductors

Recall from Section 9.6 that bonds between atoms can be described as resulting from the combination of atomic orbitals to form molecular orbitals. In a bulk sample of metal containing many, many atoms, there are many, many molecular orbitals. These molecular orbitals are so close in energy that instead of forming individual bonding and antibonding orbitals for each pair of atomic orbitals that combine, they form a band of bonding levels and a band of antibonding levels. The energies of the bonding and antibonding bands depend on the energies of the atomic orbitals that combined to form them in the first place. As a result, the band structure of a bulk sample depends on the original atoms' energy levels. The band energies and the gaps (or lack of gaps) between the bonding band (called the valence band) and the antibonding band (called the conduction band) make it possible to classify a substance as an electrical conductor, a semiconductor, or an electrical insulator based on the behavior of the electrons in the bands (Figure 25.15).

The valence band is filled with the valence (bonding) electrons, whereas the conduction band is empty or only partially filled with electrons. It is the conduction band that allows electrons to move between atoms. The gap between the valence band and the conduction band can vary from nothing (for an electrical conductor) to a small amount (for a semiconductor) to a very large amount (for an electrical insulator). Thus, the size of the band gap determines the conduction behavior of the material.

Metals have no band gap, so they are good conductors of electricity. The valence band and conduction band actually overlap or are one and the same in metallic conductors, so there is no energy barrier to the movement of electrons from one atom to another in a metal. Semiconductors have a band gap, but it is relatively small, so there is limited movement of electrons from the valence band to the conduction band. Nonconductors (electrical insulators) have large band gaps, so it is nearly impossible to promote electrons from the valence band to the conduction band.

Silicon, germanium, and carbon in the form of graphite are the only elemental semiconductors at room temperature. All three of these elements are in Group 4A and have four valence electrons. (Tin and lead are also in Group 4A, but they are metals, not semiconductors.) Other semiconductors consist of combinations of elements whose valence electron count totals 8. For example, gallium (Group 3A) and phosphorus (Group 5A) form a semiconductor because gallium contributes three valence electrons and phosphorus contributes five, giving a total of eight valence electrons. Semiconductors have also been formed between Group 2B elements (particularly Zn and Cd ) and Group 6A elements.

Sample Problem 25.5 lets you practice identifying combinations of elements that can exhibit semiconductor properties.

## Sample Problem 25.5

State whether each of the following combinations of elements could form a semiconductor:
(a) $\mathrm{Ga}-\mathrm{Se}$, (b) In-P, (c) $\mathrm{Cd}-\mathrm{Te}$.

Strategy Count the valence electrons in each type of atom. If they total eight for the two elements, then the combination will probably form a semiconductor.

Setup Locate each element in the periodic table. All of them are main group elements, so we can use their group numbers to directly determine the number of valence electrons each element contributes: (a) Ga is in Group 3A, and Se is in Group 6A. (b) In is in Group 3A, and P is in Group 5A. (c) Cd is in Group 2B, and Te is in Group 6A.

Solution (a) Ga has three valence electrons, and Se has six. This gives a total of nine, which is too many to form a semiconductor.
(b) In (three valence electrons) and P (five valence electrons) combine for a total of eight, so In- P should be a semiconductor.
(c) Cd (two valence electrons) and Te (six valence electrons) also combine for a total of eight, so Cd-Te should be a semiconductor, too.

Practice Problem A Name an element in each case that could be combined with each of the following elements to form a semiconductor: (a) O , (b) Sb , (c) Zn .
$\boldsymbol{\$ P}$ Practice Problem B For each of the elements C, As, and Ga, indicate which can be combined with silicon to produce a semiconductor, which can be added to silicon as a dopant to produce a $p$-type semiconductor, and which can be added to silicon as a dopant to produce an $n$-type semiconductor.

The conductivity of a semiconductor can be enhanced greatly by doping, the addition of very small quantities of an element with one more or one fewer valence electron than the natural semiconductor. For the purpose of simplicity, we will consider a pure silicon semiconductor. Silicon is a Group 4A element, so it has four valence electrons per atom. A small (parts per million) amount of phosphorus (Group 5A, five valence electrons) can be added, thus doping the silicon with phosphorus. Since each phosphorus atom has an "extra" electron relative to the pure semiconductor, these extra electrons must reside in the conduction band, where they increase its conductivity. This type of doped semiconductor is called an $\boldsymbol{n}$-type semiconductor because the semiconductivity has been enhanced by the addition of negative particles, the extra electrons.

It is also possible to dope a semiconductor with an element that has fewer valence electrons than the semiconductor itself. For example, a silicon semiconductor could be doped with small amounts (again, parts per million) of gallium (Group 3A, three valence electrons). Now, instead of an "extra" electron, there is a "hole" (one less electron) in every place that a gallium atom has replaced a silicon atom. These holes are effectively positive charges (because each is the absence of an electron), so this type of material is called a p-type semiconductor. A p-type semiconductor

Student Annotation: The group number for a main group element corresponds to the number of valence electrons that the atom has [ 14 Section 8.5].

Think About It Semiconductors consisting of Group 3 and Group 5 elements are used in the contact layers of light-emitting diodes (LEDs).

Figure 25.16 The effects of doping on the conduction of semiconductors.

Figure 25.17 LED arrays in traffic signals. Many communities have replaced the red and green signals with LED arrays that are much more energy efficient than the incandescent bulbs used previously. The yellow lights are being replaced more slowly, however, because LED arrays are expensive and the short duration of yellow lights would not necessarily allow an overall cost saving when the energy efficiency is factored in.

has increased conductivity because the holes (which are in the valence band) move through the silicon rather than electrons. The energy required to move an electron from the valence band into a hole (also in the valence band) is considerably less than the energy needed to promote an electron from the valence band to the conduction band of a semiconductor (Figure 25.16). Thus, the movement of the holes results from the movement of charge, and conductivity is the movement of charge.

A combination of $p$-type and $n$-type semiconductors can be used to create a solar cell in which the holes and extra electrons in the semiconductors are at equilibrium in the dark. At equilibrium, the positive holes in the $n$-type layer have offset the movement of electrons into the $p$-type layer. Light falling on the solar cell causes the electrons that have entered the p-type layer to go back to the $n$-type layer, and other electrons to pass through a wire from the $n$-type layer to the $p$-type layer. This movement of electrons constitutes an electric current.

Diodes, which are electronic devices that restrict the flow of electrons in a circuit to one direction, work in essentially the opposite direction from solar cells. A light-emitting diode (LED) consists of $n$-type and $p$-type semiconductor layers placed in contact. When a small voltage is applied, the "extra" electrons from the $n$-type side combine with the holes in the $p$-type side, thus emitting energy (light) whose wavelength depends on the band gap. The band gap is different for different semiconductors (e.g., Ga-As versus Ga-P), so the specific combination of semiconductor materials can be chosen to make the band gap correspond to a desired color of light. LEDs are finding increasing use in applications previously dominated by traditional incandescent lightbulbs such as emergency exit signs, car tail lights, and traffic signals (Figure 25.17).

## Checkpoint 25.6 Semiconductors

25.6.1 Semiconductors are substances that
a) have a large band gap.
b) have a small band gap.
c) have no band gap.
d) do not conduct electricity.
e) conduct electricity only when combined with other elements.
25.6.2 Elements that are semiconductors at room temperature are
a) members of Group 2 A .
b) members of Group 3A.
c) members of Group 4A.
d) combinations of elements from Group 3A and Group 5A.
e) combinations of elements from Group 2A and Group 6A.

### 25.7 Superconductors

No ordinary electrical conductor is perfect. Even metals have some resistance to the flow of electrons, which wastes energy in the form of heat. Superconductors have no resistance to the flow of electrons and thus could be very useful for the transmission of electricity over the long distances between power plants and cities and towns. The first superconductor was discovered in 1911 by the Dutch physicist H. Kamerlingh-Onnes. He received the 1913 Nobel Prize in Physics for showing that mercury was a superconductor at 4 K , the temperature of liquid helium. Liquid helium is very expensive, however, so there were few feasible applications of a mercury superconductor.

Since that time, more superconductors have been discovered including a lanthanum-, barium-, copper-, and oxygen-containing ceramic compound, and a series of copper oxides ("cuprates"), all of which become superconducting below 77 K , the temperature of liquid nitrogen (a much more common and less expensive refrigerant than liquid helium). The temperature below which an element, compound, or material becomes superconducting is called the superconducting transition temperature, $\boldsymbol{T}_{\boldsymbol{c}}$. The higher the $T_{\mathrm{c}}$, the more useful the superconductor.

By 1987, superconductivity was observed in another ceramic, yttrium barium copper oxide (YBCO) $\left(\mathrm{YBa}_{2} \mathrm{Cu}_{3} \mathrm{O}_{7}\right)$. Commonly called a "1-2-3 compound" because of the 1:2:3 ratio of yttrium to barium to copper, YBCO has a $T_{\mathrm{c}}$ of 93 K (above the temperature of liquid nitrogen). Although 93 K is still cold, it qualifies as quite warm in the world of superconductors, so YBCO is considered to be the first high-temperature superconductor. YBCO was first prepared by combining the three metal carbonates at high temperature ( 1000 to 1300 K ). The copper ions are present in a mixture of +2 and +3 oxidation states:

$$
4 \mathrm{BaCO}_{3}+\mathrm{Y}_{2}\left(\mathrm{CO}_{3}\right)_{3}+4 \mathrm{CuCO}_{3}+\mathrm{Cu}_{2}\left(\mathrm{CO}_{3}\right)_{3} \longrightarrow 2 \mathrm{YBa}_{2} \mathrm{Cu}_{3} \mathrm{O}_{7}+14 \mathrm{CO}_{2}
$$

YBCO must be sintered carefully to obtain the optimal superconductivity.
Superconducting wires were first made from $\mathrm{Bi}_{2} \mathrm{Sr}_{2} \mathrm{CaCu}_{2} \mathrm{O}_{8}$, known as BSCCO-2212, a high-temperature superconductor with $T_{\mathrm{c}}=95 \mathrm{~K}$. It can be prepared in wire forms because it has layers of bismuth and oxygen atoms that YBCO does not have. BSCCO-2212 is so named because its formula consists of two bismuth, two strontium, one calcium, and two copper atoms. Other BSCCO compounds exist, too, and they all have a general formula of $\mathrm{Bi}_{2} \mathrm{Sr}_{2} \mathrm{Ca}_{n} \mathrm{Cu}_{n+1} \mathrm{O}_{2 n+6}$. BSCCO-2223, for example, which has the formula $\mathrm{Bi}_{2} \mathrm{Sr}_{2} \mathrm{Ca}_{2} \mathrm{Cu}_{3} \mathrm{O}_{10}$ (where $n=2$ ), is a superconductor with $T_{\mathrm{c}}=107 \mathrm{~K}$.

Superconductors at or below $T_{\mathrm{c}}$ exhibit the Meissner effect, the exclusion of magnetic fields. In Figure 25.18 , for example, a magnet is shown levitating above a YBCO pellet, a superconductor at or below $-180^{\circ} \mathrm{C}$, its $T_{\mathrm{c}}$.

Magnetic levitation is being researched for use in trains, because the amount of friction between the train and the tracks would be drastically reduced in a magnetically levitated ("maglev") train versus one running on ordinary tracks and wheels. The engineering challenge to a maglev train is that the superconductor must be kept at or below its $T_{\mathrm{c}}$ for the magnetic levitation to occur, and the highest temperatures obtained for superconducting substances are approximately 140 K—warm on the superconductivity scale but still very cold by ordinary standards.

Superconductivity in metals can be explained satisfactorily by BCS theory, first proposed by John Bardeen, Leon Neil Cooper, and John Robert Schrieffer in 1957. They received the Nobel Prize in Physics in 1972 for their work. BCS theory treats superconductivity using quantum mechanical effects, proposing that electrons with opposite spin can pair due to fundamental attractive forces between the electrons. At temperatures below $T_{c}$, the paired electrons resist energetic interference from other atoms and experience no resistance to flow. Superconductivity in ceramics has yet to be satisfactorily explained.

Student Annotation: Allex Müller and Georg Bednorz were awarded the 1987 Nobel Prize in Physics "for their important breakthrough in the discovery of superconductivity in ceramic materials."

Student Annotation: The decomposition of a metal carbonate to the metal oxide and carbon dioxide gas is a very common reaction.

Student Annotation: Many a Nobel Prize has been won by scientists who research and develop modern materials!

Student Annotation: You might be skeptica that two negatively charged electrons would attract each other, but there is evidence that all subatomic particles do exert some attractive forces on each other.

Figure 25.18 The Meissner effect. A magnet levitates above a YBCO pellet at the temperature of liquid nitrogen $\left(-196^{\circ} \mathrm{C}\right)$.

## Applying What You've Learned

Now that you know more about polymers, we can apply some of the concepts you've learned to ring-opening metathesis polymerization (ROMP), a polymerization reaction that utilizes the metathesis reaction introduced at the beginning of the chapter. The general mechanism for ROMP is as follows:

The pi bond from the carbon-carbon double bond in the ring of the monomer reacts with the metalcarbon double bond in the transition metal catalyst $(\mathrm{M}=\mathrm{CHR})$ to first form a metallacyclobutane complex. The metallacyclobutane complex then breaks up to form a new carbon-carbon double bond and a new metal-carbon double bond. The new carbon-carbon double bond is the first in the polymer chain, and the new metal-carbon double bond is available to react with additional monomers and thus grow the chain. As long as the metal from the catalyst is attached to the polymer via this metal-carbon double bond, the polymer is said to be "living" because it will continue to grow as more monomer is added. The process we will consider is the polymerization of two cyclic alkenes (cyclobutene and 3-chlorocyclobutene) using ROMP with an appropriate transition metal catalyst (abbreviated as $\mathrm{M}=\mathrm{CHR}$ ):

Cyclobutene 3-Chlorocyclobutene

## Problems:

a) What is the formula of the polymer formed by polymerizing first fifty cyclobutene molecules and then seventy 3-chlorocyclobutene molecules? [\$4 Sample Problem 25.1]
b) What type of polymer (see Table 25.2) is this? [ 14 Sample Problem 25.2]
c) Would this polymer conduct electricity? [ 14 Sample Problem 25.3]

## Chapter Summary

## Section 25.1

- Polymers are made up of many repeating units, called monomers, that are linked together by covalent bonds.
- Thermoplastic polymers can be melted and reshaped, whereas thermosetting polymers assume their final shape as part of the chemical reaction that forms them in the first place.
- Addition polymers are formed via a radical reaction in which a pi bond in an alkene or alkyne is opened up to form new bonds to adjacent monomers.
- Polymer chains can be cross-linked to provide added durability and flexibility.
- Elastomers, such as natural rubber, can stretch and bend and then return to their original shape.
- Copolymers contain more than one type of monomer. Copolymers can be random, alternating, block, or graft, depending on the sequence of the different monomers and the way that the monomers are attached in the polymer.
- Tacticity describes the relative geometric arrangements of the groups attached to the chiral carbon atoms in vinyl polymers. In isotactic polymers, all the groups attached to the chiral carbon atoms have identical arrangements. In syndiotactic polymers, they alternate positions along the polymer chain. In atactic polymers, they have random arrangements.
- Condensation polymers form when two different groups on monomers react, thus producing a covalent bond between monomers and a small molecule (usually water) that is expelled. The two reacting groups may be on the same monomer (as in the amino acids that form polypeptides and proteins), or they may be on two different monomers (as in hexamethylenediamine and adipic acid, which form nylon 6,6). Most condensation polymers are really copolymers.
- Amines and organic acids form condensation polymers known as polyamides. Alcohols and organic acids form condensation polymers known as polyesters. Amino acids form polyamide polymers known as polypeptides. Long, straight-chain polypeptides are known as proteins.
- DNA and RNA are condensation polymers consisting of sugars, organic bases, and phosphate ions.

## Section 25.2

- Ceramics are polymeric inorganic compounds that are hard and strong and have high melting points.
- Ceramics are sintered to bond the particles to each other and to close any gaps that may exist in the material.
- The sol-gel process is used to prepare ceramics for structural applications because it produces particles of nearly uniform size that are much more likely to produce a solid ceramic without gaps or cracks.
- Composite materials contain several components each of which contributes properties to the overall material. Modern composites include reinforcing fibers and a surrounding matrix. The reinforcing fibers may be made of polymers, metals, or ceramics.

## Section 25.3

- Liquid crystals are substances that maintain an ordered arrangement in the liquid phase. Molecules containing structurally rigid regions (e.g., rings and multiple bonds) and molecules that are longer in one dimension than in another seem to form the best liquid crystals. Although ordinary liquids are isotropic, liquid crystals are anisotropic, meaning that their apparent properties depend on the direction from which we view them.
- Liquid crystals may be nematic, smectic, or cholesteric, depending on the type of ordering the molecules can adopt. Nematic liquid crystals contain order in only one dimension (parallel molecules), smectic liquid crystals contain order in two dimensions (parallel molecules in parallel layers), and cholesteric liquid crystals contain layers that are rotated with respect to one another. Within each cholesteric layer, the molecules are parallel.

## Section 25.4

- Dental amalgam consists of several metals dissolved in an alloy with mercury. Dental composite materials consist of a methacrylate polymer in a silica matrix. The composite can be varied in color to match existing teeth, making the repair more aesthetically pleasing than metallic amalgam.
- Biodegradable sutures and artificial skin are made of synthetic polyesters that support the growth of tissue around the polymer and then hydrolyze into the body.
- Artificial joint replacements can be made of metal, ceramics, and organic polymers.

## Section 25.5

- Nanotechnology is the study and development of objects with sizes on the order of a nanometer (one billionth of a meter).
- Pure carbon exists as diamond, graphite, fullerenes, and carbon nanotubes.
- Two-dimensional sheets of $s p^{2}$-hybridized carbon atoms are called graphenes.

## Section 25.6

- Electrical conductors (e.g., metals) have no gap between their valence band and conduction band, so electrons are easily promoted from the valence to the conduction band. Semiconductors, which conduct electricity more than nonconductors (insulators) but less than metallic conductors, have a small gap. The gap in nonconductors is too large for electrons to be promoted from the valence to the conduction band.
- Semiconductors generally have a total of eight valence electrons per formula unit. Thus, they typically form between two Group 4A elements, one Group 3A element and one Group 5A element, or one Group 2B element and one Group 6A element.
- Semiconductors can be doped with an element with fewer valence electrons to produce a p-type semiconductor, or with an element with more valence electrons to produce an $n$-type semiconductor.
- $\quad p$-Type and $n$-type semiconductors can be used together in solar cells and diodes.

## Section 25.7

- Superconductors offer no resistance to the flow of electrons. The earliest known superconductors only exhibited the behavior at liquid helium temperature ( 4 K ), but modern high-temperature superconductors conduct at temperatures as high as 140 K .
- The highest temperature at which a superconductor exhibits superconductivity is called the superconducting transition temperature $\left(T_{\mathrm{c}}\right)$.
- Superconducting substances exhibit the Meissner effect, the exclusion of magnetic fields in the substance's volume. This can be demonstrated by levitating a magnet above a superconductor.

## Questions and Problems

## Section 25.1: Polymers

## Review Questions

25.1 Bakelite, the first commercially produced polymer, contains monomer units of phenol and formaldehyde. If an item made of Bakelite were broken, it could not be melted down and re-formed. Is Bakelite a thermoplastic or thermosetting polymer? Can Bakelite be recycled?
25.2 How are SBS rubber [Figure 25.6(a)] and nylon 6,6 similar? How are they different?

## Problems

25.3 What type of monomer unit is needed to make an electrically conducting organic polymer?
25.4 Draw the structure of the addition polymer formed by 1-butene:

Show at least two repeating units.
25.5 Draw the structure of the alternating copolymer of these two compounds, showing at least two repeating units.

25.6 Draw the structure of an alternating copolymer of these two amino acids, showing at least two repeating units:

## Section 25.2: Ceramics and Composite Materials

Review Questions
25.7 What types of atoms and bonds are present in the polymer "backbone" in a ceramic containing a transition metal?
25.8 Describe two natural types of composite materials and the substances that they contain.

## Problems

H25.9 What steps would be used to form a ceramic material from scandium and ethanol $\left(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}\right)$ using the sol-gel process?
25.10 Amorphous silica $\left(\mathrm{SiO}_{2}\right)$ can be formed in uniform spheres from a sol-gel process using methanol $\left(\mathrm{CH}_{3} \mathrm{OH}\right)$ solvent. List the chemical reactions involved in this process.
25.11 Bakelite, described in Review Question 25.1, is manufactured using materials like cellulose paper or glass fibers that are compressed and heated among the monomer units. Is Bakelite a simple polymer? If not, what classification best fits Bakelite?

## Section 25.3: Liquid Crystals

## Review Questions

25.12 Is a normal liquid isotropic or anisotropic? How is an anisotropic material different from an isotropic material?
25.13 Describe how nematic, smectic, and cholesteric liquid crystals are similar and different.

## Problems

H25.14 Would each of these molecules be likely to form a liquid crystal? If not, why not?
(a)

(b)

(c)

25.15 Would long-chain hydrocarbons or addition polymers of alkene molecules form liquid crystals? Why or why not?
25.16 Would an ionic compound form a liquid crystal? Why or why not?

## Section 25.4: Biomedical Materials

## Review Questions

H25.17 Name three major concerns that must be addressed when proposing any material to be used in medical applications inside the body.
25.18 Name a necessary chemical property and a necessary physical property of dental materials.

## Problems

GI25.19 Is the polymer commonly used in artificial skin material (shown here) an addition polymer or a condensation polymer? Is it a block, alternating, graft, or random copolymer?

25.20 What are some advantages and disadvantages of the use of ceramics in replacement joint bearing surfaces relative to metals?
25.21 How do amalgam and composite tooth fillings differ in the ways they fail over time?

## Section 25.5: Nanotechnology

## Review Questions

25.22 How does an STM measure the peak and valley heights along the surface of a sample?
25.23 Name four allotropic forms of carbon.

## Problems

E 25.24 How does an AFM differ from an STM? Why can graphite possibly be investigated with either instrument whereas diamond can only be investigated with an AFM?
25.25 What is the hybridization of the carbon atoms in a single-walled nanotube?
25.26 What structural or bonding aspect of graphite and carbon nanotubes allows their use as semiconductors, whereas diamond is an electrical insulator?
25.27 What type of intermolecular forces holds the sheets of carbon atoms together in graphite? What type of intermolecular forces hold carbon nanotubes together in strands and fibers?

## Section 25.6: Semiconductors

## Review Questions

25.28 How do the band gaps differ among conductors, semiconductors, and insulators?
25.29 The only elemental semiconductors ( $\mathrm{Si}, \mathrm{Ge}$, and graphite) are members of Group 4A. Why are Sn and Pb , which are also in Group 4A, not classified as semiconductors?

## Problems

$\leftrightarrows 25.30$ State whether each combination of elements would be expected to produce a semiconductor: (a) Ga and Sb , (b) As and N , (c) B and P , (d) Zn and Sb , (e) Cd and S .

EI 25.31 What type of semiconductor would be formed (a) if Si were doped with Sb and (b) if Ge were doped with B ?
25.32 Describe the movement of electrons in a solar battery that uses $p$-type and $n$-type semiconductors when light shines on the solar cell.

## Section 25.7: Superconductors

## Review Questions

25.33 Why is YBCO called a "high-temperature" semiconductor when it exhibits superconductivity only below $-180^{\circ} \mathrm{C}$, which is very cold?
25.34 How might the Meissner effect be used in a real-world application? What are the engineering challenges to this application with the current superconductors?

## Problems

25.35 What is the molecular formula of BSCCO-2201?
25.36 Superconductivity at room temperature is sometimes a subject of science fiction or fantasy. For example, in the movie Terminator 2: Judgment Day, a cyborg has a CPU that contains a roomtemperature superconductor. How might a computer with such a CPU differ in design from current computers?
25.37 What are the electron configurations of the copper ions in YBCO? Are both ions expected oxidation states for copper?

## Additional Problems

25.38 Draw representations of block copolymers and graft copolymers using the symbols A and B for two types of monomer units. Are the categories exclusive? Using a third monomer type, see if you can draw a representation of a polymer that is both a block and a graft copolymer.

E 25.39 Draw the structures of the two monomer units in this polymer:

$\leftrightarrows 25.40$ Is the polymer in Problem 25.39 a condensation polymer or an addition polymer? Is it a polyester, a polyamide, or something else?
25.41 What types of bonding (covalent, ionic, network, metallic) are present in a plastic polymer? In a ceramic material?
25.42 Draw representations of isotactic, syndiotactic, and atactic polyacrylonitrile (for the monomer unit, see Table 25.1).
25.43 Fluoride ion is commonly used in drinking water supplies and in toothpaste (in the form of sodium fluoride) to prevent tooth decay. The fluoride ions replace hydroxide ions in the enamel mineral hydroxyapatite $\left[\mathrm{Ca}_{5}\left(\mathrm{PO}_{4}\right)_{3} \mathrm{OH}\right.$, the same mineral as in bone], forming fluoroapatite $\left[\mathrm{Ca}_{5}\left(\mathrm{PO}_{4}\right)_{3} \mathrm{~F}\right]$. Why does replacing the hydroxide ion with fluoride ion prevent tooth decay? How does this relate to the properties of materials used in artificial fillings?
25.44 Would the metal alkoxide in the sol-gel process be acidic or basic?

E 25.45 Would the compound shown form a liquid crystal? Why or why not?

25.46 The semiconductor band gap energy determines the color of an LED. Knowing what you learned in Chapter 6 about the energies of photons of different colors of light, which semiconductor would have the larger band gap: the one in a green exit sign's LEDs, or the one in a red traffic signal?

## Pre-Professional Practice Exam Problems: Physical and Biological Sciences

These questions are not based on a passage.

1. Which of the following would form an $n$-type semiconductor: (i) doping Ge with As , (ii) doping Si with B , (iii) doping graphite with P?
a) i, ii, and iii
b) i and iii
c) i and ii
d) iii only
2. What is unusual about the copper in YBCO ?
a) It exists as a mixture of +1 and +2 oxidation states.
b) It exists as a mixture of +1 and 0 oxidation states.
c) It exists as a mixture of +1 and +3 oxidation states.
d) It exists as a mixture of +2 and +3 oxidation states.
3. A semiconductor can be produced by the combination of two elements with a total of how many valence electrons?
a) 6
b) 8
c) 12
d) 16
4. Metals are good conductors of electricity because they
a) have no band gap.
b) have a large band gap.
c) have a small band gap.
d) combine with nonmetals to form semiconductors.

## Answers to In-Chapter Materials

## Answers to Practice Problems

25.2B Condensation.

$25.3-\mathrm{CH}=\mathrm{C}\left(\mathrm{CH}_{2} \mathrm{CH}_{3}\right)-\mathrm{CH}=\mathrm{C}\left(\mathrm{CH}_{2} \mathrm{CH}_{3}\right)-\mathrm{CH}=\mathrm{C}\left(\mathrm{CH}_{2} \mathrm{CH}_{3}\right)-$

$$
-\mathrm{CH}_{2}-\mathrm{CH}\left(\mathrm{CH}_{2} \mathrm{CH}_{3}\right)-\mathrm{CH}_{2}-\mathrm{CH}\left(\mathrm{CH}_{2} \mathrm{CH}_{3}\right)-\mathrm{CH}_{2}-\mathrm{CH}\left(\mathrm{CH}_{2} \mathrm{CH}_{3}\right)-
$$

The two structures are similar in that they both have ethyl groups on alternating carbons. They are different in that poly(1-butyne) is a conjugated system and poly(1-butene) is not. The first structure is more likely to be an electrically conducting polymer. 25.4A The top molecule would be more likely to exhibit liquid crystal behavior because it is long, thin, and has conjugated rings that limit free rotation. 25.4B Addition of an alkyl chain makes the molecule longer, contributing to its ability to exhibit liquid crystal behavior.

25.5A (a) Elements with two valence electrons, e.g., $\mathrm{Be}, \mathrm{Sr}, \mathrm{Cd}$, (b) elements with three valence electrons, e.g., B, Ga, In, (c) elements with six valence electrons, e.g., O, Se, Te. 25.5B Carbon can be combined with silicon to produce a semiconductor. Arsenic can be used to dope silicon to produce an $n$-type semiconductor; and gallium can be used to dope silicon to produce a $p$-type semiconductor.

## Answers to Checkpoints

25.1.1 a. 25.1.2 d. 25.3.1 c. 25.3.2 a, c. 25.6.1 b. 25.6.2 c.

Answers to Applying What You've Learned a) $\left(\mathrm{CHCH}_{2} \mathrm{CH}_{2} \mathrm{CH}\right)_{50}\left(\mathrm{CHCHClCH}_{2} \mathrm{CH}\right)_{70}$. b) Block. c) No.

## Appendix 1

Mathematical Operations

## Scientific Notation

Chemists often deal with numbers that are either extremely large or extremely small. For example, in 1 g of the element hydrogen there are roughly

$$
602,200,000,000,000,000,000,000
$$

hydrogen atoms. Each hydrogen atom has a mass of only

$$
0.00000000000000000000000166 \mathrm{~g}
$$

These numbers are cumbersome to handle, and it is easy to make mistakes when using them in arithmetic computations. Consider the following multiplication:

$$
0.0000000056 \times 0.00000000048=0.000000000000000002688
$$

It would be easy for us to miss one zero or add one more zero after the decimal point. Consequently, when working with very large and very small numbers, we use a system called scientific notation. Regardless of their magnitude, all numbers can be expressed in the form

$$
N \times 10^{n}
$$

where $N$ is a number between 1 and 10 and $n$, the exponent, is a positive or negative integer (whole number). Any number expressed in this way is said to be written in scientific notation.

Suppose that we are given a certain number and asked to express it in scientific notation. Basically, this assignment calls for us to find $n$. We count the number of places that the decimal point must be moved to give the number $N$ (which is between 1 and 10 ). If the decimal point has to be moved to the left, then $n$ is a positive integer; if it has to be moved to the right, $n$ is a negative integer. The following examples illustrate the use of scientific notation:

1. Express 568.762 in scientific notation:

$$
568.762=5.68762 \times 10^{2}
$$

Note that the decimal point is moved to the left by two places and $n=2$.
2. Express 0.00000772 in scientific notation:

$$
0.00000772=7.72 \times 10^{-6}
$$

Here the decimal point is moved to the right by six places and $n=-6$.
Keep in mind the following two points. First, $n=0$ is used for numbers that are not expressed in scientific notation. For example, $74.6 \times 10^{0}(n=0)$ is equivalent to 74.6. Second, the usual practice is to omit the superscript when $n=1$. Thus the scientific notation for 74.6 is $7.46 \times 10$ and not $7.46 \times 10^{1}$

Next, we consider how scientific notation is handled in arithmetic operations.

## Addition and Subtraction

To add or subtract using scientific notation, we first write each quantity—say $N_{1}$ and $N_{2}$ —with the same exponent $n$. Then we combine $N_{1}$ and $N_{2}$; the exponents remain the same. Consider the following examples:

$$
\begin{aligned}
\left(7.4 \times 10^{3}\right)+\left(2.1 \times 10^{3}\right) & =9.5 \times 10^{3} \\
\left(4.31 \times 10^{4}\right)+\left(3.9 \times 10^{3}\right) & =\left(4.31 \times 10^{4}\right)+\left(0.39 \times 10^{4}\right) \\
& =4.70 \times 10^{4} \\
\left(2.22 \times 10^{-2}\right)-\left(4.10 \times 10^{-3}\right) & =\left(2.22 \times 10^{-2}\right)-\left(0.41 \times 10^{-2}\right) \\
& =1.81 \times 10^{-2}
\end{aligned}
$$

## Multiplication and Division

To multiply numbers expressed in scientific notation, we multiply $N_{1}$ and $N_{2}$ in the usual way, but add the exponents together. To divide using scientific notation, we divide $N_{1}$ and $N_{2}$ as usual and subtract the exponents. The following examples show how these operations are performed:

$$
\begin{aligned}
\left(8.0 \times 10^{4}\right) \times\left(5.0 \times 10^{2}\right) & =(8.0 \times 5.0)\left(10^{4+2}\right) \\
& =40 \times 10^{6} \\
& =4.0 \times 10^{7} \\
\left(4.0 \times 10^{-5}\right) \times\left(7.0 \times 10^{3}\right) & =(4.0 \times 7.0)\left(10^{-5+3}\right) \\
& =28 \times 10^{-2} \\
& =2.8 \times 10^{-1} \\
\frac{6.9 \times 10^{7}}{3.0 \times 10^{-5}} & =\frac{6.9}{3.0} \times 10^{7-(-5)} \\
& =2.3 \times 10^{12} \\
\frac{8.5 \times 10^{4}}{5.0 \times 10^{9}} & =\frac{8.5}{5.0} \times 10^{4-9} \\
& =1.7 \times 10^{-5}
\end{aligned}
$$

## Basic Trigonometry

In the triangle shown, $\mathrm{A}, \mathrm{B}$, and C are angles $\left(\mathrm{C}=90^{\circ}\right)$ and $a, b$, and $c$ are side lengths. To calculate unknown angles or sides, we use the following relationships:

$$
\begin{aligned}
a^{2}+b^{2} & =c^{2} \\
\sin \mathrm{~A} & =\frac{a}{c} \\
\cos \mathrm{~A} & =\frac{b}{c} \\
\tan \mathrm{~A} & =\frac{a}{b}
\end{aligned}
$$

## Logarithms

## Common Logarithms

The concept of logarithms is an extension of the concept of exponents, which is discussed on page A-1. The common, or base-10, logarithm of any number is the power to which 10 must be raised to equal the number. The following examples illustrate this relationship:

| Logarithm | Exponent |
| :--- | :--- |
| $\log 1=0$ | $10^{0}=1$ |
| $\log 10=1$ | $10^{1}=10$ |
| $\log 100=2$ | $10^{2}=100$ |
| $\log 10^{-1}=-1$ | $10^{-1}=0.1$ |
| $\log 10^{-2}=-2$ | $10^{-2}=0.01$ |

In each case the logarithm of the number can be obtained by inspection.
Because the logarithms of numbers are exponents, they have the same properties as exponents. Thus, we have

| Logarithm | Exponent |
| :---: | :--- |
| $\log A B=\log A+\log B$ | $10^{\mathrm{A}} \times 10^{\mathrm{B}}=10^{\mathrm{A}+\mathrm{B}}$ |
| $\log \frac{\mathrm{A}}{\mathrm{B}}=\log \mathrm{A}-\log \mathrm{B}$ | $\frac{10^{\mathrm{A}}}{10^{\mathrm{B}}}=10^{\mathrm{A}-\mathrm{B}}$ |

Furthermore, $\log \mathrm{A}^{n}=n \log \mathrm{~A}$.
Now suppose we want to find the common logarithm of $6.7 \times 10^{-4}$. On most electronic calculators, the number is entered first and then the log key is pressed. This operation gives us

$$
\log 6.7 \times 10^{-4}=-3.17
$$

Note that there are as many digits after the decimal point as there are significant figures in the original number. The original number has two significant figures, and the " 17 " in -3.17 tells us that the $\log$ has two significant figures. The " 3 " in -3.17 serves only to locate the decimal point in the number $6.7 \times 10^{-4}$. Other examples are

| Number | Common Logarithm |
| :--- | :--- |
| 62 | 1.79 |
| 0.872 | -0.0595 |
| $1.0 \times 10^{-7}$ | -7.00 |

Sometimes (as in the case of pH calculations) it is necessary to obtain the number whose logarithm is known. This procedure is known as taking the antilogarithm; it is simply the reverse of taking the logarithm of a number. Suppose in a certain calculation we have $\mathrm{pH}=1.46$ and are asked to calculate $\left[\mathrm{H}^{+}\right]$. From the definition of $\mathrm{pH}\left(\mathrm{pH}=-\log \left[\mathrm{H}^{+}\right]\right)$we can write

$$
\left[\mathrm{H}^{+}\right]=10^{-1.46}
$$

Many calculators have a key labeled $\log ^{-1}$ or INV log to obtain antilogs. Other calculators have a $10^{x}$ or $y^{x}$ key (where $x$ corresponds to -1.46 in our example and $y$ is 10 for base- 10 logarithm). Therefore, we find that $\left[\mathrm{H}^{+}\right]=0.035 \mathrm{M}$.

## Natural Logarithms

Logarithms taken to the base $e$ instead of 10 are known as natural logarithms (denoted by $\ln$ or $\log _{e}$ ); $e$ is equal to 2.7183 . The relationship between common logarithms and natural logarithms is as follows:

$$
\begin{aligned}
\log 10 & =1 & 10^{1} & =10 \\
\ln 10 & =2.303 & e^{2.303} & =10
\end{aligned}
$$

Thus,

$$
\ln x=2.303 \log x
$$

To find the natural logarithm of 2.27 , say, we first enter the number on the electronic calculator and then press the ln key to get

$$
\ln 2.27=0.820
$$

If no $\ln$ key is provided, we can proceed as follows:

$$
\begin{aligned}
2.303 \log 2.27 & =2.303 \times 0.356 \\
& =0.820
\end{aligned}
$$

Sometimes we may be given the natural logarithm and asked to find the number it represents. For example,

$$
\ln x=59.7
$$

On many calculators, we simply enter the number and press the $e$ key:

$$
e^{59.7}=8 \times 10^{25}
$$

## The Quadratic Equation

A quadratic equation takes the form

$$
a x^{2}+b x+c=0
$$

If coefficients $a, b$, and $c$ are known, then $x$ is given by

$$
x=\frac{-b \pm \sqrt{b^{2}-4 a c}}{2 a}
$$

Suppose we have the following quadratic equation:

$$
2 x^{2}+5 x-12=0
$$

Solving for $x$, we write

$$
\begin{aligned}
x & =\frac{-5 \pm \sqrt{(5)^{2}-4(2)(-12)}}{2(2)} \\
& =\frac{-5 \pm \sqrt{25+96}}{4}
\end{aligned}
$$

Therefore,

$$
x=\frac{-5+11}{4}=\frac{3}{2}
$$

and

$$
x=\frac{-5-11}{4}=-4
$$

## Successive Approximation

In the determination of hydrogen ion concentration in a weak acid solution, use of the quadratic equation can sometimes be avoided using a method known as successive approximation. Consider the example of a 0.0150 M solution of hydrofluoric acid (HF). The $K_{\mathrm{a}}$ for HF is $7.10 \times 10^{-4}$. To determine the hydrogen ion concentration in this solution, we construct an equilibrium table and enter the initial concentrations, the expected change in concentrations, and the equilibrium concentrations of all species:

$$
\mathrm{HF}(a q) \rightleftarrows \mathrm{H}^{+}(a q)+\mathrm{F}^{-}(a q)
$$

Initial concentration ( $M$ ):
Change in concentration $(M)$ :
Equilibrium concentration ( $M$ ):

| 0.0150 | 0 | 0 |
| :---: | :---: | :---: |
| $-x$ | $+x$ | $+x$ |
| $0.0150-x$ | $x$ | $x$ |

Using the rule that $x$ can be neglected if the initial acid concentration divided by the $K_{\mathrm{a}}$ is greater than 100, we find that in this case $x$ cannot be neglected ( $0.0150 / 7.1 \times 10^{-4} \approx 21$ ). Successive approximation involves first neglecting $x$ with respect to initial acid concentration

$$
\frac{x^{2}}{0.0150-x} \approx \frac{x^{2}}{0.0150}=7.10 \times 10^{-4}
$$

and solving for $x$ :

$$
\begin{aligned}
x^{2} & =(0.0150)\left(7.10 \times 10^{-4}\right)=1.07 \times 10^{-5} \\
x & =\sqrt{1.07 \times 10^{-5}}=0.00326 \mathrm{M}
\end{aligned}
$$

We then solve for $x$ again, this time using the calculated value of $x$ on the bottom of the fraction:

$$
\begin{aligned}
\frac{x^{2}}{0.0150-x} & =\frac{x^{2}}{0.0150-0.00326}=7.10 \times 10^{-4} \\
x^{2} & =(0.0150-0.00326)\left(7.10 \times 10^{-4}\right)=8.33 \times 10^{-6} \\
x & =\sqrt{8.33 \times 10^{-6}}=0.00289 \mathrm{M}
\end{aligned}
$$

Note that the calculated value of $x$ decreased from 0.00326 to 0.00289 . We now use the new calculated value of $x$ on the bottom of the fraction and solve for $x$ again:

$$
\begin{aligned}
\frac{x^{2}}{0.0150-x} & =\frac{x^{2}}{0.0150-0.00289}=7.10 \times 10^{-4} \\
x^{2} & =(0.0150-0.00289)\left(7.10 \times 10^{-4}\right)=8.60 \times 10^{-6} \\
x & =\sqrt{8.60 \times 10^{-6}}=0.00293 \mathrm{M}
\end{aligned}
$$

This time the value of $x$ increased slightly. We use the new calculated value and solve for $x$ again.

$$
\begin{aligned}
\frac{x^{2}}{0.0150-x} & =\frac{x^{2}}{0.0150-0.00293}=7.10 \times 10^{-4} \\
x^{2} & =(0.0150-0.00293)\left(7.10 \times 10^{-4}\right)=8.57 \times 10^{-6} \\
x & =\sqrt{8.57 \times 10^{-6}}=0.00293 \mathrm{M}
\end{aligned}
$$

This time we find that the answer is still $0.00293 M$, so there is no need to repeat the process. In general, we apply the method of successive approximation until the value of $x$ obtained does not differ from the value obtained in the previous step. The value of $x$ determined using successive approximation is the same value we would get if we were to use the quadratic equation.

## Appendix 3

Solubility Product Constants at $25^{\circ} \mathrm{C}$

| Compound | Dissolution Equilibrium | $K_{\text {sp }}$ |
| :---: | :---: | :---: |
| Bromides |  |  |
| Copper(I) bromide | $\mathrm{CuBr}(\mathrm{s}) \rightleftarrows \mathrm{Cu}^{+}(a q)+\mathrm{Br}^{-}(\mathrm{aq})$ | $4.2 \times 10^{-8}$ |
| Lead(II) bromide | $\mathrm{PbBr}_{2}(\mathrm{~s}) \rightleftarrows \mathrm{Pb}^{2+}(\mathrm{aq})+2 \mathrm{Br}^{-}(\mathrm{aq})$ | $6.6 \times 10^{-6}$ |
| Mercury(l) bromide | $\mathrm{Hg}_{2} \mathrm{Br}_{2}(s) \rightleftarrows \mathrm{Hg}_{2}^{2+}(a q)+2 \mathrm{Br}^{-}(\mathrm{aq})$ | $6.4 \times 10^{-23}$ |
| Silver bromide | $\mathrm{AgBr}(\mathrm{s}) \rightleftarrows \mathrm{Ag}^{+}(a q)+\mathrm{Br}^{-}(a q)$ | $7.7 \times 10^{-13}$ |
| Carbonates |  |  |
| Barium carbonate | $\mathrm{BaCO}_{3}(s) \rightleftarrows \mathrm{Ba}^{2+}(\mathrm{aq})+\mathrm{CO}_{3}^{2}(\mathrm{aq})$ | $8.1 \times 10^{-9}$ |
| Calcium carbonate | $\mathrm{CaCO}_{3}(\mathrm{~s}) \rightleftarrows \mathrm{Ca}^{2+}(\mathrm{aq})+\mathrm{CO}_{3}^{2-}(a q)$ | $8.7 \times 10^{-9}$ |
| Lead(II) carbonate | $\mathrm{PbCO}_{3}(s) \rightleftarrows \mathrm{Pb}^{2+}(a q)+\mathrm{CO}_{3}^{2-}(a q)$ | $3.3 \times 10^{-14}$ |
| Magnesium carbonate | $\mathrm{MgCO}_{3}(\mathrm{~s}) \rightleftarrows \mathrm{Mg}^{2+}(\mathrm{aq})+\mathrm{CO}_{3}^{2-}(\mathrm{aq})$ | $4.0 \times 10^{-5}$ |
| Silver carbonate | $\mathrm{Ag}_{2} \mathrm{CO}_{3}(s) \rightleftarrows 2 \mathrm{Ag}^{+}(a q)+\mathrm{CO}_{3}^{2-}(a q)$ | $8.1 \times 10^{-12}$ |
| Strontium carbonate | $\mathrm{SrCO}_{3}(\mathrm{~s}) \rightleftarrows \mathrm{Sr}^{2+}(\mathrm{aq})+\mathrm{CO}_{3}^{2-}(\mathrm{aq})$ | $1.6 \times 10^{-9}$ |
| Chorides |  |  |
| Lead(II) chloride | $\mathrm{PbCl}_{2}(s) \rightleftarrows \mathrm{Pb}^{2+}(a q)+2 \mathrm{Cl}^{-}(a q)$ | $2.4 \times 10^{-4}$ |
| Mercury(l) chloride | $\mathrm{Hg}_{2} \mathrm{Cl} 2(s) \rightleftarrows \mathrm{Hg}_{2}^{2+}(a q)+2 \mathrm{Cl}^{-}(a q)$ | $3.5 \times 10^{-18}$ |
| Silver chloride | $\mathrm{AgCl}(\mathrm{s}) \rightleftarrows \mathrm{Ag}^{+}(a q)+\mathrm{Cl}^{-}(a q)$ | $1.6 \times 10^{-10}$ |
| Chromates |  |  |
| Lead(II) chromate | $\mathrm{PbCrO}_{4}(\mathrm{~s}) \rightleftarrows \mathrm{Pb}^{2+}(a q)+\mathrm{CrO}_{4}^{2-}(a q)$ | $2.0 \times 10^{-14}$ |
| Silver(I) chromate | $\mathrm{Ag}_{2} \mathrm{CrO}_{4}(\mathrm{~s}) \rightleftarrows 2 \mathrm{Ag}^{+}(\mathrm{aq})+\mathrm{CrO}_{4}^{2-}(a q)$ | $1.2 \times 10^{-12}$ |
| Fluorides |  |  |
| Barium fluoride | $\mathrm{BaF}_{2}(s) \rightleftarrows \mathrm{Ba}^{2+}(a q)+2 \mathrm{~F}^{-}(\mathrm{aq})$ | $1.7 \times 10^{-6}$ |
| Calcium fluoride | $\mathrm{CaF}_{2}(\mathrm{~s}) \rightleftarrows \mathrm{Ca}^{2+}(a q)+2 \mathrm{~F}^{-}(\mathrm{aq})$ | $4.0 \times 10^{-11}$ |
| Lead(II) fluoride | $\mathrm{PbF}_{2}(s) \rightleftarrows \mathrm{Pb}^{2+}(a q)+2 \mathrm{~F}^{-}(\mathrm{aq})$ | $4.0 \times 10^{-8}$ |

| Compound | Dissolution Equilibrium | $K_{\text {sp }}$ |
| :---: | :---: | :---: |
| Hydroxides |  |  |
| Aluminum hydroxide | $\mathrm{Al}(\mathrm{OH})_{3}(\mathrm{~s}) \rightleftarrows \mathrm{Al}^{3+}(a q)+3 \mathrm{OH}^{-}(a q)$ | $1.8 \times 10^{-33}$ |
| Calcium hydroxide | $\mathrm{Ca}(\mathrm{OH})_{2}(\mathrm{~s}) \rightleftarrows \mathrm{Ca}^{2+}(\mathrm{aq})+2 \mathrm{OH}^{-}(\mathrm{aq})$ | $8.0 \times 10^{-6}$ |
| Chromium(III) hydroxide | $\mathrm{Cr}(\mathrm{OH})_{3}(\mathrm{~s}) \rightleftarrows \mathrm{Cr}^{3+}(\mathrm{aq})+3 \mathrm{OH}^{-}(\mathrm{aq})$ | $3.0 \times 10^{-29}$ |
| Copper(II) hydroxide | $\mathrm{Cu}(\mathrm{OH})_{2}(\mathrm{~s}) \rightleftarrows \mathrm{Cu}^{2+}(\mathrm{aq})+2 \mathrm{OH}^{-}(\mathrm{aq})$ | $2.2 \times 10^{-20}$ |
| Iron(II) hydroxide | $\mathrm{Fe}(\mathrm{OH})_{2}(\mathrm{~s}) \rightleftarrows \mathrm{Fe}^{2+}(a q)+2 \mathrm{OH}^{-}(a q)$ | $1.6 \times 10^{-14}$ |
| Iron(III) hydroxide | $\mathrm{Fe}(\mathrm{OH})_{3}(\mathrm{~s}) \rightleftarrows \mathrm{Fe}^{3+}(a q)+3 \mathrm{OH}^{-}(a q)$ | $1.1 \times 10^{-36}$ |
| Magnesium hydroxide | $\mathrm{Mg}(\mathrm{OH})_{2}(\mathrm{~s}) \rightleftarrows \mathrm{Mg}^{2+}(\mathrm{aq})+2 \mathrm{OH}^{-}(\mathrm{aq})$ | $1.2 \times 10^{-11}$ |
| Strontium hydroxide | $\mathrm{Sr}(\mathrm{OH})_{2}(\mathrm{~s}) \rightleftarrows \mathrm{Sr}^{2+}(\mathrm{aq})+2 \mathrm{OH}^{-}(\mathrm{aq})$ | $3.2 \times 10^{-4}$ |
| Zinc hydroxide | $\mathrm{Zn}(\mathrm{OH})_{2}(\mathrm{~s}) \rightleftarrows \mathrm{Zn}^{2+}(\mathrm{aq})+2 \mathrm{OH}^{-}(\mathrm{aq})$ | $1.8 \times 10^{-14}$ |
| Iodides |  |  |
| Copper(I) iodide | $\mathrm{CuI}(\mathrm{s}) \rightleftarrows \mathrm{Cu}^{+}(a q)+\mathrm{I}^{-}(\mathrm{aq})$ | $5.1 \times 10^{-12}$ |
| Lead(II) iodide | $\mathrm{PbI}_{2}(\mathrm{~s}) \rightleftarrows \mathrm{Cu}^{2+}(a q)+2 \mathrm{I}^{-}(\mathrm{aq})$ | $1.4 \times 10^{-8}$ |
| Silver iodide | $\mathrm{AgI}(s) \rightleftarrows \mathrm{Ag}^{+}(a q)+\mathrm{I}^{-}(a q)$ | $8.3 \times 10^{-17}$ |
| Phosphates |  |  |
| Calcium phosphate | $\mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}(s) \rightleftarrows 3 \mathrm{Ca}^{2+}(a q)+2 \mathrm{PO}_{4}^{3-}(\mathrm{aq})$ | $1.2 \times 10^{-26}$ |
| Iron(III) phosphate | $\mathrm{FePO}_{4}(\mathrm{~s}) \rightleftarrows \mathrm{Fe}^{3+}(\mathrm{aq})+\mathrm{PO}_{4}^{3-}(\mathrm{aq})$ | $1.3 \times 10^{-22}$ |
| Sulfates |  |  |
| Barium sulfate | $\mathrm{BaSO}_{4}(\mathrm{~s}) \rightleftarrows \mathrm{Ba}^{2+}(a q)+\mathrm{SO}_{4}^{2-}(\mathrm{aq})$ | $1.1 \times 10^{-10}$ |
| Calcium sulfate | $\mathrm{CaSO}_{4}(\mathrm{~s}) \rightleftarrows \mathrm{Ca}^{2+}(\mathrm{aq})+\mathrm{SO}_{4}^{2-}(\mathrm{aq})$ | $2.4 \times 10^{-5}$ |
| Lead(II) sulfate | $\mathrm{PbSO}_{4}(\mathrm{~s}) \rightleftarrows \mathrm{Pb}^{2+}(a q)+\mathrm{SO}_{4}^{2-}(\mathrm{aq})$ | $1.8 \times 10^{-8}$ |
| Mercury(I) sulfate | $\mathrm{Hg}_{2} \mathrm{SO}_{4}(\mathrm{~s}) \rightleftarrows \mathrm{Hg}_{2}^{2+}(a q)+\mathrm{SO}_{4}^{2-}(a q)$ | $6.5 \times 10^{-7}$ |
| Silver sulfate | $\mathrm{Ag}_{2} \mathrm{SO}_{4}(\mathrm{~s}) \rightleftarrows 2 \mathrm{Ag}^{+}(a q)+\mathrm{SO}_{4}^{2-}(a q)$ | $1.5 \times 10^{-5}$ |
| Strontium sulfate | $\mathrm{SrO}_{4}(\mathrm{~s}) \rightleftarrows \mathrm{Sr}^{2+}(\mathrm{aq})+\mathrm{SO}_{4}^{2-}(\mathrm{aq})$ | $3.8 \times 10^{-7}$ |
| Sulfides |  |  |
| Bismuth sulfide | $\mathrm{Bi}_{2} \mathrm{~S}_{3}(s) \rightleftarrows 2 \mathrm{Bi}^{3+}(\mathrm{aq})+3 \mathrm{~S}^{2-}(\mathrm{aq})$ | $1.6 \times 10^{-72}$ |
| Cadmium sulfide | $\mathrm{CdS}(\mathrm{s}) \rightleftarrows \mathrm{Cd}^{2+}(\mathrm{aq})+\mathrm{S}^{2-}(\mathrm{aq})$ | $8.0 \times 10^{-28}$ |
| Cobalt(II) sulfide | $\operatorname{CoS}(\mathrm{s}) \rightleftarrows \mathrm{Co}^{2+}(a q)+\mathrm{S}^{2-}(\mathrm{aq})$ | $4.0 \times 10^{-21}$ |
| Copper(II) sulfide | $\mathrm{CuS}(\mathrm{s}) \rightleftarrows \mathrm{Cu}^{2+}(a q)+\mathrm{S}^{2-}(a q)$ | $6.0 \times 10^{-37}$ |
| Iron(II) sulfide | $\mathrm{FeS}(\mathrm{s}) \rightleftarrows \mathrm{Fe}^{2+}(\mathrm{aq})+\mathrm{S}^{2-}(a q)$ | $6.0 \times 10^{-19}$ |
| Lead(II) sulfide | $\mathrm{PbS}(\mathrm{s}) \rightleftarrows \mathrm{Pb}^{2+}(a q)+\mathrm{s}^{2-}(a q)$ | $3.4 \times 10^{-28}$ |
| Manganese(II) sulfide | $\mathrm{MnS}(\mathrm{s}) \rightleftarrows \mathrm{Mn}^{2+}(a q)+\mathrm{S}^{2-}(a q)$ | $3.0 \times 10^{-14}$ |
| Mercury(II) sulfide | $\mathrm{HgS}(\mathrm{s}) \rightleftarrows \mathrm{Hg}^{2+}(\mathrm{aq})+\mathrm{S}^{2-}(\mathrm{aq})$ | $4.0 \times 10^{-54}$ |
| Nickel(II) sulfide | $\mathrm{NiS}(\mathrm{s}) \rightleftarrows \mathrm{Ni}^{2+}(a q)+\mathrm{S}^{2-}(a q)$ | $1.4 \times 10^{-24}$ |
| Silver sulfide | $\mathrm{Ag}_{2} \mathrm{~S}(\mathrm{~s}) \rightleftarrows 2 \mathrm{Ag}^{+}(a q)+\mathrm{s}^{2-}(a q)$ | $6.0 \times 10^{-51}$ |
| Tin(II) sulfide | $\mathrm{SnS}(\mathrm{s}) \rightleftarrows \mathrm{Sn}^{2+}(\mathrm{aq})+\mathrm{S}^{2-}(\mathrm{aq})$ | $1.0 \times 10^{-26}$ |
| Zinc sulfide | $\mathrm{ZnS}(\mathrm{s}) \rightleftarrows \mathrm{Zn}^{2+}(a q)+\mathrm{S}^{2-}(a q)$ | $3.0 \times 10^{-23}$ |

## Glossary

## A

absolute temperature scale. A scale based on $-273.15^{\circ} \mathrm{C}$ (absolute zero) being the lowest point. (11.2)
absolute zero. Theoretically the lowest obtainable temperature: $-273.15^{\circ} \mathrm{C}$ or 0 K . (11.2)
absorbance. Negative base ten logarithm of transmittance. (4.5)
absorption spectrum. Plot of absorbance as a function of wavelength of incident light. (4.5)
accuracy. The closeness of a measurement to the true or accepted value. (1.5)
acid. See Arrhenius acid, Brønsted acid, and Lewis acid.
acid ionization constant $\left(K_{\mathrm{a}}\right)$. The equilibrium constant that indicates to what extent a weak acid ionizes. (16.5)
actinide series. Series of elements that has partially filled $5 f$ and/or $6 d$ subshells. (6.9)
activated complex. A transient species that forms when molecules collide in an effective collision. (14.4)
activation energy $\left(\boldsymbol{E}_{\mathrm{a}}\right)$. The minimum amount of energy to begin a chemical reaction. (14.4)
activity series. A list of metals arranged from top to bottom in order of decreasing ease of oxidation. (4.4)
actual yield. The amount of product actually obtained from a reaction. (3.7)
addition polymer. A large molecule that forms when small molecules known as monomers join together. (10.6)
addition polymerization. Process by which monomers combine to form polymers without the elimination of small molecules, such as water. (25.1)
adhesion. The attractions between unlike molecules. (12.2)
alcohol. A compound consisting of an alkyl group and the functional group -OH . (10.2)
aldehyde. A compound containing a hydrogen atom bonded to a carbonyl group. (10.2)
aliphatic. Describes organic molecules that do not contain the benzene ring. (10.1)
alkali metal. An element from Group 1A, with the exception of H (i.e., $\mathrm{Li}, \mathrm{Na}, \mathrm{K}, \mathrm{Rb}, \mathrm{Cs}$, and Fr ). (2.4)
alkaline earth metal. An element from Group $2 \mathrm{~A}(\mathrm{Be}, \mathrm{Mg}, \mathrm{Ca}, \mathrm{Sr}, \mathrm{Ba}$, and Ra$)$. (2.4)
alkane. Hydrocarbons having the general formula $\mathrm{C}_{n} \mathrm{H}_{2 n+2}$, where $n=1,2, \ldots$ (2.6)
alkyl group. A portion of a molecule that resembles an alkane. (10.2)
allotrope. One of two or more distinct forms of an element. (2.6)
alloy. Homogeneous mixture of two or more metals. (23.2)
alpha particle. A helium ion with a positive charge of +2 . (2.2)
alpha ray. See alpha particle.
amalgam. A substance made by combining mercury with one or more other metals. (Chapter 19, Opening Essay; 23.2)
amide. An organic molecule that contains an amide group. (10.2)
amine. An organic molecule that contains an amino group. (10.2)
amino acid. A compound that contains both an amino group and a carboxy group. (10.2)
amorphous solid. A solid that lacks a regular three-dimensional arrangement of atoms. (12.5)
amphoteric. Describes an oxide that displays both acidic and basic properties. $(7.7,16.2)$
amplitude. The vertical distance from the midline of a wave to the top of the peak or the bottom of the trough. (6.1)
angular momentum quantum number ( $\ell$ ). Describes the shape of the atomic orbital. (6.6)
anion. An ion with a negative charge. (2.7)
anisotropic. Dependent upon the axis of measurement. (25.3)
anode. The electrode at which oxidation occurs. (19.2)
antibonding molecular orbital. A molecular orbital that is higher in energy than the atomic orbitals that combined to produce it. (9.6)
aqueous. Dissolved in water. (3.3)
aromatic. Describes organic compounds that are related to benzene or that contain one or more benzene rings. (10.1)
Arrhenius acid. Substance that increases $\mathrm{H}^{+}$ concentration when added to water. $(2.6,4.3)$
Arrhenius base. Substance that increases $\mathrm{OH}^{-}$ concentration when added to water. (4.1, 4.3)
Arrhenius equation. An equation that gives the dependence of the rate constant of a reaction on temperature: $k=A e^{-E_{\mathrm{a}} R T}$. (14.4)
atactic. Describes polymers in which the substituents are oriented randomly along the polymer chain. (25.2)
atom. The basic unit of an element that can enter into chemical combination. (2.2)
atomic ion. Atom that has lost or gained one or more electrons, giving it a positive or negative charge. (2.7)
atomic mass. The mass of the atom given in atomic mass units (amu). (2.5)
atomic mass unit (amu). A mass exactly equal to one-twelfth the mass of one carbon-12 atom. (2.5)
atomic number $(\boldsymbol{Z})$. The number of protons in the nucleus of each atom of an element. (2.3)
atomic orbital. The wave function of an electron in an atom. (6.5)
atomic radius. Metallic: One-half the distance between the nuclei in the two adjacent atoms of the same element in a metal. Covalent: One-half the distance between the nuclei of the two identical atoms in a diatomic molecule. (7.4)
atomic weight. The average atomic mass. (2.5)
Aufbau principle. The process by which the periodic table can be built up by successively adding one proton to the nucleus and one electron to the appropriate atomic orbital. (6.8)
autoionization of water. Ionization of water molecules to give $\mathrm{H}^{+}$and $\mathrm{OH}^{-}$ions. (16.2)
Avogadro's law. The volume of a sample of gas $(V)$ is directly proportional to the number of moles $(n)$ in the sample at constant temperature and pressure: $V \propto n$. (11.2)
Avogadro's number $\left(N_{\mathrm{A}}\right)$. The number of atoms in exactly 12 g of carbon-12: $6.022 \times 10^{23}$. (3.4)
axial. Describes the two bonds that form an axis perpendicular to the trigonal plane. (9.1)

## B

band theory. A theory wherein atomic orbitals merge to form energy bands. (23.3)
barometer. An instrument used to measure atmospheric pressure. (11.1)
base. See Arrhenius base, Brønsted base, and Lewis base.
base ionization constant ( $\boldsymbol{K}_{\mathbf{b}}$ ). The equilibrium constant that indicates to what extent a weak base ionizes. (16.6)
battery. A portable, self-contained source of electric energy consisting of galvanic cells or a series of galvanic cells. (19.6)
Beer-Lambert law. Equation relating absorbance to molar absorptivity, solution concentration, and distance that light travels through a solution. (4.5)
beta particle. An electron. (2.2)
beta ray. See beta particle.
bimolecular. Describes a reaction in which two reactant molecules collide. (14.5)
binary compound. A substance that consists of just two different elements. (2.6)
blackbody radiation. The electromagnetic radiation emitted from a heated solid. (6.2)
body-centered cubic cell. A unit cell with one atom at the center of the cube and one atom at each of the eight corners. (12.3)
boiling point. The temperature at which vapor pressure equals atmospheric pressure. (12.6)
bond angle. The angle between two adjacent A-B bonds. (9.1)
bond enthalpy. The enthalpy change associated with breaking a particular bond in 1 mole of gaseous molecules. (8.9)
bonding molecular orbital. A molecular orbital that is lower in energy than the atomic orbitals that combined to produce it. (9.6)
bond order. A number based on the number of electrons in bonding and antibonding molecular orbitals that indicates, qualitatively, how stable a bond is. (9.6)
Born-Haber cycle. The cycle that relates the lattice energy of an ionic compound to quantities that can be measured. (8.2)
Boyle's law. The pressure of a fixed amount of gas at a constant temperature is inversely proportional to the volume of the gas: $P \propto 1 / V$. (11.2)
Bragg equation. An equation relating the wavelength of X rays, the angle of diffraction, and the spacing between atoms in a lattice. (12.3)
breeder reactor. A nuclear reactor that produces more fissionable material than it consumes. (20.5)
Brønsted acid. A substance that donates a proton $\left(\mathrm{H}^{+}\right) .(4.3,16.1)$
Brønsted base. A substance that accepts a proton $\left(\mathrm{H}^{+}\right) .(4.3,16.1)$
buffer. A solution that contains significant concentrations of both members of a conjugate pair (weak acid/conjugate base or weak base/conjugate acid). (17.2)

## C

calorimetry. The measurement of heat changes. (5.4)
capillary action. The movement of liquid up a narrow tube as the result of adhesive forces. (12.2)
carbocation. A species in which one of the carbons is surrounded by only six electrons. (10.5)
carbon nanotube. A tube made of carbon atoms with dimensions on the order of nanometers. (25.5)
carboxylic acid. An organic acid that contains a carboxy group. (10.2)
catalyst. A substance that increases the rate of a chemical reaction without itself being consumed. (14.6)
catenation. The formation of long carbon chains. (10.1)
cathode. The electrode at which reduction occurs. (19.2)
cation. An ion with a positive charge. (2.7)
cell potential $\left(\boldsymbol{E}_{\text {cell }}\right)$. The difference in electric potential between the cathode and the anode. (19.2)
ceramics. Polymeric inorganic compounds that share the properties of hardness, strength, and high melting points. (25.2)
chalcogens. Elements in Group 6A (O, S, Se, Te, and Po). (2.4)
Charles and Gay-Lussac's law. See Charles's law.
Charles's law. The volume of a fixed amount of gas $(V)$ maintained at constant pressure is directly proportional to absolute temperature ( $T$ ): $V \propto T$. (11.2)
chelating agent. A polydentate ligand that forms complex ions with metal ions in solution. (22.1)
chemical change. A process in which one or more substances are changed into one or more new substances. (1.4)
chemical energy. Energy stored within the structural units (molecules or polyatomic ions) of chemical substances. (5.1)
chemical equation. Chemical symbols used to represent a chemical reaction. (3.3)
chemical formula. Chemical symbols and numerical subscripts used to denote the composition of the substance. (2.6)
chemical property. Any property of a substance that cannot be studied without converting the substance into some other substance. (1.4)
chemistry. The study of matter and the changes it undergoes. (1.1)
chiral. Describes molecules with nonsuperimposable mirror images. (10.4)
cholesteric. Describes molecules that are parallel to each other within each layer, but where each layer is rotated with respect to the layers above and below it. (25.3)
cis. Describes the isomer in which two substituents both lie on the same side of a double bond. (10.4)
Clausius-Clapeyron equation. A linear relationship that exists between the natural $\log$ of vapor pressure and the reciprocal of absolute temperature. (12.2)
closed system. A system that can exchange energy (but not mass) with the surroundings. (5.2)
cohesion. The attraction between like molecules. (12.2)
colligative properties. Properties that depend on the number of solute particles in solution but do not depend on the nature of the solute particles. (13.5)
collision theory. The reaction rate is directly proportional to the number of molecular collisions per second. (14.4)
colloid. A dispersion of particles of one substance throughout another substance. (13.7)
combination reaction. A reaction in which two or more reactants combine to form a single product. (3.7)
combustion. Burning in air. (3.5)
combustion analysis. An experimental determination of an empirical formula by a reaction with oxygen to produce carbon dioxide and water. (3.5)
combustion reaction. A reaction in which a substance burns in the presence of oxygen. (3.7)
common ion effect. The presence of a common ion suppresses the ionization of a weak acid or weak base. (17.1)
complex ion. Charged species consisting of a central metal cation bonded to two or more anions or polar molecules. (17.5)
composite material. A material made from two or more substances with different properties that remain separate in the bulk material. (25.2)
compound. A substance composed of atoms of two or more elements chemically united in fixed proportions. (1.2)
concentration. Amount of solute relative to the volume of a solution or to the amount of solvent in a solution. (4.1)
concentration cell. A cell that has the same type of electrode and the same ion in solution (at different concentrations) in the anode and cathode compartments. (19.5)
condensation. The phase transition from gas to liquid. (12.2)
condensation polymer. A large molecule that forms when small molecules undergo condensation reactions. $(10.6,25.1)$
condensation reaction. An elimination reaction in which two or more molecules become connected with the elimination of a small molecule, often water. (10.6)
condensed structural formula. Shows the same information as a structural formula, but in a condensed form. (10.3)
condensed structure. Chemical structure simplified by using abbreviations for repeating structural units. (10.3)
conduction band. The antibonding band. (25.6)
conductor. A substance through which electrons move freely. (23.3)
conjugate acid. The cation that remains when a Brønsted base accepts a proton. (16.1)
conjugate base. The anion that remains when a Brønsted acid donates a proton. (16.1)
conjugate pair. The combination of a Brønsted acid and its conjugate base (or the combination of a Brønsted base and its conjugate acid). (16.1)
constitutional isomers. Compounds with the same chemical formula but different structures. (10.4)
conversion factor. A fraction in which the same quantity is expressed one way in the numerator and another way in the denominator. (1.6)
coordinate covalent bond. A covalent bond in which one of the atoms donates both electrons. (8.8)
coordination compound. A compound that contains coordinate covalent bonds between a metal ion (often a transition metal ion) and two or more polar molecules or ions. (22.1)
coordination number. The number of atoms surrounding an atom in a crystal lattice. (12.3) The number of donor atoms surrounding a metal in a complex. (22.1)
copolymer. A polymer made of two or more different monomers. $(10.6,25.1)$
corrosion. The undesirable oxidation of metals. (19.8)

Coulomb's law. The force $(F)$ between two charged objects $\left(Q_{1}\right.$ and $\left.Q_{2}\right)$ is directly proportional to the product of the two charges and inversely proportional to the distance $(d)$ between the objects squared. (7.3)
covalent bond. A shared pair of electrons. (8.3)
covalent bonding. Two atoms sharing a pair of electrons. (8.3)
covalent radius. Half the distance between adjacent, identical nuclei in a molecule. (7.4)
critical mass. The minimum amount of fissionable material required to sustain a reaction. (20.5)
critical pressure $\left(\boldsymbol{P}_{\mathbf{c}}\right)$. The minimum pressure that must be applied to liquefy a substance at its critical temperature. (12.6)
critical temperature ( $\boldsymbol{T}_{\mathrm{c}}$ ). The temperature at which the gas phase cannot be liquefied, no matter how great the applied pressure. (12.6)
cross-link. A bond that forms between a functional group off the backbone of the polymer chain that interacts with another functional group of a second polymer strand creating a new covalent bond and causing the polymer to be stronger and more rigid. (25.1)
crystal field splitting ( $\Delta$ ). The difference in energy between the lower and higher $d$-orbital energy levels. (22.3)
crystalline solid. A solid that possesses rigid and long-range order; its atoms, molecules, or ions occupy specific positions. (12.3)

## D

Dalton's law of partial pressures. The total pressure exerted by a gas mixture is the sum of the partial pressures exerted by each component of the mixture. (11.5)
dative bond. A covalent bond in which one of the atoms donates both electrons. (8.8)
de Broglie wavelength. A wavelength calculated using the following equation: $\lambda=h / m u$. (6.4)
decomposition reaction. A reaction in which one reactant forms two or more products. (3.7)
degenerate. Having an equal energy. (6.8)
delocalized. Spread out over the molecule or part of the molecule, rather than confined between two specific atoms. (9.7)
density. The ratio of mass to volume. (1.3)
deoxyribonucleic acid (DNA). Biological polymer arranged in a double-helix shape, consisting of two long chains of nucleotides in which the sugar is deoxyribose. (10.6)
deposition. The phase change from gas to solid. (12.6)
dextrorotatory. The term used to describe the enantiomer that rotates the plane-polarized light to the right. (22.2)
diagonal relationships. Similarities in chemical properties of elements that are in different groups but that are positioned diagonally to one another in the periodic table. (7.7)
diamagnetic. A species without unpaired electrons that is weakly repelled by magnetic fields. (9.6)
diatomic molecule. A molecule that contains two atoms. (2.6)
diffusion. The mixing of gases. (11.6)
dilution. The process of preparing a less concentrated solution from a more concentrated one. (4.5)
dimensional analysis. The use of conversion factors in problem solving. (1.6)
diode. An electronic device that restricts the flow of electrons in a circuit to one direction. (25.6)
dipole moment ( $\boldsymbol{\mu}$ ). A quantitative measure of the polarity of a bond. (8.4)
dipole-dipole interactions. Attractive forces that act between polar molecules. (12.1)
diprotic acid. An acid with two ionizable protons. (4.3)
dispersion forces. See London dispersion forces.
displacement. An atom or ion in a compound is replaced by an atom of another element. (4.4)
displacement reaction. Reaction in which two reactants trade components (double displacement) or where a component of a reactant is removed (single displacement). (4.4)
disproportionation. When an element undergoes both oxidation and reduction in the same reaction. (4.4)
dissociation. The process by which an ionic compound, upon dissolution, breaks apart into its constituent ions. (4.1)
donor atom. The atom that bears the unshared pair of electrons. (22.1)
doping. The addition of very small quantities of an element with one more or one fewer valence electron than the natural semiconductor. (25.6)
d orbital. Atomic orbital in which the angular momentum quantum number $(\ell)$ is 2 . (6.6)
double bond. A multiple bond in which the atoms share two pairs of electrons. (8.3)
dynamic equilibrium. Occurs when a forward process and reverse process are occurring at the same rate. (12.2)

## E

effective collision. A collision that results in a reaction. (14.4)
effective nuclear charge ( $Z_{\text {eff }}$ ). The actual magnitude of positive charge that is "experienced" by an electron in the atom. (7.3)
effusion. The escape of a gas from a container into a vacuum. (11.6)
elastomer. A material that can stretch or bend and then return to its original shape as long as the limits of its elasticity are not exceeded. (25.1)
electricity. The movement of electrons. (4.1)
electrode. A piece of conducting metal in an electrochemical cell at which either oxidation or reduction takes place. (19.2)
electrolysis. The use of electric energy to drive a nonspontaneous redox reaction. (19.7)
electrolyte. A substance that dissolves in water to yield a solution that conducts electricity. (4.1)
electrolytic cell. An electrochemical cell used for electrolysis. (19.7)
electromagnetic spectrum. Consists of radio waves, microwave radiation, infrared radiation, visible light, ultraviolet radiation, X rays, and gamma rays. (6.1)
electromagnetic wave. A wave that has an electric field component and a magnetic field component. (6.1)
electron. A negatively charged subatomic particle found outside the nucleus of all atoms. (2.2)
electron affinity (EA). The energy released (the negative of the enthalpy change, $\Delta H$ ) when an atom in the gas phase accepts an electron. (7.4)
electron configuration. The distribution of electrons in the atomic orbitals of an atom. (6.8)
electron density. The probability that an electron will be found in a particular region of an atom. (6.5)
electron domain. A lone pair or a bond, regardless of whether the bond is single, double, or triple. (9.1)
electron-domain geometry. The arrangement of electron domains (bonds and lone pairs) around a central atom. (9.1)
electron spin quantum number $\left(m_{\mathrm{s}}\right)$. The fourth quantum number that differentiates two electrons in the same orbital. (6.6)
electronegativity. The ability of an atom in a compound to draw electrons to itself. (8.4)
electrophile. A region of positive or partial positive charge. (10.5)
electrophilic addition. An addition reaction that begins when an electrophile approaches a region of electron density. (10.5)
electrostatic energy. The potential energy that results from the interaction of charged particles. (5.1)
element. A substance that cannot be separated into simpler substances by chemical means. (1.2)
elementary reaction. A reaction that occurs in a single collision of the reactant molecules. (14.5)
elimination reaction. A reaction in which a double bond forms and a molecule such as water is removed. (10.5)
emission spectrum. The light emitted, either as a continuum or in discrete lines, by a substance in an excited electronic state. (6.3)
empirical formula. The chemical formula that conveys with the smallest possible whole numbers the ratio of combination of elements in a compound. (2.6)
enantiomers. Molecules that are mirror images of each other but cannot be superimposed. (10.4, 22.2)
endothermic process. A process that absorbs heat. (5.1)
endpoint. The point at which the color of the indicator changes. $(4.6,17.3)$
energy. The capacity to do work or transfer heat. (5.1)
enthalpy $(\boldsymbol{H})$. A thermodynamic quantity defined by the equation $H=U+P V$. The change in enthalpy, $\Delta H$, is equal to the heat exchanged between the system and surroundings at constant pressure $q_{\mathrm{P}}$. (5.3)
enthalpy of reaction $\left(\Delta \boldsymbol{H}_{\mathrm{rxn}}\right)$. The difference between the enthalpy of the products and the enthalpy of the reactants. (5.3)
entropy $(\boldsymbol{S})$. A thermodynamic state function that describes how dispersed a system's energy is. (18.2)
enzymes. Biological catalysts. (14.6)
equatorial. The three bonds that are arranged in a trigonal plane in a trigonal bipyramidal geometry. (9.1)
equilibrium. A state in which forward and reverse processes are occurring at the same rate. (15.1)
equilibrium constant $(K)$. A number equal to the ratio of the equilibrium concentrations of products to the equilibrium concentrations of reactants, with each concentration raised to the power of its stoichiometric coefficient. (15.2)
equilibrium expression. The quotient of product concentrations and reactant concentrations, each raised to the power of its stoichiometric coefficient. (15.2)
equilibrium process. A process that can be made to occur by the addition or removal of energy but does not happen on its own. (18.3)
equilibrium vapor pressure. The pressure exerted by the molecules that have escaped to the gas phase, once the pressure has stopped increasing. (12.2)
equivalence point. The point in a titration where the reaction (e.g., neutralization) is complete. (4.6)
ester. An organic molecule containing a -COOR group. (10.2)
evaporation. The phase change from liquid to solid at a temperature below the boiling point. (12.2)
excess reactant. The reactant present in a greater amount than necessary to react with all the limiting reactant. (3.7)
excited state. A state that is higher in energy than the ground state. (6.3)
exothermic process. A process that gives off heat. (5.1)
extensive property. A property that depends on the amount of matter involved. (1.4)

## F

face-centered cubic cell. A cubic unit cell with one atom on each of the six faces and one atom at each of the eight corners. (12.3)
family. The elements in a vertical column of the periodic table. (2.4)
first law of thermodynamics. Energy can be converted from one form to another, but cannot be created or destroyed. (5.2)
first-order reaction. A reaction whose rate depends on the reactant concentration raised to the first power. (14.3)
$f$ orbital. Atomic orbital in which the angular momentum quantum number $(\ell)$ is 3. (6.6)
formal charge. Method of electron "bookkeeping" in which shared electrons are divided equally between the atoms that share them. (8.6)
formation constant $\left(\boldsymbol{K}_{\mathrm{f}}\right)$. The equilibrium constant that indicates to what extent complex-ion formation reactions occur. (17.5)
formula mass. The mass of a formula unit. (3.1)
formula weight. See formula mass.
fractional precipitation. The separation of a mixture based upon the components' solubilities. (17.6)
free energy. The energy available to do work. (18.4)
free radical. A molecule with an odd number of electrons. (8.8)
freezing point. The temperature at which a liquid undergoes the phase transition to solid. (12.6)
frequency $(v)$. The number of waves that pass through a particular point in 1 s . (6.1)
fuel cell. A voltaic cell in which reactants must be continually supplied. (19.6)
fullerenes. Molecules with elongated and elliptical cages of 70 and 80 carbon atoms. (25.5)
functional group. The part of a molecule characterized by a special arrangement of atoms that is largely responsible for the chemical behavior of the parent molecule. (2.6)
fusion. The phase transition from solid to liquid (melting) (12.6) or the combination of light nuclei to form heavier nuclei. (20.5)

## G

galvanic cell. An electrochemical cell in which a spontaneous chemical reaction generates a flow of electrons. (19.2)
galvanization. The cathodic protection of iron or steel using zinc. (19.8)
gamma rays. High-energy radiation. (2.2)
gas constant $(\boldsymbol{R})$. The proportionality constant that appears in the ideal gas equation. (11.3)
gas laws. Equations that relate the volume of a gas sample to its other parameters: temperature $(T)$, pressure $(P)$, and number of moles ( $n$ ). (11.2)
geometrical isomers. Molecules that contain the same atoms and bonds arranged differently in space. $(10.4,22.2)$
Gibbs free energy. The energy available to do work. (18.4)
glass. Commonly refers to an optically transparent fusion product of inorganic materials that has cooled to a rigid state without crystallizing. (12.5)
Graham's law. The rates of diffusion and effusion are inversely proportional to the square root of the molar mass of the gas. (11.6)
graphene. Two-dimensional sheet of $s p^{2}$-hybridized carbon atoms. (25.5)
gravimetric analysis. An analytical technique based on the measurement of mass. (4.6)
greenhouse effect. Describes the trapping of heat near Earth's surface by gases in the atmosphere, particularly carbon dioxide. (21.5)
ground state. The lowest energy state of an atom. (6.3)
group. The elements in a vertical column of the periodic table. (2.4)

## H

half-cell. One compartment of an electrochemical cell containing an electrode immersed in a solution. (19.2)
half-life $\left(t_{1 / 2}\right)$. The time required for the reactant concentration to drop to half its original value. (14.3)
half-reaction. The separated oxidation and reduction reactions that make up the overall redox reaction. (19.1)
half-reaction method. Balancing an oxidationreduction equation by separating the oxidation and the reduction, balancing them separately, and adding them back together. (4.4)
Hall process. Electrolytic reduction of aluminum from anhydrous aluminum oxide (corundum). (23.7)
halogens. The elements in Group 7A (F, Cl, Br, I, and At). (2.4)
heat. The transfer of thermal energy between two bodies that are at different temperatures. (5.1)
heat capacity $(\boldsymbol{C})$. The amount of heat required to raise the temperature of an object by $1^{\circ} \mathrm{C}$. (5.4)

Heisenberg uncertainty principle. It is impossible to know simultaneously both the momentum ( $p$ ) (defined as mass times velocity, $m \times u$ ) and the position $(x)$ of a particle with certainty. (6.5)
Henderson-Hasselbalch equation. $\mathrm{pH}=\mathrm{p} K_{\mathrm{a}}+$ $\log$ ([conjugate base]/[weak acid]). (17.2)
Henry's law. The solubility of a gas in a liquid is proportional to the pressure of the gas over the solution. (13.4)
Henry's law constant (k). The proportionality constant that is specific to the gas-solvent combination and varies with temperature. (13.4)

Hess's law. The change in enthalpy that occurs when reactants are converted to products in a reaction is the same whether the reaction takes place in one step or in a series of steps. (5.5)
heteroatom. Any atom in an organic molecule other than carbon or hydrogen. (10.3)
heterogeneous catalysis. A catalysis in which the reactants and the catalyst are in different phases. (14.6)
heterogeneous mixture. A mixture in which the composition varies. (1.2)
heteronuclear. Containing two or more different elements. (2.6)
high-temperature superconductor. A material that shows no resistance to the flow of electrons at an unusually high temperature. (25.7)
homogeneous catalysis. A catalysis in which the reactants and the catalyst are in the same phase. (14.6)
homogeneous mixture. A mixture in which the composition is uniform. Also called a solution. (1.2)
homonuclear. Containing atoms of only one element. (2.6)
Hund's rule. The most stable arrangement of electrons in orbitals of equal energy is the one in which the number of electrons with the same spin is maximized. (6.8)
hybridization. The mixing of atomic orbitals. (9.4)
hydrate. A compound with a specific number of water molecules within its solid structure. (2.7)
hydration. The process by which water molecules surround solute particles in an aqueous solution. (4.2)
hydrocarbon. A compound containing only carbon and hydrogen. (2.6)
hydrogen bonding. A special type of dipoledipole interaction that occurs only in molecules that contain H bonded to a small, highly electronegative atom, such as $\mathrm{N}, \mathrm{O}$, or F. (12.1)
hydronium ion. A hydrated proton $\left(\mathrm{H}_{3} \mathrm{O}^{+}\right)$. (4.3)
hydrophilic. Water-loving. (13.7)
hydrophobic. Water-fearing. (13.7)
hypertonic. Describes a solution with a higher concentration of dissolved substances than plasma. (13.5)
hypothesis. A tentative explanation for a set of observations. (1.1)
hypotonic. Describes a solution that has a lower concentration of dissolved substances than plasma. (13.5)
ideal gas. A hypothetical sample of gas whose pressure-volume-temperature behavior is predicted accurately by the ideal gas equation. (11.3)
ideal gas equation. An equation that describes the relationship among the four variables $P$, $V, n$, and $T$. (11.3)
ideal solution. A solution that obeys Raoult's law. (13.5)
indicator. A substance that has a distinctly different color in acidic and basic media. (4.6)
initial rate. The instantaneous rate at the beginning of a reaction. (14.2)
inorganic compounds. Compounds that do not contain carbon or that are derived from nonliving sources. (2.6)
instantaneous dipole. A fleeting nonuniform distribution of electron density in a molecule without a permanent dipole. (12.1)
instantaneous rate. The reaction rate at a specific time. (14.1)
insulator. A substance that does not conduct electricity. (23.3)
integrated rate law. $\ln \left([\mathrm{A}]_{t} /[\mathrm{A}]_{0}\right)=-k t$. (14.3)
intensive property. A property that does not depend on the amount of matter involved. (1.4)
intermediate. A chemical species that is produced in one step of a reaction mechanism and consumed in a subsequent step. (14.5)
intermolecular forces. The attractive forces that hold particles together in the condensed phases. (12.1)
International System of Units. See SI units. (1.3)
ion. Atom or molecule that has lost or gained one or more electrons giving it a positive or negative charge. (2.7)
ion-dipole interactions. Coulombic attractions between ions and polar molecules. (12.1)
ionic bonding. An electrostatic attraction that holds oppositely charged ions together in an ionic compound. (8.2)
ionic compound. Substance consisting of ions held together by electrostatic attraction. (2.7)
ionic equation. Chemical equation in which all strong electrolytes are shown as ions. (4.2)
ionic radius. The radius of a cation or an anion. (7.6)
ionizable hydrogen atom. A hydrogen atom that can be lost as a hydrogen ion, $\left(\mathrm{H}^{+}\right)$. (2.6)
ionization. The process by which a molecular compound forms ions when it dissolves. (4.1)
ionization energy (IE). The minimum energy required to remove an electron from an atom in the gas phase. (7.4)
ionosphere. See thermosphere.
ion pair. Ions in solution that are held together by electrostatic forces. (13.5)
isoelectronic. Describes two or more species with identical electron configurations. (7.5)
isoelectronic series. A series of two or more species that have identical electron configurations but different nuclear charges. (7.6)
isolated system. A system that can exchange neither energy nor mass with the surroundings. (5.2)
isomerization reaction. A reaction in which one isomer is converted to another. (10.5)
isotactic. Polymers in which all the substituents (i.e., the R groups) are in the same relative orientation (i.e., on the same side of the polymer chain). (25.1)
isotonic. Equal in concentration and osmotic pressure. (13.5)
isotope. Atoms that have the same atomic number $(Z)$ but different mass numbers $(A)$. (2.3)
isotropic. Independent of the axis of measurement. (25.3)

## J

joule. SI unit of energy, $1 \mathrm{~kg} \cdot \mathrm{~m}^{2} / \mathrm{s}^{2}$. (5.1)

## K

Kekulé structure. A structure similar to a Lewis structure in which the lone pairs may not be shown. (10.3)
kelvin. The SI base unit of temperature. (1.3)
Kelvin temperature scale. A temperature scale offset from the Celsius scale by 273.15 . One kelvin ( 1 K ) is equal in magnitude to one degree Celsius $\left(1^{\circ} \mathrm{C}\right)$. (11.2)
ketone. An organic compound consisting of two R groups bonded to a carbonyl. (10.2)
kinetic energy. The energy that results from motion. (5.1)
kinetic molecular theory. A theory that explains how the molecular nature of gases gives rise to their macroscopic properties. (11.6)

Lanthanide (rare earth) series. A series of 14 elements that have incompletely filled $4 f$ subshells or that readily give rise to cations that have incompletely filled $4 f$ subshells. (6.9)
lattice. A three-dimensional array of cations and anions. (2.6)
lattice energy. The amount of energy required to convert a mole of ionic solid to its constituent ions in the gas phase. (8.2)
lattice points. Positions occupied by atoms, ions, or molecules in a unit cell. (12.3)
lattice structure. The arrangement of the particles in a crystalline solid. (12.3)
law. A concise verbal or mathematical statement of a reliable relationship between phenomena. (1.1)
law of conservation of energy. First law of thermodynamics stating that energy can be neither created nor destroyed. (5.1)
law of conservation of mass. An alternate statement of the first law of thermodynamics stating that matter can be neither created nor destroyed. (2.1)
law of definite proportions. Different samples of a given compound always contain the same elements in the same mass ratio. (2.1)
law of mass action. For a reversible reaction at equilibrium and a constant temperature, the reaction quotient, $Q$, has a constant value, $K$ (the equilibrium constant). (15.2)
law of multiple proportions. Different compounds made up of the same elements differ in the number of atoms of each kind that combine. (2.1)
Le Châtelier's principle. When a stress is applied to a system at equilibrium, the system will respond by shifting in the direction that minimizes the effect of the stress. (15.5)
levorotatory. The term used to describe the enantiomer that rotates the plane-polarized light to the left. (22.2)
Lewis acid. A species that can accept a pair of electrons. (16.12)
Lewis base. A species that can donate a pair of electrons. (16.12)
Lewis dot symbol. An elemental symbol surrounded by dots, where each dot represents a valence electron. (8.1)
Lewis structure. A representation of covalent bonding in which shared electron pairs are shown either as dashes or as pairs of dots between two atoms, and lone pairs are shown as pairs of dots on individual atoms. (8.4)
Lewis theory of bonding. A chemical bond involves atoms sharing electrons. (8.3)
ligand. A molecule or anion that can form coordinate bonds to a metal to form a coordination complex. (22.1)
limiting reactant. The reactant that is completely consumed and determines the amount of product formed. (3.7)
line spectra. The emission or absorption of light only at discrete wavelengths. (6.3)
liquid crystal. A substance that exhibits properties of both a liquid, such as the ability to flow and to take on the shape of a container, and those of a crystal, such as a regular arrangement of particles in a lattice. (25.3)
localized. Describes electrons that are shared between two specific atoms and that cannot be repositioned to generate additional resonance structures. (9.7)
London dispersion forces. Attractive forces that act between all molecules, including nonpolar molecules, resulting from the formation of instantaneous dipoles and induced dipoles. (12.1)
lone pair. A pair of valence electrons that are not involved in covalent bond formation. (8.3)

## M

magnetic quantum number ( $\boldsymbol{m}_{\ell}$ ). Describes the orientation of an orbital in space. (6.6)
main group elements. Elements in the $s$ and $p$ blocks of the periodic table. (7.2)
manometer. A device used to measure the pressure of gases relative to atmospheric pressure. (11.1)
mass. A measure of the amount of matter in an object or sample. (1.3)
mass defect. The difference between the actual mass of a nucleus and the mass calculated by summing the masses of the individual nucleons. (20.2)
mass number ( $\boldsymbol{A}$ ). The number of neutrons and protons present in the nucleus of an atom of an element. (2.3)
matter. Anything that occupies space and has mass. (1.1)
Meissner effect. The exclusion of magnetic fields. (25.7)
melting point. The temperature at which solid and liquid phases are in equilibrium. (12.6)
mesosphere. The region located above the stratosphere in which the concentration of ozone and other gases is low and temperature decreases again with increasing altitude. (21.1)
metal. Element with a tendency to lose electrons, located left of the zigzag line on the periodic table. (2.4)
metallic radius. Half the distance between the nuclei of two adjacent, identical metal atoms. (7.4)
metalloid. Elements with properties intermediate between metals and nonmetals. (7.4)
metallurgy. The preparation, separation, and purification of metals. (23.2)
microstate. A specific microscopic configuration of a system. (18.2)
mineral. A naturally occurring substance with a characteristic chemical composition and specific physical properties. (23.1)
miscible. Mutually soluble in any proportions. (13.1)
mixture. A combination of two or more substances in which the substances retain their distinct identities. (1.2)
moderator. A material that limits the speed of liberated neutrons but does not itself undergo fission when bombarded with neutrons. (20.5)
molality ( $\boldsymbol{m}$ ). The number of moles of solute dissolved in $1 \mathrm{~kg}(1000 \mathrm{~g})$ of solvent. (13.3)
molar absorptivity. Proportionality constant relating absorbance to solution concentration and distance that light travels through a solution. (4.5)
molar concentration. See molarity $(M)$.
molar heat of fusion $\left(\Delta \boldsymbol{H}_{\text {fus }}\right)$. The energy, usually expressed in $\mathrm{kJ} / \mathrm{mol}$, required to melt 1 mole of a solid. (12.6)
molar heat of sublimation $\left(\Delta H_{\text {sub }}\right)$. The energy, usually expressed in kilojoules, required to sublime 1 mole of a solid. (12.6)
molar heat of vaporization $\left(\Delta H_{\text {vap }}\right)$. The amount of heat required to vaporize a mole of substance at its boiling point. (12.6)
molarity ( $\boldsymbol{M}$ ). The number of moles of solute per liter of solution. (4.5)
molar mass. The mass in grams of 1 mole of the substance. (3.4)
molar solubility. The number of moles of solute in one liter of saturated solution $(\mathrm{mol} / \mathrm{L})$. (17.4)
mole (mol). The amount of a substance that contains as many elementary entities (atoms, molecules, formula units, etc.) as there are atoms in exactly $0.012 \mathrm{~kg}(12 \mathrm{~g})$ of carbon12. (3.4)
molecular equation. A chemical equation written with all compounds represented by their chemical formulas. (4.2)
molecular formula. A chemical formula that gives the number of atoms of each element in a molecule. (2.6)
molecular geometry. The arrangement of bonded atoms. (9.1)
molecularity. The number of molecules involved in a specific step in a reaction mechanism. (14.5)
molecular mass. The sum of the atomic masses (in amu) of the atoms that make up a molecule. (3.1)
molecular orbital. An orbital that results from the interaction of the atomic orbitals of the bonding atoms. (9.6)
molecular orbital theory. A theory that describes the orbitals in a molecule as bonding and antibonding combinations of atomic orbitals. (9.6)
molecular weight. Average molecular mass. (3.1)
molecule. A combination of two or more atoms in a specific arrangement held together by chemical bonds. (2.6)
mole fraction $\left(\boldsymbol{\chi}_{\mathbf{i}}\right)$. The number of moles of a component divided by the total number of moles in a mixture. (11.5)
monatomic ion. An ion that contains only one atom. (2.7)
monomer. A small molecule that can be linked in large numbers to form a large molecule (polymer). (10.6, 25.1)
monoprotic acid. An acid with one ionizable proton. (4.3)
multiple bond. A chemical bond in which two atoms share two or more pairs of electrons. (8.3)

## N

nanotechnology. The development and study of extremely small-scale materials and objects. (25.5)
nematic. Describes an arrangement in which molecules are all aligned parallel to one another but with no organization into layers or rows. (25.3)
Nernst equation. An equation relating the emf of a galvanic cell with the standard emf and the concentrations of reactants and products. (19.5)
net ionic equation. Chemical equation from which spectator ions have been removed. (4.2)
neutralization reaction. A reaction between an acid and a base. (4.3)
neutron. An electrically neutral subatomic particle with a mass slightly greater than that of a proton. (2.2)
newton (N). The SI unit of force. (11.1)
nitrogen fixation. The conversion of molecular nitrogen into nitrogen compounds. (21.1)
noble gas core. A representation in an electron configuration that shows in brackets the most recently completed noble gas. (6.9)
noble gases. Elements in Group 8A (He, Ne, Ar, $\mathrm{Kr}, \mathrm{Xe}$, and Rn ). (2.4)
node. A collection of points at which electron density in an atom is zero. (6.4)
nonconductor. A substance that does not conduct electricity. (25.6)
nonelectrolyte. A substance that dissolves in water to yield a solution that does not conduct electricity. (4.1)
nonmetal. Element with a tendency to gain electrons, located in the upper right portion of the periodic table. (2.4)
nonpolar. Having a uniform distribution of electron density. (8.4)
nonspontaneous process. A process that does not occur under a specified set of conditions. (18.1)
nonvolatile. Having no measurable vapor pressure. (13.5)
normal boiling point. Temperature at which a substance boils at 1 atm pressure. (12.6)
n-type semiconductor. Semiconductors in which an electron-rich impurity is added to enhance conduction. $(23.3,25.6)$
nuclear binding energy. The energy required to separate the nucleons in a nucleus. (20.2)
nuclear chain reaction. A self-sustaining reaction sequence of fission reactions. (20.5)
nuclear fission. The splitting of a large nucleus into smaller nuclei and one or more neutrons. (20.5)
nuclear fusion. The combination of two light nuclei to form one heavier nucleus. (20.6)
nuclear transmutation. The conversion of one nucleus to another. (20.1)
nucleic acid. Macromolecule formed by polymerization of nucleotides. (10.6)
nucleons. Protons, neutrons, and electrons. (2.2)
nucleophile. A region of negative or partial negative charge. (10.5)
nucleophilic addition. An addition reaction that begins when a nucleophile donates a pair of electrons to an electron-deficient atom. (10.5)
nucleotide. A structural unit consisting of a sugar (ribose or deoxyribose) bonded to both a cyclic-amine base and a phosphate group. (10.6)
nucleus. The central core of the atom that contains the protons and neutrons. (2.2)
0
octet rule. Atoms will lose, gain, or share electrons to achieve a noble gas electron configuration. (8.3)
open system. A system that can exchange mass and energy with its surroundings. (5.2)
optical isomers. Nonsuperimposable mirror images. (10.4, 22.2)
ore. A mineral deposit concentrated enough to allow economical recovery of a desired metal. (23.1)
organic compounds. Compounds containing carbon and hydrogen, sometimes in combination with other elements such as oxygen, nitrogen, sulfur, and the halogens. (2.6)
osmosis. The selective passage of solvent molecules through a porous membrane from a more dilute solution to a more concentrated one. (13.5)
osmotic pressure $(\boldsymbol{\pi})$. The pressure required to stop osmosis. (13.5)
overvoltage. The difference between the electrode potential and the actual voltage required to cause electrolysis. (19.7)
oxidation. Loss of electrons. (4.4)
oxidation number. See oxidation state.
oxidation-reduction reaction. See redox reaction.
oxidation state. The charge an atom would have if electrons were transferred completely. (4.4)
oxidizing agent. A species that accepts electrons. (4.4)
oxoacid. An acid consisting of one or more ionizable protons and an oxoanion. (2.7)
oxoanion. A polyatomic anion that contains one or more oxygen atoms bonded to a central atom. (2.7)

## P

paramagnetic. A species with unpaired electrons that are attracted by magnetic fields. (9.6)
partial pressure $\left(\boldsymbol{P}_{\mathbf{i}}\right)$. The pressure exerted by a component in a gas mixture. (11.5)
pascal ( $\mathbf{P a}$ ). The SI unit of pressure. (11.1)
Pauli exclusion principle. No two electrons in an atom can have the same four quantum numbers. (6.8)
peptide bond. The bond that forms between amino acids. (10.6)
percent by mass. The ratio of the mass of an individual component to the total mass, multiplied by 100 percent. (13.3)
percent composition by mass. The percent of the total mass contributed by each element in a compound. (3.2)
percent dissociation. The percentage of dissolved molecules (or formula units, in the case of an ionic compound) that separate into ions in solution. (13.6)
percent ionization. Quantitative description of the degree to which an electrolyte exists as ions in solution. (13.6)
percent yield. The ratio of actual yield to theoretical yield, multiplied by 100 percent. (3.7)
period. A horizontal row of the periodic table. (2.4)
periodic table. A chart in which elements having similar chemical and physical properties are grouped together. (2.4)
pH. A scale used to measure acidity. $\mathrm{pH}=-\log \left[\mathrm{H}^{+}\right]$. (16.3)
phase change. When a substance goes from one phase to another phase. (12.6)
phase diagram. Summarizes the conditions (temperature and pressure) at which a substance exists as a solid, a liquid, or a gas. (12.7)
photochemical smog. Air pollution resulting from the interaction of sunlight with nitrogen monoxide and carbon monoxide from automobile exhaust. (21.7)
photoelectric effect. A phenomenon in which electrons are ejected from the surface of a metal exposed to light of at least a certain minimum frequency. (6.2)
photon. A particle of light. (6.2)
physical change. A process in which the state of matter changes but the identity of the matter does not change. (1.4)
physical property. A property that can be observed and measured without changing the identity of a substance. (1.4)
pi $(\boldsymbol{\pi})$ bond. Bonds that form from the interaction of parallel $p$ orbitals. (9.5)
pOH. A scale used to measure basicity. $\mathrm{pOH}=-\log \left[\mathrm{OH}^{-}\right] .(16.3)$
polar. Having a nonuniform electron density. (8.4)
polar covalent bond. Bonds in which electrons are unequally shared. (8.4)
polarimeter. Device used to measure the angle of rotation of plane-polarized light caused by an optically active compound. (22.3)
polarized. A molecule in which a dipole moment has been induced. (12.1)
polyamide. Polymers in which the monomers are connected by amide linkages. (25.1)
polyatomic. Molecules containing more than two atoms. (2.6)
polyatomic ion. Molecule that has lost or gained one or more electrons giving it a positive or negative charge. (2.7)
polyester. Polymers in which the monomers are connected by ester linkages. (25.1)
polymer. Molecular compounds, either natural or synthetic, that are made up of many repeating units called monomers. $(10.6,25.1)$
polypeptide. Short chains of amino acids. (10.6)
polyprotic acid. An acid with more than two ionizable protons. $(2.7,4.3)$
polysaccharides. Biological polymer consisting of sugars. (10.6)
$\boldsymbol{p}$ orbital. Atomic orbital in which the angular momentum quantum number $(\ell)$ is 1 . (6.6)
positron. A subatomic particle with the same mass as an electron, but with a positive charge. (20.1)
potential energy. The energy possessed by an object by virtue of its position. (5.1)
precipitate. An insoluble solid product that separates from a solution. (4.2)
precipitation reaction. A chemical reaction in which a precipitate forms. (4.2)
precision. The closeness of agreement of two or more measurements of the same quantity. (1.5)
pressure. The force applied per unit area. (11.1)
principal quantum number $(\boldsymbol{n})$. Designates the size of the orbital. (6.6)
product. A substance that forms in a chemical reaction. (3.3)
protein. A polymer of amino acids. (10.6)
proton. A positively charged particle in the nucleus of an atom. (2.2)
p-type semiconductor. A semiconductor in which an electron-poor impurity is added to enhance conduction. $(23.3,25.6)$
pyrometallurgy. Metallurgic processes carried out at high temperatures. (23.2)

## Q

qualitative analysis. The determination of the types of ions present in a solution. (17.6)
qualitative property. A property of a system that can be determined by general observation. (1.4)
quantitative property. A property of a system that can be measured and expressed with a number. (1.4)
quantum. The smallest quantity of energy that can be emitted (or absorbed) in the form of electromagnetic radiation. (6.2)
quantum numbers. Numbers required to describe the arrangement of electrons in an atom. (6.6)

## R

racemic mixture. An equimolar mixture of enantiomers that does not rotate the plane of plane-polarized light. $(10.4,22.2)$
racemization. The conversion of a single enantiomer to a racemic mixture of both enantiomers. (10.5)
radiation. The emission and transmission of energy through space in the form of waves. (2.2)
radical. A chemical species with an odd number of electrons. $(8.8,20.8)$
radioactive decay series. A sequence of nuclear reactions that ultimately result in the formation of a stable isotope. (20.3)
radioactivity. The spontaneous emission of particles or radiation from unstable nuclei. (2.2, 20.1)

Raoult's law. The partial pressure of a solvent over a solution, $P_{\mathrm{i}}$, is given by the vapor pressure of the pure solvent, $P^{\circ}$, times the mole fraction of the solvent in the solution, $\chi_{i} \cdot$ (13.5)
rate constant $(k)$. The proportionality constant in a rate law. (14.1)
rate-determining step. The slowest step in a reaction mechanism. (14.5)
rate law. An equation relating the rate of reaction to the concentrations of reactants. (14.2)
rate of reaction. The change in concentration of reactants or products per unit time. (14.1)
reactant. A substance that is consumed in a chemical reaction. (3.3)
reaction mechanism. Series of steps by which a chemical reaction occurs. (14.5)
reaction order. The sum of the powers to which all reactant concentrations appearing in the rate law are raised. (14.2)
reaction quotient $(\mathbb{Q})$. A fraction with product concentrations in the numerator and reactant concentrations in the denominator, each raised to its stoichiometric coefficient. (15.2)
redox reaction. A chemical reaction in which electrons are transferred from one reactant to another. (4.4)
reducing agent. A species that can donate electrons. (4.4)
reduction. A gain of electrons. (4.4)
resonance structures. Two or more equally valid Lewis structures for a single molecule that differ only in the positions of electrons. (8.7)
reversible process. A process in which the products can react to form reactants. (15.1)
ribonucleic acid (RNA). Biological polymer consisting of nucleotides in which the sugar is ribose. (10.6)
root-mean-square speed ( $\mu_{\mathrm{rms}}$ ). The molecular speed that is inversely proportional to the molecular mass. (11.6)

## S

salt. An ionic compound made up of the cation
from a base and the anion from an acid. (4.3)
salt bridge. An inverted $U$ tube containing an inert electrolyte solution, such as KCl or $\mathrm{NH}_{4} \mathrm{NO}_{3}$, that maintains electrical neutrality in an electrochemical cell. (19.2)
salt hydrolysis. The reaction of a salt's constituent ions with water to produce either hydroxide ions or hydronium ions. (16.10)
saturated solution. A solution that contains the maximum amount of a solute that will dissolve in a solvent at a specific temperature. (13.1)
scientific method. A systematic approach to experimentation. (1.1)
second law of thermodynamics. The entropy of the universe increases in a spontaneous process and remains unchanged in an equilibrium process. (18.2)
second-order reaction. A reaction whose rate depends on the concentration of one reactant raised to the second power or on the product of the concentrations of two different reactants each raised to the first power. (14.3)
semiconductor. A substance that normally does not conduct electricity but that will conduct at elevated temperatures or when combined with a small amount of certain other elements. $(23.3,25.6)$
semipermeable membrane. A membrane that allows the passage of solvent molecules but blocks the passage of solute molecules. (13.5)
shielding. The partial obstruction of nuclear charge by core electrons. (7.3)
$\operatorname{sigma}(\boldsymbol{\sigma})$ bond. A bond in which the shared electron density is concentrated directly along the internuclear axis. (9.5)
significant figures. Meaningful digits in a measured or calculated value. (1.5)
simple cubic cell. The basic repeating unit in which there is one atom at each of the eight corners in a cube. (12.3)
single bond. A pair of electrons shared by two atoms. (8.3)
sintering. A method used to form objects by heating a finely divided substance. (25.2)
SI units. International System of Units. A system of units based on metric units. (1.3)
skeletal structure. A structure in which straight lines represent carbon-carbon bonds. (10.3)
smectic. Containing molecules ordered in two dimensions. The molecules are aligned parallel to one other and are further arranged in layers that are parallel to one another. (25.3)
solubility. The maximum amount of solute that will dissolve in a given quantity of solvent at a specific temperature. $(4.2,13.1,17.4)$
solubility product constant ( $\boldsymbol{K}_{\text {sp }}$ ). The equilibrium constant that indicates to what extent a slightly soluble ionic compound dissolves in water. (17.4)
solute. The dissolved substance in a solution. (4.1)
solution. A homogeneous mixture consisting of a solvent and one or more solutes. (4.1)
solvent. A substance in a solution that is present in the largest amount. (4.1)
$s$ orbital. Atomic orbital in which the angular momentum quantum number $(\ell)$ is 0 . (6.6)
specific heat (s). The amount of heat required to raise the temperature of 1 g of a substance by $1^{\circ} \mathrm{C}$. (5.4)
spectator ion. An ion that does not participate in the reaction and appears on both the reactant and product side in the ionic equation. (4.2)
spectrochemical series. A list of ligands arranged in increasing order of their abilities to split the $d$ orbital energy levels. (22.3)
spontaneous process. A process that occurs under a specified set of conditions. (18.1)
standard atmospheric pressure. The pressure that would support a column of mercury exactly 760 mm high at $0^{\circ} \mathrm{C}$. (11.1)
standard enthalpy of formation $\left(\Delta \boldsymbol{H}_{\mathrm{f}}^{\circ}\right)$. The heat change that results when 1 mole of a compound is formed from its constituent elements in their standard states. (5.6)
standard enthalpy of reaction $\left(\Delta H_{\mathrm{rxn}}^{\circ}\right)$. The enthalpy of a reaction carried out under standard conditions. (5.6)
standard entropy ( $\boldsymbol{S}^{\circ}$ ). The absolute entropy of a substance at 1 atm . (18.2)
standard free energy of formation ( $\Delta \boldsymbol{G}_{\mathrm{f}}^{\mathbf{\circ}}$ ). The free-energy change that occurs when 1 mole of the compound forms from its constituent elements in their standard states. (18.4)
standard free energy of reaction $\left(\Delta G_{\mathrm{rxn}}^{\circ}\right)$. The free-energy change for a reaction when it occurs under standard-state conditions. (18.4)
standard hydrogen electrode (SHE). A half-cell based on the half-reaction $2 \mathrm{H}^{+}(1 M)+2 e^{-} \longrightarrow \mathrm{H}_{2}$ (1 atm), which has an arbitrarily defined standard reduction potential of zero. (19.3)
standard reduction potential $\left(\boldsymbol{E}_{\text {red }}\right)$. The potential associated with a reduction half-reaction at an electrode when the ion concentration is $1 M$ and the gas pressure is 1 atm. (19.3)
standard solution. A solution of precisely known concentration. (4.6)
standard temperature and pressure (STP). $0^{\circ} \mathrm{C}$ and 1 atm . (11.3)
state function. Properties that are determined by the state of the system, independent of how the state was achieved. (5.2)
state of a system. The values of all relevant macroscopic properties, such as composition, energy, temperature, pressure, and volume. (5.2)
stereoisomers. Molecules that contain identical bonds but differ in the orientation of those bonds in space. $(10.4,22.2)$
stoichiometric amounts. Quantities of reactants in the same relative amounts as those represented in the balanced chemical equation. (3.6)
stoichiometric coefficients. The numeric values written to the left of each species in a chemical equation to balance the equation. (3.3)
stratosphere. The region of the atmosphere located above the troposphere and consisting of nitrogen, oxygen, and ozone. (21.1)
strong conjugate acid. The conjugate acid of a weak base. Acts as a weak Brønsted acid in water. (16.7)
strong conjugate base. The conjugate base of a weak acid. Acts as a weak Brønsted base in water. (16.7)
strong electrolyte. An electrolyte that ionizes or dissociates completely. (4.1)
structural formula. A chemical formula that shows the general arrangement of atoms within the molecule. (2.6)
structural isomer. Molecules that have the same chemical formula but different arrangements of atoms. (9.2)
sublimation. The phase change from solid to gas. (12.6)
substance. Matter with a definite (constant) composition and distinct properties. (1.2)
substituent. A group other than -H bonded to the carbons of an organic molecule. (10.2)
substitution reaction. One group is replaced by another group by electrophilic or nucleophilic attack. (10.5)
superconducting transition temperature $\left(\boldsymbol{T}_{\mathrm{c}}\right)$. The temperature below which an element, compound, or material becomes superconducting. (25.7)
superconductor. A substance with no resistance to the flow of electrons. (25.7)
supercooling. A phenomenon in which a liquid can be temporarily cooled to below its freezing point. (12.6)
supercritical fluid. A fluid at a temperature and pressure that exceed $T_{\mathrm{c}}$ and $P_{\mathrm{c}}$. (12.6)
supersaturated solution. A solution that contains more dissolved solute than is present in a saturated solution. (13.1)
surface tension. The amount of energy required to stretch or increase the surface of a liquid by a unit area. (12.2)
surroundings. The part of the universe not included in the system. (5.1)
suture. Thread used by physicians to close wounds and/or incisions. (25.4)
syndiotactic. Polymers in which the substituents alternate positions along the polymer chain. (25.1)
system. The specific part of the universe that is of interest to us. (5.1)

## T

tacticity. Describes the relative arrangements of chiral carbon atoms within a polymer. (25.1)
termolecular. Involving three reactant molecules. (14.5)
theoretical yield. The maximum amount of product that can be obtained from a reaction. (3.7)
theory. A unifying principle that explains a body of experimental observations and the laws that are based on them. (1.1)
thermal energy. The energy associated with the random motion of atoms and molecules. (5.1)
thermochemical equation. A chemical equation that includes the enthalpy change. (5.3)
thermochemistry. The study of the heat associated with chemical reactions and physical processes. (5.1)
thermodynamics. The scientific study of the interconversion of heat and other kinds of energy. (5.1)
thermonuclear reaction. Generally refers to a fusion reaction. (20.6)
thermoplastic. Polymers that can be melted and reshaped. (25.1)
thermosetting. Polymers that assume their final shape as part of the chemical reaction that forms them. (25.1)
thermosphere. The outermost layer of the atmosphere. (21.1)
third law of thermodynamics. The entropy of a pure crystalline solid is zero at absolute zero ( 0 K ). (18.3)
titration. The gradual addition of a solution of known concentration to another solution of unknown concentration until the chemical reaction between the two solutions is complete. (4.6)
tracers. Radioactive isotopes that are used to trace the path of the atoms of an element in a chemical or biological process. (20.7)
trans. The isomer in which two substituents lie on opposite sides of a double bond. (10.4)
transition element. An element that has-or readily forms one or more ions that have-an incompletely filled $d$ subshell (Groups 3B to 8B or Group 1B). (2.4)
transition metals. The elements in Group 1B and Groups 3B to 8B. (2.4)
transition state. See activated complex.
transmittance. Ratio of the intensity of light transmitted through a sample $(l)$ to the intensity of the incident light $\left(l_{0}\right)$. (4.5)
transuranium elements. Elements with atomic numbers greater than 92 , created by bombarding other elements with accelerated neutrons, protons, alpha particles, or other nuclei. (20.4)
triple bond. A multiple bond in which the atoms share three pairs of electrons. (8.3)
triple point. The point at which all three phase boundary lines meet. (12.7)
triprotic acid. An acid molecule with three ionizable protons. (4.3)
troposphere. The layer of the atmosphere closest to Earth's surface. (21.1)
Tyndall effect. The scattering of visible light by colloidal particles. (13.7)

## U

unimolecular. Describes a reaction involving one reactant molecule. (14.5)
unit cell. The basic repeating structural unit of a crystalline solid. (12.3)
unsaturated solution. A solution that contains less solute than it has the capacity to dissolve. (13.1)

## V

valence band. The bonding band. (25.6)
valence bond theory. Atoms share electrons when an atomic orbital on one atom overlaps with an atomic orbital on the other. (9.3)
valence electrons. The outermost electrons of an atom. (7.2)
valence-shell electron-pair repulsion
(VSEPR). A model that accounts for electron pairs in the valence shell of an atom repelling one another. (9.1)
van der Waal's equation. An equation relating the volume of a real gas to the other parameters, $P, T$, and $n$. (11.7)
van der Waal's forces. The attractive forces that hold particles together in the condensed phases that include dipole-dipole interactions (including hydrogen bonding) and dispersion forces. (12.1)
van't Hoff factor (i). The ratio of the actual number of particles in solution after dissociation to the number of formula units initially dissolved in solution. (13.5)
vaporization. The phase change from liquid to gas at the boiling point. (12.6)
viscosity. A measure of a fluid's resistance to flow. (12.2)
visible spectrophotometry. Measurement of absorption of visible light for qualitative and quantitative analysis. (4.5)
volatile. Describes a substance that has a high vapor pressure. (12.2)

## W

wavelength $(\boldsymbol{\lambda})$. The distance between identical points on successive waves. (6.1)
weak acid. An acid that ionizes only partially. (16.5)
weak base. A base that ionizes only partially. (16.6)
weak conjugate acid. A conjugate acid of a strong base. Does not react with water. (16.7)
weak conjugate base. A conjugate base of a strong acid. Does not react with water. (16.7)
weak electrolyte. A compound that produces ions upon dissolving but exists in solution predominantly as molecules that are not ionized. (4.1)

## X

X-ray diffraction. A method of using $X$ rays to bombard a crystalline sample to determine the structure of the crystal. (12.3)

## Z

zeroth-order reaction. A constant rate, independent of reactant concentration. (14.3)

(j) $\mathrm{BCl}_{3} .2 .85$ (a) $\mathrm{Mg}\left(\mathrm{NO}_{3}\right)_{2}$. (b) $\mathrm{Al}_{2} \mathrm{O}_{3}$. (c) LiH . (d) $\mathrm{Na}_{2} \mathrm{~S} .2 .87$ Acid: compound that produces $\mathrm{H}^{+}$; Base: compound that produces $\mathrm{OH}^{-}$; Oxoacids: acids that contain oxygen; Oxoanions: the anions that remain when oxoacids lose $\mathrm{H}^{+}$ions; Hydrates: ionic solids that have water molecules in their formulas. 2.89 (c) Changing the electrical charge of an atom usually has a major effect on its chemical properties. The two electrically neutral carbon isotopes should have nearly identical chemical properties. $2.91 \mathrm{I}^{-} . \mathbf{2 . 9 3} \mathrm{NaCl}$ is an ionic compound; it doesn't consist of molecules. 2.95 (a) Molecule and compound. (b) Element and molecule. (c) Element. (d) Molecule and compound. (e) Element. (f) Element and molecule. (g) Element and molecule. (h) Molecule and compound. (i) Compound, not molecule. (j) Element. (k) Element and molecule. (l) Compound, not molecule. 2.97 It establishes a standard mass unit that permits the measurement of masses of all other isotopes relative to carbon-12. 2.99 ${ }_{5}^{11} \mathrm{~B}$, protons $=5$, neutrons $=6$, electrons $=5$, net charge $=0 ;{ }_{26}^{54} \mathrm{Fe}^{2+}$, protons $=26$, neutrons $=28$, electrons $=24$, net charge $=+2 ;{ }_{15}^{31} \mathrm{P}^{3-}$, protons $=15$, neutrons $=16$, electrons $=18$, net charge $=-3 ;{ }_{79}^{196} \mathrm{Au}$, protons $=79$, neutrons $=117$, electrons $=79$, net charge $=0 ;{ }_{86}^{222} \mathrm{Rn}$, protons $=86$, neutrons $=136$, electrons $=86$, net charge $=0.2 .101$ (a) $\mathrm{Li}^{+}$. (b) $\mathrm{S}^{2-}$. (c) $\mathrm{I}^{-}$. (d) $\mathrm{N}^{3-}$. (e) $\mathrm{Al}^{3+}$. (f) $\mathrm{Cs}^{+}$. (g) $\mathrm{Mg}^{2+}$. 2.103 Group 7A, binary: HF, hydrofluoric acid; HCl , hydrochloric acid; HBr , hydrobromic acid; HI , hydroiodic acid.

Group 7A, oxoacids: $\mathrm{HClO}_{4}$, perchloric acid; $\mathrm{HClO}_{3}$, chloric acid; $\mathrm{HClO}_{2}$, chlorous acid; HClO , hypochlorous acid; $\mathrm{HBrO}_{3}$, bromic acid; $\mathrm{HBrO}_{2}$, bromous acid; HBrO , hypobromous acid; $\mathrm{HIO}_{4}$, periodic acid; $\mathrm{HIO}_{3}$, iodic acid; HIO, hypoiodous acid. Examples of oxoacids containing other Group A-block elements are: $\mathrm{H}_{3} \mathrm{BO}_{3}$, boric acid; $\mathrm{H}_{2} \mathrm{CO}_{3}$, carbonic acid; $\mathrm{HNO}_{3}$, nitric acid; $\mathrm{HNO}_{2}$, nitrous acid; $\mathrm{H}_{3} \mathrm{PO}_{4}$, phosphoric acid; $\mathrm{H}_{3} \mathrm{PO}_{3}$, phosphorous acid; $\mathrm{H}_{3} \mathrm{PO}_{2}$, hypophosphorous acid; $\mathrm{H}_{2} \mathrm{SO}_{4}$, sulfuric acid; $\mathrm{H}_{2} \mathrm{SO}_{3}$, sulfurous acid. Binary acids formed from other Group A-block elements other than Group 7A: $\mathrm{H}_{2} \mathrm{~S}$, hydrosulfuric acid. 2.105 ${ }_{2}^{4} \mathrm{He}$ : protons $=2$, neutrons $=2$, neutrons/protons $=1.00 ;{ }_{10}^{20} \mathrm{Ne}$ : protons $=10$, neutrons $=10$, neutrons/protons $=1.00 ;{ }_{18}^{40} \mathrm{Ar}$ : protons $=$ 18 , neutrons $=22$, neutrons/protons $=1.22 ;{ }_{36}^{84} \mathrm{Kr}$ : protons $=36$, neutrons $=48$, neutrons/protons $=1.33 ;{ }_{54}^{132} \mathrm{Xe}:$ protons $=54$, neutrons $=78$, neutrons/protons $=1.44$. The neutron/proton ratio increases with increasing atomic number. $2.107 \mathrm{Cu}, \mathrm{Ag}$, and Au are fairly chemically unreactive. This makes them especially suitable for making coins and jewelry that you want to last a very long time. $\mathbf{2 . 1 0 9} \mathrm{MgO}$ and SrO . $\mathbf{2 . 1 1 1}$ (a) Berkelium (Berkeley, CA); Europium (Europe); Francium (France); Scandium (Scandinavia); Ytterbium (Ytterby, Sweden); Yttrium (Ytterby, Sweden). (b) Einsteinium (Albert Einstein); Fermium (Enrico Fermi); Curium (Marie and Pierre Curie); Mendelevium (Dmitri Mendeleev); Lawrencium (Ernest Lawrence); Meitnerium (Lise Meitner). (c) Arsenic, Cesium, Chlorine, Chromium, Iodine, 2.113 The mass of fluorine reacting with hydrogen and deuterium would be the same. The ratio of F atoms to hydrogen (or deuterium) atoms is $1: 1$ in both compounds. This does not violate the law of definite proportions. When the law of definite proportions was formulated, scientists did not know of the existence of isotopes. 2.115 (a) Br . (b) Rn . (c) Se . (d) Rb . (e) Pb . $2.117 \mathrm{Mg}^{2+}, \mathrm{HCO}_{3}^{-}$, $\mathrm{Mg}\left(\mathrm{HCO}_{3}\right)_{2}$, Magnesium bicarbonate; $\mathrm{Sr}^{2+}, \mathrm{Cl}^{-}, \mathrm{SrCl}_{2}$, Strontium chloride; $\mathrm{Fe}^{3+}, \mathrm{NO}_{2}^{-}, \mathrm{Fe}\left(\mathrm{NO}_{2}\right)_{3}$, Iron(III) nitrite; $\mathrm{Mn}^{2+}, \mathrm{ClO}_{3}^{-}, \mathrm{Mn}\left(\mathrm{ClO}_{3}\right)_{2}$, Manganese(II) chlorate; $\mathrm{Sn}^{4+}, \mathrm{Br}^{-}, \mathrm{SnBr}_{4}, \mathrm{Tin}(\mathrm{IV})$ bromide; $\mathrm{Co}^{2+}, \mathrm{PO}_{4}^{3-}$, $\mathrm{Co}_{3}\left(\mathrm{PO}_{4}\right)_{2}$, Cobalt(II) phosphate; $\mathrm{Hg}_{2}^{2+}, \mathrm{I}^{-}, \mathrm{Hg}_{2} \mathrm{I}_{2}$, Mercury(I) iodide; $\mathrm{Cu}^{+}, \mathrm{CO}_{3}^{2-}, \mathrm{Cu}_{2} \mathrm{CO}_{3}$, Copper(I) carbonate; $\mathrm{Li}^{+}, \mathrm{N}^{3-}, \mathrm{Li}_{3} \mathrm{~N}$, Lithium nitride; $\mathrm{Al}^{3+}, \mathrm{S}^{2-}, \mathrm{Al}_{2} \mathrm{~S}_{3}$, Aluminum sulfide. $2.1191 .908 \times 10^{-8} \mathrm{~g}$. The predicted change (loss) in mass is too small a quantity to measure. Therefore, for all practical purposes, the law of conservation of mass is assumed to hold for ordinary chemical processes.

$\mathrm{C}_{5} \mathrm{H}_{12}$ :

2.123 (a) Yes. (b) Acetylene: any formula with $\mathrm{C}: \mathrm{H}=1: 1\left(\mathrm{CH}, \mathrm{C}_{2} \mathrm{H}_{2}\right.$, etc.); Ethane: any formula with $\mathrm{C}: \mathrm{H}=1: 3\left(\mathrm{CH}_{3}, \mathrm{C}_{2} \mathrm{H}_{6}\right.$, etc.). $\mathbf{2 . 1 2 5}$ Manganese, Mn. 2.127 Chloric acid, nitrous acid, hydrocyanic acid, and sulfuric acid.

(b) $0.631 \mathrm{~kg} \mathrm{~K}_{2} \mathrm{O}$. $\mathbf{3} .161 \mathrm{BaBr}_{2}$. $\mathbf{3 . 1 6 3} 32.17 \% \mathrm{NaCl}, 20.09 \% \mathrm{Na}_{2} \mathrm{SO}_{4}$, $47.75 \% \mathrm{NaNO}_{3} .3 .1650 .709 \mathrm{~g} \mathrm{NO}_{2}$ are produced. $\mathrm{O}_{3}$ is the limiting reactant. 0.0069 mol NO are left. $\mathbf{3 . 1 6 7}$ (a) $\mathrm{NH}_{4} \mathrm{NO}_{2}$ is the only reactant. When a reaction involves only a single reactant, we usually do not describe that reactant as the "limiting reactant" because it is understood that this is the case. (b) In principle, two or more reactants can be limiting reactants if they are exhausted simultaneously. In practice, it is virtually impossible to measure the reactants so precisely that two or more run out at the same time.

## Chapter 4

4.7 Diagram (c). 4.9 (a) Strong electrolyte. (b) Nonelectrolyte. (c) Weak electrolyte. (d) Strong electrolyte. 4.11 (a) Nonconducting. (b) Conducting. (c) Conducting. 4.13 Since HCl dissolved in water conducts electricity, $\mathrm{HCl}(a q)$ must actually exist as $\mathrm{H}^{+}(a q)$ cations and $\mathrm{Cl}^{-}(a q)$ anions. Since HCl dissolved in benzene solvent does not conduct electricity, then we must assume that the HCl molecules in benzene solvent do not ionize, but rather exist as un-ionized molecules. 4.17 Diagram (c). 4.19 (a) Insoluble. (b) Insoluble. (c) Soluble. (d) Soluble. 4.21 (a) $2 \mathrm{Ag}^{+}(a q)+2 \mathrm{NO}_{3}^{-}(a q)+2 \mathrm{Na}^{+}(a q)+\mathrm{SO}_{4}^{2-}(a q)$ $\longrightarrow \mathrm{Ag}_{2} \mathrm{SO}_{4}(s)+2 \mathrm{Na}^{+}(a q)+2 \mathrm{NO}_{3}^{-}(a q) ; 2 \mathrm{Ag}^{+}(a q)+\mathrm{SO}_{4}^{2-}(a q)$ $\longrightarrow \mathrm{Ag}_{2} \mathrm{SO}_{4}(s)$. (f) +6 . (g) +2 . (h) +4 . (i) +2 . (j) +3 . (k) +5.4 .49 If nitric acid is a strong oxidizing agent and zinc is a strong reducing agent, then zinc metal will probably reduce nitric acid when the two react; that is, N will gain electrons and the oxidation number of N must decrease. Since the oxidation number of nitrogen in nitric acid is +5 , then the nitrogencontaining product must have a smaller oxidation number for nitrogen. The only compound in the list that doesn't have a nitrogen oxidation number less than +5 is $\mathrm{N}_{2} \mathrm{O}_{5}$. This is never a product of the reduction of nitric acid. 4.51 Molecular oxygen is a powerful oxidizing agent. In $\mathrm{SO}_{3}$, the oxidation number of the element bound to oxygen $(\mathrm{S})$ is at its maximum value $(+6)$; the sulfur cannot be oxidized further. The other elements bound to oxygen in this problem have less than their maximum oxidation number and can undergo further oxidation. Only $\mathrm{SO}_{3}$ does not react with molecular oxygen. $\mathbf{4 . 5 3}$ (a) Decomposition. (b) Displacement. (c) Decomposition. ## Chapter 5

5.13 48 J. 5.15 577 J (work done on the system). $\mathbf{5 . 2 3}$ (a) 0. (b) -9.5 J. (c) -18 J. $\mathbf{5 . 2 5} 4.51 \mathrm{~kJ} / \mathrm{g} . \mathbf{5 . 2 7} 4.80 \times 10^{2}$ kJ. $\mathbf{5 . 2 9}$ For processes occurring in solution (cellular fluids), there is usually almost no volume change, so $P \Delta V \approx 0$ and $\Delta U+P \Delta V \approx \Delta U$ (see Equation 5.10). 5.35 728 kJ . $5.3750 .7^{\circ} \mathrm{C} .5 .3926 .3^{\circ} \mathrm{C} . \mathbf{5 . 4 1} 47.8^{\circ} \mathrm{C} /$ day; 4.1 kg water/day. $5.450 .30 \mathrm{~kJ} / \mathrm{mol}$. $5.47-238.7 \mathrm{~kJ} / \mathrm{mol}$. $\mathbf{5 . 5 3} \mathrm{CH}_{4}(g)$ and $\mathrm{H}(g)$. 5.55 $\Delta H_{\mathrm{f}}^{\circ}\left[\mathrm{H}_{2} \mathrm{O}(l)\right]$. $\mathbf{5 . 5 7} \Delta H_{\mathrm{f}}^{\circ}\left[\mathrm{H}_{2} \mathrm{O}(l)\right]$ is more negative than $\Delta H_{\mathrm{f}}^{\circ}\left[\mathrm{H}_{2} \mathrm{O}_{2}(l)\right]$. $5.59177 .8 \mathrm{~kJ} / \mathrm{mol} .5 .61$ (a) $-571.6 \mathrm{~kJ} / \mathrm{mol}$. (b) $-2599 \mathrm{~kJ} / \mathrm{mol}$. 5.63 (a) $-724 \mathrm{~kJ} / \mathrm{mol}$. (b) $-1.37 \times 10^{3} \mathrm{~kJ} / \mathrm{mol}$. (c) $-2.01 \times 10^{3} \mathrm{~kJ} / \mathrm{mol}$. $5.65-3924 \mathrm{~kJ} / \mathrm{mol}$. $5.67-3.43 \times 10^{4} \mathrm{~kJ}$. 5.69 In a chemical reaction the same elements and the same numbers of atoms are always on both sides of the equation. This provides a consistent reference that allows the energy change in the reaction to be interpreted in terms of the chemical or physical changes that have occurred. In a nuclear reaction the same elements are not always on both sides of the equation and no common reference point exists. $5.71-44.35 \mathrm{~kJ} / \mathrm{mol} .5 .73-175.3 \mathrm{~kJ} .5 .75$ (a) Although we cannot measure $\Delta H_{\mathrm{rxn}}^{\circ}$ for this reaction, the reverse process is the combustion of glucose. We could easily measure $\Delta H_{\mathrm{rxn}}^{\circ}$ for this combustion by burning a mole of glucose in a bomb calorimeter. (b) $1.1 \times 10^{19} \mathrm{~kJ} .5 .77-350.7 \mathrm{~kJ} / \mathrm{mol} .5 .790 .492 \mathrm{~J} / \mathrm{g} \cdot{ }^{\circ} \mathrm{C} . \mathbf{5 . 8 1}$ The first reaction, which is exothermic, can be used to promote the second reaction, which is endothermic. Thus, the two gases are produced alternately. $\mathbf{5 . 8 3} 446 \mathrm{~mol} \mathrm{H}_{2} . \mathbf{5 . 8 5} 0.167 \mathrm{~mol}$ ethane. $\mathbf{5 . 8 7} 5.60 \mathrm{~kJ} / \mathrm{mol}$. 5.89 (a). 5.91 (a) 0 J. (b) -9.1 J. 5.93 (a) The more closely packed, the greater the mass of food. Heat capacity depends on both the mass and specific heat: $C=m s$. The heat capacity of the food is greater than the heat capacity of air; hence, the cold in the freezer will be retained longer. (b) Tea and coffee are mostly water; whereas, soup might contain vegetables and meat. Water has a higher heat capacity than the other ingredients in soup; therefore, coffee and tea retain heat longer than soup. $5.95-1.84 \times 10^{3} \mathrm{~kJ} .5 .973 .0 \times 10^{9}$ atomic bombs. 5.99 (a) $2 \mathrm{LiOH}(a q)+\mathrm{CO}_{2}(g) \longrightarrow \mathrm{Li}_{2} \mathrm{CO}_{3}(a q)+\mathrm{H}_{2} \mathrm{O}(l)$. (b) $1.1 \mathrm{~kg} \mathrm{CO}_{2}$, 1.2 kg LiOH. $5.101-5.2 \times 10^{6} \mathrm{~kJ} .5 .103-3.60 \times 10^{2} \mathrm{~kJ} / \mathrm{mol} \mathrm{Zn}$ or $-3.60 \times 10^{2} \mathrm{~kJ} / 2 \mathrm{~mol} \mathrm{Ag}{ }^{+} . \mathbf{5 . 1 0 5} \mathrm{We}$ assume that when the car is stopped, its kinetic energy is completely converted into heat (friction of the brakes and friction between the tires and the road). Thus, $q=$ $(1 / 2) m u^{2}$, and the amount of heat generated must be proportional to the braking distance, $d: d \propto q$ or $d \propto u^{2}$. Therefore, as $u$ increases to $2 u, d$ increases to $(2 u)^{2}=4 u^{2}$, which is proportional to $4 d .5 .107$ Water has a larger specific heat than air. Thus cold, damp air can extract more heat from the body than cold, dry air. By the same token, hot, humid air can deliver more heat to the body. 5.109 5.8 $\times 10^{2} \mathrm{~m}$. 5.111 This law does not hold for Hg because it is a liquid. $5.113 \Delta H_{\mathrm{f}}^{\circ}\left(\mathrm{C}_{2} \mathrm{H}_{2}\right)=226.6 \mathrm{~kJ} / \mathrm{mol}$, $\Delta H_{\mathrm{f}}^{\circ}\left(\mathrm{C}_{6} \mathrm{H}_{6}\right)=49.0 \mathrm{~kJ} / \mathrm{mol}, \Delta H_{\mathrm{rxn}}=-630.8 \mathrm{~kJ} / \mathrm{mol} .5 .1154 .1$ cents.
$5.117(\mathrm{a}) \mathrm{CaC}_{2}(\mathrm{~s})+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{Ca}(\mathrm{OH})_{2}(\mathrm{~s})+\mathrm{C}_{2} \mathrm{H}_{2}(g)$.
(b) $1.51 \times 10^{6} \mathrm{~J} .5 .119$ (a) glucose: 31 kJ , sucrose: 33 kJ .
(b) glucose: 15 m , sucrose: $16 \mathrm{~m} .5 .121 \mathrm{w}=0, \Delta U=-5153 \mathrm{~kJ} / \mathrm{mol}$.

## Chapter 6

6.5 (a) $3.5 \times 10^{3} \mathrm{~nm}$. (b) $5.30 \times 10^{14} \mathrm{~Hz}$. $6.77 .0 \times 10^{2}$ s. $6.93 .26 \times$ $10^{7} \mathrm{~nm}$, microwave. $6.152 .82 \times 10^{-19} \mathrm{~J} .6 .17$ (a) $4.6 \times 10^{7} \mathrm{~nm}$, not in the visible region. (b) $4.3 \times 10^{-24} \mathrm{~J} /$ photon. (c) $2.6 \mathrm{~J} / \mathrm{mol}$. $6.191 .29 \times$ $10^{-15} \mathrm{~J}$. 6.21 Infrared photons have insufficient energy to cause the
chemical changes. $6.23 \nu=3.23 \times 10^{20} \mathrm{~s}^{-1}, \lambda=9.29 \times 10^{-13} \mathrm{~m} .6 .29$ Analyze the emitted light by passing it through a prism. 6.31 Excited atoms of the chemical elements emit the same characteristic frequencies or lines in a terrestrial laboratory, in the sun, or in a star many light-years distant from Earth. $6.333 .027 \times 10^{-19} \mathrm{~J} .6 .35 v=1.60 \times 10^{14} \mathrm{~Hz}, \lambda=$ $1.88 \times 10^{3} \mathrm{~nm} .6 .375 .6 .410 .565 \mathrm{~nm} .6 .439 .96 \times 10^{-32} \mathrm{~cm} .6 .51 \Delta u \geq$ $4.38 \times 10^{-26} \mathrm{~m} / \mathrm{s}$. This uncertainty is far smaller than can be measured. $6.55 \ell=1, m_{\ell}=-1,0$, and $1 ; \ell=0, m_{\ell}=0.6 .574 s, 4 p, 4 d$, and $4 f$ subshells; $1,3,5$, and 7 orbitals, respectively. $\mathbf{6 . 6 3}$ (a) $n=2, \ell=1, m_{\ell}=$ 1,0 , or -1 . (b) $n=3, \ell=0, m_{\ell}=0$. (c) $n=5, \ell=2, m_{\ell}=2,1,0,-1$, or -2 . 6.65 A $2 s$ orbital is larger than a $1 s$ orbital and exhibits a node. Both have the same spherical shape. The $1 s$ orbital is lower in energy than the $2 s$. 6.67 In H, energy depends only on $n$, but for all other atoms, energy depends on $n$ and $\ell .6 .69$ (a) $2 s$. (b) 3 . (c) equal. (d) equal. (e) $5 s$. 6.75 In the $n$th shell, there are $n^{2}$ orbitals and $2 n^{2}$ electrons. 6.77 (a) 3 . (b) 6. (c) 0.6 .79 Al : two $2 p$ electrons missing, $1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2} 3 p^{1}$; B: too many $2 p$ electrons, $1 s^{2} 2 s^{2} 2 p^{1}$; F : too many $2 p$ electrons, $1 s^{2} 2 s^{2} 2 p^{5}$. $\mathbf{6 . 8 1}$ $1 s:(1,0,0,+1 / 2)$ and $(1,0,0,-1 / 2), 2 s:(2,0,0,+1 / 2)$ and $(2,0,0,-1 / 2)$, $2 p(2,1,-1,+1 / 2),(2,1,-1,-1 / 2),(2,1,0,+1 / 2),(2,1,0,-1 / 2),(2,1$, $+1,+1 / 2)$, and $(2,1,+1,-1 / 2), 3 s(3,0,0,+1 / 2)$ and $(3,0,0,-1 / 2)$. The element is Mg. $\mathbf{6 . 9 1}[\mathrm{Kr}] 5 s^{2} 4 d^{5} . \mathbf{6 . 9 3} \mathrm{Ge}:[\mathrm{Ar}] 4 s^{2} 3 d^{10} 4 p^{2} ; \mathrm{Fe}:[\mathrm{Ar}] 4 s^{2} 3 d^{6}$; $\mathrm{Zn}:[\mathrm{Ar}] 4 s^{2} 3 d^{10}$; Ni: $[\mathrm{Ar}] 4 s^{2} 3 d^{8}$; W: $[\mathrm{Xe}] 6 s^{2} 4 f^{14} 5 d^{4}$; Tl: [Xe] $6 s^{2} 4 f^{14} 5 d^{10} 6 p^{1}$. 6.95 Part (b) is correct in the view of contemporary quantum theory. Bohr's explanation of emission and absorption line spectra appears to have universal validity. Parts (a) and (c) are artifacts of Bohr's early planetary model of the hydrogen atom and are not considered to be valid today. 6.97 (a) 4. (b) 6. (c) 10. (d) 1. (e) 2. 6.99 In the photoelectric effect, light of sufficient energy shining on a metal surface causes electrons to be ejected (photoelectrons). Since the electrons are charged particles, the metal surface becomes positively charged as more electrons are lost. After a long enough period of time, the positive surface charge becomes large enough to start attracting the ejected electrons back toward the metal with the result that the kinetic energy of the departing electrons becomes smaller. $\mathbf{6 . 1 0 1}$ (a) $1.20 \times 10^{18}$ photons. (b) $3.76 \times 10^{8} \mathrm{~W} .6 .103 \lambda=419 \mathrm{~nm}$. This wavelength is in the visible region of the electromagnetic spectrum. Since water is continuously being struck by visible radiation without decomposition, it seems unlikely that photodissociation of water by this method is feasible. $6.1053 .0 \times 10^{19}$ photons $/ \mathrm{s} .6 .107 \mathrm{He}^{+}: n=3 \longrightarrow$ $2: \lambda=164 \mathrm{~nm} ; n=4 \longrightarrow 2: \lambda=121 \mathrm{~nm} ; n=5 \longrightarrow 2: \lambda=108 \mathrm{~nm}$; $n=6 \longrightarrow 2: \lambda=103 \mathrm{~nm} . \mathrm{H}: n=3 \longrightarrow 2: \lambda=656 \mathrm{~nm} ; n=4$
$2: \lambda=486 \mathrm{~nm} ; n=5 \longrightarrow 2: \lambda=434 \mathrm{~nm} ; n=6 \longrightarrow 2: \lambda$ $=410 \mathrm{~nm}$. All the Balmer transitions for $\mathrm{He}^{+}$are in the ultraviolet region; whereas, the transitions for H are all in the visible region.
$\mathbf{6 . 1 0 9} \frac{1}{\lambda_{1}}=\frac{1}{\lambda_{2}}+\frac{1}{\lambda_{3}} . \mathbf{6 . 1 1 1}$ (a) $\mathrm{He}, 1 s^{2}$. (b) $\mathrm{N}, 1 s^{2} 2 s^{2} 2 p^{3}$.
(c) $\mathrm{Na}, 1 s^{2} 2 s^{2} 2 p^{6} 3 s^{1}$. (d) As, $[\mathrm{Ar}] 4 s^{2} 3 d^{10} 4 p^{3}$. (e) $\mathrm{Cl},[\mathrm{Ne}] 3 s^{2} 3 p^{5}$.
6.113 (a) $\frac{1 L}{1 s^{2}} \frac{1 L}{2 s^{2}} \frac{1 \downarrow}{1 L} \frac{1}{2 p^{5}} \underline{1}$. (b) $[\mathrm{Ne}] \frac{1 \downarrow}{3 s^{2}} \frac{1}{3 p^{3}} \frac{1}{}$.

$6.115 \lambda=0.596 \mathrm{~m}$; Microwave/radio region. 6.117 (a) False. (b) False. (c) True. (d) False. (e) True. $6.1194 .9 \times 10^{23}$ photons; $34 \mathrm{H}_{2} \mathrm{O}$ molecules/photon. 6.121 $2.2 \times 10^{5} \mathrm{~J} .6 .123$ (b) and (d) are allowed transitions. Any of the transitions in Figure 6.11 is possible as long as $\ell$ for the final state differs from $\ell$ of the initial state by 1.6 .12517 .4 pm . $\mathbf{6 . 1 2 7} \lambda=0.382 \mathrm{pm}, v=7.86 \times 10^{20} \mathrm{~s}^{-1} .6 .129 n_{\mathrm{i}}=1: \Delta E=1.96 \times$ $10^{-17} \mathrm{~J} ; n_{\mathrm{i}}=5: \Delta E=7.85 \times 10^{-19} \mathrm{~J}$; transition from $n=5$ to $n=1: \Delta E$ $=-1.88 \times 10^{-17} \mathrm{~J} ; \lambda=10.6 \mathrm{~nm} .6 .1313 .9 \times 10^{5} \mathrm{~m} / \mathrm{s} .6 .133$ (a) We note that the maximum solar radiation centers around 500 nm . Thus, over billions of years, organisms have adjusted their development to capture energy at or near this wavelength. The two most notable cases are photosynthesis and vision. (b) Astronomers record blackbody radiation curves from stars and compare them with those obtained from objects at different temperatures in the laboratory. Because the shape of the curve
and the wavelength corresponding to the maximum depend on the temperature of an object, astronomers can reliably determine the temperature at the surface of a star from the closest matching curve and wavelength. 6.1351 .06 nm .

## Chapter 7

7.17 Sulfur, $1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2} 3 p^{4} .7 .19$ (a) and (d); (b) and (e); (c) and (f). 7.21 (a) Group 1A or 1. (b) Group 5A or 15. (c) Group 8A or 18. (d) Group 8B or 10.7 .25 (a) $\sigma=2$ and $Z_{\text {eff }}=+4$. (b) $2 s, Z_{\text {eff }}=+3.22 ; 2 p, Z_{\text {eff }}=$ +3.14 . The values are lower than those in part (a) because the $2 s$ and $2 p$ electrons actually do shield each other somewhat. $7.33 \mathrm{Na}>\mathrm{Mg}>\mathrm{Al}>$ $\mathrm{P}>\mathrm{Cl}$. 7.35 Fluorine. 7.37 Left to right: $\mathrm{S}, \mathrm{Se}, \mathrm{Ca}, \mathrm{K}$. 7.39 The atomic radius is largely determined by how strongly the outer-shell electrons are held by the nucleus. The larger the effective nuclear charge, the more strongly the electrons are held and the smaller the atomic radius. For the second period, the atomic radius of Li is largest because the $2 s$ electron is well shielded by the filled $1 s$ shell. The effective nuclear charge that the outermost electrons feel increases across the period as a result of incomplete shielding by electrons in the same shell. Consequently, the orbital containing the electrons is compressed and the atomic radius decreases. 7.41 $\mathrm{K}<\mathrm{Ca}<\mathrm{P}<\mathrm{F}<\mathrm{Ne}$. 7.43 The Group 3A elements (such as Al ) all have a single electron in the outermost $p$ subshell, which is well shielded from the nuclear charge by the inner electrons and the $n s^{2}$ electrons. Therefore, less energy is needed to remove a single $p$ electron than to remove a paired $s$ electron from the same principal energy level (such as for Mg ). $\mathbf{7 . 4 5} 496 \mathrm{~kJ} / \mathrm{mol}$ is paired with $1 s^{2} 2 s^{2} 2 p^{6} 3 s^{1} .2080 \mathrm{~kJ} /$ mol is paired with $1 s^{2} 2 s^{2} 2 p^{6}$, a very stable noble gas configuration. 7.47 $8.40 \times 10^{6} \mathrm{~kJ} / \mathrm{mol}$. 7.49 Cl . 7.51 Alkali metals have a valence electron configuration of $n s^{1}$ so they can accept another electron in the $n s$ orbital. On the other hand, alkaline earth metals have a valence electron configuration of $n s^{2}$. Alkaline earth metals have little tendency to accept another electron, as it would have to go into a higher energy $p$ orbital. 7.57 Fe .7 .59 (a) [Ne]. (b) [Ne]. (c) [Ar]. (d) [Ar]. (e) $[\mathrm{Ar}]$. (f) $[\mathrm{Ar}] 3 d^{6}$. (g) $[\mathrm{Ar}] 3 d^{9}$. (h) $[\mathrm{Ar}] 3 d^{10} .7 .61$ (a) $\mathrm{Cr}^{3+}$. (b) $\mathrm{Sc}^{3+}$. (c) $\mathrm{Rh}^{3+}$. (d) $\mathrm{Ir}^{3+} .7 .63$ $\mathrm{Be}^{2+}$ and $\mathrm{He} ; \mathrm{N}^{3-}$ and $\mathrm{F}^{-} ; \mathrm{Fe}^{2+}$ and $\mathrm{Co}^{3+} ; \mathrm{S}^{2-}$ and Ar. 7.67 (a) Cl . (b) $\mathrm{Na}^{+}$. (c) $\mathrm{O}^{2-}$. (d) $\mathrm{Al}^{3+}$. (e) $\mathrm{Au}^{3+}$. $7.69 \mathrm{The}_{\mathrm{Cu}}{ }^{+}$ion is larger than $\mathrm{Cu}^{2+}$ because it has one more electron. 7.71 The binding of a cation to an anion results from electrostatic attraction. As the +2 cation gets smaller (from $\mathrm{Ba}^{2+}$ to $\mathrm{Mg}^{2+}$ ), the distance between the opposite charges decreases and the electrostatic attraction increases. $7.75-199.7^{\circ} \mathrm{C}$. 7.77 Since ionization energies decrease going down a column in the periodic table, francium should have the lowest first ionization energy of all the alkali metals. As a result, Fr should be the most reactive of all the Group 1A elements toward water and oxygen. The reaction with oxygen would probably be similar to that of $\mathrm{K}, \mathrm{Rb}$, or Cs . 7.79 The Group 1B elements are much less reactive than the Group 1A elements. The 1B elements are more stable because they have much higher ionization energies resulting from incomplete shielding of the nuclear charge by the inner $d$ electrons. The $n s^{1}$ electron of a Group 1A element is shielded from the nucleus more effectively by the completely filled noble gas core. Consequently, the outer $s$ electrons of 1 B elements are more strongly attracted by the nucleus. $7.81\left(\right.$ a) $\mathrm{Li}_{2} \mathrm{O}(s)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{LiOH}(a q)$. (b) $\mathrm{CaO}(s)+$ $\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{Ca}(\mathrm{OH})_{2}(a q)$. (c) $\mathrm{SO}_{3}(g)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}_{2} \mathrm{SO}_{4}(a q) .7 .83$ BaO . As we move down a column, the metallic character of the elements increases. 7.85 (a) Br . (b) N . (c) Rb . (d) Mg . $7.87 \mathrm{O}^{2-}<\mathrm{F}^{-}<\mathrm{Na}^{+}<$ $\mathrm{Mg}^{2+}$. $7.89 \mathrm{M}=\mathrm{K}, \mathrm{X}=\mathrm{Br} .7 .91 \mathrm{O}^{+}$and $\mathrm{N} ; \mathrm{S}^{2-}$ and $\mathrm{Ar} ; \mathrm{N}^{3-}$ and Ne ; $\mathrm{As}^{3+}$ and Zn ; $\mathrm{Cs}^{+}$and Xe. 7.93 (a) and (d). 7.95 Fluorine is a yellowgreen gas that attacks glass; chlorine is a pale yellow gas; bromine is a fuming red liquid; iodine is a dark, metallic-looking solid. 7.97 F. 7.99 $\mathrm{H}^{-}$. Since $\mathrm{H}^{-}$has only one proton compared to two protons for He , the nucleus of $\mathrm{H}^{-}$will attract the two electrons less strongly compared to He . 7.101 $\mathrm{Li}_{2} \mathrm{O}$, lithium oxide, basic; BeO , beryllium oxide, amphoteric; $\mathrm{B}_{2} \mathrm{O}_{3}$, diboron trioxide, acidic; $\mathrm{CO}_{2}$, carbon dioxide, acidic; $\mathrm{N}_{2} \mathrm{O}_{5}$, dinitrogen pentoxide, acidic. 7.103 Hydrogen has just one valence electron but it is also just one electron short of a noble gas configuration.

Thus, it can behave like a member of Group 1A or like a member of Group 7A. 7.105 0.66. 7.107 77.5\%. 7.109 $6.94 \times 10^{-19} \mathrm{~J} /$ electron. If there are no other electrons with lower kinetic energy, then this is the electron from the valence shell. UV light of the longest wavelength (lowest energy) that can still eject electrons should be used. 7.111 X must belong to Group 4A; it is probably Sn or Pb because it is not a very reactive metal (it is certainly not reactive like an alkali metal). Y is a nonmetal since it does not conduct electricity. Since it is a light yellow solid, it is probably phosphorus (Group 5A). Z is an alkali metal since it reacts with air to form a basic oxide or peroxide. 7.113 (a) $I E_{1}=3 s^{1}$ electron, $I E_{2}=2 p^{6}$ electron, $I E_{3}=2 p^{5}$ electron, $I E_{4}=2 p^{4}$ electron, $I E_{5}=2 p^{3}$ electron, $I E_{6}=2 p^{2}$ electron, $I E_{7}=2 p^{1}$ electron, $I E_{8}=2 s^{2}$ electron, $I E_{9}=2 s^{1}$ electron, $I E_{10}=1 s^{2}$ electron, $I E_{11}=1 s^{1}$ electron. (b) Each break $\left(I E_{1} \longrightarrow I E_{2}\right.$ and $\left.I E_{9} \longrightarrow I E_{10}\right)$ represents the transition to another shell $(n=3 \longrightarrow 2$ and $n=2 \longrightarrow 1)$.

7.115 Considering electron configurations, $\mathrm{Fe}^{2+}[\mathrm{Ar}] 3 d^{6} \longrightarrow$ $\mathrm{Fe}^{3+}[\mathrm{Ar}] 3 d^{5}, \mathrm{Mn}^{2+}[\mathrm{Ar}] 3 d^{5} \longrightarrow \mathrm{Mn}^{3+}[\mathrm{Ar}] 3 d^{4}$, a half-filled shell has extra stability. In oxidizing $\mathrm{Fe}^{2+}$, the product is a $d^{5}$-half-filled shell. In oxidizing $\mathrm{Mn}^{2+}$, a $d^{5}$-half-filled shell electron is being lost, which requires more energy. 7.117 The electron configuration of titanium is [ Ar$] 4 s^{2} 3 d^{2} . \mathrm{K}_{2} \mathrm{TiO}_{4}$ is unlikely to exist because of the oxidation state of Ti of $+6 . \mathrm{Ti}$ in an oxidation state greater than +4 is unlikely because of the very high ionization energies needed to remove the fifth and sixth electrons. 7.119 (a) $2 \mathrm{KClO}_{3}(s) \longrightarrow 2 \mathrm{KCl}(s)+3 \mathrm{O}_{2}(g)$. (b) $\mathrm{N}_{2}(g)+$ $3 \mathrm{H}_{2}(g) \longrightarrow 2 \mathrm{NH}_{3}(g)$ (industrial); $\mathrm{NH}_{4} \mathrm{Cl}(s)+\mathrm{NaOH}(a q) \longrightarrow$ $\mathrm{NH}_{3}(g)+\mathrm{NaCl}(a q)+\mathrm{H}_{2} \mathrm{O}(l)$. (c) $\mathrm{CaCO}_{3}(s) \longrightarrow \mathrm{CaO}(s)+\mathrm{CO}_{2}(g)$ (industrial); $\mathrm{CaCO}_{3}(s)+2 \mathrm{HCl}(a q) \longrightarrow \mathrm{CaCl}_{2}(a q)+\mathrm{H}_{2} \mathrm{O}(l)+$ $\mathrm{CO}_{2}(g)$. (d) $\mathrm{Zn}(s)+\mathrm{H}_{2} \mathrm{SO}_{4}(a q) \longrightarrow \mathrm{ZnSO}_{4}(a q)+\mathrm{H}_{2}(g)$. (e) Same as (c), (first equation). 7.121 Examine a solution of $\mathrm{Na}_{2} \mathrm{SO}_{4}$, which is colorless. This shows that the $\mathrm{SO}_{4}^{2-}$ ion is colorless. Thus the blue color is due to $\mathrm{Cu}^{2+}(a q) . \mathbf{7 . 1 2 3} Z_{\text {eff }}$ increases from left to right across the table, so electrons are held more tightly. (This explains the electron affinity values of C and O .) Nitrogen has a zero value of electron affinity because of the stability of the half-filled $2 p$ subshell (that is, N has little tendency to accept another electron). 7.125 Once an atom gains an electron forming a negative ion, adding additional electrons is typically an unfavorable process due to electron-electron repulsions. Second and third electron affinities do not occur spontaneously and are therefore difficult to measure. 7.127 (a) It was determined that the periodic table was based on atomic number, not atomic mass. (b) Argon: 39.95 amu ; Potassium: 39.10 amu . 7.129 Element 119: $[\mathrm{Rn}] 7 s^{2} 5 f^{14} 6 d^{10} 7 p^{6} 8 s^{1}$. 7.131 2A. There is a large jump from the second to the third ionization energy, indicating a change in the principal quantum number $n .7 .133$ (a) $\mathrm{SiH}_{4}, \mathrm{GeH}_{4}, \mathrm{SnH}_{4}$, $\mathrm{PbH}_{4}$. (b) RbH should be more ionic than NaH . (c) $\mathrm{Ra}(s)+2 \mathrm{H}_{2} \mathrm{O}(l)$ $\longrightarrow \mathrm{Ra}(\mathrm{OH})_{2}(\mathrm{aq})+\mathrm{H}_{2}(\mathrm{~g})$. (d) Be (diagonal relationship). 7.135 See sections 7.1 and 7.2. 7.137 (c) Carbon. $7.139 \mathrm{Li}: Z_{\text {eff }}=1.26, Z_{\text {eff }} / n=$ $0.630 ; \mathrm{Na}: Z_{\text {eff }}=1.84, Z_{\text {eff }} / n=0.613 ; \mathrm{K}: Z_{\text {eff }}=2.26, Z_{\text {eff }} / n=0.565$. As we move down a group, $Z_{\text {eff }}$ increases. This is what we would expect because shells with larger $n$ values are less effective at shielding the outer electrons from the nuclear charge. The $Z_{\text {eff }} / n$ values are fairly constant, meaning that the screening per shell is about the same. 7.141 Nitrogen. Lithium forms a stable nitride $\left(\mathrm{Li}_{3} \mathrm{~N}\right)$.

## Chapter 8

8.19 (a) Decreases the ionic bond energy. (b) Triples the ionic bond energy. (c) Increases the bond energy by a factor of 4. (d) Increases the bond energy by a factor of 2 .
8.21
(a) $\mathrm{Na} \cdot+: \stackrel{\ddot{\mathrm{F}}}{ }$. $\mathrm{Na}^{+}: \ddot{\mathrm{F}}:-$

(b) $\mathrm{H}-\ddot{\mathrm{S}} \mathrm{e}-\mathrm{H}$
(c) $\begin{aligned} & \mathrm{H}-\ddot{\mathrm{N}}-\mathrm{H} \\ &!\mathrm{O}-\mathrm{H}\end{aligned}$
(d)

(e)

(f)

(g)

8.47 (a) $\ddot{O}=\stackrel{+}{N}=\ddot{O}$
(b) $\ddot{\mathrm{S}}=\mathrm{C}=\ddot{\mathrm{N}}^{-}$or $\ddot{:} \ddot{\mathrm{S}}-\mathrm{C} \equiv \mathrm{N}$ :
(c) $\ddot{:} \ddot{S}-\ddot{S}-$
(d) : $\ddot{\mathrm{F}}-\ddot{\mathrm{C}} \mathrm{l}^{+}-\ddot{\mathrm{F}}$ :
8.49 (a) Neither oxygen atom has a complete octet, and the left-most hydrogen atom shows two bonds (4 electrons). Hydrogen can hold only two electrons in its valence shell.
(b)

8.53 (a)

(b)

8.55 $\mathrm{H}-\ddot{\mathrm{N}}=\stackrel{+}{\mathrm{N}}=\ddot{\mathrm{N}}-\stackrel{\mathrm{H}}{\mathrm{H}} \underset{\mathrm{N}}{\mathrm{N}}-\stackrel{+}{\mathrm{N}} \equiv \mathrm{N}: \longleftrightarrow \mathrm{H}-\stackrel{+}{\mathrm{N}} \equiv \stackrel{+}{\mathrm{N}}-\stackrel{.}{\mathrm{N}}:{ }^{2-}$ $8.57 \ddot{\mathrm{O}}=\mathrm{C}=\ddot{\mathrm{N}}^{-} \longleftrightarrow \stackrel{\ddot{\mathrm{O}}}{ } \mathrm{O}-\mathrm{C} \equiv \mathrm{N}: \longleftrightarrow: \stackrel{+}{\mathrm{O}} \equiv \mathrm{C}-\ddot{\mathrm{N}}^{2-}$

8.67 No. : $\ddot{\mathrm{C}} \mathrm{l}-\mathrm{Be}-\ddot{\mathrm{C}} \mathrm{l}:$ To make an octet on Be is not plausible,

$8.77303 .0 \mathrm{~kJ} / \mathrm{mol} .8 .79$ (a) $-2759 \mathrm{~kJ} / \mathrm{mol}$. (b) $-2855.4 \mathrm{~kJ} / \mathrm{mol}$.
$8.81-651 \mathrm{~kJ} / \mathrm{mol}$. 8.83 Ionic: $\mathrm{RbCl}, \mathrm{KO}_{2}$. Covalent: $\mathrm{PF}_{5}, \mathrm{BrF}_{3}, \mathrm{CI}_{4}$. 8.85 Ionic: $\mathrm{NaF}, \mathrm{MgF}_{2}, \mathrm{AlF}_{3}$. Covalent: $\mathrm{SiF}_{4}, \mathrm{PF}_{5}, \mathrm{SF}_{6}, \mathrm{ClF}_{3}$. 8.87 KF is an ionic compound. It is a solid at room temperature made up of $\mathrm{K}^{+}$and $\mathrm{F}^{-}$ions. It has a high melting point, and it is a strong electrolyte.
Benzene, $\mathrm{C}_{6} \mathrm{H}_{6}$, is a covalent compound that exists as discrete molecules. It is a liquid at room temperature. It has a low melting point, is insoluble in water, and is a nonelectrolyte.

8.91 (a) $\mathrm{AlCl}_{4}^{-}$. (b) $\mathrm{AlF}_{6}^{3-}$. (c) $\mathrm{AlCl}_{3} .8 .93 \mathrm{CF}_{2}$ would be very unstable because carbon does not have an octet. $\mathrm{LiO}_{2}$ would not be stable because the lattice energy between $\mathrm{Li}^{+}$and superoxide $\mathrm{O}_{2}^{-}$would be too low to stabilize the solid. $\mathrm{CsCl}_{2}$ requires a $\mathrm{Cs}^{2+}$ cation. The second ionization energy is too large to be compensated by the increase in lattice energy. $\mathrm{PI}_{5}$ appears to be a reasonable species. However, the iodine atoms are too large to have five of them "fit" around a single P atom. $\mathbf{8 . 9 5}$ (a) False. (b) True. (c) False. (d) False. $8.97-67 \mathrm{~kJ} / \mathrm{mol} .8 .99 \mathrm{~N}_{2}$, since it has a triple bond. $8.101 \mathrm{CH}_{4}$ and $\mathrm{NH}_{4}^{+} ; \mathrm{N}_{2}$ and $\mathrm{CO} ; \mathrm{C}_{6} \mathrm{H}_{6}$ and $\mathrm{B}_{3} \mathrm{~N}_{3} \mathrm{H}_{6}$.
8.103

8.105

8.107 The central iodine atom in $\mathrm{I}_{3}^{-}$has ten electrons surrounding it: two bonding pairs and three lone pairs. The central iodine has an expanded octet. Elements in the second period such as fluorine cannot have an expanded octet as would be required for $\mathrm{F}_{3}^{-}$.
8.109

8.111 Form (a) is the most important structure with no formal charges and all satisfied octets. (b) is likely not as important as (a) because of the positive formal charge on O. Forms (c) and (d) do not satisfy the octet rule for all atoms and are likely not important.
8.113 (a)

(b) :

(c)

(d)

8.115 (a) $-9.2 \mathrm{~kJ} / \mathrm{mol}$. (b) $-9.2 \mathrm{~kJ} / \mathrm{mol}$.
8.117 (a) $\overline{\mathrm{C}} \mathrm{C} \equiv \mathrm{O}{ }^{+}$
(b) $: \mathrm{N} \equiv \mathrm{O}:^{+}$
(c) $\overline{ }$ C $\equiv \mathrm{N}$ :
(d) $: \mathrm{N} \equiv \mathrm{N}$ :
8.119 True. Each noble gas atom already has completely filled $n s$ and $n p$ subshells. 8.121 (a) $114 \mathrm{~kJ} / \mathrm{mol}$. (b) The bond in $\mathrm{F}_{2}^{-}$is weaker.
8.123 (a) $: \dot{\mathrm{N}}=\ddot{\mathrm{O}} \longleftrightarrow \overline{\mathrm{O}}=\ddot{\mathrm{O}} \dot{\mathrm{O}}^{+}$The first structure is the most important. (b) No. 8.125 The arrows indicate coordinate covalent bonds.

This dimer does not possess a dipole moment.
 8.127 (a) $\cdot \ddot{\mathrm{O}}-\mathrm{H}$ (b) To complete its octet, the OH radical has a strong tendency to form a bond with a H atom. (c) $-46 \mathrm{~kJ} / \mathrm{mol}$. (d) 260 nm . $8.129347 \mathrm{~kJ} / \mathrm{mol}$. $8.131 \mathrm{EN}(\mathrm{O})=3.2$ (Pauling 3.5); $\mathrm{EN}(\mathrm{F})=4.4$ (Pauling 4.0); $\mathrm{EN}(\mathrm{Cl})=3.5$ (Pauling 3.0). 8.133 (1) You could estimate the lattice energy of the solid by trying to measure its melting point. $\mathrm{Mg}^{+} \mathrm{O}^{-}$would have a lattice energy (and, therefore, a melting point) similar to that of $\mathrm{Na}^{+} \mathrm{Cl}^{-}$. This lattice energy and melting point are much lower than those of $\mathrm{Mg}^{2+} \mathrm{O}^{2-}$. (2) You could determine the magnetic properties of the solid. $\mathrm{An}_{\mathrm{Mg}}{ }^{+} \mathrm{O}^{-}$solid would be paramagnetic while $\mathrm{Mg}^{2+} \mathrm{O}^{2-}$ solid is diamagnetic. See Chapter 9 of the text.
8.135
(a) $\mathrm{H}^{-\mathrm{H}} \mathrm{H}^{+} \longleftrightarrow \mathrm{H}^{+}{ }^{\mathrm{H}} \mathrm{H} \longleftrightarrow \mathrm{H} \xrightarrow{\mathrm{H}^{+}} \mathrm{H} \quad$ (b) $-413 \mathrm{~kJ} / \mathrm{mol}$. 8.137

8.139 C-C: $347 \mathrm{~kJ} / \mathrm{mol}$; $\mathrm{N}-\mathrm{N}: 193 \mathrm{~kJ} / \mathrm{mol}$; $\mathrm{O}-\mathrm{O}: 142 \mathrm{~kJ} / \mathrm{mol}$. Lone pairs appear to weaken the bond.

## Chapter 9

9.7 (a) Trigonal pyramidal. (b) Tetrahedral. (c) Tetrahedral. (d) See-saw. 9.9 (a) Tetrahedral. (b) Trigonal planar. (c) Trigonal pyramidal. (d) Bent.
(e) Bent. 9.11 (a) Linear. (b) Tetrahedral. (c) Trigonal bipyramidal.
(d) Trigonal pyramidal. (e) Tetrahedral. 9.13 Carbon at the center of $\mathrm{H}_{3} \mathrm{C}-$ : electron domain geometry $=$ tetrahedral, molecular geometry $=$ tetrahedral; Carbon at center of $-\mathrm{CO}-\mathrm{OH}$ : electron-domain geometry $=$ trigonal planar, molecular geometry $=$ trigonal planar; Oxygen in $-\mathrm{O}-\mathrm{H}$ : electron domain geometry $=$ tetrahedral, molecular geometry $=$ bent. 9.17 (a) Polar. (b) Nonpolar. 9.19 Only (c) is polar. 9.29 (a) $s p^{3}$. (b) $s p^{3}$. 9.31 In $\mathrm{BF}_{3}, \mathrm{~B}$ is $s p^{2}$ hybridized. In $\mathrm{NH}_{3}, \mathrm{~N}$ is $s p^{3}$ hybridized. In $\mathrm{F}_{3} \mathrm{~B}-\mathrm{NH}_{3}, \mathrm{~B}$ and N are both $s p^{3}$ hybridized. $9.33 s p^{3} d .9 .37$ (a) $s p$. (b) $s p$. (c) $\operatorname{sp.9.39} s p .9 .41$ Nine $\sigma$ bonds and nine $\pi$ bonds. $9.4336 \sigma$ bonds and $10 \pi$ bonds. 9.49 In order for the two hydrogen atoms to combine to form a $\mathrm{H}_{2}$ molecule, the electrons must have opposite spins. If two H atoms collide and their electron spins are parallel, no bond will form. $9.51 \mathrm{Li}_{2}^{-}$ $=\mathrm{Li}_{2}^{+}<\mathrm{Li}_{2}$. (Both $\mathrm{Li}_{2}^{+}$and $\mathrm{Li}_{2}^{-}$have bond order of $1 / 2 . \mathrm{Li}_{2}$ has a bond order of 1.) $9.53 \mathrm{~B}_{2}^{+}$, with a bond order of $1 / 2$. ( $\mathrm{B}_{2}$ has a bond order of 1.) 9.55 The Lewis diagram has all electrons paired (incorrect) and a double bond (correct). The MO diagram has two unpaired electrons (correct), and a bond order of 2 (correct). $\mathbf{9 . 5 7} \mathrm{O}_{2}$ : bond order $=2$, paramagnetic; $\mathrm{O}_{2}^{+}$: bond order $=2.5$, paramagnetic; $\mathrm{O}_{2}^{-}$: bond order $=1.5$, paramagnetic; $\mathrm{O}_{2}^{2-}:$ bond order $=1$, diamagnetic. 9.59 The two shared electrons that make up the single bond in $\mathrm{B}_{2}$ both lie in pi molecular orbitals and constitute a pi bond. The four shared electrons that make up the double bond in $\mathrm{C}_{2}$ all lie in pi molecular orbitals and constitute two pi bonds. 9.63 The left symbol shows three delocalized double bonds (correct). The right symbol shows three localized double bonds and three
single bonds (incorrect). 9.65 (a)

(b) $s p^{2}$. (c) Sigma bonds join the nitrogen atom to the fluorine and oxygen atoms. There is a pi molecular orbital delocalized over the N and O
atoms. 9.67 The central oxygen atom is $s p^{2}$ hybridized. The unhybridized $2 p_{\mathrm{z}}$ orbital on the central oxygen overlaps with the $2 p_{\mathrm{z}}$ orbitals on the two terminal atoms. $9.69: \ddot{\mathrm{B}} \mathrm{r}-\mathrm{Hg}-\ddot{\mathrm{Br}}$ : Linear. You could establish the geometry of $\mathrm{HgBr}_{2}$ by measuring its dipole moment. 9.71 Bent; $s p^{3}$. 9.73 (a) $\mathrm{C}_{6} \mathrm{H}_{8} \mathrm{O}_{6}$. (b) Five central O atoms $s p^{3}$; hybridization of the sixth (double bonded) peripheral O atom is $s p^{2}$. Three C atoms $s p^{2}$; three C atoms $s p^{3}$. (c) The five central O atoms bent. The three $s p^{2} \mathrm{C}$ atoms are trigonal planar. The three $s p^{3} \mathrm{C}$ atoms are tetrahedral. 9.75 (a) $180^{\circ}$.
(b) $120^{\circ}$. (c) $109.5^{\circ}$
(d) $109.5^{\circ}$.
(e) $180^{\circ}$.
(f) $120^{\circ}$.
(g) $109.5^{\circ}$.
(h) $109.5^{\circ}$.
9.77 (a)
 , planar. (
 , nonplanar.
 $120^{\circ}$. Experimental value is around $135^{\circ} .9 .79$ The $\mathrm{S}-\mathrm{S}$ bond is a normal 2-electron shared pair covalent bond. Each S is $s p^{3}$ hybridized, so the $\mathrm{X}-\mathrm{S}-\mathrm{S}$ angle is about $109^{\circ} . \mathbf{9 . 8 1}$ Only $\mathrm{ICl}_{2}^{-}$and $\mathrm{CdBr}_{2}$ are linear. 9.83 (a) $s p^{2}$. (b) The molecule on the right is polar. 9.85 Rotation about the sigma bond in 1,2-dichloroethane does not destroy the bond, so the bond is free to rotate. Thus, the molecule is nonpolar because the $\mathrm{C}-\mathrm{Cl}$ bond moments cancel each other because of the averaging effect brought about by rotation. The $\pi$ bond between the C atoms in cis-dichloroethylene prevents rotation (in order to rotate, the $\pi$ bond must be broken). Therefore, the molecule is polar. 9.87 All except homonuclear diatomic molecules $\mathrm{N}_{2}$ and $\mathrm{O}_{2}$.
9.89

The carbon atoms and nitrogen atoms marked with an asterisk ( $\mathrm{C}^{*}$ and $\mathrm{N}^{*}$ ) are $s p^{2}$ hybridized; unmarked carbon atoms and nitrogen atoms are $s p^{3}$ hybridized; and the nitrogen atom marked with (\#) is $s p$ hybridized. 9.91 C has no $d$ orbitals but Si does ( $3 d$ ). Thus, $\mathrm{H}_{2} \mathrm{O}$ molecules can add to Si in hydrolysis (valence-shell expansion). 9.93 The carbons are all $s p^{2}$ hybridized. The nitrogen double bonded to carbon in the ring is $s p^{2}$ hybridized. The other nitrogens are $s p^{3}$ hybridized. $9.95 \mathrm{~F}_{2}$ has 8 electrons in bonding orbitals and 6 electrons in antibonding orbitals, giving it a bond order of $1 . \mathrm{F}_{2}^{-}$has 8 electrons in bonding orbitals and 7 electrons in antibonding orbitals, giving it a bond order of $1 / 2.9 .9743 .6 \%$. 9.99 The second ("asymmetric stretching mode") and third ("bending mode"). 9.101

The four carbons marked with an asterisk are $s p^{2}$ hybridized. The remaining carbons are $s p^{3}$ hybridized. 9.103 (a) $\left[\mathrm{Ne}_{2}\right]\left(\sigma_{3 s}\right)^{2}\left(\sigma_{3 s}^{*}\right)^{2}\left(\pi_{3 p y}\right)^{2}$ $\left(\pi_{3 p_{z}}\right)^{2}\left(\sigma_{3 p_{x}}\right)^{2}$. (b) 3. (c) Diamagnetic. 9.105 In the Lewis structure, all the electrons are paired. From molecular orbital theory, the electrons would be arranged as follows: $\left[\mathrm{He}_{2}\right]\left(\sigma_{2 s}\right)^{2}\left(\sigma_{2 s}^{*}\right)^{2}\left(\sigma_{2 p_{x}}\right)^{2}\left(\pi_{2 p_{y}}\right)^{2}\left(\pi_{2 p_{z}}\right)^{2}\left(\pi_{2 p_{y}}^{*}\right)^{1}\left(\pi_{2 p_{z}}^{*}\right)^{1}$. This shows two unpaired electrons. To pair these electrons, energy is required to flip the spin of one, thus making the Lewis structure an excited state. 9.107 (a) Although the O atoms are $s p^{3}$ hybridized, they are locked in a planar structure by the benzene rings. The molecule is symmetrical and therefore is not polar. (b) $20 \sigma$ bonds and $6 \pi$ bonds. 9.109 (a) : $\overline{\mathrm{C}} \equiv \stackrel{+}{\mathrm{O}}$ : The electronegativity difference between O and C suggests that electron density should concentrate on the O atom, but assigning formal charges places a negative charge on the C atom. Therefore, we expect CO to have a small dipole moment. (b) CO is isoelectronic with $\mathrm{N}_{2}$, bond order 3 . This agrees with the triple bond in the Lewis structure. (c) Since C has a negative formal charge, it is more likely to form bonds with $\mathrm{Fe}^{2+} .\left(\mathrm{OC}-\mathrm{Fe}^{2+}\right.$ rather than $\left.\mathrm{CO}-\mathrm{Fe}^{2+}\right)$.
9.111 Tetrahedral. 9.113 No.

10.91 Since N is less electronegative than O , electron donation in the amide would be more pronounced. $\mathbf{1 0 . 9 3}$ (a) The more negative $\Delta H$ implies stronger alkane bonds; branching decreases the total bond enthalpy (and overall stability) of the alkane. (b) The least highly branched isomer (n-octane). $\mathbf{1 0 . 9 5}$ (a) $15.81 \mathrm{mg} \mathrm{C}, 1.32 \mathrm{mg} \mathrm{H}, 3.49 \mathrm{mg} \mathrm{O}$.
(b) $\mathrm{C}_{6} \mathrm{H}_{6} \mathrm{O}$.

10.101 8 different tripeptides: Lys—Lys—Lys, Lys—Lys—Ala, Lys-Ala-Lys, Ala-Lys-Lys, Lys-Ala-Ala, Ala-Lys-Ala, Ala-Ala-Lys, Ala-Ala-Ala.

## Chapter 11

11.13 $0.493 \mathrm{~atm}, 0.500$ bar, 375 torr, $5.00 \times 10^{4} \mathrm{~Pa}$. 11.1513 .1 m .11 .17 7.3 atm. 11.21 (a) Diagram (d). (b) Diagram (b). $\mathbf{1 1 . 2 3} 45.9$ mL. 11.25 587 mmHg . 11.27 31.8 L. 11.29 1 volume of NO. 11.356 .6 atm .11 .37 $1590^{\circ} \mathrm{C}$. $11.391 .8 \mathrm{~atm} .11 .410 .70 \mathrm{~L} .11 .4363 .31 \mathrm{~L} .11 .456 .1 \times 10^{-3}$ atm. $11.4735 .0 \mathrm{~g} / \mathrm{mol}$. $11.492 .1 \times 10^{22} \mathrm{~N}_{2}$ molecules, $5.6 \times 10^{22} \mathrm{O}_{2}$ molecules, $2.7 \times 10^{20} \mathrm{O}_{2}$ molecules. $11.512 .98 \mathrm{~g} / \mathrm{L} .11 .53 \mathrm{SF}_{4} .11 .55$ $3.70 \times 10^{2} \mathrm{~L} .11 .5788 .9 \% .11 .59 \mathrm{M}(s)+3 \mathrm{HCl}(a q) \longrightarrow 1.5 \mathrm{H}_{2}(g)+$ $\mathrm{MCl}_{3}(\mathrm{aq}), \mathrm{M}_{2} \mathrm{O}_{3} ; \mathrm{M}_{2}\left(\mathrm{SO}_{4}\right)_{3} . \mathbf{1 1 . 6 1} 94.7 \%$. Assuming the impurity (or impurities) do not produce $\mathrm{CO}_{2}$. $11.63 \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(l)+3 \mathrm{O}_{2}(g) \longrightarrow$ $2 \mathrm{CO}_{2}(g)+3 \mathrm{H}_{2} \mathrm{O}(l) ; 1.44 \times 10^{3} \mathrm{~L}$ air. 11.67 (a) 0.89 atm . (b) 1.4 L . $11.69349 \mathrm{mmHg} .11 .7119 .8 \mathrm{~g} \mathrm{Zn} .11 .73 P_{\mathrm{N}_{2}}=217 \mathrm{mmHg}, P_{\mathrm{H}_{2}}=$ 650 mmHg .11 .75 (a) Box 2. (b) Box 2. $11.83 u_{\text {rms }}\left(\mathrm{N}_{2}\right)=472 \mathrm{~m} / \mathrm{s}$, $u_{\mathrm{rms}}\left(\mathrm{O}_{2}\right)=441 \mathrm{~m} / \mathrm{s}, u_{\mathrm{rms}}\left(\mathrm{O}_{3}\right)=360 \mathrm{~m} / \mathrm{s} .11 .85 \mathrm{RMS}=2.8 \mathrm{~m} / \mathrm{s}$, Average speed $=2.7 \mathrm{~m} / \mathrm{s}$. The root-mean-square value is always greater than the average value, because squaring favors the larger values compared to just taking the average value. $11.8743 .8 \mathrm{~g} / \mathrm{mol}, \mathrm{CO}_{2} .11 .9318 .0 \mathrm{~atm}$; Ideal: 18.5 atm .11 .95 (a) Neither the amount of gas in the tire nor its volume changes appreciably. The pressure is proportional to the temperature. Therefore, as the temperature rises, the pressure increases. (b) As the paper bag is hit, its volume decreases so that its pressure increases. The popping sound occurs when the bag is broken. (c) As the balloon rises, the pressure outside decreases steadily, and the balloon expands. (d) The pressure inside the bulb is less than $1 \mathrm{~atm} .11 .971 .7 \times 10^{2} \mathrm{~L} . P_{\mathrm{CO}_{2}}=$ $0.49 \mathrm{~atm}, P_{\mathrm{H}_{2} \mathrm{O}}=0.41 \mathrm{~atm}, P_{\mathrm{N}_{2}}=0.25 \mathrm{~atm}$, and $P_{\mathrm{O}_{2}}=0.041 \mathrm{~atm} .11 .99$ (a) $\mathrm{NH}_{4} \mathrm{NO}_{2}(s) \longrightarrow \mathrm{N}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(l)$. (b) 0.273 g .11 .101 (a) $P_{\mathrm{ii}}=4.0$ $\mathrm{atm}, P_{\mathrm{iii}}=2.67 \mathrm{~atm}$. (b) $2.67 \mathrm{~atm}, P_{\mathrm{A}}=1.33 \mathrm{~atm}, P_{\mathrm{B}}=1.33 \mathrm{~atm}$.
$\mathbf{1 1 . 1 0 3}$ (a) 9.54 atm . (b) If the tetracarbonylnickel gas starts to decompose significantly above $43^{\circ} \mathrm{C}$, then for every mole of tetracarbonylnickel gas decomposed, four moles of carbon monoxide would be produced. 11.105 $1.3 \times 10^{22}$ molecules. $\mathrm{CO}_{2}, \mathrm{O}_{2}, \mathrm{~N}_{2}$ and $\mathrm{H}_{2} \mathrm{O} .11 .107$ (a) $2 \mathrm{KClO}_{3}(s)$ $\longrightarrow 2 \mathrm{KCl}(s)+3 \mathrm{O}_{2}(g)$. (b) 6.21 L . $11.1090 .0701 M .11 .111 P_{\mathrm{He}}=$ $0.16 \mathrm{~atm}, P_{\mathrm{Ne}}=2.0 \mathrm{~atm}$. 11.113 When the water enters the flask from the dropper, some hydrogen chloride dissolves, creating a partial vacuum. Pressure from the atmosphere forces more water up the vertical tube. 11.115 7. 11.117 (a) $61.2 \mathrm{~m} / \mathrm{s}$. (b) $4.58 \times 10^{-4} \mathrm{~s}$. (c) $328 \mathrm{~m} / \mathrm{s}$. $u_{\mathrm{rms}}=366$ $\mathrm{m} / \mathrm{s}$. The magnitudes of the speeds are comparable, but not identical. The rms speed is derived for 3-dimensional motion and is not applicable to the speed distributions in directed molecular beams. Also, the experiment is measuring a most-probable speed, not an rms speed. $11.11920 .9 \mathrm{~kg} \mathrm{O}_{2}$; $1.58 \times 10^{4} \mathrm{~L} \mathrm{O}_{2} .11 .121$ The fruit ripens more rapidly because the
quantity (partial pressure) of ethylene gas inside the bag increases. 11.123 As the pen is used the amount of ink decreases, increasing the volume inside the pen. As the volume increases, the pressure inside the pen decreases. The hole is needed to equalize the pressure as the volume inside the pen increases. 11.125 (a) $\mathrm{NH}_{4} \mathrm{NO}_{3}(s) \longrightarrow \mathrm{N}_{2} \mathrm{O}(g)+$ $2 \mathrm{H}_{2} \mathrm{O}(l)$. (b) $0.0821 \mathrm{~L} \cdot \mathrm{~atm} / \mathrm{K} \cdot \mathrm{mol}$. 11.127 $\mathrm{C}_{6} \mathrm{H}_{6}$. 11.129 The gases inside the mine were a mixture of carbon dioxide, carbon monoxide, methane, and other harmful compounds. The low atmospheric pressure caused the gases to flow out of the mine (the gases in the mine were at a higher pressure), and the man suffocated. 11.131 (a) 4.90 L . (b) 6.0 atm . (c) 1 atm .11 .133 (a) $4 \times 10^{-22} \mathrm{~atm}$. (b) $6 \times 10^{20} \mathrm{~L} / \mathrm{g}$ of $\mathrm{H} . \mathbf{1 1 . 1 3 5} 91 \%$. $11.1371 .7 \times 10^{12}$. $11.139 \mathrm{NO}_{2}$. $11.1411 .4 \mathrm{~g} .11 .143 P_{\mathrm{CO}_{2}}=8.7 \times 10^{6}$ $\mathrm{Pa}, P_{\mathrm{N}_{2}}=3.2 \times 10^{5} \mathrm{~Pa}, P_{\mathrm{SO}_{2}}=1.4 \times 10^{3} \mathrm{~Pa} .11 .145$ (a) (i) He atoms in both flasks have the same rms speed. (ii) The atoms in the larger volume strike the walls of their container with the same average force as those in the smaller volume, but pressure in the larger volume will be less. (b) (i) $u_{2}$ is greater than $u_{1}$ by a factor of $\sqrt{T_{2} / T_{1}}$. (ii) Both the frequency of collision and the average force of collision of the atoms at $T_{2}$ will be greater than those at $T_{1}$. (c) (i) False. The rms speed of He is greater than that of Ne because He is less massive. (ii) True. The average kinetic energies of the two gases are equal. (iii) The rms speed of the whole collection of atoms is $1.47 \times 10^{3} \mathrm{~m} / \mathrm{s}$, but the speeds of the individual atoms are random and constantly changing. $\mathbf{1 1 . 1 4 7}$ Vapor: 3.7 nm ; Liquid: 0.31 nm . Water molecules are packed very closely together in the liquid, but much farther apart in steam. 11.149 9.98 atm . 11.151 1.41 atm . $11.153 \chi_{\text {methane }}=0.789, \chi_{\text {ethane }}=0.211 .11 .155$ (a) $0.154 \%$. (b) $1.5 \%$. (c) $7.7 \%$. $\mathbf{1 1 . 1 5 7}$ NO. $\mathbf{1 1 . 1 5 9}$ Reaction (b). $11.1611 .80 \times 10^{-4} \mathrm{~g} / \mathrm{mL}$. 11.163 The kinetic energy of a particle depends on its mass and its speed $\left(\mathrm{KE}=m u^{2} / 2\right)$. At a given temperature, the more massive $\mathrm{UF}_{6}$ molecules move more slowly than do the $\mathrm{H}_{2}$ molecules. 11.165 Intermolecular attractions tend to lower $Z$ at low pressures and excluded volume tends to increase $Z$ at high pressures.

## Chapter 12

12.9 Butane would be a liquid in winter (boiling point $-44.5^{\circ} \mathrm{C}$ ), and on the coldest days even propane would become a liquid (boiling point $-0.5^{\circ} \mathrm{C}$ ). Only methane would remain gaseous (boiling point $-161.6^{\circ} \mathrm{C}$ ). 12.11 (a) Dispersion. (b) Dispersion and dipole-dipole. (c) Dispersion and dipole-dipole. (d) Dispersion and ionic. (e) Dispersion. 12.13 (e) $\mathrm{CH}_{3} \mathrm{COOH}$. 12.15 1-butanol has greater intermolecular forces because it can form hydrogen bonds. $\mathbf{1 2 . 1 7}$ (a) Xe , it is larger and therefore has stronger dispersion forces. (b) $\mathrm{CS}_{2}$, it is larger and therefore has stronger dispersion forces. (c) $\mathrm{Cl}_{2}$, it is larger and therefore has stronger dispersion forces. (d) LiF , it is an ionic compound, and the ion-ion attractions are much stronger than the dispersion forces between $\mathrm{F}_{2}$ molecules. (e) $\mathrm{NH}_{3}$, it can form hydrogen bonds and $\mathrm{PH}_{3}$ cannot. 12.19 (a) Dispersion and dipole-dipole, including hydrogen bonding. (b) Dispersion only. (c) Dispersion only. (d) Covalent bonds. 12.21 The compound with $-\mathrm{NO}_{2}$ and -OH groups on adjacent carbons can form hydrogen bonds with itself (intramolecular hydrogen bonds). Such bonds do not
contribute to intermolecular attraction and do not help raise the melting point of the compound. The other compound, with the $-\mathrm{NO}_{2}$ and -OH groups on opposite sides of the ring, can form only intermolecular hydrogen bonds; therefore, it will take a higher temperature to escape into the gas phase. 12.33 Ethylene glycol has two -OH groups, allowing it to exert strong intermolecular forces through hydrogen bonding. Its viscosity should fall between ethanol (1 OH group) and glycerol (3 OH groups). $\mathbf{1 2 . 3 5} 331 \mathrm{~mm} \mathrm{Hg} . \mathbf{1 2 . 3 7} 29.9 \mathrm{~kJ} / \mathrm{mol}$. $\mathbf{1 2 . 4 5}$ Simple cubic: one sphere; body-centered cubic: two spheres; face-centered cubic: four spheres. $\mathbf{1 2 . 4 7} 6.20 \times 10^{23}$ atoms $/ \mathrm{mol}$. $\mathbf{1 2 . 4 9} 458 \mathrm{pm} . \mathbf{1 2 . 5 1 ~ X Y} 3$. $\mathbf{1 2 . 5 3}$ 0.220 nm . $\mathbf{1 2 . 5 5} \mathrm{ZnO}$. $\mathbf{1 2 . 5 9}$ Molecular solid. $\mathbf{1 2 . 6 1}$ Molecular: $\mathrm{Se}_{8}, \mathrm{HBr}$, $\mathrm{CO}_{2}, \mathrm{P}_{4} \mathrm{O}_{6}$, and $\mathrm{SiH}_{4}$; covalent: Si and C. 12.63 Diamond: each carbon atom is covalently bonded to four other carbon atoms. Because these bonds are strong and uniform, diamond is a very hard substance. Graphite: the carbon atoms in each layer are linked by strong bonds, but the layers are bound by weak dispersion forces. As a result, graphite may be cleaved easily between layers and is not hard. In graphite, all atoms are $s p^{2}$ hybridized; each atom is covalently bonded to three other atoms. The remaining unhybridized $2 p$ orbital is used in pi bonding, forming a delocalized molecular orbital. The electrons are free to move around in this extensively delocalized molecular orbital, making graphite a good conductor of electricity in directions along the planes of carbon atoms. $\mathbf{1 2 . 8 5} 2.72 \times 10^{3} \mathrm{~kJ} . \mathbf{1 2 . 8 7} 47.03 \mathrm{~kJ} / \mathrm{mol}$. $\mathbf{1 2 . 8 9}$ Two phase changes occur in this process. First, the liquid is turned to solid (freezing), then the solid ice is turned to gas (sublimation). 12.91 When steam condenses to liquid water at $100^{\circ} \mathrm{C}$, it releases a large amount of heat equal to the enthalpy of vaporization. Thus, steam at $100^{\circ} \mathrm{C}$ exposes one to more heat than an equal amount of water at $100^{\circ} \mathrm{C} . \mathbf{1 2 . 9 5}$ Initially, the ice melts because of the increase in pressure. As the wire sinks into the ice, the water above the wire refreezes. Eventually the wire actually moves completely through the ice block without cutting it in half. $\mathbf{1 2 . 9 7}$ (a) Ice would melt. (If heating continues, the liquid water would eventually boil and become a vapor.) (b) Liquid water would vaporize. (c) Water vapor would solidify without becoming a liquid. $\mathbf{1 2 . 9 9}$ (d). $\mathbf{1 2 . 1 0 1}$ Covalent. $\mathbf{1 2 . 1 0 3} \mathrm{CCl}_{4}$. $\mathbf{1 2 . 1 0 5} 0.26 \mathrm{~cm} ; 7.69 \times 10^{6}$ base pairs. $\mathbf{1 2 . 1 0 7} 760 \mathrm{mmHg} .12 .109$ It has reached the critical point; the point of critical temperature $\left(T_{\mathrm{c}}\right)$ and critical pressure $\left(P_{\mathrm{c}}\right)$. 12.111 Crystalline $\mathrm{SiO}_{2}$. Its regular structure results in a more efficient packing. $\mathbf{1 2 . 1 1 3}$ (a) and (b). $\mathbf{1 2 . 1 1 5} 8.3 \times 10^{-3} \mathrm{~atm}$. $\mathbf{1 2 . 1 1 7}$ (a) $\mathrm{K}_{2} \mathrm{~S}$. Ionic forces are much stronger than the dipole-dipole forces in $\left(\mathrm{CH}_{3}\right)_{3} \mathrm{~N}$. (b) $\mathrm{Br}_{2}$. Both molecules are nonpolar; but $\mathrm{Br}_{2}$ has a larger mass. 12.119 $\mathrm{SO}_{2}$ will behave less ideally because it is polar and has greater intermolecular forces. $\mathbf{1 2 . 1 2 1} 62.4 \mathrm{~kJ} / \mathrm{mol}$. $\mathbf{1 2 . 1 2 3}$ Smaller ions can approach polar water molecules more closely, resulting in larger ion-dipole interactions. The greater the ion-dipole interaction, the larger is the heat of hydration. $\mathbf{1 2 . 1 2 5}$ (a) $30.7 \mathrm{~kJ} / \mathrm{mol}$. (b) $192.5 \mathrm{~kJ} / \mathrm{mol}$. It requires more energy to break the bond than to vaporize the molecule. $\mathbf{1 2 . 1 2 7}$ (a) Decreases. (b) No change. (c) No change. $\mathbf{1 2 . 1 2 9} \mathrm{CaCO}_{3}(s)$ $\longrightarrow \mathrm{CaO}(s)+\mathrm{CO}_{2}(g)$. Initial state: one solid phase, final state: two solid phase components and one gas phase component. 12.131 The molecules are all polar. The F atoms can form H-bonds with water and other -OH and -NH groups in the membrane, so water solubility plus easy attachment to the membrane would allow these molecules to pass the blood-brain barrier. 12.133 The time required to cook food depends on the boiling point of the water in which it is cooked. The boiling point of water increases when the pressure inside the cooker increases. 12.135 (a) Extra heat produced when steam condenses at $100^{\circ} \mathrm{C}$. (b) Avoids extraction of ingredients by boiling in water. $\mathbf{1 2 . 1 3 7}$ (a) ~2.3 K. (b) $\sim 10$ atm. (c) $\sim 5$ K. (d) No. 12.139 (a) Pumping allows Ar atoms to escape, thus removing heat from the liquid phase. Eventually the liquid freezes. (b) The slope of the solid-liquid line of cyclohexane is positive. Therefore, its melting point increases with pressure. (c) These droplets are super-cooled liquids. (d) When the dry ice is added to water, it sublimes. The cold $\mathrm{CO}_{2}$ gas generated causes nearby water vapor to condense, hence the appearance of fog. $\mathbf{1 2 . 1 4 1}$ (a) Two triple points: Diamond/graphite/liquid and graphite/liquid/vapor. (b) Diamond. (c) Apply high pressure at high temperature. 12.143 Ethanol mixes well
with water. The mixture has a lower surface tension and readily flows out of the ear channel. 12.145 When water freezes it releases heat, helping keep the fruit warm enough not to freeze. Also, a layer of ice is a thermal insulator. 12.147 The fuel source for the Bunsen burner is most likely methane gas. When methane burns in air, carbon dioxide and water are produced. The water vapor produced during the combustion condenses to liquid water when it comes in contact with the outside of the cold beaker. $\mathbf{1 2 . 1 4 9} 6.019 \times 10^{23} \mathbf{1 2 . 1 5 1} 127 \mathrm{mmHg} . \mathbf{1 2 . 1 5 3} 55^{\circ} \mathrm{C} . \mathbf{1 2 . 1 5 5} 0.833 \mathrm{~g} / \mathrm{L}$. The hydrogen-bonding interactions in HF are relatively strong, and since the ideal gas equation ignores intermolecular forces, it underestimates significantly the density of HF gas near its boiling point. $\mathbf{1 2 . 1 5 7}$ Fluoromethane. Of the three compounds, only fluoromethane has a permanent dipole moment.

## Chapter 13

13.9 "Like dissolves like." Naphthalene and benzene are nonpolar, whereas CsF is ionic. $\mathbf{1 3 . 1 1} \mathrm{O}_{2}<\mathrm{Br}_{2}<\mathrm{LiCl}<\mathrm{CH}_{3} \mathrm{OH}$. 13.15 (a) $8.47 \%$. (b) $17.7 \%$. (c) $11 \% .13 .17$ (a) 0.0610 m . (b) $2.04 \mathrm{~m} . \mathbf{1 3 . 1 9}$ (a) 1.7 m . (b) 0.87 m . (c) $7.0 \mathrm{~m} . \mathbf{1 3 . 2 1} 3.0 \times 10^{2} \mathrm{~g} . \mathbf{1 3 . 2 3} 18.3 \mathrm{M}$; 27.4 m . $13.25 \chi\left(\mathrm{~N}_{2}\right)=0.677, \chi\left(\mathrm{O}_{2}\right)=0.323$. Due to the greater solubility of oxygen, it has a larger mole fraction in solution than it does in the air. 13.3345 .9 g. 13.35 According to Henry's law, the solubility of a gas in a liquid increases as the pressure increases $(c=k P)$. The soft drink tastes flat at the bottom of the mine because the carbon dioxide pressure is greater and the dissolved gas is not released from the solution. As the miner goes up in the elevator, the atmospheric carbon dioxide pressure decreases and dissolved gas is released from his stomach. 13.37 $1.0 \times$ $10^{-5} \mathrm{~mol} / \mathrm{L}$. 13.393 .3 atm . This pressure is only an estimate since we ignored the amount of $\mathrm{CO}_{2}$ that was present in the unopened container in the gas phase. $13.571 .3 \times 10^{3} \mathrm{~g} .13 .59 P_{\text {ethanol }}=30 \mathrm{mmHg} ; P_{1 \text {-propanol }}=$ $26.3 \mathrm{mmHg} .13 .61187 \mathrm{~g} .13 .630 .59 \mathrm{~m} .13 .65-5.4^{\circ} \mathrm{C} .13 .67$ (a) $\mathrm{CaCl}_{2}$. (b) Urea. (c) $\mathrm{CaCl}_{2} . \mathrm{CaCl}_{2}$ is an ionic compound and is therefore an electrolyte in water. Assuming that $\mathrm{CaCl}_{2}$ completely dissociates, the total ion concentration will be $3 \times 0.35=1.05 \mathrm{~m}$, which is larger than the urea (nonelectrolyte) concentration of $0.90 \mathrm{~m} . \mathbf{1 3 . 6 9} 0.15 \mathrm{~m}$ $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}>0.15 m \mathrm{CH}_{3} \mathrm{COOH}>0.10 m \mathrm{Na}_{3} \mathrm{PO}_{4}>0.20 m \mathrm{MgCl}_{2}>$ 0.35 m NaCl . 13.71 Boiling point: $102.8^{\circ} \mathrm{C}$, Freezing point: $-10.0^{\circ} \mathrm{C}$. (b) Boiling point: $102.0^{\circ} \mathrm{C}$, Freezing point: $-7.14^{\circ} \mathrm{C}$. 13.73 Both NaCl and $\mathrm{CaCl}_{2}$ are strong electrolytes. Urea and sucrose are nonelectrolytes. The NaCl or $\mathrm{CaCl}_{2}$ will yield more particles per mole of the solid dissolved, resulting in greater freezing point depression. Also, sucrose and urea would make a mess when the ice melts. 13.75 2.47. 13.77 9.16 atm. $\mathbf{1 3 . 8 1}$ $282.5 \mathrm{~g} / \mathrm{mol} ; \mathrm{C}_{19} \mathrm{H}_{38} \mathrm{O} .13 .834 .3 \times 10^{2} \mathrm{~g} / \mathrm{mol} ; \mathrm{C}_{24} \mathrm{H}_{20} \mathrm{P}_{4} .13 .851 .75 \times$ $10^{4} \mathrm{~g} / \mathrm{mol}$. $13.87342 \mathrm{~g} / \mathrm{mol}$. 13.89 15.7\%. 13.93 $\Delta P=2.05 \times 10^{-5} \mathrm{mmHg}$; $\Delta T_{\mathrm{f}}=8.9 \times 10^{-5}{ }^{\circ} \mathrm{C} ; \Delta T_{\mathrm{b}}=2.5 \times 10^{-5}{ }^{\circ} \mathrm{C} ; \pi=0.889 \mathrm{mmHg}$. 13.95 Before: $7.77 \times 10^{-6} \mathrm{~mol}$ glucose $/ \mathrm{mL}$ blood; $3.89 \times 10^{-3} \mathrm{~mol}$ glucose; 7.00 g glucose. After: $1.33 \times 10^{-5} \mathrm{~mol}$ glucose $/ \mathrm{mL}$ blood; $6.66 \times 10^{-2}$ mol glucose; 12.0 g glucose. 13.97 Water migrates through the semipermeable cell walls of the cucumber into the concentrated salt solution. 13.99 3.5. 13.101 $\mathrm{X}=$ water, $\mathrm{Y}=\mathrm{NaCl}, \mathrm{Z}=$ urea. 13.103 The pill is in a hypotonic solution. Consequently, by osmosis, water moves across the semipermeable membrane into the pill. The increase in pressure pushes the elastic membrane to the right, causing the drug to exit through the small holes at a constant rate. 13.105 Reverse osmosis involves no phase changes and is usually cheaper than distillation or freezing. 34 atm . $\mathbf{1 3 . 1 0 7} 0.295 \mathrm{M} ;-0.55^{\circ} \mathrm{C}$. $\mathbf{1 3 . 1 0 9}$ (a) $2.14 \times 10^{3} \mathrm{~g} / \mathrm{mol}$. (b) $4.50 \times 10^{4} \mathrm{~g} / \mathrm{mol} 13.111$ (a) 0.099 L . (b) 9.9 .13 .113 (a) At reduced pressure, the solution is supersaturated with $\mathrm{CO}_{2}$. (b) As the escaping $\mathrm{CO}_{2}$ expands it cools, condensing water vapor in the air to form fog. 13.115 (a) Runoff of the salt solution into the soil increases the salinity of the soil. If the soil becomes hypertonic relative to the tree cells, osmosis would reverse, and the tree would lose water to the soil and eventually die of dehydration. (b) Assuming the collecting duct acts as a semipermeable membrane, water would flow from the urine into the hypertonic fluid, thus returning water to the body. $\mathbf{1 3 . 1 1 7} 33 \mathrm{~mL}, 67 \mathrm{~mL} .13 .11912 .3 \mathrm{M}$. 13.121 $14.2 \%$. 13.123 (a) Solubility decreases with increasing lattice
energy. (b) Ionic compounds are more soluble in a polar solvent. (c) Solubility increases with enthalpy of hydration of the cation and anion. $\mathbf{1 3 . 1 2 5} 1.43 \mathrm{~g} / \mathrm{mL} ; 37.0 \mathrm{~m}$. $\mathbf{1 3 . 1 2 7} \mathrm{NH}_{3}$ can form hydrogen bonds with water; $\mathrm{NCl}_{3}$ cannot. $\mathbf{1 3 . 1 2 9} 3 \%$. $\mathbf{1 3 . 1 3 1} \mathrm{Egg}$ yolk contains lecithins that solubilize oil in water (See Figure 13.18 of the text). The nonpolar oil becomes soluble in water because the nonpolar tails of lecithin dissolve in the oil, and the polar heads of the lecithin molecules dissolve in polar water (like dissolves like). 13.133 Yes. 13.135 As the water freezes, dissolved minerals in the water precipitate from solution. The minerals refract light and create an opaque appearance. $13.1371 .8 \times 10^{2} \mathrm{~g} / \mathrm{mol}$. $13.1391 .9 \mathrm{~m} .13 .141 P_{\mathrm{B}}^{\circ}=4.0 \times 10^{2} \mathrm{mmHg} ; P_{\mathrm{A}}^{\circ}=1.9 \times 10^{2} \mathrm{mmHg}$. $13.143-0.737^{\circ} \mathrm{C}$. $\mathbf{1 3 . 1 4 5}$ About 0.4 molal.

## Chapter 14

14.5 (a) Rate $=-\frac{\Delta\left[\mathrm{H}_{2}\right]}{\Delta t}=-\frac{\Delta\left[\mathrm{I}_{2}\right]}{\Delta t}=\frac{1}{2} \frac{\Delta[\mathrm{HI}]}{\Delta t}$.
(b) Rate $=-\frac{1}{5} \frac{\Delta\left[\mathrm{Br}^{-}\right]}{\Delta t}=-\frac{\Delta\left[\mathrm{BrO}_{3}^{-}\right]}{\Delta t}=-\frac{1}{6} \frac{\Delta\left[\mathrm{H}^{+}\right]}{\Delta t}=\frac{1}{3} \frac{\Delta\left[\mathrm{Br}_{2}\right]}{\Delta t}$.
$\mathbf{1 4 . 7}$ (a) $0.066 \mathrm{M} / \mathrm{s}$. (b) $0.033 \mathrm{M} / \mathrm{s} . \mathbf{1 4 . 1 5} 8.1 \times 10^{-6} \mathrm{M} / \mathrm{s}$. 14.17 The reaction is first order in A and first order overall; $k=0.213 \mathrm{~s}^{-1} . \mathbf{1 4 . 1 9}$ (a) 2. (b) 0. (c) 2.5. (d) 3. 14.21 First order; $k=1.19 \times 10^{-4} \mathrm{~s}^{-1} .14 .27$ $30 \mathrm{~min} \mathbf{1 4 . 2 9}$ (a) 0.034 M . (b) $17 \mathrm{~s} ; 23 \mathrm{~s} . \mathbf{1 4 . 3 1} 4.5 \times 10^{-10} \mathrm{M} / \mathrm{s} ; 5.4 \times$ $10^{6} \mathrm{~s} .14 .33$ (a) 4:3:6. (b) The relative rates would be unaffected, each absolute rate would decrease by $50 \%$. (c) $1: 1: 1.14 .41103 \mathrm{~kJ} / \mathrm{mol} .14 .43$ $3.0 \times 10^{3} \mathrm{~s}^{-1}$. $\mathbf{1 4 . 4 5} 51.8 \mathrm{~kJ} / \mathrm{mol} .14 .471 .3 \times 10^{2} \mathrm{~kJ} / \mathrm{mol}$. For maximum freshness, fish should be frozen immediately after capture and kept frozen until cooked. 14.49 Diagram (a). $\mathbf{1 4 . 5 9}$ (a) Second-order. (b) The first step is the slower (rate-determining) step. 14.61 Mechanism I can be discarded. Mechanisms II and III are possible. 14.71 (i) and (iv). 14.73 Temperature, energy of activation, concentration of reactants, and a catalyst. $\mathbf{1 4 . 7 5}$ Temperature must be specified. $\mathbf{1 4 . 7 7} 0.035 \mathrm{~s}^{-1}$.
14.79272 s .14 .81 Since the methanol contains no oxygen-18, the oxygen atom must come from the phosphate group and not the water. The mechanism must involve a bond-breaking process like:

14.83 Most transition metals have several stable oxidation states. This allows the metal atoms to act as either a source or a receptor of electrons in a broad range of reactions. $\mathbf{1 4 . 8 5}$ (a) rate $=k\left[\mathrm{CH}_{3} \mathrm{COCH}_{3}\right]\left[\mathrm{H}^{+}\right]$. (b) $3.8 \times 10^{-3} M^{-1} \cdot \mathrm{~s}^{-1}$. (c) $k=k_{1} k_{2} / k_{-1} .14 .87$ (I) $\mathrm{Fe}^{3+}$ oxidizes $\mathrm{I}^{-}$: $2 \mathrm{Fe}^{3+}+2 \mathrm{I}^{-} \longrightarrow 2 \mathrm{Fe}^{2+}+\mathrm{I}_{2}$; (II) $\mathrm{Fe}^{2+}$ reduces $\mathrm{S}_{2} \mathrm{O}_{8}^{2-}: 2 \mathrm{Fe}^{2+}+\mathrm{S}_{2} \mathrm{O}_{8}^{2-}$ $\longrightarrow 2 \mathrm{Fe}^{3+}+2 \mathrm{SO}_{4}^{2-}$; Overall Reaction: $2 \mathrm{I}^{-}+\mathrm{S}_{2} \mathrm{O}_{8}^{2-} \longrightarrow \mathrm{I}_{2}+$ $2 \mathrm{SO}_{4}^{2-} .\left(\mathrm{Fe}^{3+}\right.$ undergoes a redox cycle: $\left.\mathrm{Fe}^{3+} \longrightarrow \mathrm{Fe}^{2+} \longrightarrow \mathrm{Fe}^{3+}\right)$. The uncatalyzed reaction is slow because both $\mathrm{I}^{-}$and $\mathrm{S}_{2} \mathrm{O}_{8}^{2-}$ are negatively charged, which makes their mutual approach unfavorable. 14.89 (a) (i) rate $=k[\mathrm{~A}]^{0}=k$,

(ii) $[\mathrm{A}]=-k t+[\mathrm{A}]_{0}$,

(b) $t_{1 / 2}=\frac{[\mathrm{A}]_{0}}{2 k}$ can measure only the total pressure of the gases. To measure the partia pressure of azomethane at a particular time, we must withdraw a sample of the mixture, analyze and determine the mole fractions. Then,

Reaction progress
14.95 (a) A catalyst works by changing the reaction mechanism, thus lowering the activation energy. (b) A catalyst changes the reaction mechanism. (c) A catalyst does not change the enthalpy of reaction. (d) A catalyst increases the forward rate of reaction. (e) A catalyst increases the reverse rate of reaction.
14.97 At very high $\left[\mathrm{H}_{2}\right]: k_{2}\left[\mathrm{H}_{2}\right] \gg 1$, rate $=\frac{k_{1}[\mathrm{NO}]^{2}\left[\mathrm{H}_{2}\right]}{k_{2}\left[\mathrm{H}_{2}\right]}=\frac{k_{1}}{k_{2}}[\mathrm{NO}]^{2}$.

At very low $\left[\mathrm{H}_{2}\right]: k_{2}\left[\mathrm{H}_{2}\right] \ll 1$, rate $=\frac{k_{1}[\mathrm{NO}]^{2}\left[\mathrm{H}_{2}\right]}{1}=k_{1}[\mathrm{NO}]^{2}\left[\mathrm{H}_{2}\right]$.
The result from Problem 14.80 agrees with the rate law determined for low $\left[\mathrm{H}_{2}\right]$. 14.99 Rate $=k\left[\mathrm{~N}_{2} \mathrm{O}_{5}\right] ; k=1.0 \times 10^{-5} \mathrm{~s}^{-1}$. 14.101 The red bromine vapor absorbs photons of blue light and dissociates to form bromine atoms: $\mathrm{Br}_{2} \longrightarrow 2 \mathrm{Br}$. The bromine atoms collide with methane molecules and abstract hydrogen atoms: $\mathrm{Br} \cdot+\mathrm{CH}_{4} \longrightarrow \mathrm{HBr}+\cdot \mathrm{CH}_{3}$. The methyl radical then reacts with $\mathrm{Br}_{2}$, giving the observed product and regenerating a bromine atom to start the process over again: $\cdot \mathrm{CH}_{3}+\mathrm{Br}_{2} \longrightarrow \mathrm{CH}_{3} \mathrm{Br}+$ $\mathrm{Br} \cdot \mathrm{Br} \cdot+\mathrm{CH}_{4} \longrightarrow \mathrm{HBr}+\cdot \mathrm{CH}_{3}$, and so on. $\mathbf{1 4 . 1 0 3}$ Lowering the temperature would slow all chemical reactions, which would be especially important for those that might damage the brain. $\mathbf{1 4 . 1 0 5}$ (a) rate $=$ $k[\mathrm{X}][\mathrm{Y}]^{2}$. (b) $0.019 \mathrm{M}^{-2} \mathrm{~s}^{-1}$. $\mathbf{1 4 . 1 0 7}$ Second-order; $k=2.4 \times 10^{7} \mathrm{M}^{-1} \mathrm{~s}^{-1}$. 14.109 During the first five minutes or so the engine is relatively cold, so the exhaust gases will not fully react with the components of the catalytic converter. Remember, for almost all reactions, the rate of reaction increases with temperature. $\mathbf{1 4 . 1 1 1}$ (a) The activation energy of reaction $B$ is larger than that of reaction A . (b) $E_{\mathrm{a}} \approx 0$. Orientation factor is not important. $\mathbf{1 4 . 1 1 3} 5.7 \times 10^{5}$ yr. 14.115 (a) Catalyst: $\mathrm{Mn}^{2+}$; intermediates: $\mathrm{Mn}^{3+}$, $\mathrm{Mn}^{4+}$; first step is rate-determining. (b) Without the catalyst, the reaction would be a termolecular one involving 3 cations! ( $\mathrm{Tl}^{+}$and two $\mathrm{Ce}^{4+}$ ). The reaction would be slow. (c) The catalyst is a homogeneous catalyst because it has the same phase (aqueous) as the reactants. $\mathbf{1 4 . 1 1 7} 0.45 \mathrm{~atm} . \mathbf{1 4 . 1 1 9}$ (a) $\Delta[\mathrm{B}] / \Delta t=k_{1}[\mathrm{~A}]-k_{2}[\mathrm{~B}]$. (b) $[\mathrm{B}]=\left(k_{1} / k_{2}\right)[\mathrm{A}] .14 .121$ (a) $k=0.0247$ $\mathrm{yr}^{-1}$. (b) $9.8 \times 10^{-4}$. (c) 187 yr. $\mathbf{1 4 . 1 2 3}$ (a) Three. (b) Two. (c) The third step. (d) Exothermic. $\mathbf{1 4 . 1 2 5} 1.8 \times 10^{3} \mathrm{~K} .14 .127$ (a) $2.5 \times 10^{-5} \mathrm{M} / \mathrm{s}$. (b) $2.5 \times 10^{-5} \mathrm{M} / \mathrm{s}$. (c) $8.3 \times 10^{-6} \mathrm{M}$.
$14.129 n=0, t_{1 / 2}=C \frac{1}{[A]_{0}^{-1}}=C[A]_{0}$;
$n=1, t_{1 / 2}=C \frac{1}{[A]_{0}^{0}}=C ;$

$$
n=2, t_{1 / 2}=C \frac{1}{[A]_{0}}
$$

14.131 (a) $1.13 \times 10^{-3} \mathrm{M} / \mathrm{min}$. (b) $6.83 \times 10^{-4} \mathrm{M} / \mathrm{min}$; $8.8 \times 10^{-3} M$. 14.133 Second-order, $k=0.42 / M \cdot \min \mathbf{1 4 . 1 3 5} 60 \%$ increase. The result shows the profound effect of an exponential dependence. 14.137 $4.1 \times$ $10^{2} \mathrm{~kJ} / \mathrm{mol}$.

## Chapter 15

15.9 (a) $\frac{\left[\mathrm{N}_{2}\right]\left[\mathrm{H}_{2} \mathrm{O}\right]^{2}}{[\mathrm{NO}]^{2}\left[\mathrm{H}_{2}\right]^{2}}$. (b) $7.2 \times 10^{2} .15 .111 .08 \times 10^{7}$.
15.21 (1) Diagram (a). (2) Diagram (d). Volume will cancel from the $K_{\mathrm{c}}$ expression. $15.232 .40 \times 10^{33}$. $15.253 .5 \times 10^{-7} . \mathbf{1 5 . 2 7}$ (a) $8.2 \times 10^{-2}$. (b) 0.29 . 15.29 $K_{P}=0.105, K_{\mathrm{c}}=2.05 \times 10^{-3} .15 .31 K_{P}=7.09 \times 10^{-3}$. $\mathbf{1 5 . 3 3} K_{P}=9.6 \times 10^{-3}, K_{\text {c }}=3.9 \times 10^{-4} . \mathbf{1 5 . 3 5} 4.0 \times 10^{-6} . \mathbf{1 5 . 3 7} 5.6 \times$ $10^{23}$. 15.39 The equilibrium pressure is less than the original pressure. $15.410 .173 \mathrm{~mol} \mathrm{H}_{2} .15 .43\left[\mathrm{H}_{2}\right]=\left[\mathrm{Br}_{2}\right]=1.80 \times 10^{-4} M ;[\mathrm{HBr}]=$ 0.267 M. 15.45 $P_{\mathrm{COCl}_{2}}=0.408 \mathrm{~atm} ; P_{\mathrm{CO}}=P_{\mathrm{Cl}_{2}}=0.352 \mathrm{~atm} .15 .47 P_{\mathrm{CO}}$ $=1.96 \mathrm{~atm} ; P_{\mathrm{CO}_{2}}=2.54 \mathrm{~atm}$. 15.49 The forward reaction will not occur. $\mathbf{1 5 . 5 5}$ (a) The equilibrium would shift to the right. (b) The equilibrium would be unaffected. (c) The equilibrium would be unaffected. $\mathbf{1 5 . 5 7}$ (a) No effect. (b) No effect. (c) Shift to the left. (d) No effect. (e) Shift to the left. $\mathbf{1 5 . 5 9}$ (a) Shift to the right. (b) Shift to the left. (c) Shift to the right. (d) Shift to the left. (e) A catalyst has no effect on equilibrium position. $\mathbf{1 5 . 6 1}$ No change. $\mathbf{1 5 . 6 3}$ (a) Shift to the right. (b) No effect.
(c) No effect. (d) Shift to the left. (e) Shift to the right. (f) Shift to the left. (g) Shift to the right. 15.65 (a) $2 \mathrm{O}_{3}(g) \rightleftarrows 3 \mathrm{O}_{2}(g), \Delta H_{\mathrm{rxn}}^{\circ}=-284.4 \mathrm{~kJ} /$ mol. (b) Equilibrium would shift to the left. The number of $\mathrm{O}_{3}$ molecules would increase and the number of $\mathrm{O}_{2}$ molecules would decrease. $\mathbf{1 5 . 6 7}$ (a) $P_{\mathrm{NO}}=0.24 \mathrm{~atm} ; P_{\mathrm{Cl}_{2}}=0.12 \mathrm{~atm}$. (b) $K_{P}=0.017 .15 .69$ (a) No effect. (b) More $\mathrm{CO}_{2}$ and $\mathrm{H}_{2} \mathrm{O} .15 .71$ (a) $K_{\mathrm{c}}=8 \times 10^{-44}$. (b) A mixture of $\mathrm{H}_{2}$ and $\mathrm{O}_{2}$ can be kept at room temperature because of a very large activation energy. 15.73 (a) $K_{P}=1.7$. (b) $P_{\mathrm{A}}=0.69 \mathrm{~atm}, P_{\mathrm{B}}=0.81 \mathrm{~atm} .15 .75$ $K_{P}=1.5 \times 10^{5} .15 .77 P_{\mathrm{H}_{2}}=0.28 \mathrm{~atm} ; P_{\mathrm{Cl}_{2}}=0.051 \mathrm{~atm} ; P_{\mathrm{HCl}}=$ 1.67 atm . $15.795 .0 \times 10^{1^{2}}$ atm. 15.810 .038 . $15.833 .3 \times 10^{2}$ atm. $\mathbf{1 5 . 8 5}$ $K_{\mathrm{c}}=6.28 \times 10^{-4} .15 .87 P_{\mathrm{N}_{2}}=0.860 \mathrm{~atm}, P_{\mathrm{H}_{2}}=0.366 \mathrm{~atm}, P_{\mathrm{NH}_{3}}=$ $4.40 \times 10^{-3} \mathrm{~atm} .15 .89$ (a) $K_{\mathrm{c}}=1.16$. (b) $53.7 \% .15 .91$ (a) $K_{P}=0.49$. (b) $0.23(23 \%)$. (c) $0.037(3.7 \%)$. (d) Greater than $0.037 \mathrm{~mol} .15 .93\left[\mathrm{H}_{2}\right]$ $=0.07 M,\left[\mathrm{I}_{2}\right]=0.18 M,[\mathrm{HI}]=0.83 M .15 .95$ (c). $\mathrm{N}_{2} \mathrm{O}_{4}$ (colorless) $\longrightarrow$ $2 \mathrm{NO}_{2}$ (brown) is consistent with the observations. The reaction is endothermic so heating darkens the color. Above $150^{\circ} \mathrm{C}$, the $\mathrm{NO}_{2}$ breaks up into colorless NO and $\mathrm{O}_{2}: 2 \mathrm{NO}_{2}(g) \longrightarrow 2 \mathrm{NO}(g)+\mathrm{O}_{2}(g)$. An increase in pressure shifts the equilibrium back to the left, restoring the color by producing $\mathrm{NO}_{2} . \mathbf{1 5 . 9 7}$ (a) $K_{P}=4.2 \times 10^{-4}$. (b) 0.83 . (c) 1.1 . (d) $2.3 \times 10^{3} ; 2.1 \times 10^{-2} .15 .99$ (a) Color deepens. (b) Increases. (c) Decreases. (d) Increases. (e) Unchanged. 15.101 Potassium is more volatile than sodium. Therefore, its removal shifts the equilibrium from left to right. $\mathbf{1 5 . 1 0 3} 3.5 \times 10^{-2} . \mathbf{1 5 . 1 0 5}$ (a) Shifts to the right. (b) Shifts to the right. (c) No change. (d) No change. (e) No change. (f) Shifts to the left. 15.107 (a) $1.8 \times 10^{-16}$. (b) $\left[\mathrm{H}^{+}\right]\left[\mathrm{OH}^{-}\right]=1.0 \times 10^{-14} ;\left[\mathrm{H}^{+}\right]=$ $\left[\mathrm{OH}^{-}\right]=1.0 \times 10^{-7} M .15 .109 P_{\mathrm{N}_{2} \mathrm{O}_{4}}=0.09 \mathrm{~atm} ; P_{\mathrm{NO}_{2}}=0.10 \mathrm{~atm}$. 15.111 (a) 1.03 atm . (b) 0.39 atm . (c) 1.67 atm . (d) 0.620 ( $62.0 \%$ ). 15.113 (a) $K_{P}=2.6 \times 10^{-6} ; K_{\mathrm{c}}=1.1 \times 10^{-7}$. (b) $2.2 \mathrm{~g} ; 22 \mathrm{mg} / \mathrm{m}^{3}$; Yes. 15.115 There is a temporary dynamic equilibrium between the melting of ice cubes and the freezing of water between the ice cubes.
$15.117\left[\mathrm{NH}_{3}\right]=0.042 \mathrm{M} ;\left[\mathrm{N}_{2}\right]=0.086 \mathrm{M}$;
$\left[\mathrm{H}_{2}\right]=0.26 M .15 .119$ (a) $K_{P}=\frac{\left(\frac{4 x^{2}}{1+x}\right) P}{1-x}=\frac{4 x^{2}}{1-x^{2}} P$. (b) If $P$ increases, the fraction $\frac{4 x^{2}}{1-x^{2}}$ (and therefore $x$ ) must decrease. Equilibrium shifts to the left to produce less $\mathrm{NO}_{2}$ and more $\mathrm{N}_{2} \mathrm{O}_{4}$ as predicted. $\mathbf{1 5 . 1 2 1} P_{\mathrm{SO}_{2} \mathrm{Cl}_{2}}$ $=3.58 \mathrm{~atm}, P_{\mathrm{SO}_{2}}=P_{\mathrm{Cl}_{2}}=2.71 \mathrm{~atm} .15 .1234 .0 .15 .125-3.15 .127$ $K_{P}=K_{\mathrm{c}}:(\mathrm{d}),(\mathrm{g})$; cannot write a $K_{P}:(\mathrm{c}),(\mathrm{f})$.

(b) $\mathrm{B}^{-} .16 .77 K_{\mathrm{b}}\left(\mathrm{CN}^{-}\right)=$ $2.0 \times 10^{-5} ; K_{\mathrm{b}}\left(\mathrm{F}^{-}\right)=1.4 \times 10^{-11} ; K_{\mathrm{b}}\left(\mathrm{CH}_{3} \mathrm{COO}^{-}\right)=5.6 \times 10^{-10}$; $K_{\mathrm{b}}\left(\mathrm{HCO}_{3}^{-}\right)=2.4 \times 10^{-8} .16 .79$ (1) Diagram (c). (2) Diagrams (b) and (d). $16.81 \mathrm{pH}(0.040 M \mathrm{HCl})=1.40 ; \mathrm{pH}\left(0.040 \mathrm{M} \mathrm{H}_{2} \mathrm{SO}_{4}\right)=1.31$. $\mathbf{1 6 . 8 3}\left[\mathrm{H}^{+}\right]=\left[\mathrm{HCO}_{3}^{-}\right]=1.0 \times 10^{-4} \mathrm{M},\left[\mathrm{CO}_{3}^{2-}\right]=4.8 \times 10^{-11} \mathrm{M}$. $16.85 \mathrm{pH}=1.00 .16 .89$ (a) $\mathrm{H}_{2} \mathrm{SO}_{4}>\mathrm{H}_{2} \mathrm{SeO}_{4}$. (b) $\mathrm{H}_{3} \mathrm{PO}_{4}>\mathrm{H}_{3} \mathrm{AsO}_{4}$. 16.91 The conjugate bases are $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}^{-}$from phenol and $\mathrm{CH}_{3} \mathrm{O}^{-}$from methanol. The $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}^{-}$is stabilized by resonance:

The $\mathrm{CH}_{3} \mathrm{O}^{-}$ion has no such resonance stabilization. A more stable conjugate base means an increase in the strength of the acid. 16.97 (a) Neutral. (b) Basic. (c) Acidic. (d) Acidic. 16.99 HZ $<\mathrm{HY}<\mathrm{HX}$. 16.101 $\mathrm{pH}>7$. 16.103 4.82. 16.105 5.39. 16.109 (a) $\mathrm{Al}_{2} \mathrm{O}_{3}<\mathrm{BaO}<$ $\mathrm{K}_{2} \mathrm{O}$. (b) $\mathrm{CrO}_{3}<\mathrm{Cr}_{2} \mathrm{O}_{3}<\mathrm{CrO}$. $16.111 \mathrm{Al}(\mathrm{OH})_{3}(s)+\mathrm{OH}^{-}(a q) \longrightarrow$ $\mathrm{Al}(\mathrm{OH})_{4}^{-}(a q)$. This is a Lewis acid-base reaction. 16.115 $\mathrm{AlCl}_{3}$ is a Lewis acid with an incomplete octet of electrons and $\mathrm{Cl}^{-}$is the Lewis base donating a pair of electrons. 16.117 $\mathrm{CO}_{2}, \mathrm{SO}_{2}$, and $\mathrm{BCl}_{3}$. 16.119 (a) $\mathrm{AlBr}_{3}$ is the Lewis acid; $\mathrm{Br}^{-}$is the Lewis base. (b) Cr is the Lewis acid; CO is the Lewis base. (c) $\mathrm{Cu}^{2+}$ is the Lewis acid; $\mathrm{CN}^{-}$is the Lewis base. 16.121 A strong acid: Diagram (b); a weak acid: Diagram (c); a very weak acid: Diagram (d). $\mathbf{1 6 . 1 2 3} \mathrm{CH}_{3} \mathrm{COO}^{-}(a q)$ and $\mathrm{HCl}(a q)$. This reaction will not occur to any measurable extent. $\mathbf{1 6 . 1 2 5} \mathrm{pH}=1.70$; $\%$ ionization $=2.3 \% . \mathbf{1 6 . 1 2 7}$ (c). $\mathbf{1 6 . 1 2 9}$ (a) For the forward reaction $\mathrm{NH}_{4}^{+}$and $\mathrm{NH}_{3}$ are the acid and base, respectively. For the reverse reaction $\mathrm{NH}_{3}$ and $\mathrm{NH}_{2}^{-}$are the acid and base, respectively. (b) $\mathrm{H}^{+}$ corresponds to $\mathrm{NH}_{4}^{+} ; \mathrm{OH}^{-}$corresponds to $\mathrm{NH}_{2}^{-}$. For the neutral
solution, $\left[\mathrm{NH}_{4}^{+}\right]=\left[\mathrm{NH}_{2}^{-}\right]$. $16.131 K_{\mathrm{a}}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{A}^{-}\right]}{[\mathrm{HA}]},[\mathrm{HA}] \approx 0.1 \mathrm{M}$, $\left[\mathrm{A}^{-}\right] \approx 0.1 M$. Therefore, $K_{\mathrm{a}}=\left[\mathrm{H}^{+}\right]=\frac{K_{\mathrm{w}}}{\left[\mathrm{OH}^{-}\right]}$and $\left[\mathrm{OH}^{-}\right]=\frac{K_{\mathrm{w}}}{K_{\mathrm{a}}}$. 16.133 $1.7 \times 10^{10}$. $16.135($ a $) \mathrm{H}^{-}\left(\right.$base $\left._{1}\right)+\mathrm{H}_{2} \mathrm{O}\left(\right.$ acid $\left._{2}\right) \longrightarrow \mathrm{OH}^{-}$ (base 2$)+\mathrm{H}_{2}\left(\right.$ acid $\left._{1}\right)$. (b) $\mathrm{H}^{-}$is the reducing agent and $\mathrm{H}_{2} \mathrm{O}$ is the oxidizing agent. $\mathbf{1 6 . 1 3 7} 2.8 \times 10^{-2}$. $\mathbf{1 6 . 1 3 9} \mathrm{PH}_{3}$ is a weaker base than $\mathrm{NH}_{3} .16 .141$ (a) $\mathrm{HNO}_{2}$. (b) HF . (c) $\mathrm{BF}_{3}$. (d) $\mathrm{NH}_{3}$. (e) $\mathrm{H}_{2} \mathrm{SO}_{3}$. (f) $\mathrm{HCO}_{3}^{-}$ and $\mathrm{CO}_{3}^{2-} .16 .143$ (a) Trigonal pyramidal. (b) $\mathrm{H}_{4} \mathrm{O}^{2+}$ does not exist because the positively charged $\mathrm{H}_{3} \mathrm{O}^{+}$has no affinity to accept the positive $\mathrm{H}^{+}$ion. If $\mathrm{H}_{4} \mathrm{O}^{2+}$ existed, it would have a tetrahedral geometry. 16.145 $\mathrm{Cl}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{HCl}(a q)+\mathrm{HClO}(a q) ; \mathrm{HCl}(a q)+\mathrm{AgNO}_{3}(a q)$ $\rightleftarrows \mathrm{AgCl}(s)+\mathrm{HNO}_{3}(a q)$. In the presence of $\mathrm{OH}^{-}$ions, the first equation is shifted to the right: $\mathrm{H}^{+}($from HCl$)+\mathrm{OH}^{-} \longrightarrow \mathrm{H}_{2} \mathrm{O}$. Therefore, the concentration of HClO increases. (The 'bleaching action' is due to $\mathrm{ClO}^{-}$ions.) $\mathbf{1 6 . 1 4 7} 11.80$. $\mathbf{1 6 . 1 4 9}$ (a) 0.181 or $18.1 \%$. (b) $4.63 \times$ $10^{-3}$. 16.151 4.26. 16.153 $7.2 \times 10^{-3}$ g. 16.155 1.000. 16.157 (a) The pH of the solution of HA would be lower. (b) The electrical conductance of the HA solution would be greater. (c) The rate of hydrogen evolution from the HA solution would be greater. $\mathbf{1 6 . 1 5 9} 1.4 \times 10^{-4}$. 16.161 $2.7 \times$ $10^{-3}$ g. 16.163 (a) $\mathrm{NH}_{2}^{-}$(base) $+\mathrm{H}_{2} \mathrm{O}$ (acid) $\longrightarrow \mathrm{NH}_{3}+\mathrm{OH}^{-}$; $\mathrm{N}^{3-}$ (base) $+3 \mathrm{H}_{2} \mathrm{O}$ (acid) $\longrightarrow \mathrm{NH}_{3}+3 \mathrm{OH}^{-}$. (b) $\mathrm{N}^{3-}$. 16.165 When the smelling salt is inhaled, some of the powder dissolves in the basic solution. The ammonium ions react with the base as follows: $\mathrm{NH}_{4}^{+}(a q)+$ $\mathrm{OH}^{-}(a q) \longrightarrow \mathrm{NH}_{3}(a q)+\mathrm{H}_{2} \mathrm{O}$. It is the pungent odor of ammonia that prevents a person from fainting. $\mathbf{1 6 . 1 6 7}$ (c). $\mathbf{1 6 . 1 6 9} 21 \mathrm{~mL} . \mathbf{1 6 . 1 7 1}$ Magnesium. 16.173 Both NaF and $\mathrm{SnF}_{2}$ provide $\mathrm{F}^{-}$ions in solution. The $\mathrm{F}^{-}$ions replace $\mathrm{OH}^{-}$ions during the remineralization process $5 \mathrm{Ca}^{2+}+3 \mathrm{PO}_{4}{ }^{3-}+\mathrm{F}^{-} \longrightarrow \mathrm{Ca}_{5}\left(\mathrm{PO}_{4}\right)_{3} \mathrm{~F}$ (fluorapatite). Because $\mathrm{F}^{-}$ is a weaker base than $\mathrm{OH}^{-}$, fluorapatite is more resistant to attacks by acids compared to hydroxyapatite. $\mathbf{1 6 . 1 7 5} K_{\mathrm{a}}=5.2 \times 10^{-10}$.

## Chapter 17

17.5 (a) 2.57. (b) 4.44. 17.9 (c) and (d). 17.11 8.89. 17.13 0.024. 17.15 0.58. 17.17 9.25; 9.18. 17.19 $\mathrm{Na}_{2} \mathrm{~A} / \mathrm{NaHA}$. 17.21 (1) Solutions (a), (b), and (c); (2) Solution (a). $\mathbf{1 7 . 2 7} 202 \mathrm{~g} / \mathrm{mol} 17.290 .25$ M. 17.31 (a) $1.10 \times$ $10^{2} \mathrm{~g} / \mathrm{mol}$. (b) $1.6 \times 10^{-6} .17 .335 .82 .17 .35$ (a) 2.87 . (b) 4.56 . (c) 5.34 . (d) 8.78. (e) 12.10. $\mathbf{1 7 . 3 7}$ (a) Cresol red or phenolphthalein. (b) Most of the indicators in Table 17.3, except thymol blue and, to a lesser extent, bromophenol blue and methyl orange. (c) Bromophenol blue, methyl orange, methyl red, or chlorophenol blue. 17.39 Red. 17.41 (1) Diagram (c), (2) Diagram (b), (3) Diagram (d), (4) Diagram (a). The pH at the equivalence point is below 7 (acidic). 17.49 (a) $\left[\mathrm{I}^{-}\right]=9.1 \times 10^{-9} \mathrm{M}$. (b) $\left[\mathrm{Al}^{3+}\right]=7.4 \times 10^{-8} \mathrm{M} .17 .511 .8 \times 10^{-11} . \mathbf{1 7 . 5 3} 3.3 \times 10^{-93} . \mathbf{1 7 . 5 5}$ 9.52. 17.57 Yes. $\mathbf{1 7 . 6 3}$ (a) $0.013 M$ or $1.3 \times 10^{-2} M$. (b) $2.2 \times 10^{-4} M$. (c) $3.3 \times 10^{-3} M .17 .65$ (a) $1.0 \times 10^{-5} M$. (b) $1.1 \times 10^{-10} M .17 .67$ (b), (c), (d), and (e) $\mathbf{1 7 . 6 9}$ (a) 0.016 M or $1.6 \times 10^{-2} \mathrm{M}$. (b) $1.6 \times 10^{-6} \mathrm{M}$. 17.71 A precipitate of $\mathrm{Fe}(\mathrm{OH})_{2}$ will form. $17.73\left[\mathrm{Cd}^{2+}\right]=1.1 \times 10^{-18} \mathrm{M}$, $\left[\mathrm{Cd}(\mathrm{CN})_{4}^{2-}\right]=4.2 \times 10^{-3} \mathrm{M},\left[\mathrm{CN}^{-}\right]=0.48 \mathrm{M} .17 .753 .5 \times 10^{-5} \mathrm{M}$. $17.77 \mathrm{Cu}^{2+}(a q)+4 \mathrm{NH}_{3}(a q) \rightleftarrows\left[\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}\right]^{2+}(a q)$. (b) $\mathrm{Ag}^{+}(a q)+$ $2 \mathrm{CN}^{-}(a q) \rightleftarrows\left[\mathrm{Ag}(\mathrm{CN})_{2}\right]^{-}(a q)$. (c) $\mathrm{Hg}^{2+}(a q)+4 \mathrm{Cl}^{-}(a q) \rightleftarrows$ $\left[\mathrm{HgCl}_{4}\right]^{2-}(a q)$ 17.81 Greater than 2.68 but less than 8.11 . 17.83 0.011 M . 17.85 Chloride ion will precipitate $\mathrm{Ag}^{+}$but not $\mathrm{Cu}^{2+}$. So, dissolve some solid in $\mathrm{H}_{2} \mathrm{O}$ and add HCl . If a precipitate forms, the salt was $\mathrm{AgNO}_{3}$. A flame test will also work. $\mathrm{Cu}^{2+}$ gives a green flame test. 17.872 .51 to 4.41. 17.89 1.3 M. 17.91 $\left[\mathrm{Na}^{+}\right]=0.0835 M,\left[\mathrm{HCOO}^{-}\right]=0.0500 \mathrm{M}$; $\left[\mathrm{OH}^{-}\right]=0.0335 \mathrm{M} ;\left[\mathrm{H}^{+}\right]=3.0 \times 10^{-13} \mathrm{M} ;[\mathrm{HCOOH}]=8.8 \times 10^{-11} \mathrm{M}$. $17.93 \mathrm{Cd}(\mathrm{OH})_{2}(s)+2 \mathrm{OH}^{-}(a q) \rightleftarrows \mathrm{Cd}(\mathrm{OH})_{4}^{2-}(a q)$. This is a Lewis acid-base reaction. 17.95 (d). $17.97\left[\mathrm{Ag}^{+}\right]=2.0 \times 10^{-9} M ;\left[\mathrm{Cl}^{-}\right]=$ $0.080 \mathrm{M} ;\left[\mathrm{Zn}^{2+}\right]=0.070 \mathrm{M} ;\left[\mathrm{NO}_{3}^{-}\right]=0.060 \mathrm{M} .17 .990 .035 \mathrm{~g} / \mathrm{L} .17 .101$ $2.4 \times 10^{-13} . \mathbf{1 7 . 1 0 3}\left[\mathrm{Ba}^{2+}\right]=1.0 \times 10^{-5} \mathrm{M} . \mathrm{Ba}\left(\mathrm{NO}_{3}\right)_{2}$ is too soluble to be used for this purpose. $\mathbf{1 7 . 1 0 5}$ (a) AgBr . (b) $1.8 \times 10^{-7} \mathrm{M}$. (c) $0.0018 \%$.
$\mathbf{1 7 . 1 0 7} 3.0 \times 10^{-8} . \mathbf{1 7 . 1 0 9}$ (a) $1.0 \times 10^{14}$. (b) $1.8 \times 10^{9}$. (c) $1.8 \times 10^{9}$. (b) Mix 500 mL of $0.80 \mathrm{M} \mathrm{CH}_{3} \mathrm{COOH}$ with 500 mL of 0.40 M NaOH . (c) Mix 500 mL of $0.80 \mathrm{M} \mathrm{CH}_{3} \mathrm{COONa}$ with 500 mL of 0.40 M HCl 17.113 (a) Figure (b). (b) Figure (a). $\mathbf{1 7 . 1 1 5 \text { (a) }}$ Add sulfate. (b) Add sulfide. (c) Add iodide. 17.117 They are insoluble in water. 17.119 The ionized polyphenols have a dark color. In the presence of citric acid from lemon juice, the anions are converted to the lightercolored acids. 17.121 Yes. $\mathbf{1 7 . 1 2 3}$ (c). 17.125 Decreasing the pH would increase the solubility of calcium oxalate and should help minimize the formation of calcium oxalate kidney stones. 17.127 At $\mathrm{pH}=1.0$ : ${ }^{+} \mathrm{NH}_{3}-\mathrm{CH}_{2}-\mathrm{COOH}$. At $\mathrm{pH}=7.0$ : ${ }^{+} \mathrm{NH}_{3}-\mathrm{CH}_{2}-\mathrm{COO}^{-}$. At $\mathrm{pH}=12.0$ : $\mathrm{NH}_{2}-\mathrm{CH}_{2}-\mathrm{COO}^{-} .17 .129$ (a) Before dilution: $\mathrm{pH}=4.74$. After a 10 -fold dilution: $\mathrm{pH}=4.74$. (b) Before dilution: $\mathrm{pH}=2.52$. After dilution, $\mathrm{pH}=$ 3.02. 17.131 $\mathrm{AgBr}(s)$ will precipitate first. $\mathrm{Ag}_{2} \mathrm{SO}_{4}(s)$ will precipitate last. $\mathbf{1 7 . 1 3 3}$ (c). $\mathbf{1 7 . 1 3 5} 8.8 \times 10^{-12} .17 .1374 .75$.

## Chapter 18

18.7 (a) With barrier: 16; Without barrier: 64. (b) $16 ; 16 ; 32$. Both particles on one side: $S=3.83 \times 10^{-23} \mathrm{~J} / \mathrm{K}$; particles on opposite sides: $S=4.78 \times 10^{-23}$. The most probable state is the one with the larger entropy; that is, the state in which the particles are on opposite sides. 18.13 (a) $\Delta S_{\text {sys }}=-0.031 \mathrm{~J} / \mathrm{K}$. (b) $\Delta S_{\text {sys }}=-0.29 \mathrm{~J} / \mathrm{K}$. (c) $\Delta S_{\text {sys }}=1.5 \times$ $10^{2} \mathrm{~J} / \mathrm{K} .18 .15$ (c) $<$ (d) $<$ (e) $<$ (a) $<$ (b). 18.17 (a) $47.5 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$. (b) $-12.5 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$. (c) $-242.8 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol} .18 .21$ (a) $291 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$; spontaneous. (b) $2.10 \times 10^{3} \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$; spontaneous. (c) $\Delta S_{\text {surr }}=2.99 \times$ $10^{3} \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$; spontaneous. 18.23 (a) $\Delta S_{\text {sys }}=-75.6 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol} ; \Delta S_{\text {surr }}=$ $185 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$; spontaneous. (b) $\Delta S_{\text {sys }}=215.8 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol} ; \Delta S_{\text {surr }}=$ $-304 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$; not spontaneous. (c) $\Delta S_{\text {sys }}=98.2 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol} ; \Delta S_{\text {surr }}=$ $-1.46 \times 10^{3} \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$; not spontaneous. (d) $\Delta S_{\text {sys }}=-282 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$; $\Delta S_{\text {surr }}=7.20 \times 10^{3} \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$; spontaneous. 18.29 (a) $-1139 \mathrm{~kJ} / \mathrm{mol}$. (b) $-140.0 \mathrm{~kJ} / \mathrm{mol}$. (c) $-2935 \mathrm{~kJ} / \mathrm{mol} 18.31$ (a) All temperatures. (b) Below $111 \mathrm{~K} .18 .33 \Delta S_{\text {fus }}=99.9 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol} ; \Delta S_{\text {vap }}=93.6 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$. $\mathbf{1 8 . 3 5} \Delta G_{\mathrm{rxn}}^{\circ}=-226.6 \mathrm{~kJ} / \mathrm{mol}$. 18.3775 .9 kJ . $18.410 .35 .18 .4379 \mathrm{~kJ} /$ mol. 18.45 (a) $\Delta G_{\mathrm{rxn}}^{\circ}=35.4 \mathrm{~kJ} / \mathrm{mol} ; K_{P}=6.2 \times 10^{-7}$. (b) $44.6 \mathrm{~kJ} / \mathrm{mol}$. 18.47 (a) $1.6 \times 10^{-23} \mathrm{~atm}$. (b) $0.535 \mathrm{~atm} 18.493 .1 \times 10^{-2} \mathrm{~atm}$ or 23.6 mmHg . 18.53 93 ATP molecules. $18.55 \Delta H_{\text {fus }}>0 . \Delta S_{\text {fus }}>0$. (a) $\Delta G_{\text {fus }}<0$. (b) $\Delta G_{\text {fus }}=0$. (c) $\Delta G_{\text {fus }}>0.18 .57 U$ and $H .18 .5942^{\circ} \mathrm{C}$. 18.61 $\Delta S$ must be positive $(\Delta S>0)$. $\mathbf{1 8 . 6 3}$ (a) Benzene: $\Delta S_{\text {vap }}=$ $87.8 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$; hexane: $\Delta S_{\text {vap }}=90.1 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$; mercury: $\Delta S_{\text {vap }}=$ $93.7 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$; toluene: $\Delta S_{\text {vap }}=91.8 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$. Trouton's rule is a statement about $\Delta S_{\text {vap. }}^{\circ}$. In most substances, the molecules are in constant and random motion in both the liquid and gas phases, so $\Delta S_{\text {vap }}^{\circ} \approx$ $90 \mathrm{~J} / \mathrm{K} \cdot$ mol. (b) Ethanol: $\Delta S_{\text {vap }}=111.9 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$; water: $\Delta S_{\text {vap }}=$ $109.4 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$. In ethanol and water, there are fewer possible arrangements of the molecules due to the network of H-bonds, so $\Delta S_{\text {vap }}^{\circ}$ is greater. $\mathbf{1 8 . 6 5}$ (a) $2 \mathrm{CO}+2 \mathrm{NO} \longrightarrow 2 \mathrm{CO}_{2}+\mathrm{N}_{2}$. (b) The oxidizing agent is NO ; the reducing agent is CO . (c) $K_{P}=3 \times 10^{120}$. (d) $Q_{P}=$ $1.2 \times 10^{14}$. To the right. (e) No. $18.672 .6 \times 10^{-9} . \mathbf{1 8 . 6 9} 976 \mathrm{~K}=703^{\circ} \mathrm{C}$. $18.7138 \mathrm{~kJ} .18 .73174 \mathrm{~kJ} / \mathrm{mol} 18.75$ (a) Positive. (b) Negative. (c) Positive. (d) Positive. $\mathbf{1 8 . 7 7} 625 \mathrm{~K}$. We assume that $\Delta H^{\circ}$ and $\Delta S^{\circ}$ do not depend on temperature. 18.79 No. A negative $\Delta G^{\circ}$ tells us that a reaction has the potential to happen, but gives no indication of the rate. 18.81 (a) $\Delta G^{\circ}=-106.4 \mathrm{~kJ} / \mathrm{mol} ; K_{P}=4 \times 10^{18}$. (b) $\Delta G^{\circ}=-53.2 \mathrm{~kJ} /$ $\mathrm{mol} ; K_{P}=2 \times 10^{9}$. The $K_{P}$ in (a) is the square of the $K_{P}$ in (b). Both $\Delta G^{\circ}$ and $K_{P}$ depend on the number of moles of reactants and products specified in the balanced equation. 18.83 Talking involves various biological processes (to provide the necessary energy) that lead to an increase in the entropy of the universe. Since the overall process (talking) is spontaneous, the entropy of the universe must increase. 18.85 (a) $86.7 \mathrm{~kJ} / \mathrm{mol}$. (b) $4 \times 10^{-31}$. (c) $3 \times 10^{-6}$. (d) Lightning supplies the energy necessary to drive this reaction, converting the two most abundant gases in the atmosphere into $\mathrm{NO}(g)$. The NO gas dissolves in the rain, which carries it into the soil where it is converted into nitrate and
nitrite by bacterial action. This "fixed" nitrogen is a necessary nutrient for plants. $\mathbf{1 8 . 8 7} T>673.2 \mathrm{~K}$. $\mathbf{1 8 . 8 9}$ (a) $7.6 \times 10^{14}$. (b) $4.1 \times 10^{-12}$. The activity series is correct. The very large value of $K$ for reaction (a) indicates that products are highly favored; whereas, the very small value of $K$ for reaction (b) indicates that reactants are highly favored. $\mathbf{1 8 . 9 1}$ (a) Disproportionation redox reaction. (b) $8.2 \times 10^{15}$. This method is feasible for removing $\mathrm{SO}_{2}$. (c) Less effective. $18.931 .8 \times 10^{70}$. Due to the large magnitude of $K$, you would expect this reaction to be spontaneous in the forward direction. However, this reaction has a large activation energy, so the rate of reaction is extremely slow. $\mathbf{1 8 . 9 5} \Delta S_{\text {sys }}=$ $91.1 \mathrm{~J} / \mathrm{K} ; \Delta S_{\text {surr }}=-91.1 \mathrm{~J} / \mathrm{K} ; \Delta S_{\text {univ }}=0$. The system is at equilibrium. $18.978 .5 \mathrm{~kJ} / \mathrm{mol} 18.99$ (a) $\mathrm{CH}_{3} \mathrm{COOH}: 27 \mathrm{~kJ} / \mathrm{mol} ; \mathrm{CH}_{2} \mathrm{ClCOOH}$ : $16 \mathrm{~kJ} / \mathrm{mol}$. (b) The system's entropy change dominates. (c) The breaking and making of specific $\mathrm{O}-\mathrm{H}$ bonds. Other contributions include solvent separation and ion solvation. (d) The $\mathrm{CH}_{3} \mathrm{COO}^{-}$ion, which is smaller than $\mathrm{CH}_{2} \mathrm{ClCOO}^{-}$, can participate in hydration to a greater extent, leading to solutions with fewer possible arrangements. $18.101 \chi_{\mathrm{CO}}=0.45$; $\chi_{\mathrm{CO}_{2}}=0.55$. We assumed that $\Delta G^{\circ}$ calculated from $\Delta G_{\mathrm{f}}^{\circ}$ values was temperature independent. $\mathbf{1 8 . 1 0 3} 249 \mathrm{~J} / \mathrm{K} .18 .105 \Delta S_{\text {sys }}=-327 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$; $\Delta S_{\text {surr }}=1918 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol} ; \Delta S_{\text {univ }}=1591 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol} .18 .107 q$, and $w$. 18.109 $\Delta G$ must be negative. $\Delta S$ must be negative. $\Delta H$ must be negative. 18.111 (a) $S=5.76 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$. (b) The fact that the actual residual entropy is $4.2 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol}$ means that the orientation is not totally random. $\mathbf{1 8 . 1 1 3}$ $\Delta H^{\circ}=33.89 \mathrm{~kJ} / \mathrm{mol} ; \Delta S^{\circ}=96.4 \mathrm{~J} / \mathrm{K} \cdot \mathrm{mol} ; \Delta G^{\circ}=5.2 \mathrm{~kJ} / \mathrm{mol} . \Delta H^{\circ}$ is positive because this is an endothermic process. We also expect $\Delta S^{\circ}$ to be positive because this is a liquid $\longrightarrow$ vapor phase change. $\Delta G^{\circ}$ is positive because we are at a temperature that is below the boiling point of benzene $\left(80.1^{\circ} \mathrm{C}\right)$.

## Chapter 19

19.1 (a) $2 \mathrm{H}^{+}+\mathrm{H}_{2} \mathrm{O}_{2}+2 \mathrm{Fe}^{2+} \longrightarrow 2 \mathrm{Fe}^{3+}+2 \mathrm{H}_{2} \mathrm{O}$. Isolate red blood cells from a blood sample and monitor radioactivity from the hemoglobin molecules present in the red blood cells. 20.6365 .3 yr.
20.65 (a) ${ }_{1}^{3} \mathrm{H} \longrightarrow{ }_{2}^{3} \mathrm{He}+{ }_{-1}^{0} \beta$ (b) 70.5 dpm .
20.67 (a) ${ }_{36}^{93} \mathrm{Kr}$. (b) ${ }_{0}^{1} \mathrm{n}$. (c) ${ }_{57}^{146} \mathrm{La}$. (d) ${ }_{0}^{1} \mathrm{n}$.
20.69 (a) ${ }_{1}^{3} \mathrm{H} \longrightarrow{ }_{2}^{3} \mathrm{He}+{ }_{-1}^{0} \beta$. (b) ${ }_{94}^{242} \mathrm{Pu} \longrightarrow{ }_{2}^{4} \alpha+{ }_{92}^{238} \mathrm{U}$.
(c) ${ }_{53}^{131} \mathrm{I} \longrightarrow{ }_{54}^{131} \mathrm{Xe}+{ }_{-1}^{0} \beta$. (d) ${ }_{98}^{251} \mathrm{Cf} \longrightarrow{ }_{96}^{247} \mathrm{Cm}+{ }_{2}^{4} \alpha$.
20.71 Because both Ca and Sr belong to Group 2A, radioactive strontium that has been ingested into the human body becomes concentrated in bones (replacing Ca ) and can damage blood cell production. $2.12 \times$ $10^{3} \mathrm{mCi}$. 20.73 Normally the human body concentrates iodine in the thyroid gland. The purpose of the large doses of KI is to displace radioactive iodine from the thyroid and allow its excretion from the body. 20.75 (a) ${ }_{83}^{209} \mathrm{Bi}+{ }_{2}^{4} \alpha \longrightarrow{ }_{85}^{211} \mathrm{At}+2{ }_{0}^{1} \mathrm{n}$. (b) ${ }_{83}^{209} \mathrm{Bi}(\alpha, 2 \mathrm{n}){ }_{85}^{211} \mathrm{At} .20 .77$ $2.77 \times 10^{3}$ yr. $20.790 .070 \%$. 20.81 (a) $5.59 \times 10^{-15} \mathrm{~J} ; 2.84 \times 10^{-13} \mathrm{~J}$. (b) 0.024 mol. (c) $4.26 \times 10^{6} \mathrm{kJ} .20.832 .8 \times 10^{14}$ iodine- 131 atoms. $20.856 .1 \times 10^{23}$ atoms $/ \mathrm{mol} 20.87$ (a) $1.83 \times 10^{-12} \mathrm{~J}$. (b) The $\alpha$ particle will move away faster because it is smaller. $20.89 \mathrm{U}-238, t_{1 / 2}=4.5 \times$ $10^{9} \mathrm{yr}$ and Th-232, $t_{1 / 2}=1.4 \times 10^{10} \mathrm{yr}$. They are still present because of their long half-lives. $20.918 .3 \times 10^{-4} \mathrm{~nm} .20 .93$ Only ${ }^{3} \mathrm{H}$ has a suitable half-life. The other half-lives are either too long or too short to determine the time span of 6 years accurately. 20.95 A small-scale chain reaction (fission of ${ }^{235} \mathrm{U}$ ) took place. Copper played the crucial role of reflecting neutrons from the splitting uranium- 235 atoms back into the uranium sphere to trigger the chain reaction. Note that a sphere has the most appropriate geometry for such a chain reaction. In fact, during the implosion process prior to an atomic explosion, fragments of uranium235 are pressed roughly into a sphere for the chain reaction to occur (see Section 20.5 of the text). $20.972 .1 \times 10^{2} \mathrm{~g} / \mathrm{mol} .20 .99$ (a) $r=r_{0} A^{1 / 3}$, where $r_{0}$ is a proportionality constant. (b) $1.7 \times 10^{-42} \mathrm{~m}^{3} . \mathbf{2 0 . 1 0 1}$ 0.49 rem. 20.103 3.4 mL .

## Chapter 21

$21.53 .30 \times 10^{-4} ; 330 \mathrm{ppm}$. 21.7 In the stratosphere, the air temperature rises with altitude. This warming effect is the result of exothermic reactions triggered by UV radiation from the sun. $\mathbf{2 1 . 1 1} 260 \mathrm{~nm}$. $21.214 .0 \times 10^{37}$ molecules; $3.2 \times 10^{12} \mathrm{~kg} \mathrm{O}_{3} . \mathbf{2 1 . 2 3} \mathrm{CCl}_{4}+\mathrm{HF} \longrightarrow$ $\mathrm{HCl}+\mathrm{CFCl}_{3}$ (Freon-11); $\mathrm{CFCl}_{3}+\mathrm{HF} \longrightarrow \mathrm{HCl}+\mathrm{CF}_{2} \mathrm{Cl}_{2}$ (Freon-12). 21.25 $E=479 \mathrm{~kJ} / \mathrm{mol}$. Solar radiation preferentially breaks the $\mathrm{C}-\mathrm{Cl}$ bond. There is not enough energy to break the $\mathrm{C}-\mathrm{F}$ bond.
 $10^{19} \mathrm{~kJ} ; 4.8 \times 10^{16} \mathrm{~kg} .21 .495 . \ddot{2} \times 10^{8} \mathrm{~L} .21 .57$ (a) rate $=k[\mathrm{NO}]^{2}\left[\mathrm{O}_{2}\right]$. (b) rate $=k^{\prime}[\mathrm{NO}]^{2}$, where $k^{\prime}=k\left[\mathrm{O}_{2}\right]$. (c) $1.3 \times 10^{3} \min .21 .594 .1 \times$ $10^{-7} \mathrm{~atm} ; 1 \times 10^{16}$ molecules/L. 21.65378 g. $21.67 \mathrm{O}_{3}$ : greenhouse gas, toxic to humans, attacks rubber; $\mathrm{SO}_{2}$ : toxic to humans, forms acid rain; $\mathrm{NO}_{2}$ : forms acid rain, destroys ozone; CO : toxic to humans; PAN: a powerful lachrymator, causes breathing difficulties; Rn : causes lung cancer. 21.69 (a) $K_{\mathrm{c}}=\frac{\left[\mathrm{O}_{2}\right][\mathrm{HbCO}]}{[\mathrm{CO}]\left[\mathrm{HbO}_{2}\right]}$ (b) $4.7 \times 10^{-2} .21 .71$ (a) $\mathrm{N}_{2} \mathrm{O}+$ $\mathrm{O} \longrightarrow 2 \mathrm{NO} ; 2 \mathrm{NO}+2 \mathrm{O}_{3} \longrightarrow 2 \mathrm{NO}_{2}+2 \mathrm{O}_{2}$; overall: $\mathrm{N}_{2} \mathrm{O}+\mathrm{O}+$ $2 \mathrm{O}_{3} \longrightarrow 2 \mathrm{NO}_{2}+2 \mathrm{O}_{2}$. (b) $\mathrm{N}_{2} \mathrm{O}$ is a more effective greenhouse gas than $\mathrm{CO}_{2}$ because it has a permanent dipole. (c) $3.0 \times 10^{10} \mathrm{~mol}$. $21.731 .8 \times$ $10^{19} \mathrm{Rn}$ atoms; $6.4 \times 10^{16} \mathrm{Rn}$ atoms. 21.75 (a) Its small concentration is the result of the high reactivity of the OH radical. (b) OH has an unpaired electron; free radicals are always good oxidizing agents. (c) $\mathrm{OH}+\mathrm{NO}_{2}$ $\longrightarrow \mathrm{HNO}_{3}$. (d) $\mathrm{OH}+\mathrm{SO}_{2} \longrightarrow \mathrm{HSO}_{3} ; \mathrm{HSO}_{3}+\mathrm{O}_{2}+\mathrm{H}_{2} \mathrm{O} \longrightarrow$ $\mathrm{H}_{2} \mathrm{SO}_{4}+\mathrm{HO}_{2}$. 21.77 The blackened bucket has a large deposit of elemental carbon. When heated over the burner, it forms poisonous carbon monoxide. $\mathrm{C}+\mathrm{CO}_{2} \longrightarrow 2 \mathrm{CO}$. A smaller amount of CO is also formed as follows: $2 \mathrm{C}+\mathrm{O}_{2} \longrightarrow 2 \mathrm{CO} .21 .79$ The use of the aerosol liberates CFCs that destroy the ozone layer. 21.81 Yes. Light of wavelength 409 nm (visible) or shorter will break the $\mathrm{C}-\mathrm{Br}$ bond. $\mathbf{2 1 . 8 3}$ (a) $6.2 \times 10^{8}$. (b) The $\mathrm{CO}_{2}$ liberated from limestone contributes to global warming. 21.85 Most water molecules contain oxygen-16, but a small percentage of water molecules contain oxygen-18. The ratio of the two isotopes in the ocean is essentially constant, but the ratio in the water vapor evaporated from the oceans is temperature-dependent, with the vapor becoming slightly enriched with oxygen-18 as temperature increases. The water locked up in ice cores provides a historical record of this oxygen-18 enrichment, and thus ice cores contain information about past global temperatures.

## Chapter 22

$\mathbf{2 2 . 1 1}$ (a) +3. (b) 6. (c) Oxalate ion $\left(\mathrm{C}_{2} \mathrm{O}_{4}^{2-}\right) . \mathbf{2 2 . 1 3}$ (a) $\mathrm{Na}:+1$; $\mathrm{Mo}:+6$. (b) $\mathrm{Mg}:+2 ; \mathrm{W}:+6$. (c) Fe: 0.22 .15 (a) cis-dichlorobis(ethylenediamine) cobalt(III). (b) pentamminechloroplatinum(IV) chloride.
(c) pentamminechlorocobalt(III) chloride. 22.17 (a) $\left[\mathrm{Cr}(\mathrm{en})_{2} \mathrm{Cl}_{2}\right]^{+}$.
(b) $\mathrm{Fe}(\mathrm{CO})_{5}$. (c) $\mathrm{K}_{2}\left[\mathrm{Cu}(\mathrm{CN})_{4}\right]$. (d) $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{4}\left(\mathrm{H}_{2} \mathrm{O}\right) \mathrm{Cl}\right] \mathrm{Cl}_{2}$. 22.23 (a) Two. (b) Two.
22.25 (a)

22.31 Cyanide ion is a very strong-field ligand. It causes a larger crystal field splitting than water, resulting in the absorption of higher energy (shorter wavelength) radiation when a $d$ electron is excited to a higher energy $d$ orbital. 22.33 (a) Orange. (b) $255 \mathrm{~kJ} / \mathrm{mol}$ 22.35 Two moles. $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}_{2}\right] \mathrm{Cl}$. Refer to Problem 22.25 (a) for a diagram of the structure of the complex ion. $22.37 \Delta$ would be greater for the higher oxidation state. 22.41 Use a radioactive label such as ${ }^{14} \mathrm{CN}^{-}$(in NaCN ). Add NaCN to a solution of $\mathrm{K}_{3} \mathrm{Fe}(\mathrm{CN})_{6}$. Isolate some of the $\mathrm{K}_{3} \mathrm{Fe}(\mathrm{CN})_{6}$ and check its radioactivity. If the complex shows radioactivity, then it must mean that the $\mathrm{CN}^{-}$ion has participated in the exchange reaction.
 formation of $\left[\mathrm{Cu}(\mathrm{CN})_{4}\right]^{2-}$, so the concentration of $\mathrm{Cu}^{2+}$ is too small for $\mathrm{Cu}^{2+}$ ions to precipitate with sulfide. $22.451 .4 \times 10^{2}$. 22.47 The purple color is caused by the build-up of deoxyhemoglobin. When either oxyhemoglobin or deoxyhemoglobin takes up CO , the carbonylhemoglobin takes on a red color, the same as oxyhemoglobin. 22.49 $\mathrm{Mn}^{3+}$ is $3 d^{4}$ and $\mathrm{Cr}^{3+}$ is $3 d^{5}$. Therefore, $\mathrm{Mn}^{3+}$ has a greater tendency to accept an electron and is a stronger oxidizing agent. The $3 d^{5}$ electron configuration of $\mathrm{Cr}^{3+}$ is a stable configuration. $22.51 \mathrm{Ti}^{3+} ; \mathrm{Fe}^{3+}$. $22.531 .6 \times 10^{4} \mathrm{~g}$ hemoglobin $/ \mathrm{mol} \mathrm{Fe}$. The discrepancy between our minimum value and the actual value can be explained by realizing that there are four iron atoms per mole of hemoglobin. 22.55 (a) $\left[\mathrm{Cr}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right] \mathrm{Cl}_{3}$, number of ions: 4. (b) $\left[\mathrm{Cr}\left(\mathrm{H}_{2} \mathrm{O}\right)_{5} \mathrm{Cl}^{2} \mathrm{Cl}_{2} \cdot \mathrm{H}_{2} \mathrm{O}\right.$, number of ions: 3 .
(c) $\left[\mathrm{Cr}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4} \mathrm{Cl}_{2}\right] \mathrm{Cl} \cdot 2 \mathrm{H}_{2} \mathrm{O}$, number of ions: 2. Compare the compounds with equal molar amounts of $\mathrm{NaCl}, \mathrm{MgCl}_{2}$, and $\mathrm{FeCl}_{3}$ in an electrical conductance experiment. The solution that has similar conductance to the NaCl solution contains (c); the solution with the conductance similar to $\mathrm{MgCl}_{2}$ contains (b); and the solution with conductance similar to $\mathrm{FeCl}_{3}$ contains (a).22.57 $\Delta G^{\circ}=-1.8 \times 10^{2} \mathrm{~kJ} / \mathrm{mol} ; K=6 \times 10^{30} .22 .59$ Iron is much more abundant than cobalt. 22.61 Oxyhemoglobin absorbs higher energy light than deoxyhemoglobin. Oxyhemoglobin is diamagnetic (low spin), while deoxyhemoglobin is paramagnetic (high spin). These differences occur because oxygen $\left(\mathrm{O}_{2}\right)$ is a strong-field ligand. $\mathbf{2 2 . 6 3}$ Complexes are expected to be colored when the highest occupied orbitals have between one and nine $d$ electrons. $\mathrm{Zn}^{2+}, \mathrm{Cu}^{+}$, and $\mathrm{Pb}^{2+}$ are $d^{10}$ ions. $\mathrm{V}^{5+}, \mathrm{Ca}^{2+}$, and $\mathrm{Sc}^{3+}$ are $d^{0}$ ions. 22.65 Dipole moment measurement. Only the cis isomer has a dipole moment. 22.67 EDTA sequesters metal ions (like $\mathrm{Ca}^{2+}$ and $\mathrm{Mg}^{2+}$ ), which are essential for the growth and function of bacteria. $22.693 .22 .712 .2 \times 10^{-20} M .22 .73$ (a) $2.7 \times 10^{6}$. (b) Free $\mathrm{Cu}^{+}$ions are unstable in solution. Therefore, the only stable compounds containing $\mathrm{Cu}^{+}$ions are insoluble. 22.75 Y .22 .770 .0 M .22 .79 $\left[\mathrm{Mn}(\mathrm{CN})_{6}\right]^{5-}: \mathrm{Mn}$ is +1 , one unpaired $d$ electron. $\left[\mathrm{Mn}(\mathrm{CN})_{6}\right]^{4-}$ : Mn is +2 , one unpaired $d$ electron. $\left[\mathrm{Mn}(\mathrm{CN})_{6}\right]^{3-}: \mathrm{Mn}$ is +3 , two unpaired $d$ electrons.

## Chapter 23

23.3 (a) $\mathrm{CaCO}_{3}$. (b) $\mathrm{CaCO}_{3} \cdot \mathrm{MgCO}_{3}$. (c) $\mathrm{CaF}_{2}$. (d) NaCl . (e) $\mathrm{Al}_{2} \mathrm{O}_{3}$. (f) $\mathrm{Fe}_{3} \mathrm{O}_{4}$. (g) $\mathrm{Be}_{3} \mathrm{Al}_{2} \mathrm{Si}_{6} \mathrm{O}_{18}$. (h) PbS . (i) $\mathrm{MgSO}_{4} \cdot 7 \mathrm{H}_{2} \mathrm{O}$. (j) $\mathrm{CaSO}_{4} .23 .13$ $K_{P}=4.5 \times 10^{5} .23 .15 \mathrm{Ag}, \mathrm{Pt}$, and Au will not be oxidized, but the other metals will. 23.17 (a) $8.9 \times 10^{12} \mathrm{~cm}^{3}$. (b) $4.0 \times 10^{8} \mathrm{~kg} .23 .19 \mathrm{Al}, \mathrm{Na}$, and Ca .23 .33 (a) $2 \mathrm{Na}(s)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{NaOH}(a q)+\mathrm{H}_{2}(g)$. (b) $2 \mathrm{NaOH}(a q)+\mathrm{CO}_{2}(g) \longrightarrow \mathrm{Na}_{2} \mathrm{CO}_{3}(a q)+\mathrm{H}_{2} \mathrm{O}(l)$. (c) $\mathrm{Na}_{2} \mathrm{CO}_{3}(s)+$ $2 \mathrm{HCl}(a q) \longrightarrow 2 \mathrm{NaCl}(a q)+\mathrm{CO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l)$. (d) $\mathrm{NaHCO}_{3}(a q)+$ $\mathrm{HCl}(a q) \longrightarrow \mathrm{NaCl}(a q)+\mathrm{CO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l)$. (e) $2 \mathrm{NaHCO}_{3}(s) \longrightarrow$ $\mathrm{Na}_{2} \mathrm{CO}_{3}(s)+\mathrm{CO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(g)$. (f) No reaction. 23.35 5.59 L. 23.39 $3 \mathrm{Mg}(s)+8 \mathrm{HNO}_{3}(a q) \longrightarrow 3 \mathrm{Mg}\left(\mathrm{NO}_{3}\right)_{2}(a q)+4 \mathrm{H}_{2} \mathrm{O}(l)+2 \mathrm{NO}(g)$. The magnesium nitrate is recovered from solution by evaporation, dried, and heated in air to obtain magnesium oxide: $2 \mathrm{Mg}\left(\mathrm{NO}_{3}\right)_{2}(s) \longrightarrow$ $2 \mathrm{MgO}(s)+4 \mathrm{NO}_{2}(g)+\mathrm{O}_{2}(g)$. 23.41 The electron configuration of magnesium is $[\mathrm{Ne}] 3 s^{2}$. The $3 s$ electrons are outside the neon core (shielded), so they have relatively low ionization energies. Removing the third electron means separating an electron from the neon (closed shell) core, which requires a great deal more energy. 23.43 Even though helium and the Group 2A metals have $n s^{2}$ outer electron configurations, helium has a closed shell noble gas configuration and the Group 2A metals do not. The electrons in He are much closer to and more strongly attracted by the nucleus. Hence, the electrons in He are not easily removed. Helium is inert. 23.45 (a) $\mathrm{CaO}(s)$. (b) $\mathrm{Ca}(\mathrm{OH})_{2}(s) .23 .4960 .7 \mathrm{~h} .23 .51$ (a) 1.03 V . (b) $3.32 \times 10^{4} \mathrm{~kJ} / \mathrm{mol}$. $23.534 \mathrm{Al}\left(\mathrm{NO}_{3}\right)_{3}(s) \longrightarrow 2 \mathrm{Al}_{2} \mathrm{O}_{3}(s)+$ $12 \mathrm{NO}_{2}(g)+3 \mathrm{O}_{2}(g)$. 23.55 The "bridge" bonds in $\mathrm{Al}_{2} \mathrm{Cl}_{6}$ break at high temperature: $\mathrm{Al}_{2} \mathrm{Cl}_{6}(g) \rightleftarrows 2 \mathrm{AlCl}_{3}(g)$. This increases the number of molecules in the gas phase and causes the pressure to be higher than expected for pure $\mathrm{Al}_{2} \mathrm{Cl}_{6}$. 23.57 In $\mathrm{Al}_{2} \mathrm{Cl}_{6}$, each aluminum atom is surrounded by 4 bonding pairs of electrons ( $\mathrm{AB}_{4}$-type molecule), and therefore each aluminum atom is $s p^{3}$ hybridized. VSEPR analysis shows
$\mathrm{AlCl}_{3}$ to be an $\mathrm{AB}_{3}$-type molecule (no lone pairs on the central atom). The geometry should be trigonal planar, and the aluminum atom should therefore be $s p^{2}$ hybridized. $\mathbf{2 3 . 5 9} 65.4 \mathrm{~g} / \mathrm{mol}$. $\mathbf{2 3 . 6 1}$ Copper(II) ion is more easily reduced than either water or hydrogen ion. Copper metal is more easily oxidized than water. Water should not be affected by the copper purification process under standard conditions. 23.63 (a) $1482 \mathrm{~kJ} /$ mol. (b) $3152.8 \mathrm{~kJ} / \mathrm{mol}$. $23.65 \mathrm{Mg}(s)$ reacts with $\mathrm{N}_{2}(g)$ at high temperatures to produce $\mathrm{Mg}_{3} \mathrm{~N}_{2}(s)$. $\mathrm{Ti}(s)$ also reacts with $\mathrm{N}_{2}(g)$ at high temperatures to produce $\operatorname{TiN}(s) .23 .67$ (a) In water the aluminum(III) ion causes an increase in the concentration of hydrogen ion (lower pH ). This results from the effect of the small diameter and high charge (3+) of the aluminum ion on surrounding water molecules. The aluminum ion draws electrons in the $\mathrm{O}-\mathrm{H}$ bonds to itself, thus allowing easy formation of $\mathrm{H}^{+}$ ions. (b) $\mathrm{Al}(\mathrm{OH})_{3}$ is an amphoteric hydroxide. It will dissolve in strong base with the formation of a complex ion. $\mathrm{Al}(\mathrm{OH})_{3}(s)+\mathrm{OH}^{-}(a q) \longrightarrow$ $\mathrm{Al}(\mathrm{OH})_{4}^{-}(a q)$. The concentration of $\mathrm{OH}^{-}$in aqueous ammonia is too low for this reaction to occur. 23.69 $\mathrm{CaO}(s)+2 \mathrm{HCl}(a q) \longrightarrow \mathrm{CaCl}_{2}(a q)+$ $\mathrm{H}_{2} \mathrm{O}(l)$. 23.71 Metals have closely spaced energy levels and a very small energy gap between filled and empty levels. Consequently, many electronic transitions can take place with absorption and subsequent emission of light continually occurring. Some of these transitions fall in the visible region of the spectrum and give rise to the flickering appearance. $\mathbf{2 3 . 7 3} \mathrm{NaF}$ : cavity prevention. $\mathrm{Li}_{2} \mathrm{CO}_{3}$ : antidepressant. $\mathrm{Mg}(\mathrm{OH})_{2}$ : laxative. $\mathrm{CaCO}_{3}$ : calcium supplement; antacid. $\mathrm{BaSO}_{4}$ : radiocontrast agent. 23.75 Both Li and Mg form oxides $\left(\mathrm{Li}_{2} \mathrm{O}\right.$ and MgO$)$. Other Group 1A metals ( $\mathrm{Na}, \mathrm{K}$, etc.) also form peroxides and superoxides. In Group 1A, only Li forms nitride $\left(\mathrm{Li}_{3} \mathrm{~N}\right)$, like $\mathrm{Mg}\left(\mathrm{Mg}_{3} \mathrm{~N}_{2}\right)$. Li resembles Mg in that its carbonate, fluoride, and phosphate have low solubilities. 23.77 Zn. 23.79 87.66\%; $12.34 \%$. 23.81727 atm.

## Chapter 24

24.11 $\mathrm{HCl} ; \mathrm{CaH}_{2}$. A water solution of HCl is called hydrochloric acid. Calcium hydride will react according to the equation $\mathrm{CaH}_{2}(s)+$ $2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{Ca}(\mathrm{OH})_{2}(\mathrm{aq})+2 \mathrm{H}_{2}(g)$. 24.13 NaH : Ionic compound, reacts with water as follows: $\mathrm{NaH}(s)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{NaOH}(a q)+$ $\mathrm{H}_{2}(\mathrm{~g}) ; \mathrm{CaH}_{2}$ : Ionic compound, reacts with water as follows: $\mathrm{CaH}_{2}(s)+$ $2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{Ca}(\mathrm{OH})_{2}(a q)+2 \mathrm{H}_{2}(g) ; \mathrm{CH}_{4}$ : Covalent compound, unreactive, burns in air or oxygen: $\mathrm{CH}_{4}(g)+2 \mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g)+$ $2 \mathrm{H}_{2} \mathrm{O}(l) ; \mathrm{NH}_{3}$ : Covalent compound, weak base in water: $\mathrm{NH}_{3}(\mathrm{aq})+$ $\mathrm{H}_{2} \mathrm{O}(l) \rightleftarrows \mathrm{NH}_{4}^{+}(a q)+\mathrm{OH}^{-}(a q) ; \mathrm{H}_{2} \mathrm{O}$ : Covalent compound, forms strong intermolecular hydrogen bonds, good solvent for both ionic compounds and substances capable of forming hydrogen bonds; HCl : Covalent compound (polar), acts as a strong acid in water: $\mathrm{HCl}(g)+$ $\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{Cl}^{-}(a q)$. $24.15 \mathrm{CaH}_{2}(s)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow$ $\mathrm{Ca}(\mathrm{OH})_{2}(a q)+2 \mathrm{H}_{2}(g) ; 22.7$ g. $24.17\left(\right.$ a) $\mathrm{CuO}(s)+\mathrm{H}_{2}(g) \longrightarrow \mathrm{Cu}(s)+$ $\mathrm{H}_{2} \mathrm{O}(l)$. (b) No reaction. $24.25[: \mathrm{C} \equiv \mathrm{C}:]^{2-} .24 .27$ (a) $2 \mathrm{NaHCO}_{3}(s) \longrightarrow$ $\mathrm{Na}_{2} \mathrm{CO}_{3}(s)+\mathrm{H}_{2} \mathrm{O}(g)+\mathrm{CO}_{2}(g)$. (b) $\mathrm{Ca}(\mathrm{OH})_{2}(a q)+\mathrm{CO}_{2}(g) \longrightarrow$ $\mathrm{CaCO}_{3}(s)+\mathrm{H}_{2} \mathrm{O}(l)$. The visual proof is the formation of a white precipitate of $\mathrm{CaCO}_{3}$. 24.29 Heat causes bicarbonates to decompose according to the reaction: $2 \mathrm{HCO}_{3}^{-} \longrightarrow \mathrm{CO}_{3}^{2-}+\mathrm{H}_{2} \mathrm{O}+\mathrm{CO}_{2}$. Generation of carbonate ion causes precipitation of the insoluble $\mathrm{MgCO}_{3}$. $\mathbf{2 4 . 3 1} \mathrm{NaHCO}_{3}$ plus some $\mathrm{Na}_{2} \mathrm{CO}_{3}$. 24.33 Yes. 24.39 (a) $2 \mathrm{NaNO}_{3}(s) \longrightarrow$ $2 \mathrm{NaNO}_{2}(s)+\mathrm{O}_{2}(g)$. (b) $\mathrm{NaNO}_{3}(s)+\mathrm{C}(s) \longrightarrow \mathrm{NaNO}_{2}(s)+\mathrm{CO}(g)$. $24.41 \mathrm{NH}_{3}(g)+\mathrm{CO}_{2}(g) \longrightarrow\left(\mathrm{NH}_{2}\right)_{2} \mathrm{CO}(s)+\mathrm{H}_{2} \mathrm{O}(l)$. The reaction should be run at high pressure. 24.43 The oxidation state of N in nitric acid is +5 , the highest oxidation state for $\mathrm{N} . \mathrm{N}$ can be reduced to an oxidation state $-3.24 .45\left(\right.$ a) $\mathrm{NH}_{4} \mathrm{NO}_{3}(s) \longrightarrow \mathrm{N}_{2} \mathrm{O}(g)+2 \mathrm{H}_{2} \mathrm{O}(l)$. (b) $2 \mathrm{KNO}_{3}(s) \longrightarrow 2 \mathrm{KNO}_{2}(s)+\mathrm{O}_{2}(g)$. (c) $\mathrm{Pb}\left(\mathrm{NO}_{3}\right)_{2}(s) \longrightarrow$
$\mathrm{PbO}(s)+2 \mathrm{NO}_{2}(g)+\mathrm{O}_{2}(g) .24 .47 \mathrm{KNO}_{3}(s)+\mathrm{C}(s) \longrightarrow \mathrm{KNO}_{2}(s)+$ $\mathrm{CO}(\mathrm{g}) ; 48.0 \mathrm{~g} .24 .49$ (a) $86.7 \mathrm{~kJ} / \mathrm{mol}$. (b) $4 \times 10^{-31}$. (c) $4 \times 10^{-31} .24 .51$ $125 \mathrm{~g} / \mathrm{mol} ; \mathrm{P}_{4} .24 .534 \mathrm{HNO}_{3}(a q)+\mathrm{P}_{4} \mathrm{O}_{10}(s) \longrightarrow 2 \mathrm{~N}_{2} \mathrm{O}_{5}(g)+$ $4 \mathrm{HPO}_{3}(l) ; 60.4 \mathrm{~g} .24 .55 \mathrm{sp}^{3} .24 .63 G^{\circ}=-198.3 \mathrm{~kJ} / \mathrm{mol} ; K_{P}=6 \times 10^{34}$; $K_{\mathrm{c}}=K_{P} .24 .65$ (a) To exclude light. (b) $0.371 \mathrm{~L} .24 .67 \mathrm{~F}:-1$; O: 0. 24.69 (a) $\mathrm{HCOOH}(l) \rightleftarrows \mathrm{CO}(g)+\mathrm{H}_{2} \mathrm{O}(l)$. (b) $4 \mathrm{H}_{3} \mathrm{PO}_{4}(l) \rightleftarrows$ $\mathrm{P}_{4} \mathrm{O}_{10}(s)+6 \mathrm{H}_{2} \mathrm{O}(l)$. (c) $2 \mathrm{HNO}_{3}(l) \rightleftarrows \mathrm{N}_{2} \mathrm{O}_{5}(g)+\mathrm{H}_{2} \mathrm{O}(l)$. (d) $2 \mathrm{HClO}_{3}(l) \rightleftarrows \mathrm{Cl}_{2} \mathrm{O}_{5}(l)+\mathrm{H}_{2} \mathrm{O}(l) .24 .71$ To form $\mathrm{OF}_{6}$ there would have to be six bonds (twelve electrons) around the oxygen atom. This would violate the octet rule. Since oxygen does not have $d$ orbitals, it cannot have an expanded octet. 24.7335 g. $\mathbf{2 4 . 7 5} 9_{2} \mathrm{SO}_{4}(a q)+$
$8 \mathrm{NaI}(a q) \longrightarrow 4 \mathrm{I}_{2}(s)+\mathrm{H}_{2} \mathrm{~S}(g)+4 \mathrm{H}_{2} \mathrm{O}(l)+8 \mathrm{NaHSO}_{4}(a q) .24 .79$
(a) $\mathrm{H}-\ddot{\mathrm{F}}:---\mathrm{H}-\ddot{\mathrm{F}}:$ (b) $[\ddot{\mathrm{F}}: \cdot---\mathrm{H}-\cdots: \ddot{\mathrm{F}}:]^{-} 24.81$ (a) Linear. (b) Tetrahedral. (c) Trigonal bipyramidal. (d) See-saw. 24.83 25.3 L. 24.85 2.81 L. $\mathbf{2 4 . 8 7}$ $\mathrm{I}_{2} \mathrm{O}_{5}(\mathrm{~s})+5 \mathrm{CO}(\mathrm{g}) \longrightarrow 5 \mathrm{CO}_{2}(\mathrm{~g})+\mathrm{I}_{2}(\mathrm{~s})$. Iodine is reduced; carbon is oxidized. 24.89 (a) $2 \mathrm{H}_{3} \mathrm{PO}_{3}(a q) \longrightarrow \mathrm{H}_{3} \mathrm{PO}_{4}(a q)+\mathrm{PH}_{3}(g)+\mathrm{O}_{2}(g)$.
(b) $\mathrm{Li}_{4} \mathrm{C}(s)+4 \mathrm{HCl}(a q) \longrightarrow 4 \mathrm{LiCl}(a q)+\mathrm{CH}_{4}(g)$. (c) $2 \mathrm{HI}(g)+$ $2 \mathrm{HNO}_{2}(a q) \longrightarrow \mathrm{I}_{2}(s)+2 \mathrm{NO}(g)+2 \mathrm{H}_{2} \mathrm{O}(l)$. (d) $\mathrm{H}_{2} \mathrm{~S}(g)+2 \mathrm{Cl}_{2}(g)$ $\longrightarrow 2 \mathrm{HCl}(g)+\mathrm{SCl}_{2}(l) .24 .91$ (a) $\mathrm{SiCl}_{4}$. (b) $\mathrm{F}^{-}$. (c) F . (d) $\mathrm{CO}_{2} .24 .93$ There is no change in oxidation number; it is zero for both compounds.

$24.9725^{\circ} \mathrm{C}: K=9.61 \times 10^{-22} ; 100^{\circ} \mathrm{C}: K=1.2 \times 10^{-15} .24 .99$ The glass is etched by the reaction: $6 \mathrm{HF}(a q)+\mathrm{SiO}_{2}(s) \longrightarrow \mathrm{H}_{2} \mathrm{SiF}_{6}(a q)+$ $2 \mathrm{H}_{2} \mathrm{O}(l)$. This process gives the glass a frosted appearance. 24.101 1.18. $\mathbf{2 4 . 1 0 3} 0.833 \mathrm{~g} / \mathrm{L}$. The molar mass derived from the observed density is 74.41 , which suggests that the molecules are associated to some extent in the gas phase. This makes sense due to strong hydrogen bonding in HF.

## Chapter 25

25.3 The monomer must have a triple bond.

25.9 (1) Produce the alkoxide: $\mathrm{Sc}(s)+2 \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(l) \longrightarrow$ $\mathrm{Sc}\left(\mathrm{OC}_{2} \mathrm{H}_{5}\right)($ alc $)+2 \mathrm{H}^{+}($alc $)$("alc" indicates a solution in alcohol); (2) Hydrolyze to produce hydroxide pellets: $\mathrm{Sc}\left(\mathrm{OC}_{2} \mathrm{H}_{5}\right)(\mathrm{alc})+$ $2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{Sc}(\mathrm{OH})_{2}(s)+2 \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}($ alc $)$; (3) Sinter pellets to produce ceramic: $\mathrm{Sc}(\mathrm{OH})_{2}(s) \longrightarrow \mathrm{ScO}(s)+2 \mathrm{H}_{2} \mathrm{O}(g)$. 25.11 Bakelite is best described as a thermosetting composite polymer. 25.15 No. These polymers are too flexible, and liquid crystals require long, relatively rigid molecules. 25.19 As shown, it is an alternating condensation copolymer of the polyester class. 25.21 Metal amalgams expand with age; composite fillings tend to shrink. 25.25 $s p^{2}$. 25.27 Dispersion forces; dispersion forces. 25.31 (a) n-type. (b) p-type. $25.35 \mathrm{Bi}_{2} \mathrm{Sr}_{2} \mathrm{CuO}_{6}$. 25.37 Two are $+2\left([\mathrm{Ar}] 3 d^{9}\right)$, one is $+3\left([\mathrm{Ar}] 3 d^{8}\right)$. The +3 oxidation state is unusual for
copper. $\mathbf{2 5 . 3 9} \mathrm{H}_{2} \mathrm{~N}-\left(\mathrm{CH}_{2}\right)_{8}-\mathrm{NH}_{2}$
 25.41 Plastic polymer: covalent bonds, disulfide (covalent) bonds, H-bonds and dispersion forces. Ceramics: ionic and network covalent bonds. $\mathbf{2 5}$.43 Fluoroapatite is less soluble than hydroxyapatite, particularly in acidic solutions. Dental fillings must also be insoluble. 25.45 The molecule is long, flat and rigid, so it should form a liquid crystal.

Balmer, Johann, 221
band theory, 952
band theory of conductivity, 952
conductors, 952-953
semiconductors, 953-954
Bardeen, John, 1021
barometer, 444, 445
base
Brønsted acids and bases, 129-131
defined, 118
strong acids and bases, 128-129
base ionization constants, 695
basic oxygen process, 949-950
batteries
defined, 838
dry cells and alkaline, 838-839
fuel cells, 840-841
lead storage, 839
lithium-ion, 840
Becquerel, Antoine, 40-41
Beer-Lambert law, 150
belt of stability, 862
bends, the, 466
benzene, 375-376, 542, 544
beta $(\beta)$ particles, 41
beta ( $\beta$ ) rays, 41
beta-particle emission, 862-863
bimolecular, 604
binary hydrides, 971-972
binary molecular compounds, 52
biological catalysts, 613-615
biological concentration cells, 836
biological polymers, 422-426
biomedical materials, 1013-1016
bioterrorism agents, 3,25
bipolar disorder, 288
birth defects, 387
blackbody radiation, 215
blast furnace, 948, 949
blood, maintaining pH of, 735-736
blood alcohol concentration (BAC), 117
blood doping, 629
blood lead level (BLL), 921
blood plasma, 735
body-centered cubic cell, 506, 507
Bohr, Niels, 221-222
Bohr's theory of the hydrogen atom, 220-223, 228, 232
atomic line spectra, 220-221
line spectrum of hydrogen, 221-223, 226
boiling point, 518, 519
boiling-point elevation, 555-556
Boltzmann constant, 779
Boltzmann, Ludwig, 470
bond angle, 342, 345
bond dipoles, 347,348
bond enthalpy, 307, 325-328, 350
bond length, 307
bond order, 370
bonding molecular orbital, 369
bonding theories, 375-377
bone, radioactive, 286
Born-Haber cycle, 302, 304-305
boron neutron capture therapy (BNCT), 859
Boyle, Robert, 447
Boyle's law, 447-449, 470
Bragg equation, 511
Breathalyzer test, 116, 117, 159
breeder reactors, 878
bromine, 991
Brønsted acids and bases, 130, 674-675
Brønsted base, 130
Brønsted, Johannes, 130
Buck, Linda, 339
buckyballs, 1017
buffer, 729
buffer solutions, 729, 732-733
with a specific $\mathrm{pH}, 734-735$
calculating the pH of a buffer, 729-731
burette, 8, 9
burns, 522
burst lung, 441

electrolysis, 841-845
galvanic cells, 821-823
spontaneity of redox reactions under conditions other than standard state, 833-838
spontaneity of redox reactions under standard-state conditions, 830-833
standard reduction potentials, 824-830
electrodes, 821
electrolysis
of an aqueous sodium chloride solution, 842-843
defined, 841
in metals purification, 951-952
of molten sodium chloride, 841-842
quantitative applications of, 844-845
of water, 842
electrolyte solutions, 558-559
electrolytes
in aqueous solutions, 118-120
compounds as, 122
defined, 118
electrolytic cells, 841
electrolytic reduction, 948
electromagnetic spectrum, 212, 213
electromagnetic wave, 213
electron affinity $(E A), 269-271$
electron capture, 863
electron configuration
Aufbau principle, 241
defined, 239
energies of atomic orbitals in many-electron systems, 239-240
general rules for writing, 242
Hund's rule, 241-242
Pauli exclusion principle, 240-241
and the periodic table, 243-246
electron density, 232
electron-domain geometry, 342-345
defined, 342
electron domains, 340-341
electron spin quantum number, 234-235
electronegativity, 309-310
electronic structure of atoms, 211
electrons, 39-40, 43, 44, 45
diffraction of, 230
discovery of, 39-40
free, 222
odd number of, 320-321
in orbitals, 350
electrophile addition, 412-413
electrophiles, 410
electrospinning, 1015
electrostatic energy, 172
elemental iron, 35
elementary reactions, 604-605
elements. See also periodic table
defined, 5, 6-7
elimination reactions, 418
emission spectra, 220, 221
emission spectrum of hydrogen, 224-225
empirical formula mass, 79, 92
empirical formulas, 54-55,56
determination of, 91-92
from percent composition, 90-91
emulsifier/emulsifying agent, 567
enantiomers, 408, 410, 930
end point, 744
endothermic process, 173, 182
entropy changes, 789
ionic bonds, 300
in solution-formation, 542
endpoints, 155
energy
defined, 172
energy changes in chemical reactions, 172-173
forms of, 172
ionization energy, 267-269
nuclear binding energy, 863-865
quantization of, 215-216
in solution formation, 542
units of, 173-175
English units, 9
enthalpy
bond, 307, 325-328, 350
defined, 181
and enthalpy changes, 81-182
reactions under constant-volume or constantpressure conditions, 179-181
thermochemical equations, 182-183
enthalpy of reactions, 181
entropy, 542, 776-777
defined, 779
entropy changes in a system, 780-788
entropy changes in the universe, 788-793
living systems in, 777
probability, 780
standard, 782-784
third law of thermodynamics, 792-793
environmental chemistry, 892-893
acid rain, 907-909
depletion of ozone in the stratosphere, 899-902
Earth's atmosphere, 894-897
greenhouse effect, 902-907
indoor pollution, 910-912
phenomena in the outer layers of the atmosphere, 897-898
photochemical smog, 909-910
volcanoes, 901, 902
Environmental Protection Agency (EPA), 911
enzymes, biological catalysts, 613
equatorial, 342
equilibrium. See also chemical equilibrium
concept of, 630-632
defined, 630
and tooth decay, 727
equilibrium constants
calculating, 633
defined, 632
magnitude of the, 636
units in, 660
equilibrium expressions, 632, 637
calculating equilibrium concentrations, 645-649
containing gases, 641-642
heterogeneous equilibria, 637-638
manipulating, 638-639
predicting the direction of a reaction, 644-645
in problem solving, 644-649
equilibrium mixture, 656
equilibrium process, 789
equilibrium vapor pressure, 502
equivalence points, 155
erythrocytes, 735-736
esters, 390, 394, 398-399
ethanol, 615
ethyl group, 390-391

exact numbers, 17
excess reactants, 97
excited state, 222
exothermic process, 173
entropy changes, 789
ionic bonds, 300
in solution-formation, 542
expanded octets, 321-323
extensive properties, 15

## F

$f$ orbitals, 238
face-centered cubic cell, 506, 507
factor-label method, 22
Fahrenheit, Daniel Gabriel, 11
Fahrenheit temperature scale, 11
families, in periodic table, 46

Faraday constant, 830
Faraday, Michael, 844
ferromagnetic metals, 947
ferrous sulfate, 35
first law of thermodynamics, 177-178, 777
first-order reactions, 592
flotation, 947
fluoresce, 40
fluoride, 569, 766
fluorine, 985-986
fluoroapatite, 766
Food and Drug Administration (FDA), U.S., 25, 77, 171, 288, 387, 410, 427
food labels, 171
formal charge, 315-318
formaldehyde, 912
formation constants, 758-759
formic acid, 52
formula mass, 78
formula weight, 78
fossil fuels, 907-908
fractional precipitation, 763-764
Frasch process, 983
free electrons, 222
free energy
and chemical equilibrium, 799-803
defined, 794, 831
Gibbs free energy, 793-795
free radicals, 321, 883
freezing, 520
freezing point, 520
freezing-point depression, 556-557
Freon, 899
frequency, 212
fuel cells, 840-841
Fuller, R. Buckminster, 1017
fullerenes, 1017
functional groups, 54, 56
fusion, 520

## G

galvanic cells, 821-823
galvanization, 847
gamma rays, 212
Gamow Bag, 480
Gamow, Igor, 480
gangue, 947
gas, 6,7
gas constant $(R), 455$
gas embolism, 441
gas laws, 447-454
application to the, 470-471
defined, 447
gases
characteristics of, 443
deviation from ideal behavior, 476-479
diving and the property of, 441
equilibrium expressions containing, 641-642
gas laws, 447-454, 470-471
gas mixtures, 462-467
gas pressure, 443-444
ideal gas equation, 455-458
kinetic molecular theory of gases, 470-476
molar volume of, 468-469
properties of, 442-447
reactions with gaseous reactants and products, 458-461

Gatorade, 120-121
Geiger, Hans, 42
General Conference on Weights and Measures, 9 geodesic dome, 1017
geometrical isomers, 406, 407, 929
Gerlach, Walther, 235
Germer, Lester Halbert, 230
Gibbs free energy, 794
glass, 517, 518
Goodyear, Charles, 1001
graduated cylinder, 8,9
Graham's law, 475
graphene, 1017
graphite, 1016-1017
Graves, Ray, 121
gravimetric analysis, 154-155
Greek prefixes, 52
greenhouse effect, 902-907
ground state, 222, 243, 355
Group 1A elements, 279-280, 285-286
Group 1B elements, 285-286
Group 2A elements, 280-281
Group 3A elements, 281-282
Group 4A elements, 282
Group 5A elements, 282-283
Group 6A elements, 283-284
Group 7A elements, 284
Group 8A elements, 285
group number, 314
groups, in periodic table, 46
Grubbs, Robert H., 998, 999
Guldberg, Cato, 633, 635
Guy-Lussac, Joseph, 449-451

## H

Haber process, 650
half-cell potentials, 824
half-cell reactions, 826-828
half-cells, 821
half-life, 594-596, 868-869
half-reaction method, 136, 818
half-reactions, 134, 818-819
halides, 284
Hall process, 959-960
halogens, 47, 970, 985-991
compounds of, 989-990
properties of, 986, 987-989
uses of, 990-991
hangovers, 615
heart medication, explosives and, 297
heat
specific heat and heat capacity, 184-185
thermal energy and, 173
and work, 178-179
heat capacity, 184-185
heavy water, 878,972
Heisenberg uncertainty principle, 231
Heisenberg, Werner, 231
hemochromatosis, 67
hemodialysis, 562-563
hemoglobin, 655, 912
hemolysis, 561
Henderson-Hasselbalch equation, 731, 734, 740
Henry's law, 551-552
Henry's law constant, 551
Hess's law, 195-196
heteroatoms, 402
heterogeneous catalysis, 612
heterogeneous equilibria, 637-638
heterogeneous mixtures, 8
heteronuclear diatomic molecules, 51
hexagonal close-packed (hcp) structure, 508
high-temperature superconductor, 1021
homogeneous catalysis, 612-613
homogeneous mixtures, 7-8
homonuclear diatomic molecules, 51
Hund's rule, 241-242, 933-934
hybridization
defined, 354
in molecules containing multiple bonds, 361-368
hybridization of atomic orbitals, 353-354, 375
$s$ and $p$ orbitals, 354-357
$s, p$, and $d$ orbitals, 357-359
hydrated ions, 126
hydrates, 64-65
hydration, 123, 124, 416, 544
hydrazine, 976-977
hydride ions, 279
hydrocarbons, 54
hydrocyanic acid, 975
hydrofluoric acid, 986
hydrogen, 970-971
binary hydrides, 971-972
hydrogen economy, 973-974
hydrogenation, 973
isotopes of, 972-973
in the periodic table, 279
hydrogen atom
Bohr's theory of the, 220-228
quantum mechanical description of the, 232
hydrogen bomb, 880
hydrogen bonding, 495-496
hydrogen displacement, 140
hydrogen fluoride, 986
hydrogen peroxide, 981-982
hydrogen sulfide, 983-984
hydrohalic acids, 703
hydronium ion, 130
hydrophilic, 566, 567
hydrophobic, 566, 567
hydroxy group, 390, 394
hydroxyapatite, 727
hyperbaric oxygen therapy, 466
hypertonic, 561
hypothermia
heat capacity and, 189
phase changes and, 522
hypothesis, 5-6
hypotonic, 561
hypoxic tents, 629,661
ideal behavior (gas), 476
factors that cause deviation from, 476
van der Waals equation, 476-478
ideal gas, 455
ideal gas equation, 455
ideal solution, 555
implosion, 880
in phase, 213
incomplete octets, 320
indicators, 155
indoor pollution, 910-912
inert complex, 936
inert gases, 285
inexact numbers, 17
initial rate, 587
inorganic compounds, 54, 65 defined, 388
insoluble compounds, 123, 125
instantaneous dipole, 498
instantaneous rates, 582-584
insulators, 953
integrated rate law, 592
intensive properties, 15
interatomic, 5
interference, 213
interference pattern, 213, 214
intermediates, 604
intermolecular bonding, 307
intermolecular forces
defined, 494
dipole-dipole interactions, 494-495
dispersion forces, 498-499
hydrogen bonding, 495-496
ion-dipole interactions, 500
solutions and, 541
International System of Units, 9
International Union of Pure and Applied Chemistry, 262
interstitial hydrides, 972
intramolecular bonding, 307
intravenous fluids, 560-561
iodine, 991
ion-dipole interactions, 500
ion pairs, 559
ion-product constant, 676
ionic bonding, 299
ionic bonds, 308, 310
ionic compounds
defined, 58, 122
formulas of, 60-61
halides as, 989
lattice energy of, 300-302
naming, 61-64
solubility products of, 748-749
in water, solubility guidelines, 122-124
ionic crystals, 513-514, 516
ionic equations, 126
net, 126-127
ionic hydrides, 971-972
ionic radius, 275-277
ionizable hydrogen atoms, 54
ionization, electroytes and, 118
ionization constants
acid, 686-694
base, 694-697
ionization energy (IE), 267-269
ionosphere, 897
ions
atomic, 58-59
common ion effect, 728-729, 753-758
complex ion formation, 758-760
defined, 48, 58
electron configuration of, 273-275
formulas of ionic compounds, 60-61
ionic and covalent compounds, 307-308
ionic bonding, 299
ionic compounds, 58, 60-64, 122, 122-128
naming ionic compounds, 61-64
polyatomic, 59-60
solubility and separation of, 763-765
iron, 67, 948-949
iron deficiency, 35
iron deficiency anemia (IDA), 35
isoelectronic, 273
isoelectronic series, 276-277
isolated system, 176, 193
isomerism, 406-410
isomerization reactions, 419
isopropyl group, 391
isotactic, 1005
isotonic, 558
isotopes, 44-45
chemical analysis, 881
hydrogen, 972-973
in medicine, 882
parent and daughter, 867
isotropic, 1011

## J

Jenner, Edward, 3
joule, 173-174
Joule, James, 173

## K

Kamerlingh-Onnes, H., 1020
Kekulé structures, 401
Kelvin temperature scale, 10, 450-451
ketones, 390, 394, 399
kidney stones, 527
kinetic energy, 172
kinetic isotope effect, 973
kinetic lability, 936
kinetic molecular theory, 470
kinetic molecular theory of gases, 470-476

## L

labile complexes, 936
lanthanide (rare earth) series, 244-245
lasers, 227
laser pointers, 216
in medicine, 211
LASIK surgery, 210, 211
lattice, 61
lattice energy, 300-302
lattice points, 505
lattice structure, 505
laughing gas, 977
law of conservation of energy, 172
law of conservation of mass, 37
law of definite proportions, 36
law of mass action, 633
law of multiple proportions, 37
law of octaves, 258
law, scientific, 5
Le Châtelier's principle, 650
lead poisoning, 921
lead storage batteries, 839
levorotatory isomer, 409, 930
Lewis acids and bases, 712-714
Lewis dot symbols, 298-299
Lewis, Gilbert, 298, 306
Lewis structures, 306-308
drawing, 313-315
and formal charge, 315-318

Lewis theory of bonding, 306, 350, 375
ligand exchange, 936
ligands, 924-925
light, nature of, 212, 215
double-slit experiment, 213-214
electromagnetic spectrum, 213
properties of waves, 212-213
light water reactors, 877
liming, 909,959
limiting reactant, 97
determining the, 97-101
reaction yield, 101-102
line spectra, 221
liquid crystals, 1011-1013
liquids, 6, 7
gases as, 443
liquid-vapor phase transition, 518-520
properties of, 500-505
solid-liquid phase transition, 520-521
surface tension, 500-501
vapor pressure, 502-504
viscosity, 501-502
liter, 12
lithium, 288
lithium-ion batteries, 840
living systems
entropy in, 777
thermodynamics in, 804-805
localized bonds, 376, 403
London's dispersion forces, 498
lone pairs, 306, 307

## M

macroscopic level, 5
magic numbers, 862
magma, 902
magnesium, 958
magnetic confinement, 880
magnetic quantum number, 233-234
main group elements, 261
manometer, 445
Mars Climate Orbiter, 14
Marsden, Ernest, 42
mass, 10
atomic, 49-50
law of conservation of mass, 37
molecular and formula, 78
percent composition by mass, 79
of reactants and products, 95-96
mass defect, 864
mass-energy equivalence relationship,
Einstein's, 864
mass number ( $A$ ), 44
mass spectrometer, 49
mathematical operations, A1-A-5 matter
classification of, 6-8
defined, 4
properties of, 14-16
states of, 6, 7
Maxwell, James Clerk, 213, 470, 473
measured numbers, 18-19
measurement, uncertainty in, 17-21
medicine
lasers in, 211
nuclear, 882
Meissner effect, 1021
melamine, 492, 493, 527
melting, 520
melting point, 520
membrane potential, 836
Mendeleev, Dimitri, 258
meniscus, 500
Menkes disease, 945
mercury, 444-445, 446
mesosphere, 897
metabolic acidosis, 579
metabolism, stoichiometry of, 84
metal matrix composites, 1010
metallic character, 271
metallic crystals, 516
metallic radius, 265
metalloids, 46, 264, 271, 969, 970
metallurgy, 937, 944-945
alkali metals, 955-957
alkaline earth metals, 957-959
aluminum, 959-961
band theory of conductivity, 952-954
defined, 947
of iron, 948-949
metallurgical processes, 947-952
metals in human biology, 945
occurrence of metals, 946
periodic trends in metallic properties, 954-955
preparation of the ore, 947
production of metals, 947-948
purification of metals, 951-952
steelmaking, 949-951
metals, 46, 47, 59
in chemical equations, 264
oxidation of metals in aqueous solutions, 135
oxides of, 711-712
qualitative analysis of metal ions in solution, 764-765
metathesis method, 998, 999
meterstick, 8
methanol, 616
methanol poisoning, 579
methyl group, 390, 391
metric system, 9, 12
Meyer, Lothar, 258
millicurie (mCi), 882
Millikan, R. A., 40
milliliter (mL), 12
millimeters mercury (mmHg), 444
minerals, 946
miscible, 544
mixtures, 7-8
gas, 462-467
moderators, 878
modern materials, 998-999
biomedical materials, 1013-1016
ceramics and composite materials, 1009-1010
liquid crystals, 1011-1013
nanotechnology, 1016-1018
polymers, 1000-1009
semiconductors, 1018-1020
superconductors, 1020-1021
molality, 547, 548
molar absorptivity, 150
molar concentration, 142
molar enthalpy of sublimation, 521-522
molar heat of fusion, 520
molar heat of vaporization, 518-519
molar mass, 88
molar solubility, 749
molar volume of gas, 468-469
molarity, 142, 142-144
mole and molar masses
determining molar mass, 88-89
empirical formula from percent composition, 90-91
interconverting mass, moles, and numbers of particles, 89-90
the mole, 86-88
mole defined, 86
moles of reactants and products, 94-95
mole fractions, 463-464, 547, 548, 553
molecular art, 5
molecular compounds, 50, 52-54, 122, 443
molecular crystals, 515-516
molecular equations, 125-126
molecular formula, determination of, 92
molecular geometry, 340
defined, 342
deviation from ideal bond angles, 345
electron-domain geometry and, 342-345
geometry of molecules with more than one central atom, 345-346
and polarity, 347-350
VSEPR model, 340-341
molecular level, 5
molecular mass, 78
molecular orbital theory, 368, 375
bond order, 370
bonding and antibonding molecular orbitals, 368-369
defined, 368
molecular orbital diagrams, 372-373
molecular orbitals, 368, 369-373
molecular parity, 347
molecular speed, 471, 473-474
molecular weight, 78
molecularity, 604
molecules, 4, 5, 50-51
with delocalized bonding, 376
empirical formulas, 54-55, 56
hybridization and multiple bonds, 361-368
molecular formulas, 51
naming molecular compounds, 52-54, 55, 397
representation of organic molecules, 400-406
Molina, Mario, 893
molybdenum, 947
monatomic cations, 58
monatomic ions, 58,59
monatomic molecules, 50
Mond process, 951
monomers, 420,1000
monoprotic acids, 130
Montreal Protocol, 893, 901
Moseley, Henry, 258
multiple bonds, 307
musk, 378

## N

n-type semiconductors, 954, 1019
nanofibers, 1015
nanotechnology, 1016-1018
nanotubes, 1017
NASA, 14
natural rubber, 1000-1001
Nelmes, Sarah, 3
nematic, 1013
Nernst equation, 833-835
net ionic equations, 126-127
neutralization reactions, 131
neutron-to-proton ratio ( $\mathrm{n} / \mathrm{p}$ ), 862
neutrons, 43, 44
Newlands, John, 258
Newton's laws of motion, 232
newtons (N), 14, 444
night vision, 218
nitric acid, 977-978
nitric oxide, 329, 909-910, 977
nitrogen, 975-978
nitrogen dioxide, 977
nitrogen fixation, 895, 977
nitroglycerin, 297
nitrous oxide, 977
Nobel, Alfred, 297
Nobel Prize, 297, 339, 893, 913, 998, 999, 1020
noble gas core, 243
noble gases, 47, 261, 264
noble metals, 135
nodes, 228
nomenclature, chemical, 52, 53
nonconductors, 1019
nonelectrolytes, 118
nonmetals, 46
carbon, 974-975
in chemical equations, 264
general properties of, 970
halogens, 985-991
hydrogen, 970-974
nitrogen, 975-978
oxides of, 711-712
oxygen, 980-982
phosphorus, 978-980
sulfur, 982-985
nonpolar, 310, 347
nonpolar covalent bonds, 310
nonspontaneous processes, 778
nonvolatile, 553
normal boiling point, 518, 519
northern lights, 897
nuclear binding energy, 863-865
nuclear chain reaction, 876
nuclear chemistry, 858-859
biological effects of radiation, 882-883
natural radioactivity, 866-870
nuclear fission, 873-879
nuclear fusion, 879-881
nuclear stability, 861-866
nuclear transmutation, 871-873
nuclei and nuclear reactions, 860-861
uses of isotopes, 881-882
nuclear fission, 873-879
nuclear fusion, 879-881
nuclear medicine, 882
nuclear reactors, 877-879
nuclear transmutation, 860, 871-873
nucleic acids, 422, 423, 426
nucleophile addition, 412-413
nucleophiles, 410, 412
nucleotides, 423, 426
nucleus, 42
Nutrition Facts labels, 171
nylon, 421-422

## 0

octet rule, 306, 306-307
exceptions to, 320-324
old quantum theory, 232
olefin metathesis, 999
olfactory receptors, 339
open system, 176
optical isomers, 407, 929-930
orbitals
electrons in, 350
hybridization of atomic, 353-361, 375
molecular orbital theory, 368-374
ore, 946,947
organic chemistry
carbon, 388-389
classes of organic compounds, 390-399
and drugs, 387
isomerism, 406-410
organic polymers, 420-426
organic reactions, 410-420
representation of organic molecules, 400-406
organic compounds, 54
classes of, 390-399
defined, 388
naming, 392-393
osmosis, 557, 562
osmotic pressure, 557-558
out of phase, 213
overvoltage, 843
oxidation, 134
oxidation number, 134, 137-138
oxidation-reduction reactions, 133-134, 418
balancing simple redox equations, 135-136
oxidation numbers, 134-135
oxidation of metals in aqueous solutions, 135
oxidation state, 134
oxides
acid-base properties of hydroxides and, 711-712
basic and amphoteric hydroxides, 712
of metals and nonmetals, 711-712
variation of third-period elements, 286-287
oxidizing agent, 134
oxoacids, 62, 703-704
oxoanions, 62
oxygen, 980-982
oxygen transport, 938
ozone, 982
CFCs and, 893, 899
depletion of stratospheric, 899-900
polar ozone holes, 900-902

## P

$p$ orbitals, 237, 354-359
p-type semiconductors, $954,1019-1020$
packing spheres, 506-508
paramagnetic, 368
partial pressure, 462-463
particle accelerator, 873
particles ( $N$ ), 89
pascal (Pa), 444
passivation, 847
patina, 847
Pauli exclusion principle, 240-241, 934
Pauling, Linus, 309
peptide bonds, 423
per mole of the reaction, 182
percent by mass, 547
percent composition by mass, 79, 90-91
percent dissociation, 564
percent ionic character, 310, 312
percent yield, 101
periodic table, 45-47, 142
atomic radius, 265-267, 275
classification of elements, 261-263
comparing ionic radius with atomic radius, 275-276
conparison of Group 1A and Group 1B elements, 285-286
development of, 258-260
effective nuclear charge, 264-265
electron affinity ( $E A$ ), 269-271
electron configuration of ions, 273-275
electron configurations and the, 243-246
elements essential for life, 259-260
gaseous elements in, 442
general trends in chemical properties, 278-279
Group 1A elements, 279-280
Group 1B elements, 285-286
Group 2A elements, 280-281
Group 3A elements, 281-282
Group 4A elements, 282
Group 5A elements, 282-283
Group 6A elements, 283-284
Group 7A elements, 284
Group 8A elements, 285
ionic radius, 275-277
ionization energy (IE), 267-269
ions of $d$-block elements, 274
ions of main group elements, 273
isoelectronic series, 276-277
main group elements, 278-287
metallic character, 271
modern, 261-264
numbers at top of, 262
periodic trends in metallic properties, 954-955
periodic trends in properties, 265, 265-273, 278-287
properties of other main group elements, 281-285
properties of the active metals, 279-281
properties of transition metals, 922-923
representing free elements in chemical equations, 264
salt and salt substitutes, 257
variation in properties of oxides within a period, 286-287
periodicity, 258
periods, in periodic table, 46
peroxide, 981-982
pH, 677
of acid-base titrations, 737
acid ionization constants and, 686-689
base ionization constants and, 696
buffer solutions and, 729-735
mean precipitation pH in the U.S., 907
pH scale, 677-682
phase boundary line, 524
phase changes, 517-518
dangers of, 522-523
liquid-vapor phase transition, 518-520
solid-liquid phase transition, 520-521
solid-vapor phase transition, 521-522
phase diagrams, 524-526
Phipps, James, 3
phosphine, 978-979
phosphorus, 978-980
photochemical smog, 909-910
photodecomposition, 894
photodissociation, 899
photoelectric effect, 217-218
photons, 217-218
photosynthesis, 894, 896
physical change, 15
physical properties, 14-15
pi bonds, 362, 366-367
pig iron, 949
pipette, 8,9
Planck, Max, 211, 215, 217
plasma, 880
Platinol, 77
Plato, 36
pOH scale, 679
polar, 308
polar covalent bonds, 308, 310
polar molecules, 123, 347, 494, 495
polar ozone holes, 900-902
polar stratospheric clouds (PSCs), 900, 901
polar vortex, 900
polarimeter, 930
polarity, molecular geometry and, 347-350
polarized light, 408, 409-410, 930
polarized molecules, 499
pollution
acid rain, 907-909
greenhouse effect, 902-907
indoor, 910-912
photochemical smog, 909-910
polyamides, 1006
polyatomic ions, 59-60
polyatomic molecules, 51, 904
polyesters, 1006
polyisoprene, 1000-1001
polymer matrix composites, 1010
polymers
addition, 420-421, 422, 1000-1005
biological, 422-426
condensation, 421-422, 1005-1008
defined, 420, 1000, 1005
electrically conducting, 1007-1008
organic, 420-426
polypeptides, 423
polyprotic acids, 62, 130-131, 700-703
polysaccharides, 422, 423
polystyrene, 1002
polyvinyl chloride (PVC), 1002
porphyria, 992
positron, 860
potassium hydroxide, 957
potassium nitrate, 957
potential energy, 172
pounds, 14
precipitate, 122
precipitation, fractional, 763-764
precipitation reactions
in aqueous solutions, 122-128
defined, 122
solubility and, 751-752
precision, 20-21
prefixes, Greek, 52
pressure
calculation of, 444
Dalton's law of partial pressures, 462-463
defined, 444
equilibrium and, 652-653
measurement of, 444-446
pressure-temperature-amount-volume relationship, 453
pressure-volume relationship, 449-451
solubility and, 550-552
using partial pressure to solve problems, 464-466
primary amides, 399
primary amines, 399
primary pollutants, 909
primary structure, protein, 497
principal quantum number, 233, 234
probability, 780
probability density, 236-237
problem solving, using units and, 22-24
products, in chemical reactions, 82
proteins, 422-423, 424-425
protein structure, 496-497
proton acceptor, 130
proton donor, 130
protons, 43, 44
Proust, Joseph, 36
pure covalent bonds, 308, 310
pyrometallurgy, 948

## Q

qualitative analysis, 764-765
qualitative properties, 14
quantitative properties, 8,14
quantum mechanics, 230-232
beginning of, 232
quantum mechanical description of the hydrogen atom, 232
Schrödinger equation, 232
uncertainty principle, 231
quantum numbers, 232, 233-235
electron spin quantum number, 234-235
quantum theory, 25,211
developments in, 232
photons and the photoelectric effect, 217-219
quantization of energy, 215-216
quantum defined, 215
quaternary structure, protein, 497
quicklime, 908-909

## R

racemic mixture, 409, 930
racemization, 415
radial probability distribution, 236-237
radiation, 39
biological effects of, 882-883
ultraviolet (UV), 894
radiation absorbed dose (rad), 882
radicals, 321, 883
radio waves, 212, 213-214
radioactive bone, 286
radioactive decay
dating based on, 868-870
defined, 860
kinetics of, 868-869
radioactive decay series, 867
radioactivity, 40-41, 860
radiocarbon dating, 868-870
radon, 884, 910-911
Raoult's law, 553
rate constant, 583
rate-determining step, 605-606
rate law, 587
rate of reaction, 584
reactants. See also limiting reactant
in chemical equations, 82
gaseous, 458-461
mass of reactants and products, 95-96
moles of reactants and products, 94-95
reversible, 630
reaction mechanism, 604
reaction order, 587
reaction quotient, 633
reaction rates, 580
Arrhenius equation, 600-602
average, 580-582
catalysis, 610-615
collision theory, 599-600
elementary reactions, 604-605
experimental determination of the rate law, 587-590
first-order reactions, 592-596
instantaneous rate, 582-584
rate-determining step, 605-606
rate law, 587
reaction mechanisms, 604-610
second-order reactions, 596-598
stoichiometry and, 584-586
reactions
organic, 410-420
types of, 104
red phosphorus, 978
redox reactions, 133
balancing, 818-820
balancing simple redox equations, 135-136
spontaneity under conditions other than standard state, 833-838
spontaneity under standard-state conditions, 830-833
types of, 140-141
reduced iron, 35
reducing agent, 134
reduction, 134
Reinitzer, Frederick, 1011
relative biological effectiveness (RBE), 883
remineralization, 727
representative elements, 261
repulsion, 172
repulsive force, 264,272
resonance, 318-319, 403-405
resonance stabilized, 403
resonance structures, 318, 403
reversible process, 630
revised metric system (SI) units, 9
rhombic sulfur, 983
ribonucleic acid (RNA), 423, 426
roentgen equivalent for man (rem), 883
Roman numerals, cations with, 59
Röntgen, Wilhelm, 40
root-mean-square (rms) speed, 473
Rosenberg, Barnett, 77
Rowland, F. Sherwood, 893
rubber, 1000-1002
Rutherford, Ernest, 42, 43, 211
Rydberg equation, 221
Rydberg, Johannes, 221

## S

$s$ orbitals, 236-237, 354-359
salt
in acid-base reactions, 131
and salt substitutes, 257
salt bridge, 821
salt hydrolysis, 706
salt solutions
acid-base properties of, 706-710
acidic, 707-709
basic, 706-707
cations and anions, 709, 710
neutral, 709-710
saturated solutions, 540
scanning tunneling microscope (STM), 1016
Schrieffer, John Robert, 1021
Schrock, Richard R., 998, 999
Schrödinger equation, 232
Schrödinger, Erwin, 232
scientific measurement, 8-14
scientific method, 3, 5-6
scientific notation, 17
second law of thermodynamics, 777, 790-791
second-order reactions, 596
secondary pollutants, 909
secondary structure, protein, 497
semiconductors, 953-954, 1018-1020
semipermeable membrane, 557
sequestrants, 938
shielding, 264
SI base units, 9, 10, 12
sickle cell disease, 496-498
sigma bonds, 362,363
significant figures, 17
silver fluoride, 986
simple cubic cell, 506, 507
single bonds, 307
sintering, 1009-1010
skeletal structures, 401-402
slag, 949
smallpox, 3, 25
smectic, 1011

[^0]:    Student Annotation: A compound may consist of molecules or ions, which we will discuss in Chapter 2.

[^1]:    1. John Dalton (1766-1844). English chemist, mathematician, and philosopher. In addition to the atomic theory, Dalton formulated several gas laws and gave the first detailed description of the type of color blindness, now called "Daltonism," from which he suffered. He also assigned relative weights to the elements, many of which differ considerably from those that we use today. He was described by his friends as awkward and without social grace.
[^2]:    2. According to Albert Einstein, mass and energy are alternate aspects of a single entity called mass-energy. Chemical reactions usually involve a gain or loss of heat and other forms of energy. Thus, when energy is lost in a reaction, for example, mass is also lost. Except for nuclear reactions (see Chapter 20), however, changes of mass in chemical reactions are far too small to detect. Therefore, for all practical purposes mass is conserved.
[^3]:    3. Alfred E. Stock (1876-1946). German chemist. Stock did most of his research in the synthesis and characterization of boron, beryllium, and silicon compounds. He was a pioneer in the study of mercury poisoning.
[^4]:    1. Lorenzo Romano Amedeo Carlo Avogadro di Quaregua e di Cerret (1776-1856). Italian mathematical physicist. He practiced law for many years before he became interested in science. His most famous work, now known as Avogadro's law (see Chapter 11), was largely ignored during his lifetime, although in the late nineteenth century, it became the basis for determining atomic masses.
[^5]:    1. Svante August Arrhenius (1859-1927). Swedish chemist. Arrhenius made important contributions to the study of chemical kinetics and electrolyte solutions. (He also speculated that life had come to Earth from other planets.) Arrhenius was awarded the Nobel Prize in Chemistry in 1903.
[^6]:    2. Johannes Nicolaus Brønsted (1879-1947). Danish chemist. In addition to his theory of acids and bases, Brønsted worked on thermodynamics and the separation of mercury into its isotopes. In some books, Brønsted acids and bases are called Brønsted-Lowry acids and bases. Thomas Martin Lowry (1874-1936). English chemist. Brønsted and Lowry developed essentially the same acid-base theory independently in 1923.
[^7]:    1. James Prescott Joule (1818-1889). English physicist. As a young man, Joule was tutored by John Dalton. He is most famous for determining the mechanical equivalent of heat, the conversion between mechanical energy and thermal energy.
[^8]:    2. Germain Henri Hess (1802-1850). Swiss chemist. Hess was born in Switzerland but spent most of his life in Russia. For formulating Hess's law, he is called the father of thermochemistry.
[^9]:    1. Max Karl Ernst Ludwig Planck (1858-1947). German physicist. Planck received the Nobel Prize in Physics in 1918 for his quantum theory. He also made significant contributions in thermodynamics and other areas of physics.
[^10]:    2. Albert Einstein (1879-1955). German-born American physicist. Regarded by many as one of the two greatest physicists the world has known (the other is Isaac Newton). The three papers (on special relativity, Brownian motion, and the photoelectric effect) that he published in 1905 while employed as a technical assistant in the Swiss patent office in Berne have profoundly influenced the development of physics. He received the Nobel Prize in Physics in 1921 for his explanation of the photoelectric effect.
[^11]:    3. Johann Jakob Balmer (1825-1898). Swiss mathematician. From 1859 until his death in 1898 Balmer taught math at a secondary school for girls in Basel, Switzerland. Although physicists did not understand why his equation worked until long after his death, the visible series of lines in the spectrum of hydrogen is named for him.
    4. Johannes Robert Rydberg (1854-1919). Swedish mathematician and physicist. Rydberg analyzed many atomic spectra in an effort to understand the periodic properties of elements. Although he was nominated twice for the Nobel Prize in Physics, he never received it.
    5. Niels Henrik David Bohr (1885-1962). Danish physicist. One of the founders of modern physics, he received the Nobel Prize in Physics in 1922 for his theory explaining the line spectrum of hydrogen.
[^12]:    6. Louis Victor Pierre Raymond Duc de Broglie (1892-1977). French physicist. A member of an old and noble family in France, he held the title of a prince. In his doctoral dissertation, he proposed that matter and radiation have the properties of both wave and particle. For this work, de Broglie was awarded the Nobel Prize in Physics in 1929.
[^13]:    7. Clinton Joseph Davisson (1881-1958). American physicist. He and G. P. Thomson shared the Nobel Prize in Physics in 1937 for demonstrating the wave properties of electrons.
    8. Lester Halbert Germer (1896-1972). American physicist. Discoverer (with Davisson) of the wave properties of electrons.
    9. George Paget Thomson (1892-1975). English physicist. Son of J. J. Thomson, he received the Nobel Prize in Physics in 1937, along with Clinton Davisson, for demonstrating the wave properties of electrons.
[^14]:    10. Werner Karl Heisenberg (1901-1976). German physicist. One of the founders of modern quantum theory. Heisenberg received the Nobel Prize in Physics in 1932.
[^15]:    11. Erwin Schrödinger (1887-1961). Austrian physicist. Schrödinger formulated wave mechanics, which laid the foundation for modern quantum theory. He received the Nobel Prize in Physics in 1933.
[^16]:    12. The unusual sequence of letters ( $s, p, d$, and $f$ ) has an historical origin. Physicists who studied atomic emission spectra tried to correlate their observations of spectral lines with the energy states involved in the transitions. They described the emission lines as sharp, principal, diffuse, and fundamental.
[^17]:    13. Otto Stern (1888-1969). German physicist. He made important contributions to the study of the magnetic properties of atoms and the kinetic theory of gases. Stern was awarded the Nobel Prize in Physics in 1943.
    14. Walther Gerlach (1889-1979). German physicist. Gerlach's main area of research was in quantum theory.
[^18]:    15. Wolfgang Pauli (1900-1958). Austrian physicist. One of the founders of quantum mechanics, Pauli was awarded the Nobel Prize in Physics in 1945.
[^19]:    16. Frederick Hund (1896-1997). German physicist. Hund's work was mainly in quantum mechanics. He also helped to develop the molecular orbital theory of chemical bonding.
[^20]:    1. John Alexander Reina Newlands (1838-1898). English chemist. Newlands's work was a step in the right direction in the classification of the elements. Unfortunately, because of its shortcomings, he was subjected to much criticism, and even ridicule. At one meeting he was asked if he had ever examined the elements according to the order of their initial letters! Nevertheless, in 1887 Newlands was honored by the Royal Society of London for his contribution.
    2. Dmitri Ivanovich Mendeleev (1836-1907). Russian chemist. His work on the periodic classification of elements is regarded by many as the most significant achievement in chemistry in the nineteenth century.
    3. Julius Lothar Meyer (1830-1895). German chemist. In addition to his contribution to the periodic table, Meyer also discovered the chemical affinity of hemoglobin for oxygen.
    4. Henry Gwyn-Jeffreys Moseley (1887-1915). English physicist. Moseley discovered the relationship between X-ray spectra and atomic number. A lieutenant in the Royal Engineers, he was killed in action at the age of 28 during the British campaign in Gallipoli, Turkey.
[^21]:    *Cells shaded with blue represent the removal of core electrons.

[^22]:    1. Gilbert Newton Lewis (1875-1946). American chemist. Lewis made many important contributions in the areas of chemical bonding, thermodynamics, acids and bases, and spectroscopy. Despite the significance of Lewis's work, he was never awarded a Nobel Prize.
[^23]:    3. Peter Joseph William Debye (1884-1966). American chemist and physicist of Dutch origin. Debye made many significant contributions to the study of molecular structure, polymer chemistry, X-ray analysis, and electrolyte solutions. He was awarded the Nobel Prize in Chemistry in 1936.
[^24]:    1. Hermann Staudinger (1881-1963). German chemist. One of the pioneers in polymer chemistry. Staudinger was awarded the Nobel Prize in Chemistry in 1953.
[^25]:    1. Evangelista Torricelli (1608-1674). Italian mathematician. Torricelli was supposedly the first person to recognize the existence of atmospheric pressure.
[^26]:    2. Robert Boyle (1627-1691). British chemist and natural philosopher. Although Boyle is commonly associated with the gas law that bears his name, he made many other significant contributions to the fields of chemistry and physics.
[^27]:    3. Jacques Alexandre Cesar Charles (1746-1823). French physicist. Charles was a gifted lecturer, an inventor of scientific apparatus, and the first person to use hydrogen to inflate balloons.
    4. Joseph Louis Gay-Lussac (1778-1850). French chemist and physicist. Like Charles, Gay-Lussac was a balloon enthusiast. He once ascended to an altitude of $20,000 \mathrm{ft}$ to collect air samples for analysis.
[^28]:    5. William Thomson, Lord Kelvin (1824-1907). Scottish mathematician and physicist. Kelvin did important work in many branches of physics.
[^29]:    6. Ludwig Eduard Boltzmann (1844-1906). Austrian physicist. Although Boltzmann was one of the greatest theoretical physicists of all time, his work was not recognized by other scientists in his own lifetime. He suffered from poor health and severe depression and committed suicide in 1906.
    7. James Clerk Maxwell (1831-1879). Scottish physicist. Maxwell was one of the great theoretical physicists of the nineteenth century. His work covered many areas in physics, including the kinetic theory of gases, thermodynamics, and electricity and magnetism.
[^30]:    8. Johannes Diderik van der Waals (1837-1923). Dutch physicist. Van der Waals received the Nobel Prize in Physics in 1910 for his work on the properties of gases and liquids.
[^31]:    1. Fritz London (1900-1954). German physicist. London was a theoretical physicist whose major work was on superconductivity in liquid helium.
[^32]:    2. Rudolf Julius Emanuel Clausius (1822-1888). German physicist. Clausius's work was mainly in electricity, kinetic theory of gases, and thermodynamics.
    3. Benoit Paul Emile Clapeyron (1799-1864). French engineer. Clapeyron made contributions to the thermodynamics of steam engines.
[^33]:    4. Max Theodor Felix von Laue (1879-1960). German physicist. Von Laue received the Nobel Prize in Physics in 1914 for his discovery of X-ray diffraction.
[^34]:    5. William Henry Bragg (1862-1942) and Sir William Lawrence Bragg (1890-1972). English physicists, father and son. Both worked on X-ray crystallography. The younger Bragg formulated the fundamental equation for X-ray diffraction. The two shared the Nobel Prize in Physics in 1915.
[^35]:    *Diamond is a good conductor of heat.
    ${ }^{\dagger}$ Included in this category are crystals made up of individual atoms.

[^36]:    1. William Henry (1775-1836). English chemist. Henry's major contribution to science was his discovery of the law describing the solubility of gases, which now bears his name.
[^37]:    2. François Marie Raoult (1839-1901). French chemist. Raoult's work was mainly in solution properties and electrochemistry.
[^38]:    3. Jacobus Henricus van't Hoff (1852-1911). Dutch chemist. One of the most prominent chemists of his time, van't Hoff did significant work in thermodynamics, molecular structure and optical activity, and solution chemistry. In 1901 he received the first Nobel Prize in Chemistry.
[^39]:    4. John Tyndall (1820-1893). Irish physicist. Tyndall did important work in magnetism and also explained glacier motion.
[^40]:    1. Cato Maximilian Guldberg (1836-1902). Norwegian chemist and mathematician. Guldberg's research was primarily in the field of thermodynamics.
    2. Peter Waage (1833-1900). Norwegian chemist. Like his coworker, Guldberg, Waage did research in thermodynamics.
[^41]:    *The second ionization constant of $\mathrm{H}_{2} \mathrm{~S}$ is very low and difficult to measure. The value in this table is an estimate.

[^42]:    1. Josiah Willard Gibbs (1839-1903). American physicist. One of the founders of thermodynamics. Gibbs was a modest and private individual who spent almost all his professional life at Yale University. Because he published most of his work in obscure journals, Gibbs never gained the eminence that his contemporary and admirer James Maxwell did. Even today, very few people outside of chemistry and physics have ever heard of Gibbs.
[^43]:    *For all half-reactions the concentration is $1 M$ for dissolved species and the pressure is 1 atm for gases. These are the standard-state values.

[^44]:    1. Michael Faraday (1791-1867). English chemist and physicist. Faraday is regarded by many as the greatest experimental scientist of the nineteenth century. He started as an apprentice to a bookbinder at the age of 13, but became interested in science after reading a book on chemistry. Faraday invented the electric motor and was the first person to demonstrate the principle governing electric generators. Besides making notable contributions to the fields of electricity and magnetism, Faraday also worked on optical activity and discovered and named benzene.
[^45]:    2. Walter Hermann Nernst (1864-1941). German chemist and physicist. Nernst's work was mainly on electrolyte solutions and thermodynamics. He also invented an electric piano. Nernst was awarded the Nobel Prize in Chemistry in 1920 for his contribution to thermodynamics.
[^46]:    1. Alfred Werner (1866-1919). Swiss chemist. Werner started as an organic chemist but did his most notable work in coordination chemistry. For his theory of coordination compounds, Werner was awarded the Nobel Prize in Chemistry in 1913.
[^47]:    1. Ludwig Mond (1839-1909). British chemist of German origin. Mond made many important contributions to industrial chemistry. His method for purifying nickel by converting it to the volatile $\mathrm{Ni}(\mathrm{CO})_{4}$ compound has been described as having given "wings" to the metal.
[^48]:    * Refers to the cation $\mathrm{M}^{+}$, where M denotes an alkali metal atom.
    $\dagger$ The half-reaction is $\mathrm{M}^{+}(a q)+e^{-} \longrightarrow \mathrm{M}(s)$.

[^49]:    2. Ernest Solvay (1838-1922). Belgian chemist. Solvay's main contribution to industrial chemistry was the development of the process for the production of sodium carbonate that now bears his name.
[^50]:    3. Charles Martin Hall (1863-1914). American inventor. While Hall was an undergraduate at Oberlin College, he became interested in finding an inexpensive way to extract aluminum. Shortly after graduation, when he was only 22 years old, Hall succeeded in obtaining aluminum from aluminum oxide in a backyard woodshed. Amazingly, the same discovery was made at almost the same moment in France by Paul Héroult, another 22-year-old inventor working in a similar makeshift laboratory.
[^51]:    1. Herman Frasch (1851-1914). German chemical engineer. Besides inventing the process for obtaining pure sulfur, Frasch developed methods for refining petroleum.
[^52]:    * The number in parentheses indicates the oxidation number of the halogen.

[^53]:    1. Charles Goodyear (1800-1860). American chemist. Goodyear was the first person to realize the potential of natural rubber. His vulcanization process made the use of rubber practical, contributing greatly to the development of the automobile industry.
[^54]:    *A and B represent different monomers (e.g., ethylene and styrene).

[^55]:    elimination reaction.
